Attachment E

Regional Summary of Distribution of Shortages (2008-2060)

This attachment to Appendix G contains tables produced by the Shortage Allocation Model that provide a summary of the distribution of shortages by priority within the three Lower Division states (Arizona, California, and Nevada) and also to Mexico, for the years 2008, 2017, 2026, 2027, 2040, and 2060.

Table Att. E-1

2008 Regional Summary of Shortages (Based on Consumptive Use)

	200,000	400,000	500,000	600,000	800,000	1,000,000	1,200,000	1,800,000	2,500,000

Attachment F

Supporting Documentation to the Shortage Allocation Model

This attachment to Appendix G contains tables that comprise supporting documentation to the Shortage Allocation Model as follows:

Table Att. F-1:	Provides a list of Present Perfected Rights who are the first entitlement holders to receive Colorado River water in a shortage year in date order regardless of state lines.
Table Att. F-2:	Information from Exhibit B of the Quantification Settlement Agreement, which displays quantified entitlements for Imperial Irrigation District and Coachella Valley Water District, which are referenced in the Shortage Allocation Model.
Table Att. F-3:	This table shows a comparison of the shortage results generated in the Shortage Allocation Model based on different modeling assumptions used in the Draft EIS and the Final EIS.

1Exhibit B is independent of increases and reductions as allowed under the Inadvertent Overrun and Payback Policy.
2Any higher use covered by MWD, any lesser use will produce water for MWD and help satisfy ISG Benchmarks and Annual Targets.
3IID/MWD 1988 Conservation Program conserves up to 110,000 AFY and the amount is based upon periodic verification. Of amount conserved, up to 20,000 AFY to CVWD (column 19), which does not count toward ISG Benchmarks and Annual Targets, and remainder to MWD.
4Ramp-up amounts may vary based upon construction progress, and final amounts will be determined by the Secretary pursuant to the Allocation Agreement.
5Any amount identified in Exhibit B for mitigation purposes will only be from non-Colorado River sources and these amounts may be provided by exchange for Colorado River water.

Table Att. F-2
Exhibit B of the QSA

In Thousands of Acre-feet

		IID Priority 3a											CVWD Priority 3a									
			Reductions											Reductions			Additions					
Calendar Year	2 Priority 1, 2 and 3b	IID Priority 3a Quantified Amount	3 IID Reduction: MWD 1988 Agreement Transfer	IID Reduction: SDCWA Transfer	4 IID Reduction: AAC Lining IID, SDCWA & SLR	5,6IID Reduction: SDCWA Mitigation Transfer	7Intra-Priority 3 Transfer IID/CVWD	6 IID Reduction: MWD Transfer with Salton Sea Restoration	8IID Reduction: Conditional ISG Backfill	9IID Reduction: Misc. PPRs	IID Reductions: Total Amount (sum of columns 4 through 11)	10 IID Net Consumptive Use Amount (difference between column 3 and column 12)	CVWD Priority 3a Quantified Amount	4 CVWD Reduction: CC Lining, SDCWA & SLR	9 CVWD Reduction: Misc. PPRs	11 CVWD Reductions: Total Amount (sum of columns 15 + 16)	7 Intra-Priority 3 Transfer IID / CVWD	3 Intra-Priority 3 Transfer MWD / CVWD	CVWD Net Consumptive Use Amount (columns 14 - 17 plus columns 18 + 19)	Total Priority 1-3 Use Plus PPR Consumptive Use (sum of columns 2+13+20 plus 11+16)	12 ISG Bench-marks	12 Annual Targets

6Water would be transferred to MWD subject to satisfaction of certain conditions and to appropriate Federal approvals. These transfers may also be subject to state approvals. Schedules are subject to adjustments with mutual consent. After 2006, these quantities will count toward the ISG Benchmarks (column 22) and Annual Targets (column 23) only if and to the extent that water is transferred into the Colorado River Aqueduct for use by MWD and/or SDCWA.

7MWD can acquire if CVWD declines the water. Any water obtained by MWD will be counted as additional agricultural reduction to help satisfy the ISG Benchmarks and Annual Targets. MWD will provide CVWD 50,000 AFY of the 100,000 AFY starting in year 46.

8IID has agreed to provide transfer amounts to meet the minimum ISG benchmarks, not to exceed a cumulative total of 145,000 AF. Maximum transfer amounts are 25,000 AF in 2006, 50,000 AF plus the unused amount from 2006 in 2009, and 70,000 AF plus the unused amounts from 2006 and 2009 in 2012. In addition to the maximum transfer amounts IID has also committed that no more than 72,500 AF of reduced inflow to the Salton Sea would result from these additional transfers.

9Up to the amount shown, as agreed upon reduction to IID or CVWD to cover collectively the sum of individual Miscellaneous PPRs, Federal reserved rights and Decreed rights. This is a reduction that counts towards ISG Benchmarks and Annual Targets.

10For purposes of Subparagraph 8(b)(2)(i) and (ii) and 8(c)(1) and (4) the Secretary will take into account: (i) the satisfaction of necessary conditions to certain transfers (columns 7 and 9) not within IID's control: (ii) the amounts of conserved water as determined, where such amounts may vary (columns 4, 6, 9 and 10); and (iii) with respect to column 7, reductions by IID will be considered in determining IID's compliance regardless of whether the conserved water is diverted into the Colorado River Aqueduct.

11For purposes of Subparagraph 8(c)(1) and (4) the Secretary will take into account: (i) the satisfaction of necessary conditions to certain transfers (columns 15 and 16) not within CVWD's control; and (ii) the amounts of conserved water as determined, where such amounts may vary (column 15).

12All consumptive use of priorities 1 through 3 plus 14,500 AF of PPRs must be within 25,000 AF of the amount stated.

13Assumes SDCWA does not elect termination in year 35.

14Assumes SDCWA and IID mutually consent to renewal term of 30 years.

Notes:

Substitute transfers can be made provided the total volume of water to be transferred remains equal or greater than amounts shown consistent with applicable Federal approvals.

The shaded columns represent amounts of water that may vary.

Appendix H

Socioeconomics Data

This appendix includes detailed information that supports the analysis contained in Section 4.14 (Socioeconomics) of the EIS. The analysis in Section 4.14 is based on a network of models. The Shortage Allocation Model (described in Appendix G of the Final EIS) was used to generate shortages, which served as input to an agricultural model. The agricultural model contains crop budgets and crop growing patterns that were used to assess the effect of shortages on crop acres and production. Arizona agricultural cropping patterns and crop budgets included in the analysis are displayed on Tables H-1 through H-19. The change in gross dollar output determined in the agricultural model were used as an input to the economic model "IMPLAN", which produced a detailed breakdown of estimated changes in employment, income, and tax revenues for each county by shortage amount and year evaluated (Tables H-20 through H-147).

Table of Contents

List of Tables

H.1 Introduction

This appendix supports the agricultural analysis in Section 4.14 (Socioeconomics) of the EIS. Indian and non-Indian agricultural shortages were generated in the Shortage Allocation Model. The results are incorporated in an agricultural model, which determines the quantity of acres within a district which will go out of production based on crop budgets and production patterns. The agricultural model produces the estimated reduction in crops by acre and a reduction in gross dollar output. The change in gross dollar output is then used as an input to IMPLAN to ascertain changes in employment, personal income, and tax revenues by county. The output of both the Shortage Allocation Model and the agricultural model must be summarized by county in order for IMPLAN to operate.

Listed below are the counties analyzed in IMPLAN. For informational purposes, the irrigation districts and Indian communities contained within those counties are also listed below. Pinal, Maricopa, and Pima Counties contain the majority of Central Arizona Project irrigation districts and Indian communities. Mohave, La Paz, and Yuma Counties contain the majority of individual entitlement holders along the Colorado River. When an irrigation district, Indian community, or entitlement holder crosses a county line, the analysis is distributed proportionately to the estimated use in each county:

- Mohave
- La Paz
- Yuma
- Pinal: Maricopa-Stanfield Irrigation & Drainage District (MSIDD)
  Central Arizona Irrigation and Drainage District (CAIDD)
  San Carlos Irrigation and Drainage District (SCIDD)
  Hohokam Irrigation and Drainage District (HIDD)
  New Magma Irrigation and Drainage District (NMIDD)
  Tohono O'odham Nation (TON) – Chui Chu District
  Gila River Indian Community (GRIC)
- Maricopa: Queen Creek Irrigation District (QCID)
  Harquahala Valley Irrigation District (HVID)
  Tonopah Irrigation District (TID)
  Salt River Pima-Maricopa Community

Fort McDowell Yavapai Nation

- Pima: Tohono O'odham Nation - Schuk Toak and San Xavier Districts

H.2 Arizona Cropping Patterns

Historic cropping patterns for the major districts in Arizona are summarized in Table H-1.

Table H-1
Cropping Patterns for Shortage Analysis (acres)

Irrigation Districts[1]	Cotton	Grains	Forage	Vegetables	Trees	Totals
MSIDD	27,862	18,154	8,711	3,106	3,886	61,719

[1] See Section H.1 for Irrigation District names and acronyms.

H.3 Crop Budgets for Arizona Counties

H.3.1 Partial Crop Budgeting and Impacts Upon Crop Selection due to Water Cost and Water Shortages

This analysis is referred to as partial crop budgeting for two reasons. The first reason is that only aggregated costs and returns are presented for each crop, with essentially little detail regarding the composition of the values. Secondly, as explained below, not all costs of production are taken into consideration; the emphasis is primarily on variable or cash costs. Partial crop budget tables are located at the end of this text.

Partial crop budgets were generated for upland cotton, forage crops, and food and feed grains. This analysis focuses on these categories of crops because these crops are historically the first affected by water availability. Such crops may be subject to elimination from a crop rotation in any given year as the availability of irrigation water changes.

Theoretical economic production assumptions were applied in developing the partial budgets. The first assumption is that farmers will continue to produce a particular crop only as long as the returns from the crop cover all variable costs and contribute something toward fixed costs. For the partial crop budget analysis, the intent is to identify only the variable production costs or only those costs which a farmer in Arizona is assumed to include when making the decision whether to continue to produce a particular crop in the face of declining water availability. The goal of the partial crop budget analysis is to estimate a set of cost and return values that represent typical farm operations in various districts although it is recognized that each farmer is faced with unique production costs, realized yields, and crop prices. The partial crop budgets provide what is assumed to be the typical costs and returns faced by a range of farmers in the counties included in this analysis. The outcome provided by the partial budgets is identification of the cost of irrigation water at which farmers, on the average, would decide to fallow fields of a particular crop because the returns failed to cover the variable costs of production. It is assumed that, if each farmer's production costs and prices were used, on the average, the impacts would be similar to those resulting from this analysis.

University of Arizona 1998 crop enterprise budgets were used as the starting point for the partial crop budget analysis. Costs of farming inputs (equipment maintenance, fertilizer application, fuel, etc.) were adjusted to reflect 2005 costs using cost indices available from the National Agricultural Statistics Service. Average commodity prices and yields over a five-year period, from 2001 to 2005, were the basis for gross revenues. The total cash cost for land preparation and growing expenses including irrigation water costs, and total harvest and post-harvest costs developed by the University of Arizona were used in this analysis. Costs which were specifically excluded from the analysis include farm pickup use costs for a particular crop, taxes, housing, insurance on farm equipment, capital replacement on machinery and vehicles, interest on equity in machinery and vehicles, property taxes, opportunity interest on land, water assessment, returns to management, and profit.

The values derived are not indicative of the profitability of a particular crop. The values are intended to represent a marginal analysis relative to farmers' growing decisions. For example, the crop profitability decision value for wheat in Maricopa County is shown to be $59.55 per acre. The $59.55 represents the revenues above variable expenses that contribute to payment of fixed costs of the farming operation. To the $59.55 is added the current estimated irrigation water cost. Total estimated irrigation water cost plus the profitability decision value is then divided by the acre-feet of water applied per acre to calculate the threshold value. The threshold value for wheat in Maricopa County is $23.96. The threshold value is the maximum amount a farmer would pay for water to irrigate wheat or at what point he would decide to not include wheat in his rotation. In this study, a farmer is assumed not to consider all economic costs when deciding whether to grow a particular crop. This assumption is based on historic agricultural production practices and decision making in the Lower Basin states. In addition, the economic costs associated with total farm production are unique to each farm operation. The values used in this analysis represent average conditions for farms in the counties included in this study.

Tables H-3 through H-20 show the partial budgeting results. In summary, the estimated maximum average amount a farmer would pay for irrigation water per acre foot is shown in Table H-2, below.

Table H-2
Estimated Maximum Average Amount a
Farmer Would Pay for Irrigation Water

Crop	County	Max Amount Paid for Irrigation Water ($/af)
Wheat	Pinal	$25.84
	Maricopa	$23.96
	Pima[1]	$25.84
	La Paz	$10.98
	Mojave	$44.88
	Yuma	$16.77
Cotton	Pinal	$70.48
	Maricopa	$40.56
	Pima[1]	$70.48
	La Paz	$42.23
	Mojave	$54.84
	Yuma	$46.43
Alfalfa Hay	Pinal	$66.55
	Maricopa	$40.35
	Pima[1]	$66.55
	La Paz	$56.83
	Mojave	$32.70
	Yuma	$69.37

[1] *Partial farm budget information not available for Pima County. Assumed maximum amount paid for irrigation water would be similar to that of Pinal County.*

The differences in the wheat estimates between counties are due mainly to yield differences and required water assumptions. For cotton, the differences in estimates between counties are also due to yield differences and required water assumptions. In Pinal County, the first crop projected to drop out of production is wheat, followed by alfalfa, and then cotton, given increasing irrigation water costs or water shortages and assuming that all other variables remained unchanged.

Table H-3
Hay and Forage Production Profitability in Maricopa County—Partial Budget

	Total
Crops sales revenues—Alfalfa Hay (yield in tons = 8.3, price per ton = $102.20)	$850.30
Total cash growing costs (includes $112.50 for irrigation water)	$319.62
Cash harvest costs	$207.97
Interest on operating costs at 10%	$15.98
Total cash expenses	$543.56
General and office overhead—5% of operating expenses	$27.18
General farm maintenance—3% of operating expense	$16.31
Share of stand establishment	$73.13
Total variable costs	$660.18
Crop returns over variable costs	$190.13
Annual crop water use— 90 acre-inches or 7.50 af	
Returns to crop and water over variable costs	$302.63
Maximum average amount a farmer would pay for irrigation water per af	$40.35

Note: Dollar values are on a per acre basis. Information is for October 2006.

Table H-4
Food and Feed Grain Production Profitability in Maricopa County—Partial Budget

	Total
Crops sales revenues—Durum Wheat (yield in pounds = 5,578, price per pound = $0.071)	$396.04
Total cash growing costs (includes $8.33 for irrigation water)	$220.70
Cash harvest costs	$79.83
Interest on operating costs at 10%	$11.03
Total cash expenses	$311.57
General and office overhead—5% of operating expenses	$15.58
General farm maintenance—3% of operating expense	$9.35
Total variable costs	$336.49
Crop returns over variable costs	$59.55
Annual crop water use— 34 acre-inches or 2.83 af	
Returns to crop and water over variable costs	$67.88
Maximum average amount a farmer would pay for irrigation water per af	$23.96

Note: Dollar values are on a per acre basis. Information is for October 2006.

Table H-5
Upland Cotton Production Profitability in Maricopa County—Partial Budget

	Total
Crops sales revenues—Cotton Lint (yield in pounds = 1,298, price per pound = $0.636)	$825.53
Crops sales revenues—Cottonseed (yield in tons = 1.14, price per ton = $142.00)	$161.88
Total revenues	$987.41
Total cash growing costs (includes $30.00 for irrigation water)	$453.41
Cash harvest costs	$275.07
Interest on operating costs at 10%	$22.67
Total cash expenses	$751.15
General and office overhead—5% of operating expenses	$37.56
General farm maintenance—3% of operating expense	$22.53
Total variable costs	$811.24
Crop returns over variable costs	$176.17
Annual crop water use— 61 acre-inches or 5.08 af	
Returns to crop and water over variable costs	$206.17
Maximum average amount a farmer would pay for irrigation water per af	$40.56

Note: Dollar values are on a per acre basis. Information is for October 2006.

Table H-6
Hay and Forage Production Profitability in Pinal County—Partial Budget

	Total
Crops sales revenues—Alfalfa Hay (yield in tons = 8.86, price per ton = $102.20)	$905.49
(grazing = 250 hd, cents per hd = $0.13)	$32.50
Total revenues	$937.99
Total cash growing costs (includes $237.00 for irrigation water)	$354.89
Cash harvest costs	$231.87
Interest on operating costs at 10%	$17.74
Total cash expenses	$604.51
General and office overhead—5% of operating expenses	$30.23
General farm maintenance—3% of operating expense	$18.14
Share of stand establishment	$84.22
Total variable costs	$737.09
Crop returns over variable costs	$200.90
Annual crop water use— 79 acre-inches or 6.58 af	
Returns to crop and water over variable costs	$437.90
Maximum average amount a farmer would pay for irrigation water per af	$66.55

Note: Dollar values are on a per acre basis. Information is for October 2006.

Table H-7
Food and Feed Grain Production Profitability in Pinal County—Partial Budget

	Total
Crops sales revenues—Durum Wheat (yield in pounds = 5,812, price per pound = $0.071)	$412.65
Total cash growing costs (includes $96.00 for irrigation water)	$317.06
Cash harvest costs	$74.26
Interest on operating costs at 10%	$15.85
Total cash expenses	$407.18
General and office overhead—5% of operating expenses	$20.36
General farm maintenance—3% of operating expense	$12.22
Total variable costs	$439.75
Crop returns over variable costs	$27.10
Annual crop water use— 32 acre-inches or 2.67 af	
Returns to crop and water over variable costs	$68.90
Maximum average amount a farmer would pay for irrigation water per af	$25.84

Note: Dollar values are on a per acre basis. Information is for October 2006.

Table H-8
Upland Cotton Production Profitability in Pinal County—Partial Budget

	Total
Crops sales revenues—Cotton Lint (yield in pounds = 1,361, price per pound = $0.636)	$865.60
Crops sales revenues—Cottonseed (yield in tons = 1.2, price per ton = $142.00)	$170.40
Total revenues	$1,036.00
Total cash growing costs (includes $30.00 for irrigation water)	$519.23
Cash harvest costs	$280.94
Interest on operating costs at 10%	$25.96
Total cash expenses	$826.13
General and office overhead—5% of operating expenses	$41.31
General farm maintenance—3% of operating expense	$24.78
Total variable costs	$892.22
Crop returns over variable costs	$143.78
Annual crop water use— 49 acre-inches or 4.08 af	
Returns to crop and water over variable costs	$287.78
Maximum average amount a farmer would pay for irrigation water per af	$70.48

Note: Dollar values are on a per acre basis. Information is for October 2006.

Table H-9
Hay and Forage Production Profitability in Cochise County—Partial Budget

	Total
Crops sales revenues—Alfalfa Hay (yield in tons = 7.84, price per ton = $102.20)	$801.25
(grazing = 250 hd, cents per hd = $0.13)	$32.50
Total revenues	$833.75
Total cash growing costs (includes $243.63 for irrigation water)	$585.30
Cash harvest costs	$102.67
Interest on operating costs at 10%	$29.26
Total cash expenses	$717.23
General and office overhead—5% of operating expenses	$35.86
General farm maintenance—3% of operating expense	$21.52
Share of stand establishment	$84.22
Total variable costs	$858.83
Crop returns over variable costs	($25.08)
Annual crop water use— 68 acre-inches or 5.67 af	
Returns to crop and water over variable costs	$218.55
Maximum average amount a farmer would pay for irrigation water per af	$38.57

Note: Dollar values are on a per acre basis. Information is for October 2006.

Table H-10
Food and Feed Grain Production Profitability in Cochise County—Partial Budget

	Total
Crops sales revenues—Durum Wheat (yield in pounds = 6,210, price per pound = $0.071)	$440.91
Total cash growing costs (includes $107.04 for irrigation water)	$427.90
Cash harvest costs	$68.57
Interest on operating costs at 10%	$21.39
Total cash expenses	$517.87
General and office overhead—5% of operating expenses	$25.89
General farm maintenance—3% of operating expense	$15.54
Total variable costs	$559.29
Crop returns over variable costs	$118.38
Annual crop water use— 28 acre-inches or 2.33 af	
Returns to crop and water over variable costs	$11.34
Maximum average amount a farmer would pay for irrigation water per af	$4.86

Note: Dollar values are on a per acre basis. Information is for October 2006.

Table H-11
Upland Cotton Production Profitability in Cochise County—Partial Budget

	Total
Crops sales revenues—Cotton Lint (yield in pounds = 1,032, price per pound = $0.636)	$656.35
Crops sales revenues—Cottonseed (yield in tons = 0.91, price per ton = $142.00)	$129.22
Total revenues	$785.57
Total cash growing costs (includes $132.57 for irrigation water)	$527.74
Cash harvest costs	$183.44
Interest on operating costs at 10%	$26.39
Total cash expenses	$737.57
General and office overhead—5% of operating expenses	$36.88
General farm maintenance—3% of operating expense	$22.13
Total variable costs	$796.57
Crop returns over variable costs	($11.00)
Annual crop water use— 37 acre-inches or 3.08 af	
Returns to crop and water over variable costs	$121.57
Maximum average amount a farmer would pay for irrigation water per af	$39.43

Note: Dollar values are on a per acre basis. Information is for October 2006.

Table H-12
Hay and Forage Production Profitability in La Paz County—Partial Budget

	Total
Crops sales revenues—Alfalfa Hay (yield in tons = 7.9, price per ton = $102.20)	$804.31
(grazing = 250 hd, cents per hd = $0.13)	$32.50
Total revenues	$836.81
Total cash growing costs (includes $243.63 for irrigation water)	$187.67
Cash harvest costs	$171.67
Interest on operating costs at 10%	$9.38
Total cash expenses	$368.73
General and office overhead—5% of operating expenses	$18.44
General farm maintenance—3% of operating expense	$11.06
Share of stand establishment	$84.22
Total variable costs	$482.44
Crop returns over variable costs	$354.37
Annual crop water use— 79 acre-inches or 6.58 af	
Returns to crop and water over variable costs	$374.16
Maximum average amount a farmer would pay for irrigation water per af	$56.83

Note: Dollar values are on a per acre basis. Information is for October 2006.

Table H-13
Food and Feed Grain Production Profitability in La Paz County—Partial Budget

	Total
Crops sales revenues—Durum Wheat (yield in pounds = 5,642, price per pound = $0.071)	$400.58
Total cash growing costs (includes $0 for irrigation water)	$266.05
Cash harvest costs	$61.90
Interest on operating costs at 10%	$13.30
Total cash expenses	$341.26
General and office overhead—5% of operating expenses	$17.06
General farm maintenance—3% of operating expense	$10.24
Total variable costs	$368.56
Crop returns over variable costs	$32.03
Annual crop water use— 35 acre-inches or 2.92 af	
Returns to crop and water over variable costs	$32.03
Maximum average amount a farmer would pay for irrigation water per af	$10.98

Note: Dollar values are on a per acre basis. Information is for October 2006.

Table H-14
Hay and Forage Production Profitability in Yuma County—Partial Budget

	Total
Crops sales revenues—Alfalfa Hay (yield in tons = 9.1, price per ton = $102.20)	$933.09
(grazing = 250 hd, cents per hd = $0.13)	$32.50
Total revenues	$965.59
Total cash growing costs (includes $25.83 for irrigation water)	$153.29
Cash harvest costs	$224.07
Interest on operating costs at 10%	$7.66
Total cash expenses	$385.02
General and office overhead—5% of operating expenses	$19.25
General farm maintenance—3% of operating expense	$11.55
Share of stand establishment	$84.22
Total variable costs	$500.04
Crop returns over variable costs	$465.54
Annual crop water use— 85 acre-inches or 7.08 af	
Returns to crop and water over variable costs	$491.37
Maximum average amount a farmer would pay for irrigation water per af	$69.37

Note: Dollar values are on a per acre basis. Information is for October 2006.

Table H-15
Food and Feed Grain Production Profitability in Yuma County—Partial Budget

	Total
Crops sales revenues—Durum Wheat (yield in pounds = 5,976, price per pound = $0.071)	$424.30
Total cash growing costs (includes $0 for irrigation water)	$246.97
Cash harvest costs	$83.09
Interest on operating costs at 10%	$12.35
Total cash expenses	$342.41
General and office overhead—5% of operating expenses	$17.12
General farm maintenance—3% of operating expense	$10.27
Total variable costs	$369.80
Crop returns over variable costs	$54.49
Annual crop water use— 39 acre-inches or 3.25 af	
Returns to crop and water over variable costs	$54.49
Maximum average amount a farmer would pay for irrigation water per af	$16.77

Note: Dollar values are on a per acre basis. Information is for October 2006.

Table H-16
Upland Cotton Production Profitability in Yuma County—Partial Budget

	Total
Crops sales revenues—Cotton Lint (yield in pounds = 1,286, price per pound = $0.636)	$817.90
Crops sales revenues—Cottonseed (yield in tons = 1.13, price per ton = $142.00)	$160.46
Total revenues	$978.36
Total cash growing costs (includes $0 for irrigation water)	$684.90
Cash harvest costs	$337.21
Interest on operating costs at 10%	$34.24
Total cash expenses	$1,056.35
General and office overhead—5% of operating expenses	$52.82
General farm maintenance—3% of operating expense	$31.69
Total variable costs	$1,140.85
Crop returns over variable costs	($162.50)
Annual crop water use— 42 acre-inches or 3.50 af	
Returns to crop and water over variable costs	($162.50)
Maximum average amount a farmer would pay for irrigation water per af	($46.43)

Note: Dollar values are on a per acre basis. Information is for October 2006.

Crop returns over variable costs	$259.16
Annual crop water use— 60 acre-inches or 5.00 af	
Returns to crop and water over variable costs	$274.22
Maximum average amount a farmer would pay for irrigation water per af	$54.84

Note: Dollar values are on a per acre basis. Information is for October 2006.

H.4 County Level Changes in Employment and Personal Income

H.4.1 Summary Table

Tables H-20 through H-25 summarize the changes in employment and personal income for both Indian and non-Indian agricultural lands due to shortages of Colorado River water. The summaries are shown by level of shortage and by selected years. For years in which there is no probability of a particular shortage level, impacts are negligible and not displayed. Shortages generated in 2008 are not displayed because there was no probability of shortage in that year.

Table H-20
Estimated Changes in Employment as a Result of Shortages to
Non-Indian Agricultural Lands for Selected Shortage Amounts and Years

Shortage Amount (af)	Year				
	2017	2026	2027	2040	2060
400,000	(542.1)	(183.1)	–[1]	–	–
500,000	(558.0)	(193.8)	(115.6)	(43.6)	(42.6)
600,000	(568.3)	(204.3)	(126.1)	(54.1)	(53.1)
800,000	(582.4)	(225.0)	(147.1)	(75.1)	(74.1)
1,000,000	(604.0)	(246.9)	(168.7)	(96.7)	(95.7)
1,200,000	–	(267.0)	(188.8)	(116.8)	(115.9)
1,800,000	–	-	(279.2)	(215)	(214.0)
2,500,000	–	–	(702.0)	–	–

Note: (1) "-" indicates no shortage occurring.

Table H-21
Estimated Changes in Personal Income as a Result of Shortages to
Non-Indian Agricultural Lands for Selected Shortage Amounts and Years

Shortage Amount (af)	Year				
	2017	2026	2027	2040	2060

H.4.2 2017 Tables

The estimated change in employment and income as a result of shortages on Indian and Non-Indian agricultural lands are displayed in Tables H-26 through H-105 for each county by shortage amount and year evaluated.

Table H-26
Estimated Change In Employment and Income as a Result of a
400,000 af shortage to Non-Indian Agricultural Lands in Arizona—2017

	Employment			Income		
County	Direct	Indirect + Induced	Total	Direct	Indirect + Induced	Total
Maricopa	(108.6)	(50.5)	(159.1)	(3.144.695)	(1,807,440)	(4.952.135)
Pinal	(177.0)	(183.3)	(360.3)	(10,459,635)	(5,833,577)	(16,293,212)
Mohave	(4.1)	(2.8)	(6.9)	(237,307)	(83,518)	(320,825)

H.5 County Level Changes in Tax Revenue

H.5.1 Summary Tables

Tables H-106 through H-107 summarize the changes in Tax Revenue as a result of shortage to Indian and non-Indian agricultural lands. The summaries are shown by level of shortage and by selected years. For years in which there is no probability of a particular shortage level, impacts are negligible and not displayed. Shortages generated in 2008 are not displayed because there was no probability of shortage in that year.

Table H-106
Estimated Changes in Tax Revenues as a Result of Shortages to
Non-Indian Agricultural Lands for Selected Shortage Amounts and Years

Shortage Amount (af)	Year				
	2017	2026	2027	2040	2060
400,000	(7,540,614)	(1,916,810)	–	–	–

H.6 Analysis of Potential Positive and Negative Economic Effects of a Voluntary Conservation Program

This additional assessment considers potential positive and negative economic effects of a voluntary conservation program. Section 14.4 in the EIS discussed the potential socioeconomic effects of the proposed federal action. The associated impact analyses considered the potential impacts from voluntary or involuntary water delivery reductions. The voluntary water delivery reductions would be associated with a voluntary water conservation program as postulated under the Conservation Before Shortage Alternative proposal. The involuntary water delivery reductions would occur as a result of a Shortage Condition.

The assessment provided in the Draft EIS (February 2007) did not attempt to quantify the economic benefits of a voluntary conservation fallowing program. Under such a program, there is an assumption that some of the effects that would result from the voluntary reduction in agricultural production might be offset by payments made to farm owners. Reclamation did not include this type of quantitative assessment due to the many uncertainties regarding how such a program would be implemented, including the geographic extent of the participants, the level of participation, the economic characteristic and demographics of the affected area, crop types that would be affected, and payment amounts made to farm owners and operators to forego crop production. This section was added to the Final EIS to describe some of the socioeconomic effects that may result in the event a voluntary fallowing program is implemented.

H.6.1 Methodology and Study Approach

For this assessment, the positive regional economic gains could include the payments to operators and resulting investments in equipment, land improvements, and non-farm related expenditures made in the local economy. The adverse economic effects could include the loss of farm-related expenditures on labor and other inputs necessary to grow, harvest, transport and sale of crops. To better understand the economics of these types of programs, a literature search for documented programs was conducted and the information gathered from existing programs was used as the bases for this assessment.

H.6.1.1 Existing Studies

There is limited documentation on previous or existing voluntary conservation programs. Two recent studies that estimated the socioeconomic effects of voluntary land fallowing programs include programs occurring on lands within the Palo Verde Irrigation District (PVID) and the Imperial Irrigation District (IID) (Local Entity and San Diego County Water Authority 2004, and Palo Verde Irrigation District 2002). The documentation available for these two programs was reviewed along with other studies that estimated payments that farmers would accept to forego crop production (Colby et al. 2006). Information contained in these studies was used as input to the subject semi-quantitative assessment of the socioeconomic effects of a voluntarily conservation program.

H.6.1.2 Water Delivery Reduction Volumes Considered

A water delivery reduction volume of 500 kaf was selected for purposes of this assessment because shortage related water delivery reductions of this magnitude had the greatest probability of occurrence during the interim period (2008 through 2026) as shown in Tables 4.4-5 and 4.4-6 in this Final EIS. The probability of occurrence for this level of shortage range from 14 percent in 2017 to 19 percent in 2026.

H.6.1.3 Potentially Affected Land Acreage

A 500 kaf water delivery reduction to the Lower Division states in 2017 could potentially result in fallowing of up to 86,000 acres of farm land (Table 4.14-1 in Section 14.4 of this Final EIS). Reclamation's Shortage Allocation Model (Section 4.2 and Appendix G) was used to estimate the distribution of water delivery reduction among the Lower Division states and Mexico, and among the Colorado River water users within each of the three Lower Division states (Arizona, California, and Nevada).

The 500 kaf shortage value was evaluated by the Shortage Allocation Model and the amount of shortage that would be allocated to various agricultural users was generated. The output from the Shortage Allocation Model was used as input to another spreadsheet model developed by Reclamation that estimates changes in agricultural production and production value. Based on the amount of shortage realized in each county, the model estimates the amount of land that would be fallowed using the relative profitability of each crop. The model assumes that the least profitable crops are fallowed first. Once all of the irrigated land associated with the least profitable crop is fallowed, the model assumes that fallowing of the next-least profitable crop would commence. For the 500 kaf shortage evaluated in this discussion, approximately 86,000 acres would be removed from crop production consisting of 25,000 acres of cotton, 48,000 acres of grain, and 13,000 acres of forage crops.

H.6.1.4 Payment Structures

The documents reviewed showed that previous and existing voluntary conservation programs have incorporated a wide range of payment mechanisms and payment amounts to gain the participation of farm owners, water districts, and communities. For example, farmers in Arizona were thought to forgo crop production if they could receive a minimum per acre payment of $68.15, $29.78, and $365.03 for cotton, grain, and forage crops, respectively. These payments are reported per acre of land payments (net return over variable costs per acre) to forgo production of the specified crop for one season on that particular acreage (Colby et al. 2006). Other fallowing programs include a one-time up front payment to farmers to ensure they participate in the fallowing program. For example, the PVID program included an entry payment of $3,170 per acre and an annual payment of $550 per acre (PVID 2002). In contrast, the IID program included one-time up front payments of $308 to $277 per acre (Local Entity and San Diego County Water Authority 2004).

For purposes of this assessment, the following two scenarios were evaluated:

- Scenario 1 estimated the socioeconomic costs and benefits based on crop payments to Arizona farmers indicated above; and

- Scenario 2 estimated the socioeconomic costs and benefits by applying the one-time and annual payments reported for the PVID program.

H.6.1.5 Program Administration

Establishing a voluntary fallowing program would require instituting some form of program administration. The cost of managing a voluntary fallowing program was not included in this assessment because the geographic location and timing of a program and the administrative costs are not known.

H.6.1.6 Regional Economic Offsets

It is difficult to estimate the amount of payments made to operators to forego crop production that would then be spent within the regional economy and thereby offset the losses in employment and income that would occur as a result of voluntarily fallowing croplands. The amount of offset would be driven by farm-related expenditures and expenditures made for other goods and services within the regional economy. Based on information reported in the studies conducted on the IID and PVID fallowing programs, participants in the voluntary fallowing program were expected to spend a portion of their payments for on-farm improvements and/or management activities that could benefit the regional economy. Expenditures could be made on land management activities such as weed control, land preparation, erosion control, new equipment purchases or other capital improvements, and debt retirement. The studies did not identify how payments may be divided among these improvements and activities.

An additional factor that would affect the degree to which payments could benefit regional economic activity is land ownership. Landowners not residing within the local area are less likely to spend any substantial portion of the payments within the local economy. As an example, the PVID study concluded that 40 percent of landowners participating in the PVID program were considered absentee (PVID 2002). Based on information reported in the 2002 Census of Agriculture (USDA 2002) approximately 26 percent of farms in Arizona were operated by off-farm operators. For purposes of this analysis, it was assumed that 74 percent of payments made to farmers would be spent within the local economy.

H.6.2 Comparison of Costs and Benefits

A comparison of the potential costs and benefits of two hypothetical voluntary conservation programs follows.

H.6.2.1 Voluntary Fallowing Program Based on Payments to Forgo Production of Specific Crop Types

A 500 kaf shortage is estimated to result in the loss of approximately 627 jobs and some $23.8 million in personal income. It may be reasonable to assume that the compensation to farmers under a voluntary fallowing program could potentially offset some of these losses. Application of the multipliers derived from this analysis of loss of agricultural production indicate that expenditures made by operators in the regional economy as a result of payments made to fallow land could create an estimated 100 jobs and approximately $4 million in personal income. Again, these expenditures could potentially partially offset the estimated losses in employment and income reported in this Final EIS.

H.6.2.2 Voluntary Fallowing Program Based on an Entry Payment and Per Acre Payment to Forgo Crop Production

A voluntary fallowing program based on the PVID program entry payment and annual payments would generate 2,500 additional jobs and $95.6 million in personal income. A program with operator payments of this magnitude would be expected to offset the employment and income losses for a 500 kaf shortage reported in this Final EIS.

H.6.3 Conclusions

The compensation to farmers under a voluntary fallowing program could potentially offset some of the adverse socioeconomic effects of reducing agricultural production. The degree to which these payments would offset the adverse socioeconomic effects of fallowing agricultural lands would depend on the payment schemes and amounts associated with a particular program.

Instituting a voluntary fallowing program could result in positive economic effects. However, as suggested by the results of the two scenarios described above, estimating the socioeconomic effects of implementing a program with a reasonable degree of certainty is difficult without additional detail regarding payment amounts, geographic location, and timing. There are many variables that need to be considered and these will vary widely by region, program size, length of program, and the participating entities.

Appendix I

Public Outreach, Coordination, and Consultation Efforts

This appendix provides documentation of the public outreach, coordination, and consultation efforts undertaken by Reclamation with regard to the proposed federal action and the preparation of this EIS. Reclamation discussed the development of the proposed federal action with various agencies and organizations at agency/organization regular meetings; public conferences and events sponsored by the agency/organizations; and at meetings sponsored by Reclamation. The entities included the Basin States' water resource departments, water agencies within these states, contractors and associations for federal hydroelectric power, and non-governmental organizations. Reclamation also consulted with Indian tribes and Mexico. The coordination activities with each agency, entity or group are summarized in Chapter 6, Volume I of this EIS.

DEC 23 2005

Honorable Raphael Bear
President, Ft. McDowell Yavapai Nation
P.O. Box 17779
Fountain Hills, AZ 85269

Subject: Request to Initiate Consultation on the Development of Lower Colorado River Basin (Lower Basin) Shortage Guidelines and Coordinated Management Strategies

Dear President Bear:

The Secretary of the Department of the Interior has recently directed the Bureau of Reclamation to develop Lower Basin shortage guidelines and coordinated management strategies for Lake Powell and Lake Mead under low reservoir conditions. Reclamation, in accordance with National Environmental Policy Act (NEPA) and Council on Environmental Quality regulations, has begun to prepare an Environmental Impact Statement (EIS) to address the proposed guidelines and strategies. A notice was published in the Federal Register on September 30, 2005, that announced the start of the scoping process and the intent to prepare an EIS (70 Federal Register 57322).

On behalf of the Department, we would like to initiate government-to-government consultation with the Ft. McDowell Yavapai Nation, in concert with the initiation of our NEPA process for this proposed action, to identify and consider potential impacts to any tribal trust resources as a result of the proposed action.

Mr. Rick Gold, Regional Director, Upper Colorado Region, and I respectfully request an opportunity to consult with you on these planned actions and discuss your interest and involvement in the NEPA process for this proposed action. To that end, we have arranged a meeting at Two Arizona Center, 400 North 5th Street, 12th Floor Conference Room A & B in Phoenix, Arizona, on January 27, 2006, from 10:00 a.m. to 12:00 noon.

Our staff will call your office during the next few weeks regarding this request. You may call Ms. Nan Yoder at 702-293-8495 or contact her by email at nyoder@lc.usbr.gov to discuss the consultation process or to confirm your availability for the meeting.

Sincerely,

Robert W. Johnson
Regional Director

Subject: Request to Initiate Consultation on the Development of Lower Colorado River Basin (Lower Basin) Shortage Guidelines and Coordinated Management Strategies

Dear Chairman:

The Secretary of the Department of the Interior has recently directed the Bureau of Reclamation to develop Lower Basin shortage guidelines and coordinated management strategies for Lake Powell and Lake Mead under low reservoir conditions. Reclamation, in accordance with National Environmental Policy Act (NEPA) and Council on Environmental Quality regulations, has begun to prepare an Environmental Impact Statement (EIS) to address the proposed guidelines and strategies. A notice was published in the Federal Register on September 30, 2005, that announced the start of the scoping process and the intent to prepare an EIS (70 Federal Register 57322).

On behalf of the Department, we would like to initiate government-to-government consultation with the Chemehuevi Indian Tribe, in concert with the initiation of our NEPA process for this proposed action, to identify and consider potential impacts to any tribal trust resources as a result of the proposed action.

Mr. Rick Gold, Regional Director, Upper Colorado Region, and I respectfully request an opportunity to consult with you on these planned actions and discuss your interest and involvement in the NEPA process for this proposed action. To that end, we have arranged a meeting at McCarran Airport, Las Vegas, Nevada, Rooms 4 and 5, on January 19, 2006, from 10:00 a.m. to 12:00 noon.

Our staff will call your office during the next few weeks regarding this request. You may call Ms. Nan Yoder at 702-293-8495 or contact her by email at nyoder@lc.usbr.gov to discuss the consultation process or to confirm your availability for the meeting.

Sincerely,

Robert W. Johnson
Regional Director

Subject: Proposed Shortage Guidelines for the Lower Basin of the Colorado River and Coordinated Strategies for the Operation of Lake Powell and Lake Mead, Government-to-Government Consultation

Dear Chairwoman:

As you are aware, the Upper and Lower Colorado Regions of the Bureau of Reclamation are proposing to develop shortage guidelines for the Lower Basin of the Colorado River and coordinated strategies for the operation of Lake Powell and Lake Mead. A copy of the September 30, 2005 Federal Register notice initiating this process is enclosed. As part of this effort, Reclamation has already begun to engage your tribe in government-to-government consultations because of your participation in the Central Arizona Project water rights settlement.

In compliance with the National Historic Preservation Act (NHPA) and Executive Order 13007, regarding sacred sites, Reclamation is further seeking your assistance in identifying and evaluating historic properties, especially those of traditional religious or cultural importance, and what potential effects, if any, this proposed action might have on these properties.

A representative from Reclamation will be calling your office within two weeks to facilitate a government-to-government consultation regarding properties under NHPA and sacred site guidelines, or you may call Mr. John Jamrog, Environmental Compliance Group Manager for the Lower Colorado Region at 702-293-8675.

Sincerely,

William J. Liebhauser, Acting Director

BILLING CODE 4312–51–P

DEPARTMENT OF THE INTERIOR

Bureau of Reclamation

Colorado River Reservoir Operations: Development of Lower Basin Shortage Guidelines and Coordinated Management Strategies for Lake Powell and Lake Mead Under Low Reservoir Conditions

AGENCY: Bureau of Reclamation, Interior.

ACTION: Notice of intent to prepare an environmental impact statement (EIS) and notice to solicit comments and hold public scoping meetings on the development of Lower Basin shortage guidelines and coordinated management strategies for the operation of Lake Powell and Lake Mead under low reservoir conditions.

SUMMARY: Pursuant to the National Environmental Policy Act (NEPA), the Bureau of Reclamation (Reclamation) proposes to conduct public scoping meetings and prepare an EIS for the development of Lower Colorado River Basin Shortage Guidelines and Coordinated Management Strategies for Operation of Lake Powell and Lake Mead Under Low Reservoir Conditions. The Secretary of the Interior (Secretary) has directed Reclamation to develop additional Colorado River management strategies to address operations of Lake Powell and Lake Mead under low reservoir conditions.

The proposed action is to develop these guidelines and strategies. Through the NEPA process initiated by this **Federal Register** notice, Reclamation is considering development of: (1) Specific guidelines that will identify those circumstances under which the Department of the Interior (Department) would reduce annual water deliveries from Lake Mead to the Lower Basin States below the 7.5 million acre-feet (maf) Lower Basin apportionment and the manner in which those deliveries would be reduced, and (2) coordinated management strategies for the operation of Lake Powell and Lake Mead.

Alternatives to be analyzed in the EIS have not been developed at this time and will be developed through the NEPA process, including through the upcoming EIS scoping meetings.

DATES AND ADDRESSES: Four public meetings will be held to solicit comments on the scope of specific shortage guidelines and other coordinated management strategies and the issues and alternatives that should be analyzed. Oral and written comments will be accepted at the public meetings to be held at the following locations:

- Tuesday, November 1, 2005—6 p.m. to 8 p.m., Hilton Salt Lake City Center, Topaz Room, 255 South West Temple, Salt Lake City, Utah.
- Wednesday, November 2, 2005—6 p.m. to 8 p.m., Adam's Mark Hotel, Tower Court D, 1550 Court Place, Denver, Colorado.
- Thursday, November 3, 2005—6 p.m. to 8 p.m., Arizona Department of Water Resources, Third Floor, Conference Rooms A&B, 500 North Third Street, Phoenix, Arizona.
- Tuesday, November 8, 2005—6 p.m. to 8 p.m., Henderson Convention Center, Grand Ballroom, 200 South Water Street, Henderson, Nevada.

Written comments on the proposed development of these strategies may be sent by close of business on *Wednesday, November 30, 2005*, to: Regional Director, Bureau of Reclamation, Lower Colorado Region, Attention: BCOO–1000, PO Box 61470, Boulder City, Nevada 89006–1470, faxogram at (702) 293–8156, or e-mail at *strategies@lc.usbr.gov*; and/or Regional Director, Bureau of Reclamation, Upper Colorado Region, Attention: UC–402, 125 South State Street, Salt Lake City, Utah 84318–1147, faxogram at (801) 524–3858, or e-mail at *strategies@uc.usbr.gov.*

FOR FURTHER INFORMATION CONTACT: Terrance J. Fulp, PhD., at (702) 293–8500 or e-mail at *strategies@lc.usbr.gov*; and/or Randall Peterson at (801) 524–3633 or e-mail at *strategies@uc.usbr.gov*. If special assistance is required regarding accommodations for attendance at any of the public meetings, please call Nan Yoder at (702) 293–8495, faxogram at (702) 293–8156, or e-mail at *nyoder@lc.usbr.gov* no less than 5 working days prior to the applicable meeting(s).

SUPPLEMENTARY INFORMATION: In recent years the Colorado River Basin experienced the worst five-year drought

Federal Register / Vol. 70, No. 189 / Friday, September 30, 2005 / Notices 57323

in recorded history. Drought in the Basin has impacted system storage, while demands for Colorado River water supplies have continued to increase. In the future, low reservoir conditions may not be limited to drought periods as additional development of Colorado River water occurs. The Colorado River is of strategic importance in the southwestern United States for water supply, hydropower production, recreation, fish and wildlife habitat, and other benefits. In addition, the Republic of Mexico has an allocation to the waters of the Colorado River pursuant to a 1944 treaty with the United States.

In 2001, the Department adopted Interim Surplus Guidelines (66 FR 7772) that are used by the Secretary in making annual determinations regarding "Normal" and "Surplus" conditions for the operation of Lake Mead. Since adoption, these Guidelines have, among other operational and management benefits, allowed the Department and entities in Arizona, California, and Nevada that rely on the Colorado River greater predictability in identifying when Colorado River water in excess of 7.5 maf will be available for use within these three States. In contrast, at this time the Department does not have detailed guidelines in place for annual determinations of releases from Lake Mead of less than 7.5 maf to water users in the three Lower Division States of Arizona, California, and Nevada (often referred to as a "shortage" condition on the lower Colorado River). Therefore, water users who rely on the Colorado River in these States are not currently able to identify particular reservoir conditions under which the Secretary would release less than 7.5 maf for use on an annual basis. Nor are these water users able to identify the amount of any potential future annual reductions in water deliveries.

Over the past year, the seven Colorado River Basin States have been proactively discussing strategies to address the recent period of system-wide drought in the Colorado River Basin. In addition, Reclamation has conducted detailed briefings for stakeholders in the Colorado River Basin and other interested entities regarding future scenarios for Colorado River operations.

Currently, each year, the Secretary establishes an Annual Operating Plan (AOP) for the Colorado River Reservoirs. The AOP describes how Reclamation will manage the reservoirs over a 12-month period, consistent with the Criteria for Coordinated Long-Range Operation of Colorado River Reservoirs Pursuant to the Colorado River Basin Project Act of September 30, 1968 (Long-Range Operating Criteria), the Decree entered by the U.S. Supreme Court in the *Arizona* v. *California* litigation, and other provisions of applicable Federal law. Reclamation consults annually with the Colorado River Basin States, Indian tribes, and other interested parties in the development of the AOP. Further, as part of the AOP process, the Secretary makes annual determinations under the Long-Range Operating Criteria regarding the availability of Colorado River water for deliveries to the Lower Division States. To meet the consultation requirements of Federal law, Reclamation also consults with the Colorado River Basin States, Indian tribes, and other interested parties during the five-year periodic reviews of the Long-Range Operating Criteria.

During the mid-year review of the 2005 AOP conducted this past spring, the Department received conflicting recommendations from the Colorado River Basin States regarding operations of Glen Canyon Dam for the remainder of the 2005 water year. In a May 2, 2005, letter to the Governors of the Colorado River Basin States, issued to complete the 2005 AOP mid-year review, the Secretary directed Reclamation to develop additional strategies to improve coordinated management of the reservoirs in the Colorado River system. Pursuant to that direction, Reclamation conducted a public consultation workshop on May 26, 2005, in Henderson, Nevada; issued a **Federal Register** notice soliciting public comments on June 15, 2005; and conducted public meetings on July 26 and July 28, 2005, in Henderson, Nevada, and Salt Lake City, Utah, respectively. Reclamation received a broad range of public comments and suggestions from these discussions, not all of which can be addressed in this proposed process. In addition, some suggestions may be part of ongoing or future efforts.

In order to assure the continued productive management and use of the Colorado River into the future, Reclamation is now soliciting public comments on the development of Lower Basin shortage guidelines and coordinated management strategies for the operation of Lake Powell and Lake Mead under low reservoir conditions. Reclamation will utilize a public process pursuant to NEPA. By this notice, Reclamation provides notice of its intent to prepare an EIS on this action, and provides notice of its upcoming EIS scoping meetings. Reclamation invites all interested members of the general public, including the seven Colorado River Basin States, Indian tribes, water and power contractors, environmental organizations, representatives of academic and scientific communities, representatives of the recreation industry, and other organizations and agencies to present oral and written comments concerning the format and scope of specific shortage guidelines and coordinated management strategies, and the issues and alternatives to be considered during the development of these proposed guidelines and strategies. Reclamation anticipates publishing a "scoping report" after completion of the public scoping meetings identified in this **Federal Register** notice.

All comments received will be considered as Reclamation develops formal alternatives under NEPA. Similar to the surplus guidelines referenced above, it is likely that these shortage guidelines will be interim in nature. It is the Department's intent that these guidelines and coordinated management strategies will provide guidance to the Secretary's AOP decisions, and provide more predictability to water users and the public throughout the Colorado River Basin, particularly those in the Lower Division States. The Department does not intend to evaluate the decommissioning of Glen Canyon Dam.

Public Disclosure

Written comments, including names and home addresses of respondents, will be made available for public review. Individual respondents may request that their home address be withheld from public disclosure, which will be honored to the extent allowable by law. There may be circumstances in which respondents' identity may also be withheld from public disclosure, as allowable by law. If you wish to have your name and/or address withheld, you must state this prominently at the beginning of your comment. All submissions from organizations, business, and from individuals identifying themselves as representatives or officials of organizations or businesses, will be made available for public disclosure in their entirety.

Dated: September 22, 2005.

Rick L. Gold,

Regional Director—UC Region, Bureau of Reclamation.

Subject: Proposed Shortage Guidelines for the Lower Basin of the Colorado River and Coordinated Strategies for the Operation of Lake Powell and Lake Mead, Government-to-Government Consultations

Dear Chairman:

As you are aware, the Upper and Lower Colorado Regions of the Bureau of Reclamation are proposing to develop shortage guidelines for the Lower Basin of the Colorado River and coordinated strategies for the operation of Lake Powell and Lake Mead. A copy of the September 30, 2005 Federal Register notice initiating this process is enclosed. As part of this effort, Reclamation has already begun to engage in government-to-government consultations with the Ten Tribes Partnership, of which your tribe is a member.

In compliance with the National Historic Preservation Act (NHPA) and Executive Order 13007, regarding sacred sites, Reclamation is further seeking your assistance in identifying and evaluating historic properties, especially those of traditional religious or cultural importance, and what potential effects, if any, this proposed action might have on these properties.

A representative from Reclamation will be calling your office within two weeks to facilitate a government-to-government consultation regarding properties under the NHPA and sacred site guidelines, or you may call Mr. John Jamrog, Environmental Compliance Group Manager for the Lower Colorado Region at 702-293-8675.

Sincerely,

William J. Liebhauser, Acting Director
Resources Management Office

BILLING CODE 4312–51–P

DEPARTMENT OF THE INTERIOR

Bureau of Reclamation

Colorado River Reservoir Operations: Development of Lower Basin Shortage Guidelines and Coordinated Management Strategies for Lake Powell and Lake Mead Under Low Reservoir Conditions

AGENCY: Bureau of Reclamation, Interior.

ACTION: Notice of intent to prepare an environmental impact statement (EIS) and notice to solicit comments and hold public scoping meetings on the development of Lower Basin shortage guidelines and coordinated management strategies for the operation of Lake Powell and Lake Mead under low reservoir conditions.

SUMMARY: Pursuant to the National Environmental Policy Act (NEPA), the Bureau of Reclamation (Reclamation) proposes to conduct public scoping meetings and prepare an EIS for the development of Lower Colorado River Basin Shortage Guidelines and Coordinated Management Strategies for Operation of Lake Powell and Lake Mead Under Low Reservoir Conditions. The Secretary of the Interior (Secretary) has directed Reclamation to develop additional Colorado River management strategies to address operations of Lake Powell and Lake Mead under low reservoir conditions.

The proposed action is to develop these guidelines and strategies. Through the NEPA process initiated by this **Federal Register** notice, Reclamation is considering development of: (1) Specific guidelines that will identify those circumstances under which the Department of the Interior (Department) would reduce annual water deliveries from Lake Mead to the Lower Basin States below the 7.5 million acre-feet (maf) Lower Basin apportionment and the manner in which those deliveries would be reduced, and (2) coordinated management strategies for the operation of Lake Powell and Lake Mead.

Alternatives to be analyzed in the EIS have not been developed at this time and will be developed through the NEPA process, including through the upcoming EIS scoping meetings.

DATES AND ADDRESSES: Four public meetings will be held to solicit comments on the scope of specific shortage guidelines and other coordinated management strategies and the issues and alternatives that should be analyzed. Oral and written comments will be accepted at the public meetings to be held at the following locations:

- Tuesday, November 1, 2005—6 p.m. to 8 p.m., Hilton Salt Lake City Center, Topaz Room, 255 South West Temple, Salt Lake City, Utah.
- Wednesday, November 2, 2005—6 p.m. to 8 p.m., Adam's Mark Hotel, Tower Court D, 1550 Court Place, Denver, Colorado.
- Thursday, November 3, 2005—6 p.m. to 8 p.m., Arizona Department of Water Resources, Third Floor, Conference Rooms A&B, 500 North Third Street, Phoenix, Arizona.
- Tuesday, November 8, 2005—6 p.m. to 8 p.m., Henderson Convention Center, Grand Ballroom, 200 South Water Street, Henderson, Nevada.

Written comments on the proposed development of these strategies may be sent by close of business on *Wednesday, November 30, 2005*, to: Regional Director, Bureau of Reclamation, Lower Colorado Region, Attention: BCOO–1000, PO Box 61470, Boulder City, Nevada 89006–1470, faxogram at (702) 293–8156, or e-mail at *strategies@lc.usbr.gov*; and/or Regional Director, Bureau of Reclamation, Upper Colorado Region, Attention: UC–402, 125 South State Street, Salt Lake City, Utah 84318–1147, faxogram at (801) 524–3858, or e-mail at *strategies@uc.usbr.gov*.

FOR FURTHER INFORMATION CONTACT: Terrance J. Fulp, PhD., at (702) 293–8500 or e-mail at *strategies@lc.usbr.gov*; and/or Randall Peterson at (801) 524–3633 or e-mail at *strategies@uc.usbr.gov*. If special assistance is required regarding accommodations for attendance at any of the public meetings, please call Nan Yoder at (702) 293–8495, faxogram at (702) 293–8156, or e-mail at *nyoder@lc.usbr.gov* no less than 5 working days prior to the applicable meeting(s).

SUPPLEMENTARY INFORMATION: In recent years the Colorado River Basin experienced the worst five-year drought

in recorded history. Drought in the Basin has impacted system storage, while demands for Colorado River water supplies have continued to increase. In the future, low reservoir conditions may not be limited to drought periods as additional development of Colorado River water occurs. The Colorado River is of strategic importance in the southwestern United States for water supply, hydropower production, recreation, fish and wildlife habitat, and other benefits. In addition, the Republic of Mexico has an allocation to the waters of the Colorado River pursuant to a 1944 treaty with the United States.

In 2001, the Department adopted Interim Surplus Guidelines (66 FR 7772) that are used by the Secretary in making annual determinations regarding "Normal" and "Surplus" conditions for the operation of Lake Mead. Since adoption, these Guidelines have, among other operational and management benefits, allowed the Department and entities in Arizona, California, and Nevada that rely on the Colorado River greater predictability in identifying when Colorado River water in excess of 7.5 maf will be available for use within these three States. In contrast, at this time the Department does not have detailed guidelines in place for annual determinations of releases from Lake Mead of less than 7.5 maf to water users in the three Lower Division States of Arizona, California, and Nevada (often referred to as a "shortage" condition on the lower Colorado River). Therefore, water users who rely on the Colorado River in these States are not currently able to identify particular reservoir conditions under which the Secretary would release less than 7.5 maf for use on an annual basis. Nor are these water users able to identify the amount of any potential future annual reductions in water deliveries.

Over the past year, the seven Colorado River Basin States have been proactively discussing strategies to address the recent period of system-wide drought in the Colorado River Basin. In addition, Reclamation has conducted detailed briefings for stakeholders in the Colorado River Basin and other interested entities regarding future scenarios for Colorado River operations.

Currently, each year, the Secretary establishes an Annual Operating Plan (AOP) for the Colorado River Reservoirs. The AOP describes how Reclamation will manage the reservoirs over a 12-month period, consistent with the Criteria for Coordinated Long-Range Operation of Colorado River Reservoirs Pursuant to the Colorado River Basin Project Act of September 30, 1968 (Long-Range Operating Criteria), the Decree entered by the U.S. Supreme Court in the *Arizona* v. *California* litigation, and other provisions of applicable Federal law. Reclamation consults annually with the Colorado River Basin States, Indian tribes, and other interested parties in the development of the AOP. Further, as part of the AOP process, the Secretary makes annual determinations under the Long-Range Operating Criteria regarding the availability of Colorado River water for deliveries to the Lower Division States. To meet the consultation requirements of Federal law, Reclamation also consults with the Colorado River Basin States, Indian tribes, and other interested parties during the five-year periodic reviews of the Long-Range Operating Criteria.

During the mid-year review of the 2005 AOP conducted this past spring, the Department received conflicting recommendations from the Colorado River Basin States regarding operations of Glen Canyon Dam for the remainder of the 2005 water year. In a May 2, 2005, letter to the Governors of the Colorado River Basin States, issued to complete the 2005 AOP mid-year review, the Secretary directed Reclamation to develop additional strategies to improve coordinated management of the reservoirs in the Colorado River system. Pursuant to that direction, Reclamation conducted a public consultation workshop on May 26, 2005, in Henderson, Nevada; issued a **Federal Register** notice soliciting public comments on June 15, 2005; and conducted public meetings on July 26 and July 28, 2005, in Henderson, Nevada, and Salt Lake City, Utah, respectively. Reclamation received a broad range of public comments and suggestions from these discussions, not all of which can be addressed in this proposed process. In addition, some suggestions may be part of ongoing or future efforts.

In order to assure the continued productive management and use of the Colorado River into the future, Reclamation is now soliciting public comments on the development of Lower Basin shortage guidelines and coordinated management strategies for the operation of Lake Powell and Lake Mead under low reservoir conditions. Reclamation will utilize a public process pursuant to NEPA. By this notice, Reclamation provides notice of its intent to prepare an EIS on this action, and provides notice of its upcoming EIS scoping meetings. Reclamation invites all interested members of the general public, including the seven Colorado River Basin States, Indian tribes, water and power contractors, environmental organizations, representatives of academic and scientific communities, representatives of the recreation industry, and other organizations and agencies to present oral and written comments concerning the format and scope of specific shortage guidelines and coordinated management strategies, and the issues and alternatives to be considered during the development of these proposed guidelines and strategies. Reclamation anticipates publishing a "scoping report" after completion of the public scoping meetings identified in this **Federal Register** notice.

All comments received will be considered as Reclamation develops formal alternatives under NEPA. Similar to the surplus guidelines referenced above, it is likely that these shortage guidelines will be interim in nature. It is the Department's intent that these guidelines and coordinated management strategies will provide guidance to the Secretary's AOP decisions, and provide more predictability to water users and the public throughout the Colorado River Basin, particularly those in the Lower Division States. The Department does not intend to evaluate the decommissioning of Glen Canyon Dam.

Public Disclosure

Written comments, including names and home addresses of respondents, will be made available for public review. Individual respondents may request that their home address be withheld from public disclosure, which will be honored to the extent allowable by law. There may be circumstances in which respondents' identity may also be withheld from public disclosure, as allowable by law. If you wish to have your name and/or address withheld, you must state this prominently at the beginning of your comment. All submissions from organizations, business, and from individuals identifying themselves as representatives or officials of organizations or businesses, will be made available for public disclosure in their entirety.

Mr. Leigh Kuwanwisiwma
Director, Cultural Preservation Office
Hopi Tribe of Arizona
P.O. Box 123
Kykotsmovi, AZ 86039

Subject: Proposed Shortage Guidelines for the Lower Basin of the Colorado River and Coordinated Strategies for the Operation of Lake Powell and Lake Mead, Government-to-Government Consultations

Dear Mr. Kuwanwisiwma:

The Upper and Lower Colorado Regions of the Bureau of Reclamation are proposing to develop Lower Basin shortage guidelines and coordinated reservoir operations strategies for Lake Powell and Lake Mead. A copy of the September 30, 2005 Federal Register notice initiating this process is enclosed.

Reclamation would like to enter into a government-to-government consultation regarding any concerns your tribe might have with our proposed action. In addition, in compliance with the National Historic Preservation Act and Executive Order 13007, regarding sacred sites, Reclamation is seeking your assistance in identifying and evaluating historic properties, especially those of traditional religious or cultural importance, and what potential effects, if any, this proposed action might have on these properties.

A representative from Reclamation will be calling your office within two weeks to facilitate a government-to-government consultation regarding this action, or you may call Mr. John Jamrog, Environmental Compliance Group Manager for the Lower Colorado Region at 702-293-8675.

Sincerely,

William J. Liebhauser, Acting Director
Resources Management Office

BILLING CODE 4312–51–P

DEPARTMENT OF THE INTERIOR

Bureau of Reclamation

Colorado River Reservoir Operations: Development of Lower Basin Shortage Guidelines and Coordinated Management Strategies for Lake Powell and Lake Mead Under Low Reservoir Conditions

AGENCY: Bureau of Reclamation, Interior.

ACTION: Notice of intent to prepare an environmental impact statement (EIS) and notice to solicit comments and hold public scoping meetings on the development of Lower Basin shortage guidelines and coordinated management strategies for the operation of Lake Powell and Lake Mead under low reservoir conditions.

SUMMARY: Pursuant to the National Environmental Policy Act (NEPA), the Bureau of Reclamation (Reclamation) proposes to conduct public scoping meetings and prepare an EIS for the development of Lower Colorado River Basin Shortage Guidelines and Coordinated Management Strategies for Operation of Lake Powell and Lake Mead Under Low Reservoir Conditions. The Secretary of the Interior (Secretary) has directed Reclamation to develop additional Colorado River management strategies to address operations of Lake Powell and Lake Mead under low reservoir conditions.

The proposed action is to develop these guidelines and strategies. Through the NEPA process initiated by this **Federal Register** notice, Reclamation is considering development of: (1) Specific guidelines that will identify those circumstances under which the Department of the Interior (Department) would reduce annual water deliveries from Lake Mead to the Lower Basin States below the 7.5 million acre-feet (maf) Lower Basin apportionment and the manner in which those deliveries would be reduced, and (2) coordinated management strategies for the operation of Lake Powell and Lake Mead.

Alternatives to be analyzed in the EIS have not been developed at this time and will be developed through the NEPA process, including through the upcoming EIS scoping meetings.

DATES AND ADDRESSES: Four public meetings will be held to solicit comments on the scope of specific shortage guidelines and other coordinated management strategies and the issues and alternatives that should be analyzed. Oral and written comments will be accepted at the public meetings to be held at the following locations:

- Tuesday, November 1, 2005—6 p.m. to 8 p.m., Hilton Salt Lake City Center, Topaz Room, 255 South West Temple, Salt Lake City, Utah.
- Wednesday, November 2, 2005—6 p.m. to 8 p.m., Adam's Mark Hotel, Tower Court D, 1550 Court Place, Denver, Colorado.
- Thursday, November 3, 2005—6 p.m. to 8 p.m., Arizona Department of Water Resources, Third Floor, Conference Rooms A&B, 500 North Third Street, Phoenix, Arizona.
- Tuesday, November 8, 2005—6 p.m. to 8 p.m., Henderson Convention Center, Grand Ballroom, 200 South Water Street, Henderson, Nevada.

Written comments on the proposed development of these strategies may be sent by close of business on *Wednesday, November 30, 2005*, to: Regional Director, Bureau of Reclamation, Lower Colorado Region, Attention: BCOO–1000, PO Box 61470, Boulder City, Nevada 89006–1470, faxogram at (702) 293–8156, or e-mail at *strategies@lc.usbr.gov*; and/or Regional Director, Bureau of Reclamation, Upper Colorado Region, Attention: UC–402, 125 South State Street, Salt Lake City, Utah 84318–1147, faxogram at (801) 524–3858, or e-mail at *strategies@uc.usbr.gov.*

FOR FURTHER INFORMATION CONTACT: Terrance J. Fulp, PhD., at (702) 293–8500 or e-mail at *strategies@lc.usbr.gov*; and/or Randall Peterson at (801) 524–3633 or e-mail at *strategies@uc.usbr.gov.* If special assistance is required regarding accommodations for attendance at any of the public meetings, please call Nan Yoder at (702) 293–8495, faxogram at (702) 293–8156, or e-mail at *nyoder@lc.usbr.gov* no less than 5 working days prior to the applicable meeting(s).

SUPPLEMENTARY INFORMATION: In recent years the Colorado River Basin experienced the worst five-year drought

Federal Register / Vol. 70, No. 189 / Friday, September 30, 2005 / Notices 57323

in recorded history. Drought in the Basin has impacted system storage, while demands for Colorado River water supplies have continued to increase. In the future, low reservoir conditions may not be limited to drought periods as additional development of Colorado River water occurs. The Colorado River is of strategic importance in the southwestern United States for water supply, hydropower production, recreation, fish and wildlife habitat, and other benefits. In addition, the Republic of Mexico has an allocation to the waters of the Colorado River pursuant to a 1944 treaty with the United States.

In 2001, the Department adopted Interim Surplus Guidelines (66 FR 7772) that are used by the Secretary in making annual determinations regarding "Normal" and "Surplus" conditions for the operation of Lake Mead. Since adoption, these Guidelines have, among other operational and management benefits, allowed the Department and entities in Arizona, California, and Nevada that rely on the Colorado River greater predictability in identifying when Colorado River water in excess of 7.5 maf will be available for use within these three States. In contrast, at this time the Department does not have detailed guidelines in place for annual determinations of releases from Lake Mead of less than 7.5 maf to water users in the three Lower Division States of Arizona, California, and Nevada (often referred to as a "shortage" condition on the lower Colorado River). Therefore, water users who rely on the Colorado River in these States are not currently able to identify particular reservoir conditions under which the Secretary would release less than 7.5 maf for use on an annual basis. Nor are these water users able to identify the amount of any potential future annual reductions in water deliveries.

Over the past year, the seven Colorado River Basin States have been proactively discussing strategies to address the recent period of system-wide drought in the Colorado River Basin. In addition, Reclamation has conducted detailed briefings for stakeholders in the Colorado River Basin and other interested entities regarding future scenarios for Colorado River operations.

Currently, each year, the Secretary establishes an Annual Operating Plan (AOP) for the Colorado River Reservoirs. The AOP describes how Reclamation will manage the reservoirs over a 12-month period, consistent with the Criteria for Coordinated Long-Range Operation of Colorado River Reservoirs Pursuant to the Colorado River Basin Project Act of September 30, 1968 (Long-Range Operating Criteria), the Decree entered by the U.S. Supreme Court in the *Arizona* v. *California* litigation, and other provisions of applicable Federal law. Reclamation consults annually with the Colorado River Basin States, Indian tribes, and other interested parties in the development of the AOP. Further, as part of the AOP process, the Secretary makes annual determinations under the Long-Range Operating Criteria regarding the availability of Colorado River water for deliveries to the Lower Division States. To meet the consultation requirements of Federal law, Reclamation also consults with the Colorado River Basin States, Indian tribes, and other interested parties during the five-year periodic reviews of the Long-Range Operating Criteria.

During the mid-year review of the 2005 AOP conducted this past spring, the Department received conflicting recommendations from the Colorado River Basin States regarding operations of Glen Canyon Dam for the remainder of the 2005 water year. In a May 2, 2005, letter to the Governors of the Colorado River Basin States, issued to complete the 2005 AOP mid-year review, the Secretary directed Reclamation to develop additional strategies to improve coordinated management of the reservoirs in the Colorado River system. Pursuant to that direction, Reclamation conducted a public consultation workshop on May 26, 2005, in Henderson, Nevada; issued a **Federal Register** notice soliciting public comments on June 15, 2005; and conducted public meetings on July 26 and July 28, 2005, in Henderson, Nevada, and Salt Lake City, Utah, respectively. Reclamation received a broad range of public comments and suggestions from these discussions, not all of which can be addressed in this proposed process. In addition, some suggestions may be part of ongoing or future efforts.

In order to assure the continued productive management and use of the Colorado River into the future, Reclamation is now soliciting public comments on the development of Lower Basin shortage guidelines and coordinated management strategies for the operation of Lake Powell and Lake Mead under low reservoir conditions. Reclamation will utilize a public process pursuant to NEPA. By this notice, Reclamation provides notice of its intent to prepare an EIS on this action, and provides notice of its upcoming EIS scoping meetings. Reclamation invites all interested members of the general public, including the seven Colorado River Basin States, Indian tribes, water and power contractors, environmental organizations, representatives of academic and scientific communities, representatives of the recreation industry, and other organizations and agencies to present oral and written comments concerning the format and scope of specific shortage guidelines and coordinated management strategies, and the issues and alternatives to be considered during the development of these proposed guidelines and strategies. Reclamation anticipates publishing a "scoping report" after completion of the public scoping meetings identified in this **Federal Register** notice.

All comments received will be considered as Reclamation develops formal alternatives under NEPA. Similar to the surplus guidelines referenced above, it is likely that these shortage guidelines will be interim in nature. It is the Department's intent that these guidelines and coordinated management strategies will provide guidance to the Secretary's AOP decisions, and provide more predictability to water users and the public throughout the Colorado River Basin, particularly those in the Lower Division States. The Department does not intend to evaluate the decommissioning of Glen Canyon Dam.

Public Disclosure

Written comments, including names and home addresses of respondents, will be made available for public review. Individual respondents may request that their home address be withheld from public disclosure, which will be honored to the extent allowable by law. There may be circumstances in which respondents' identity may also be withheld from public disclosure, as allowable by law. If you wish to have your name and/or address withheld, you must state this prominently at the beginning of your comment. All submissions from organizations, business, and from individuals identifying themselves as representatives or officials of organizations or businesses, will be made available for public disclosure in their entirety.

Dated: September 22, 2005.

Rick L. Gold,

Regional Director—UC Region, Bureau of Reclamation.

Dated: September 22, 2005.

Jayne Harkins,

Deputy Regional Director—LC Region, Bureau of Reclamation.

Subject: Presentation of Draft Alternatives Being Considered for the Proposed Shortage Guidelines for the Lower Basin of the Colorado River and Coordinated Strategies for the Operation of Lake Powell and Lake Mead, Under Low Reservoir Conditions, Government-to-Government Consultations

Dear Chairman:

As part of continuing government-to-government consultations for the development of Lower Basin shortage guidelines and coordinated reservoir operations strategies for Lake Powell and Lake Mead, under low reservoir conditions, the Upper and Lower Colorado Regions of the Bureau of Reclamation request to meet with consulting tribes to present the draft alternatives currently being considered for analysis under the planned EIS.

During the meeting we will provide the tribal representatives with an update of progress on the project, a brief discussion of the recently published Scoping Summary Report, and a detailed presentation of the draft alternatives being considered for analysis, including preliminary results of modeling predictions of reservoir conditions as a result of each alternative being considered. A court reporter will be on hand to record the discussions at the meeting, including any input or suggestions you may have regarding the draft alternatives. The Definitions for Draft Alternatives and Elements/Options Matrix, and Draft Alternatives and Elements/Options Considered in Each Alternative, are enclosed for your review leading up to the meeting.

Although several tribal representatives have expressed interest in the potential impacts these alternatives may have on their reserved water rights, contracts, or operations, the analysis of those impacts has not yet been initiated. Therefore we will not be able to fully articulate these impacts with any certainty at this time. Our intention is to inform and engage tribal governments about the assumptions and proposals being considered for analysis at important stages of the EIS process. These impacts will be addressed through the EIS process in the future.

To accommodate the traveling distances of the majority of the consulting tribes, we are recommending a meeting in Phoenix, Arizona on one of the following days: May 22; May 23; or May 30, 2006. Please contact Mr. John Jamrog, Environmental Compliance Group Manager for the Lower Colorado Region, by phone at 702-293-8675, or via e-mail at jjamrog@lc.usbr.gov, to confirm which dates are best for you. A representative from Reclamation will also be calling your office within the week to confirm your availability and participation and to inform you of the exact location of the meeting facility in Phoenix.

Sincerely,

AMELIA C. PORTER

Definitions for Draft Alternatives and Elements/Options Matrix

(Working Draft: April 13, 2006 version)

- **Absolute protection of a specified reservoir elevation**
  - The reservoir release is reduced by the amount needed to keep the reservoir above the specified elevation (i.e., inflow = outflow)
  - Example: Absolute protection of elevation 3490' at Powell would reduce Powell's release below 8.23 MAF as Powell nears elevation 3490' and would result in additional water stored in Powell and less water in Mead
  - Example: Absolute protection of elevation 1000' in Mead would reduce Mead's release as Mead nears elevation 1000' and would result in shortages at whatever magnitude necessary

- **No protection of reservoir elevations**
  - The reservoir continues to make specified releases until there is no water above the dead pool; then inflow = outflow

- **Reservoir balancing**
  - Lake Powell's release is computed to keep it and Lake Mead at equal storage (or at the same percent full)

- **Modification of Lake Powell's annual release based on elevation**
  - The annual release changes each year depending upon where Lake Powell's elevation is at the beginning of the year (or can also be based on where the elevation is forecasted to be at the end of the year)

- **Proactive Shortage**
  - Shortages are applied at higher levels in the reservoir in order to reduce the chance of going below a lower, specified elevation
  - Results in more frequent shortages of smaller magnitudes than an absolute protection strategy
  - **Probabilistic protection -** shortages are taken at higher levels to approximate a specified chance

1

Draft Alternatives and Elements/Options Considered in Each Alternative

Working Draft: April 13, 2006 version

Alternatives		A Shortage Guidelines to reduce deliveries/releases from Lake Mead	B Coordinated Reservoir Operations (Lake Mead & Lake Powell)	C Lake Mead Storage and Delivery of Conserved and Non-system Water	D Interim Surplus Guidelines for deliveries/releases from Lake Mead
Alt. 1	No Action Alternative	• Two level shortage strategy - probabilistic protection of elevation 1050' at Lake Mead (80P1050) and absolute protection of elevation 1000' at Lake Mead.	• Minimum objective release of 8.23 MAF unless storage equalization releases are required. • Absolute protection of elevation 3490' at Lake Powell.	• No water management/accounting mechanism for storage and delivery of water conserved through extraordinary water conservation and/or water augmentation programs.	• No modification or extension of the Interim Surplus Guidelines which end in 2016. • Beginning in 2017, surplus declarations revert to the 70R strategy.
Alt. 2	Basin States Preliminary Alternative	• Stepped shortages up to 600 KAF. • Initiate efforts to develop additional guidelines for shortages if Lake Mead falls below elevation 1025' (Note: includes reconsultation with Basin States).	• Under low reservoir storage conditions, either reduce Lake Powell release or balance contents depending on projected Lake Mead and Lake Powell elevations. • No absolute protection of 3490' at Lake Powell.	• Storage/delivery water management/accounting program at Lake Mead for water conserved through extraordinary water conservation and/or water augmentation. • Maximum created storage credit of 625 KAF per year. • Maximum total additional Lake Mead storage through extraordinary conservation and/or augmentation of 2.1 MAF. • Maximum delivery from Lake Mead of water developed by extraordinary conservation and/or augmentation of 1.0 MAF per year.	• Modification of Interim Surplus Guidelines to eliminate Partial Domestic Surplus condition. • The modified guidelines are implemented from 2008 through 2025. • Beginning in 2026, surplus declarations revert to the 70R strategy.
Alt. 3	Conservation Before Shortage Alternative	• Absolute protection of SNWA intake (elevation 1000') at Lake Mead.	• Minimum objective release of 8.23 MAF unless storage equalization releases are required. • Absolute protection of elevation 3490' at Lake Powell.	• Conservation of different volumes of water tied to varying Lake Mead water levels prior to shortage.	• No modification or extension of the Interim Surplus Guidelines which end in 2016. • Beginning in 2017, surplus declarations revert to the 70R strategy.
Alt. 4	No Protections Alternative	• No protection of critical elevations. • Release full annual entitlement amounts until drawn down to top of dead pool: then outflow = inflow.	• Minimum objective release of 8.23 MAF unless storage equalization releases are required. • 8.23 MAF until drawn down to top of dead pool: then outflow = inflow	• No water management/accounting mechanism for storage and delivery of water conserved through extraordinary water conservation and/or water augmentation programs.	• No modification or extension of the Interim Surplus Guidelines which end in 2016. • Beginning in 2017, surplus declarations revert to the 70R strategy.
Alt. 5	Power Protection Alternative	• Absolute protection of minimum power pool elevation (1050') at Lake Mead.	• Minimum objective release of 8.23 MAF unless storage equalization releases are required. • Absolute protection of minimum power pool elevation (3490') at Lake Powell.	• No water management/accounting mechanism for storage and delivery of water conserved through extraordinary water conservation and/or water augmentation programs.	• No modification or extension of the Interim Surplus Guidelines which end in 2016. • Beginning in 2017, surplus declarations revert to the 70R strategy.

Common assumptions to ALL Alternatives:
1. First year of modeling under above-identified alternatives is 2008 and extends to 2060 (53 years) (Note: water elevation for January 1, 2008 will be projected using the May 2006 24-Month Study).
2. Future hydrologic sequences will be based on the 99-year natural flow record (1906-2004).
3. All alternatives revert to No Action modeling assumptions beginning in 2026.
4. Analysis of all alternatives will assume implementation of shortages to Mexico pursuant to Article 10 of 1944 Water Treaty with Mexico when Lower Basin shortage is declared.

Honorable Charles Vaughn
Chairman, Hualapai Tribe
P.O. Box 179
Peach Springs, AZ 86434

Subject: Response to Request for Consultation Meeting Regarding Shortage Guidelines EIS

Dear Chairman:

On April 6, 2006, Ms. Nancy Coulam, of the Bureau of Reclamation's Upper Colorado Region, spoke with you on the phone regarding government-to-government consultation between Reclamation and the Hualapai Tribe. This discussion was concerning Reclamation's proposal to develop Lower Basin shortage guidelines and coordinated reservoir operations strategies for Lake Powell and Lake Mead, under low reservoir conditions. An Environmental Impact Statement (EIS) is currently being prepared by Reclamation to analyze this proposal.

During that conversation, you expressed that the Hualapai Tribe had concerns about Lakes Powell and Mead, preserving a specific in-stream flow in the Colorado River, and protection of cultural resources if changes in the river level result in exposure or inundation of sites. You also stated an interest in having a face-to-face meeting to discuss the proposed action, as well as the concerns of the tribe. You should have already received a letter inviting you to a tribal consultation meeting scheduled for the end of this month regarding the alternatives being considered for analysis in the EIS. The meeting is planned to be in Phoenix, Arizona and will be hosted by Reclamation for all consulting tribes. In addition to that invitation, we would welcome the opportunity to meet with you personally, along with any staff or tribal members you wish to include, at our mutual convenience.

Please contact Mr. John Jamrog, Environmental Compliance Group Manager for the Lower Colorado Region at (702) 293-8675 or me to arrange a meeting with appropriate Reclamation management.

Sincerely,

William J. Liebhauser, Director
Resources Management Office

Subject: Request for Meeting Regarding for the Lower Colorado Basin Shortage Guidelines and Coordinated Management Strategies for Lake Powell and Lake Mead

Dear Chairman:

Thank you for your letter dated August 28, 2006, regarding the Environmental Impact Statement (EIS) for the Lower Colorado Basin Shortage Guidelines and Coordinated Management Strategies for Lake Powell and Lake Mead.

Since receipt of your letter, we have also been contacted by Mr. H. Scott Althouse, of Williams and Works P.A., who is representing the Hualapai Tribe. We have been working with him to establish a mutually acceptable date for a government-to-government consultation meeting. We will continue to work with you and Mr. Althouse to accomplish this goal. Given the current schedule for the EIS, we suggest scheduling our meeting as soon as possible.

We appreciate your assistance and willingness to consult with us regarding this important undertaking. Although we will continue to work with Mr. Althouse by phone, please feel free to contact Mr. John Jamrog, Environmental Compliance Group Manager for the Lower Colorado Region in Boulder City, NV, at (702) 293-8675, directly, at any time.

Sincerely,

William J. Liebhauser, Director

JAN 22 2007

Interested Parties (See Enclosed List)

Subject: Government-to-Government Consultation on the Colorado River Interim Guidelines for Lower Basin Shortages and Coordinated Operations for Lake Powell and Lake Mead

Dear Tribal Representatives:

As part of continuing government-to-government consultations on the Colorado River Interim Guidelines for Lower Basin Shortages and Coordinated Operations for Lake Powell and Lake Mead, the Upper and Lower Colorado Regions of the Bureau of Reclamation request to meet with tribal representatives to discuss key aspects of the Draft Environmental Impact Statement (Draft EIS).

We invite you to meet from 12:00 p.m. to 3:00 p.m. Pacific Standard Time on February 22, 2007, in Mezzanine Room #3, McCarran International Airport, Las Vegas, Nevada. During the meeting, we will provide tribal representatives with an update of progress on the project and present information on key aspects of the Draft EIS that will be published on February 28, 2007. A court reporter will be present to record the discussions during the meeting. An agenda and power point presentation will be provided for you at the meeting.

If you are unable to attend, the following conference line is provided for your convenience: 1-866-830-3963 (code: 5142989).

Please contact Amber Cunningham at 702-293-8472 if you have any questions.

Sincerely,

Terrance J. Fulp, Ph.D.
Area Manager

MAR 1 6 2007

Interested Parties (See Enclosed List)

Subject: Government-to-Government Consultation on the Colorado River Interim Guidelines for Lower Basin Shortages and Coordinated Operations for Lake Powell and Lake Mead

Dear Tribal Representative:

As part of our continuing government-to-government consultations on the Colorado River interim guidelines for Lower Basin shortages and coordinated operations for Lake Powell and Lake Mead, the Upper and Lower Colorado Regions of the Bureau of Reclamation request to meet with tribal representatives to discuss key aspects of the Draft Environmental Impact Statement (Draft EIS).

We invite you to meet from 10:00 a.m. to 1:00 p.m. on April 4, 2007, in the 12th Floor Conference Room at Two Arizona Center, 400 North 5th Street, Phoenix, Arizona. During the meeting we will provide tribal representatives with an update of progress on the project and information on key aspects of the Draft EIS that is currently available for public comment. A court reporter will be present to record the discussions during the meeting. An agenda, handouts, and presentation will be provided for you at the meeting.

A fact sheet about the project is enclosed for your consideration. It provides information on (1) obtaining copies of the Draft EIS, (2) submitting comments on the Draft EIS during the public comment period (March 1, through April 30, 2007), and (3) the announcement of three April 2007 public hearing dates on the Draft EIS.

Please contact Ms. Amber Cunningham at 702-293-8472 if you have any questions.

Sincerely,

Terrance J. Fulp, Ph.D.
Area Manager

RECLAMATION
Managing Water in the West

U.S. Department of the Interior
Bureau of Reclamation

FACT SHEET #4 FEBRUARY 2007

Colorado River Interim Guidelines for Lower Basin Shortages and Coordinated Operations for Lake Powell and Lake Mead

Draft EIS Available for Review and Comment

The Bureau of Reclamation (Reclamation) acting on behalf of the Secretary of Interior is announcing availability of the Draft environmental impact statement (Draft EIS) on the proposed adoption of specific Colorado River interim guidelines for Lower Basin shortages and operations for Lake Powell and Lake Mead, particularly under drought and low reservoir conditions. The Draft EIS presents four possible action alternatives for implementation, plus a "No Action Alternative." The action alternatives reflect input received from Reclamation staff, the cooperating agencies, stakeholders, and other interested parties.

The Draft EIS is available for viewing and copying at Reclamation's project website at: http://www.usbr.gov/lc/region/programs/strategies.html. Printed versions are available at various public facilities (see list on reverse). Parties interested in receiving a compact disc or hard copy can send a written request to the address below. Please use the same address to submit any comments on the Draft EIS. Comments must be submitted no later than April 30, 2007.

Direct Draft EIS comments or inquiries to:

Regional Director, Lower Colorado Region, Bureau of Reclamation, Attention: BCOO-1000, P.O. Box 61470, Boulder City, Nevada 89006-1470; faxogram at (702) 293-8156; or e-mail at strategies@lc.usbr.gov.

Public Hearing Dates and Locations

Reclamation has scheduled three hearings to receive public comments on the Draft EIS. Comments will be considered in the selection of the preferred alternative and will be addressed in the Final EIS.

Meetings are from 6:00 p.m. to 9:00 p.m.

Tuesday, April 3, 2007
Henderson Convention Center
Sierra Room
200 South Water Street
Henderson, Nevada

Wednesday, April 4, 2007
Phoenix Airport Marriott
Buckhorn Room
1101 North 44th Street
Phoenix, Arizona

Thursday, April 5, 2007
Hilton Salt Lake City Center
Canyon Room A & B
255 South West Temple
Salt Lake City, Utah

To request special assistance, please contact Nan Yoder at (702) 293-8495 or e-mail at strategies@lc.usbr.gov.

The public review period for the Draft EIS commenced on February 28, 2007 and will extend until April 30, 2007.

Project Need and Purpose

During the period from 2000-2006, the Colorado River has experienced the worst drought in approximately one hundred years of record keeping. During this period, storage in Colorado River reservoirs has dropped from nearly full to less than 60 percent of capacity at the end of 2006. Currently, the Department of the Interior (Department) does not have specific operational guidelines in place to address the operation of Lake Mead and Lake Powell during drought and low reservoir conditions. Accordingly, the Department proposes the adoption of specific interim guidelines for Lower Basin shortages and coordinated operations of Lake Powell and Lake Mead.

The purpose of the proposed federal action is to: 1) improve Reclamation's management of the Colorado River by considering the tradeoffs between the frequency and magnitude of reductions of water deliveries, and considering the effects on water storage in Lake Powell and Lake Mead, water supply, power production, recreation, and other environmental resources; 2) provide mainstream U.S. users of Colorado River water, particularly those in the Lower Division states, a greater degree of predictability with respect to the amount of annual water deliveries in future years, particularly under drought and low reservoir conditions; and, 3) provide additional mechanisms for the storage and delivery of water supplies in Lake Mead.

For Further Project Information

Please contact Terrance J. Fulp, Ph.D., at (702) 293-8500 or e-mail at strategies@lc.usbr.gov; and/or Randall Peterson at (801) 524-3633. You can also visit the project web site at: www.usbr.gov/lc/region/programs/strategies.html.

Subject: Government-to-Government Consultation on the Colorado River Interim Guidelines for Lower Basin Shortages and Coordinated Operations for Lake Powell and Lake Mead Environmental Impact Statement (EIS)

Dear Tribal Representative:

As part of our continuing government-to-government consultations, the Bureau of Reclamation's Upper and Lower Colorado Regions request to meet with tribal representatives on Friday, September 14, 2007, from 10:00 a.m. to 12:00 p.m., in the 1st Floor Roosevelt Conference Room at the Bureau of Reclamation, 6150 West Thunderbird Road, Glendale, Arizona 85306-4001.

During the meeting Reclamation will provide tribal representatives with an update on the progress of the project, including the identification of the preferred alternative and changes made in the Shortage Allocation Model for the final EIS. A court reporter will be present to record the discussions during the meeting. An agenda, handouts, and presentation will be provided for you at the meeting.

Additional project information is available on Reclamation's website at: http://www.usbr.gov/lc/region/programs/strategies.html.

Please contact Ms. Amber Cunningham at 702-293-8500 if you have questions.

Sincerely,

Steven C. Hvinden

Seven Basin States' Proposals Regarding Colorado River Interim Operations

The seven Colorado River Basin States developed and submitted a Preliminary Proposal Regarding Colorado River Interim Operations to the Secretary of the Department of the Interior (Secretary) in a letter dated February 3, 2006. As a comment on the Draft EIS, the seven Colorado River Basin States revised their preliminary proposal and submitted it to the Secretary in a letter dated April 30, 2007. The full text of the seven Colorado River Basin States' revised and preliminary proposals regarding the Final EIS are provided in this appendix.

J.1 Revised Basin States' Proposal – Letter to Secretary of the Interior

The States of Arizona, California, Colorado, Nevada,
New Mexico, Utah and Wyoming
Governors' Representatives on Colorado River Operations

April 30, 2007

Honorable Dirk Kempthorne, Secretary
Department of the Interior
1849 C. Street, NW
Washington, D.C. 20240

Re: Basin States' Comments on *Draft Environmental Impact Statement, Colorado River Interim Guidelines for Lower Basin Shortages and Coordinated Operations for Lake Powell and Lake Mead*

Dear Secretary Kempthorne:

Thank you for the opportunity to comment on the *Draft Environmental Impact Statement, Colorado River Interim Guidelines for Lower Basin Shortages and Coordinated Operations for Lake Powell and Lake Mead* (72 Fed. Reg. 9,026) (Feb. 28, 2007) (hereinafter "DEIS"). The Basin States emphasize that the Basin States' Alternative best meets critical elements of the purpose and need statement articulated in the DEIS. It does so by giving water managers the certainty to engage in meaningful long-range planning while also promulgating programs to increase operational and resource management flexibility on the River. This is particularly important given the impacts of the drought on the Colorado River system over the last seven years and the uncertain hydrology going forward. Thus, the Basin States strongly encourage you to select the Basin States' Alternative analyzed in the DEIS, together with the modifications outlined in this letter and the included attachments ("Basin States' Proposal"), as the preferred alternative in the Final Environmental Impact Statement ("FEIS") and the selected action in the Record of Decision ("ROD").

<u>Basin States' Proposal</u>

The Basin States have made tremendous progress over the last two years in setting aside contentious issues and reaching agreements regarding operation of the Colorado River system reservoirs. Since the Basin States originally forwarded a Preliminary Proposal and draft Seven States' Agreement to your predecessor on February 3, 2006 ("Preliminary Proposal"), the Basin States have finalized a number of agreements and proposals. These documents, which are described in detail below, incorporate and give further definition to each of the elements of the Preliminary Proposal and the Basin States' Alternative in the DEIS. The Basin States believe that if all material terms of the Basin States' Proposal are included in the ROD, it will establish the first comprehensive set of detailed operating guidelines in the history of the Colorado River.

The Basin States' Proposal consists of the following documents:

1. Agreement Concerning Colorado River Management and Operations (Attachment "A"). This agreement among major Colorado River water interests in all seven states that share the River system is the foundation document in the Basin States' Proposal. This agreement memorializes the consensus recommendation to the Secretary for Colorado River management and operations during an interim period, sets forth agreements regarding pursuit of system augmentation and efficiency projects, and establishes a rigorous process for the resolution of claims and controversies between the parties in an effort to set aside long standing disputes on the River.

2. Proposed Interim Guidelines for Colorado River Operations (Attachment "B"). Building upon the Preliminary Proposal, the Basin States have drafted a comprehensive set of guidelines to govern Colorado River operations during the interim period. If adopted, these proposed guidelines would: (1) replace the Interim Surplus Guidelines; (2) establish guidelines for coordinated operations for Lakes Powell and Mead; (3) establish shortage guidelines for use within the United States; and (4) establish parameters for the creation and release of Intentionally Created Surplus ("ICS") and Developed Shortage Supplies ("DSS").

3. Forbearance Agreement (Attachment "C"). This draft agreement among the Lower Division States and major water users within those states recognizes that, in the absence of forbearance by the parties, surplus water is apportioned for use according to the percentages provided in Article II(B)(2) of the Consolidated Decree in *Arizona v. California*. The execution of this agreement will facilitate implementation of the ICS program.

4. Shortage Sharing Agreement between Arizona and Nevada (Attachment "D"). As anticipated by the Basin States' February 3, 2006 Preliminary Proposal, Arizona and Nevada have executed a Shortage Sharing Agreement premised upon the Secretary's reductions in deliveries within the United States of 333,000, 417,000 and 500,000 acre-feet per year based upon specific Lake Mead elevations.

5. Delivery Agreement. It will be necessary for the Secretary to enter into one or more agreements that enable and obligate the United States to deliver ICS and DSS to entities that create ICS or DSS in conformance with relevant provisions of the Guidelines and the Forbearance Agreement. At this time, the Basin States are developing a draft delivery agreement for the Department of the Interior's ("Interior") consideration and look forward to working with Interior on drafting one or more agreements that can be executed concurrently with the issuance of the ROD. The Basin States request that the U.S. Bureau of Reclamation ("Reclamation") include appropriate analysis of the

anticipated execution of one or more agreements to deliver ICS or DSS within the preferred alternative in the FEIS and the selected action in the ROD.

Implementation of any alternative that does not include all material terms of the Basin States' Proposal will carry with it a significant degree of uncertainty given that the Basin States' Agreement, Forbearance Agreement and Arizona-Nevada Shortage Sharing Agreement are each contingent upon the issuance of a ROD that is consistent with the material terms of those agreements. These agreements make it possible for components of the proposed action, such as coordinated management of Lakes Mead and Powell and the creation and release of ICS, to be implemented without adversarial actions involving the Basin States and major water users on the Colorado River.

Reduced Deliveries to Mexico

Recent negotiations among the Basin States and major water users in those states have involved multiple issues of critical importance to the Basin States. However, in the course of these negotiations no issue has surpassed the importance of how the United States exercises its authority to reduce the quantity of water allotted to Mexico under Article 10(a) of the Mexican Water Treaty of 1944.

In the Preliminary Proposal the Basin States recommended that the Secretary reduce deliveries from Lake Mead by 400,000, 500,000 and 600,000 acre-feet per year within the United States and Mexico at certain Lake Mead elevations. In accordance with the Preliminary Proposal, Arizona and Nevada have executed a Shortage Sharing Agreement premised upon the imposition by the Secretary of shortages within the United States of 333,000, 417,000 and 500,000 acre-feet per year at the same Lake Mead elevations contained in the Preliminary Proposal. For the first 600,000 acre-feet per year of any reductions in deliveries in any year due to a declared shortage, the Basin States have agreed that Arizona and Nevada will not take more than 500,000 acre-feet per year in aggregate and California will not take any reductions. The DEIS substantially incorporates the assumptions contained in the Preliminary Proposal, the Basin States' Agreement and the Shortage Sharing Agreement into its consideration and analysis of the Basin States' Alternative.

Due to the critical nature of this issue, the Basin States believe that the Secretary should include these assumptions as part of the preferred alternative in the FEIS and the selected action in the ROD. The Basin States strongly urge the United States to exercise its authority to reduce the quantity of water allotted to Mexico in years in which the Secretary imposes shortages in deliveries of water from Lake Mead in the United States in a quantity consistent with the assumptions in the DEIS, and in other appropriate circumstances.

Mexican Participation in ICS Program

The Basin States support the concept of Mexico participating in the ICS program at some time in the future, provided that its participation is addressed in the context of other river operation matters and is part of a comprehensive arrangement between the two nations that incorporates, at a minimum, the material terms of the Basin States' Proposal. The Basin States stand ready to discuss this comprehensive arrangement.

Colorado River Augmentation Projects

Implementation of projects to augment the long-term supply of the Colorado River is of utmost importance not only to the Basin States and the millions of people who live here, but to the nation as a whole. While no specific augmentation projects are included in the current Basin States' Proposal, the need to develop a process to implement augmentation projects must remain at the forefront of the Basin States' and Interior's agendas. Changes to existing or new federal regulations may be necessary to effectuate augmentation projects.

The Preliminary Proposal outlined a concept for water users in Arizona, California, or Nevada to secure additional water supplies by funding the development of a non-Colorado River System water supply in one Lower Division State for use in another Lower Division State by exchange. Through the cooperation of the International Boundary and Water Commission, United States and Mexico, similar arrangements could be established by which non-Colorado River System water supplies in Mexico could be developed for use in the United States by exchange.

The Basin States view the inclusion in the DEIS of a quantitative analysis of the impacts to the Colorado River resulting from the implementation of future augmentation projects as a positive step and encourage you to include the same analysis in the FEIS in order to begin to establish the environmental compliance framework for future augmentation projects.

Conclusion

In closing, the Basin States thank you for your leadership and urge Interior to adopt a ROD that includes all of the material terms of the Basin States' Proposal.

Attachment A

Agreement Concerning Colorado River Management and Operations

This attachment to Appendix J contains the text of Attachment A to the Revised Basin States' Proposal.

ATTACHMENT A

AGREEMENT CONCERNING COLORADO RIVER MANAGEMENT AND OPERATIONS

This Agreement is entered into effective as of April 23, 2007, by and among the Arizona Department of Water Resources; Colorado River Board of California; Colorado Water Conservation Board; Governor's Representative for the State of Colorado; Colorado River Commission of the State of Nevada; Southern Nevada Water Authority; New Mexico Interstate Stream Commission; Utah Division of Water Resources; Utah Interstate Stream Commissioner; and Wyoming State Engineer.

RECITALS

A. Parties.

1. Arizona.

   a. The Arizona Department of Water Resources, through its Director, is the successor to the signatory agency of the State for the 1922 Colorado River Compact, and the 1944 Contract for Delivery of Water with the United States, both authorized and ratified by the Arizona Legislature, A.R.S. §§ 45-1301 and 1311. Pursuant to A.R.S. §§ 45-107, the Director is authorized and directed, subject to the limitations in A.R.S. §§ 45-106, for and on behalf of the State of Arizona, to consult, advise and cooperate with the Secretary of the Interior of the United States with respect to the exercise by the Secretary of Congressionally authorized authority relative to the waters of the Colorado River (including but not limited to the Boulder Canyon Project Act, 43 U.S.C. § 617, and the 1968 Colorado River Basin Project Act, 43 U.S.C. § 1501) and with respect to the development, negotiation and execution of interstate agreements. Additionally, under A.R.S. § 45-105(A)(9), the Director is authorized to "prosecute and defend all rights, claims and privileges of this state respecting interstate streams."

   b. Under A.R.S. § 11-951 et. seq., the Director is authorized to enter into Intergovernmental Agreements with other public agencies, which includes another state; departments, agencies, boards and commissions of another state; and political subdivisions of another state.

2. California. The Chairman of the Colorado River Board of California, acting as the Colorado River Commissioner pursuant to California Water Code section 12525, has the authority to exercise on behalf of California every right and power granted to California by the Boulder Canyon Project Act, and to do and perform all other things necessary or expedient to carry out the purposes of the Colorado River Board.

1

3. Colorado.

   a. Section 24-1-109, Colorado Revised Statutes (2005) provides that "Interstate compacts authorized by law shall be administered under the direction of the office of the governor." This includes the Colorado River Compact and the Upper Colorado River Basin Compact. Section 37-60-109 provides that "the governor from time to time, with approval of the board, shall appoint a commissioner, who shall represent the state of Colorado upon joint commissions to be composed of commissioners representing the state of Colorado and another state or other states for the purpose of negotiating and entering into compacts or agreements between said states…" By letter dated April 12, 2006, the Governor appointed Upper Colorado River Commissioner Scott Balcomb to represent the State of Colorado.

   b. Section 37-60-106, subsections (e) and (i), C.R.S. (2005), authorize the Colorado Water Conservation Board to "cooperate with the United States and the agencies thereof, and with other states for the purpose of bringing about the greater utilization of the water of the state of Colorado and the prevention of flood damages," and "to confer with and appear before the officers, representatives, boards, bureaus, committees, commissions, or other agencies of other states, or of the federal government, for the purpose of protecting and asserting the authority, interests, and rights of the state of Colorado and its citizens with respect to the waters of the interstate streams in this state." Therefore, by statute the Director of the Colorado Water Conservation Board is authorized to negotiate with and enter into agreements with other state entities within the Colorado River Basin.

4. Nevada.

   a. The Colorado River Commission of Nevada (CRCN) is an agency of the State of Nevada, authorized generally by N.R.S. §§ 538.041 and 538.251. CRCN is authorized by N.R.S. § 538.161 (6), (7) to enter into this Agreement. The CRCN, in furtherance of the State of Nevada's responsibility to promote the health and welfare of its people in Colorado River matters, makes this Agreement to supplement the supply of water in the Colorado River which is available for use in Nevada, augment the waters of the Colorado River, and facilitate the more flexible operation of dams and facilities by the Secretary of the Interior of the United States. The Chairman of the Commission, signatory hereto, serves as one of the Governor's representatives as contemplated by Section 602(b) of the 1968 Colorado River Basin Project Act, 43 U.S.C. § 1552(b) and the Criteria for Coordinated Long-Range Operation of Colorado River Reservoirs Pursuant to the Colorado River Basin Project Act.

b. The Southern Nevada Water Authority (SNWA) is a Nevada joint powers agency and political subdivision of the State of Nevada, created by agreement dated July 25, 1991, as amended November 17, 1994 and January 1, 1996, pursuant to N.R.S. §§ 277.074 and 277.120. SNWA is authorized by N.R.S. § 538.186 to enter into this Agreement and, pursuant to its contract issued under section 5 of the Boulder Canyon Project Act of 1928, SNWA has the right to divert "supplemental water" as defined by NRS § 538.041 (6). The General Manager of the SNWA, signatory hereto, serves as one of the Governor's Representatives as contemplated by Section 602(b) of the 1968 Colorado River Basin Project Act, 43 U.S.C. § 1552(b) and the Criteria for Coordinated Long-Range Operation of Colorado River Reservoirs Pursuant to the Colorado River Basin Project Act.

5. New Mexico. Pursuant to NMSA 1978, 72-14-3, the New Mexico Interstate Stream Commission is authorized to investigate water supply, to develop, to conserve, to protect and to do any and all other things necessary to protect, conserve and develop the waters and stream systems of the State of New Mexico, interstate or otherwise. The Interstate Stream Commission also is authorized to institute or cause to be instituted in the name of the State of New Mexico any and all negotiations and/or legal proceedings as in its judgment are necessary. By Resolution dated January 24, 2007, the Interstate Stream Commission authorizes the execution of this Agreement.

6. Utah. The Division of Water Resources (DWR) is the water resource authority for the State of Utah. Utah Code Ann. § 73-10-18. The Utah Department of Natural Resources Executive Director (Department), with the concurrence of the Utah Board of Water Resources (Board), appoints the DWR Director (Director). § 63-34-6(1). The Board makes DWR policy. § 73-10-1.5. The Board develops, conserves, protects, and controls Utah waters, § 73-10-4(4), (5), and, in cooperation with the Department and Governor, supervises administration of interstate compacts, § 73-10-4, such as the Colorado River Compact, §§ 73-12a-1 through 3, and the Upper Colorado River Basin Compact, § 73-13-10. The Board, with Department and Gubernatorial approval, appoints a Utah Interstate Stream Commissioner, § 73-10-3, currently the DWR Director, to represent Utah in interstate conferences to administer interstate compacts. §§ 73-10-3 and 73-10-4. These delegations of authority authorize the Utah Interstate Stream Commissioner/DWR Director to sign this document. He acts pursuant to a Board resolution, acknowledged by the Department, dated March 7, 2007.

7. Wyoming. Water in Wyoming belongs to the state. Wyo. Const. Art. 8 § 1. The Wyoming State Engineer is a constitutionally created office and is Wyoming's chief water official with general supervisory authority over the waters of the state. Wyo. Const. Art. 8 § 5. The Wyoming legislature conferred upon Wyoming officers the authority to cooperate with and assist

like authorities and entities of other states in the performance of any lawful power, duty, or authority. Wyo. Stat. Ann. § 16-1-101 (2005). Wyoming and its State Engineer represent the rights and interests of all Wyoming appropriators with respect to other states. *Wyoming v. Colorado*, 286 U.S. 494 (1922). See *Hinderlider v. La Plata River & Cherry Creek Ditch Co.*, 304 U.S. 92 (1938). In signing this Agreement, the State Engineer intends that this Agreement be mutually and equally binding between the Parties.

B. Background.

1. Federal law and practice (including Section 16 of the Boulder Canyon Project Act, 43 U.S.C § 617o and Section 602(b) of the 1968 Colorado River Basin Project Act, 43 U.S.C. § 1552(b), and the Criteria for Coordinated Long-Range Operation of Colorado River Reservoirs Pursuant to the Colorado River Basin Project Act), contemplate that in the operation of Lakes Powell and Mead, the Secretary of the Interior consults with the States through Governors' Representatives, who represent the Governors and their respective state agencies. Through this law and practice, the Governors' Representatives and state agencies have in the past reached agreements among themselves and with the Secretary on various aspects of Colorado River reservoir operation. This Agreement is entered into in furtherance of this law and practice.

2. On January 16, 2001, the Secretary adopted Colorado River Interim Surplus Guidelines (ISG) based on an alternative prepared by the Colorado River Basin States, for the purposes of determining annually the conditions under which the Secretary would declare the availability of surplus water for use within the states of Arizona, California and Nevada in accordance with and under the authority of the Boulder Canyon Project Act of 1928 (45 Stat. 1057) and the Decree of the United States Supreme Court in *Arizona v. California*, 376 U.S. 340 (1964), as amended and supplemented. The ISG are effective through calendar year 2015 (through preparation of the 2016 Annual Operating Plan).

3. In the years following the adoption of the ISG, drought conditions in the Colorado River Basin caused a significant reduction in storage levels in Lakes Powell and Mead, and precipitated discussions by and among the Parties, and between the Parties and the United States through the Department of the Interior and the Bureau of Reclamation. The Parties recognize that the Upper Division States have not yet developed their full apportionment under the Colorado River Compact. Although the Secretary has not imposed any shortage in the Lower Basin, the Parties also recognize that with additional Upper Basin development and in drought conditions, the Lower Division States may be required to suffer shortages in deliveries of water from Lake Mead. Therefore, these discussions focused on ways to improve the management of water in Lakes Powell and Mead so as to enhance the

4

protection afforded to the Upper Basin by Lake Powell, and to delay the onset and minimize the extent and duration of shortages in the Lower Basin.

4. On May 2, 2005, the Secretary announced her intent to undertake a process to develop Lower Basin shortage guidelines and explore management options for the coordinated operation of Lakes Powell and Mead. On June 15, 2005, the Bureau of Reclamation published a notice in the Federal Register, announcing its intent to implement the Secretary's direction. The Bureau of Reclamation has proceeded to undertake scoping and develop alternatives pursuant to the National Environmental Policy Act (the NEPA Process), which the Parties anticipate will form the basis for a ROD to be issued by the Secretary by December 2007.

5. On August 25, 2005, the Parties wrote a letter to the Secretary expressing conceptual agreement in the development and implementation of three broad strategies for improved management and operation of the Colorado River: Coordinated Reservoir Management and Lower Basin Shortage Guidelines; System Efficiency and Management; and Augmentation of Supply.

6. On February 3, 2006, the Parties transmitted to the Secretary their recommendation for the scope of the NEPA Process (Preliminary Proposal), which refined many of the elements outlined in the August 25, 2005 letter.

7. In February 2007, the Secretary issued a Draft Environmental Impact Statement (DEIS) pursuant to the NEPA Process. The DEIS includes an alternative, called the Basin States' Alternative, that is based on the recommendations of the Parties.

8. At the request of the Secretary, the Parties have continued their discussions relative to the areas of agreement outlined in the letters of August 25, 2005 and February 3, 2006, and the DEIS, and have agreed on: a) additional actions for their mutual benefit designed to augment the supply of water available for use in the Colorado River System and improve the management of water in the Colorado River; b) recommendations to the Secretary for adoption as the preferred alternative in the Final Environmental Impact Statement and in the ROD; and c) consultation processes among themselves, and consultation recommendations to the Secretary for incorporation into the ROD.

C. Purpose. The Parties intend that the actions by them contemplated in this Agreement will: improve cooperation and communication among them; provide additional security and certainty in the water supply of the Colorado River System for the benefit of the people served by water from the Colorado River System; and avoid circumstances which could otherwise form the basis for claims or controversies over interpretation or implementation of the Colorado River Compact and other applicable provisions of the law of the river.

AGREEMENT

In consideration of the above recitals and the mutual covenants contained herein, and other good and valuable consideration, the receipt and sufficiency of which is hereby acknowledged, the Parties agree as follows:

1. Recitals. The Recitals set forth above are material facts that are relevant to and form the basis for the agreements set forth herein.

2. Definitions. As used in this Agreement, the following terms have the following meanings:

A. Colorado River System. This term shall have the meaning as defined in the Colorado River Compact.

B. ISG. The Colorado River Interim Surplus Guidelines adopted by the Secretary on January 16, 2001, as modified by the ROD.

C. NEPA Process. The decision-making process pursuant to the National Environmental Policy Act, 42 U.S.C. §§ 4321 through 4347, beginning with the Bureau of Reclamation's Notice to Solicit Comments and Hold Public Meetings, 70 Fed. Reg. 34794 (June 15, 2005) and culminating in a Record of Decision.

D. Party or Parties. Any party or parties to this Agreement.

E. Parties' Recommendation. The Seven Basin States' comments on the DEIS transmitted to the Secretary of the Interior on or before April 30, 2007.

F. ROD. The Record of Decision anticipated to be issued by the Secretary after completion of the NEPA Process including but not limited to any interim guidelines promulgated pursuant thereto.

G. Secretary. The Secretary of the Interior or the Bureau of Reclamation, as applicable.

H. State or States. Any of the states of Arizona, California, Colorado, Nevada, New Mexico, Utah or Wyoming, as context requires.

3. Support for Parties' Recommendation.

A. After considering a number of alternatives, each Party has determined that the Parties' Recommendation is in the best interests of that Party, and promotes the health and welfare of that Party and of the Colorado River Basin States. The Parties support the Secretary's incorporation of the Parties'

Recommendation and this Agreement into the ROD, as appropriate to effectuate the material terms of the Parties' Recommendation. If during the course of the NEPA Process any new information becomes available which causes any Party, in its sole and absolute discretion, to reassess any provision of the Parties' Recommendation and this Agreement, that Party shall immediately notify all other Parties in writing. The Parties shall jointly consult and, if they agree to any modification of the Parties' Recommendation or this Agreement, shall consult with the Secretary to advise him/her of such modification and request the adoption thereof in the ROD.

B. If after such consultations it is apparent there is an irreconcilable conflict between the Parties as to such modification, then any Party may upon written notice to the other Parties withdraw from this Agreement, and in such event this Agreement shall no longer be effective or binding upon such withdrawing Party. All withdrawing Parties hereby reserve all rights upon withdrawal from this Agreement to take such actions, including support of or challenges to the ROD, as they in their sole and absolute discretion deem necessary or appropriate. In the event of the withdrawal of any one or more Parties from this Agreement, this Agreement shall continue in full force and effect as to the remaining Parties. The remaining Parties may consult to determine whether to continue this Agreement in effect, to amend this Agreement, or to terminate this Agreement. In the event of termination, all Parties shall be relieved from the terms hereof, except as provided in Paragraph 10, and this Agreement shall be of no further force or effect.

4. ROD Consistent with the Parties' Recommendation and this Agreement. In the event the Secretary adopts a ROD in substantial conformance with the Parties' Recommendation and this Agreement, the Parties shall take all necessary actions to implement the terms of the ROD, including the approval and execution of agreements necessary for such implementation.

5. ROD Inconsistent with the Parties' Recommendation and this Agreement. In the event the Secretary adopts a ROD that any Party, in its sole and absolute discretion, determines is not in substantial conformance with the Parties' Recommendation and this Agreement, such Party shall immediately notify all other Parties of such determination in writing. The Parties shall jointly consult, and consult with the Secretary as necessary, in order to determine whether the ROD is in substantial conformance with the Parties' Recommendation and this Agreement, or whether any action, including the amendment of this Agreement, may resolve such concern. If after such consultation it is apparent there is an irreconcilable conflict between the ROD and the concerns of such Party, then such Party may upon written notice to the other Parties withdraw from this Agreement, and in such event this Agreement shall no longer be effective or binding upon such withdrawing Party. All withdrawing Parties hereby reserve all rights upon withdrawal from this Agreement to take such actions, including support of or challenges to the ROD, as they in their sole and absolute discretion deem necessary or appropriate. In the event of the withdrawal of any one or more Parties from this Agreement, this Agreement shall

continue in full force and effect as to the remaining Parties. The remaining Parties may consult to determine whether to continue this Agreement in effect, to amend this Agreement, or to terminate this Agreement. In the event of termination, all Parties shall be relieved from the terms hereof, except as provided in Paragraph 10, and this Agreement shall be of no further force or effect.

6. Additions to the ROD. The Parties hereby request that the Secretary recognize the specific provisions of this Agreement as part of the NEPA Process and include in the ROD specific provisions that reference this Agreement as a basis for the ROD. The Parties also hereby request that the Secretary include in the ROD the following specific provisions:

A. The Secretary will first consult with all the States before making any substantive modification to these guidelines.

B. Upon a request by a State for modification of these guidelines, or upon a request by a State to resolve any claim or controversy arising under: i) the Agreement Concerning Colorado River Management and Operations; ii) these Guidelines; iii) the operations of Lakes Powell and Mead pursuant to these guidelines; or, iv) any other applicable provision of federal law, regulation, criteria, policy, rule or guideline, or the Mexican Water Treaty of 1944, the Secretary shall invite the Governors of all the Basin States, or their designated representatives, to consult with the Secretary in an attempt to resolve such claim or controversy by mutual agreement.

C. In the event projections included in any Bureau of Reclamation monthly 24 Month Study indicates Lake Mead elevations may approach an elevation that would trigger shortages in deliveries of water from Lake Mead in the United States, the Secretary shall consult with all the States on how the United States shall reduce the quantity of water allotted to Mexico.

7. Consultation on Operations. After the Secretary commences operating Lakes Powell and Mead pursuant to the ROD, the Parties shall consult among themselves as necessary, but at least annually, to assess such operations. Any Party may request consultation with the other Parties on a proposed adjustment or modification of such operations, based on changed circumstances, unanticipated conditions, or other factors. Upon such request, the Parties shall consult in good faith with each other to resolve any such issues, and based thereon may request consultation by the States with the Secretary on adjustments to or modifications of operations under the ROD. In any event, the Parties shall initiate consultations before December 31, 2020, to determine whether to extend this Agreement and recommend that the Secretary continue operations under the ROD for an additional period, or modify this Agreement and recommend that the Secretary modify operations under the ROD, or terminate this Agreement and recommend that the Secretary not continue operations under the ROD after the expiration thereof. Any extension of this Agreement and any recommendation by the Parties to the Secretary to extend or modify operations under the ROD shall be made by unanimous

consent of the Parties. If such extension and recommendation are not made, this Agreement shall terminate in accordance with Paragraph 16.

8. Development of Interim Water Supplies, System Augmentation, System Efficiency and Water Enhancement Projects. The Parties agree to diligently pursue interim water supplies, system augmentation, system efficiency and water enhancement projects within the Colorado River System. The term "system augmentation" includes the quantifiable addition of new sources of supply to the Colorado River Basin, including importation from outside the Basin or desalination of ocean water or brackish water. The term "system efficiency" includes efficiency projects in the Lower Basin that will result in the more efficient use of existing supplies, such as in-system storage and enhanced management. The term "water enhancement" includes projects that may increase available system water, including cloud seeding and non-native vegetation management. Due to the critical importance of implementing these projects in reducing the potential for shortages, the Parties shall continue to jointly pursue the study and implementation of such projects, and to regularly consult on the progress of such projects.

Specifically, the Parties agree to cooperatively pursue an interim water supply of at least a cumulative amount of 280,000 acre-feet for use in Nevada while long-term augmentation projects are being pursued. It is anticipated that this interim water supply will be made available in return for Nevada's funding of the Drop 2 Reservoir mandated for construction by the Bureau of Reclamation by P.L. 109-432 § 396. Annual recovery of this interim water supply by Nevada will not exceed 40,000 acre-feet.

In consideration of the Parties' diligent pursuit of long-term augmentation and the availability of the interim water supply, the Southern Nevada Water Authority (SNWA) agrees that it will withdraw right-of-way Application No. N-79203 filed with the Bureau of Land Management on October 1, 2004 for the purpose of developing Permit No. 58591 issued by the Nevada State Engineer in Ruling No. 4151.

The SNWA will not re-file such right-of-way application or otherwise seek to divert the water rights available under Permit No. 58591 from the Virgin River prior to 2014 so long as Nevada is allowed to utilize its pre-Boulder Canyon Project Act Virgin and Muddy River rights in accordance with the Parties' Recommendation, and the interim water supply made available to Nevada is reasonably certain to remain available. The SNWA will not re-file such right-of-way application or otherwise seek to divert the water rights available under Permit No. 58591 from the Virgin River after 2014 so long as diligent pursuit of system augmentation is proceeding to provide or has provided Nevada an annual supply of 75,000 acre-feet by the year 2020. Prior to re-filing any applications with the Bureau of Land Management, SNWA and Nevada will consult with the other Basin States.

This agreement is without prejudice to any Party's claims, rights or interests in the Virgin or Muddy River systems.

9. Consistency with Existing Law. The Parties' Recommendation has been developed with the intent to be consistent with existing law. The Parties expressly agree, for purposes of this Agreement, that the storage of water in and release of water from Lakes Powell and Mead pursuant to a ROD issued by the Secretary in substantial conformance with the Parties' Recommendation and this Agreement, and any agreements, rules and regulations adopted by the Secretary or the parties to implement such ROD, shall not constitute a violation of Article III(a)-(e) inclusive of the Colorado River Compact, or Sections 601 and 602(a) of the Colorado River Basin Project Act of 1968 (43 U.S.C. §§ 1551 and 1552(a)), and all applicable rules and regulations promulgated thereunder.

10. Resolution of Claims or Controversies Not Related to Reductions in Deliveries to Mexico under the Mexican Water Treaty of 1944. The Parties recognize that judicial or administrative proceedings are not preferred alternatives to the resolution of claims or controversies concerning the law of the river. In furtherance of this Agreement, the Parties desire to avoid judicial or administrative proceedings, and agree to pursue a consultative approach to the resolution of any claim or controversy. In the event that any Party becomes concerned that there may be a claim or controversy under this Agreement, the ROD, Article III(a)-(e) inclusive of the Colorado River Compact, or Sections 601 and 602(a) of the Colorado River Basin Project Act of 1968 (43 U.S.C. §§ 1551 and 1552(a)), and all applicable rules and regulations promulgated thereunder, such Party shall notify all other Parties in writing, and the Parties shall in good faith meet in order to resolve such claim or controversy by mutual agreement prior to initiating any judicial or administrative proceeding. No Party shall initiate any judicial or administrative proceeding against any other Party or against the Secretary under Article III (a)-(e) inclusive of the Colorado River Compact, or Sections 601 and 602(a) of the Colorado River Basin Project Act of 1968 (43 U.S.C. §§ 1551 and 1552(a)), or any other applicable provision of federal law, regulation, criteria, policy, rule or guideline, and no claim thereunder shall be ripe, until such consultation has been completed. All States shall comply with any request by the Secretary for consultation in order to resolve any claim or controversy. In addition, any State may invoke the provisions of Article VI of the Colorado River Compact. Notwithstanding anything in this Agreement to the contrary, the terms of this Paragraph shall survive for a period of five years following the termination or expiration of this Agreement, and shall apply to any withdrawing Party after withdrawal for such period.

11. Resolution of Claims and Controversies Related to Reductions in Deliveries to Mexico under the Mexican Water Treaty of 1944 and Limitations on Reductions to Lower Division States.

A. The United States has the authority to reduce the quantity of water allotted to Mexico under Article 10(a) of the Mexican Water Treaty of 1944. The timing and quantity of such reductions will directly affect the quantity of water stored in Lakes Powell and Mead, and the timing and quantity of both present and future shortages in deliveries of water from Lake Mead in the United States imposed by the Secretary. A material consideration in the

10

development of the Parties' Recommendation is the assumption that the United States will reduce the quantity of water allotted to Mexico in years in which the Secretary imposes shortages in deliveries of water from Lake Mead in the United States. The Basin States' Preliminary Proposal of February 3, 2006, proposed that total shortages of 400,000, 500,000 and 600,000 acre-feet per year should be imposed within the United States and Mexico at certain Lake Mead elevations. In accordance with the Preliminary Proposal, Arizona and Nevada have executed a Shortage Sharing Agreement premised upon the imposition by the Secretary of shortages within the United States of 333,000, 417,000 and 500,000 acre-feet per year at the same Lake Mead elevations contained in the Preliminary Proposal. The DEIS substantially incorporates these assumptions into its consideration and analysis of the Basin States' alternative. For the first 600,000 acre-feet per year of any reductions in deliveries in any year due to a declared shortage, the Basin States have agreed that Arizona and Nevada will not take more than 500,000 acre-feet per year in aggregate and California will not take any reductions. The Parties recognize that there may be other circumstances in which the United States may reduce the amount of water allotted to Mexico under the 1944 Treaty.

B. Each of the Parties to this Agreement takes the affirmative position that in years in which the Secretary imposes shortages in deliveries of water from Lake Mead in the United States, the United States must reduce the quantity of water allotted to Mexico under Article 10(a) of the Mexican Water Treaty of 1944. In the event that any Party becomes concerned that there may be a claim or controversy regarding the United States' delivery of water allotted to Mexico under Article 10(a) of the Mexican Water Treaty of 1944, such Party shall notify all other Parties in writing. Pursuant to such notification, the Parties shall in good faith meet to consult and formulate a uniform position regarding such claim or controversy. If the Parties are successful in formulating a uniform position regarding such claim or controversy, then the Parties shall cooperate in taking any and all actions appropriate to the resolution of such claim or controversy.

C. Once consultation and any subsequent actions agreed by each Party to be taken following completion of such consultation are completed, any Party may initiate litigation or other appropriate challenge against the United States relative to any action or inaction of the United States pursuant to the Mexican Water Treaty of 1944 or the modification of the ROD. Any adverse position taken by any Party to any position taken by any other Party under this Paragraph 11. C. shall not constitute a breach of this Agreement, and all of the other terms and conditions contained in this Agreement shall remain in full force and effect.

12. <u>Reservation of Rights</u>. Notwithstanding the terms of this Agreement and the Parties' Recommendation, in the event that for any reason this Agreement is terminated,

or that the term of this Agreement is not extended, or upon the withdrawal of any Party from this Agreement, the Parties reserve, and shall not be deemed to have waived, any and all rights, including any claims or defenses, they may have as of the date hereof or as may accrue during the term hereof, under any existing federal or state law or administrative rule, regulation or guideline, including without limitation the Colorado River Compact, the Upper Colorado River Basin Compact, the Consolidated Decree in *Arizona v. California*, the Colorado River Basin Project Act of 1968, the Mexican Water Treaty of 1944, and any other applicable provision of federal law, rule, regulation, or guideline. Nothing in this Agreement shall be utilized against any other Party in any administrative, judicial or other proceeding, except for the sole purpose of enforcing the terms of this Agreement. Notwithstanding anything in this Agreement to the contrary, the terms of this Paragraph shall survive the termination or expiration of this Agreement, and shall apply to any withdrawing Party after withdrawal.

13. <u>No Third-Party Beneficiaries</u>. This Agreement is made for the benefit of the Parties. No Party to this Agreement intends for this Agreement to confer any benefit upon any person or entity not a signatory upon a theory of third-party beneficiary or otherwise.

14. <u>Joint Defense Against Third Party Claims</u>. In the event the Secretary adopts a ROD in substantial conformance with the Parties' Recommendation as set forth herein, the Parties will have certain common, closely parallel, or identical interests in supporting, preserving and defending the ROD and this Agreement. The nature of this interest and the relationship among the Parties present common legal and factual issues and a mutuality of interests. Because of these common interests, the Parties will mutually benefit from an exchange of information relating to the support, preservation and defense of the ROD and this Agreement, as well as from a coordinated investigation and preparation for discussion of such interests. In furtherance thereof, in the event of any challenge by a third party as to the ROD or this Agreement (including claims by any withdrawing Party), the Parties will cooperate to proceed with reasonable diligence and to use reasonable best efforts in the support, preservation and defense thereof, including any lawsuit or administrative proceeding challenging the legality, validity or enforceability of any term of the ROD or this Agreement, and will to the extent appropriate enter into such agreements, including joint defense or common interest agreements, as are necessary therefor. Each Party shall bear its own costs of participation and representation in any such defense.

15. <u>Reaffirmation of Existing Law</u>. Nothing in this Agreement or the Parties' Recommendation is intended to, nor shall this Agreement be construed so as to, diminish or modify the right of any Party under existing law, including without limitation the Colorado River Compact, the Upper Colorado River Basin Compact, the Consolidated Decree in *Arizona v. California*, or the Mexican Water Treaty of 1944. The Parties hereby affirm the entitlement and right of each State under such existing law to use and develop the water of the Colorado River System.

16. Term. This Agreement shall be effective as of the date of the first two signatories hereto, and shall be effective as to any additional Party as of the date of execution by such Party. Unless earlier terminated, this Agreement shall be effective for so long as the ROD and the ISG are in effect, and shall terminate on December 31, 2025 or upon the termination of the ROD and the ISG, whichever is earlier.

17. Authority. The persons and entities executing this Agreement on behalf of the Parties are recognized by the Parties as representing the respective States in matters concerning the operation of Lakes Powell and Mead, and as those persons and entities authorized to bind the respective Parties to the terms hereof. Each person executing this Agreement has the full power and authority to bind the respective Party to the terms of this Agreement. No Party shall challenge the authority of any person or Party to execute this Agreement and bind such Party to the terms hereof, and the Parties waive the right to challenge such authority.

Attachment B

Proposed Interim Guidelines for Colorado River Operations

This attachment to Appendix J contains the text of Attachment B to the Revised Basin States' Proposal.

ATTACHMENT B

Proposed Interim Guidelines for Colorado River Operations

The Basin States propose the following Guidelines to be implemented and used for determinations made pursuant to the *Criteria for Coordinated Long-Range Operation of the Colorado River Reservoirs Pursuant to the Colorado River Basin Project Act of September 30, 1968 (LROC)* during the period identified in Section 9[1]:

Section 1. Definitions

A. Each of the following terms shall have the meaning provided herein. All defined terms are identified by initial letter capitalization.

1. "Basin States" shall mean the Colorado River Basin States of Arizona, California, Colorado, New Mexico, Nevada, Utah, and Wyoming.

2. "Certification Report" shall mean the written documentation provided by a Contractor pursuant to Section 5.D.5 that provides the Secretary with sufficient information to verify the quantity of ICS created and that the creation was consistent with the approved project.

3. "Colorado River System" shall have the same meaning as defined in the 1922 Colorado River Compact.

4. "Consolidated Decree" shall mean the Consolidated Decree entered by the United States Supreme Court in *Arizona v. California*, 126 S. Ct. 1543, 547 U.S. 150 (2006).

5. "Contractor" shall mean a Boulder Canyon Project Act Section 5 Contractor or an entity receiving Mainstream water pursuant to other applicable federal statutes or the Consolidated Decree.

6. "Delivery Agreement" shall mean an agreement consistent with these guidelines entered into between the Parties to the Forbearance Agreement, one or more Contractors creating ICS, and the Secretary of the Interior.

7. "Developed Shortage Supply ("DSS")" shall mean water available for use by a Contractor under the terms and conditions of a Delivery Agreement and Section 6.

8. "Direct Delivery Domestic Use" shall mean direct delivery of water to domestic end users or other municipal and industrial water providers within the contractor's area of normal service, including incidental regulation of Colorado River water supplies within the Year of operation but not including Off-stream Banking. For the Metropolitan Water District of Southern California (MWD), Direct Delivery Domestic Use shall include delivery of water to end users within its area of normal service, incidental regulation of Colorado River water

[1] Unless otherwise specified, references to "Section" or "Sections" in these Guidelines are in reference to sections of these Guidelines.

1

supplies within the Year of operation and Off-stream Banking only with water delivered through the Colorado River Aqueduct.

9. "Domestic Use" shall have the same meaning as defined in the 1922 Colorado River Compact.

10. "Forbearance Agreement" shall mean the Lower Colorado River Intentionally Created Surplus Forbearance Agreement, to be entered into among the Lower Division States, and certain Contractors in the Lower Division States.

11. "Intentionally Created Surplus ("ICS")" shall mean intentionally created surplus available for use under the terms and conditions of the Forbearance Agreement and a Delivery Agreement.

    a. ICS created through extraordinary conservation, as provided for in Section 5.D.1, shall be referred to as "Extraordinary Conservation ICS."

    b. ICS created through tributary conservation, as provided for in Section 5.D.2, shall be referred to as "Tributary Conservation ICS."

    c. ICS created through system efficiency projects, as provided for in Section 5.D.3, shall be referred to as "System Efficiency ICS."

    d. ICS created through the importation of non-Colorado River System Water, as provided for in Section 5.D.4, shall be referred to as "Imported ICS."

12. "ICS Account" shall mean records established by the Secretary.

13. "ICS Declaration" shall mean a declaration by the Secretary that ICS is available for release.

14. "Interim Period" refers to the effective period as described in Section 9.

15. "Lower Division States" shall mean the Colorado River Basin States of Arizona, California, and Nevada.

16. "Mainstream" shall have the same meaning as defined in the Consolidated Decree.

17. "Off-stream Banking" shall mean the diversion of Colorado River water to underground storage facilities for use in subsequent Years from the facility used by a Contractor diverting such water.

18. "Parties" shall mean all of the signatories to the Forbearance Agreement.

19. "ROD" shall mean the Record of Decision issued by the Secretary for the Colorado River Interim Guidelines for Lower Basin Shortages and Coordinated Operations for Lake Powell and Lake Mead.

20. "Upper Division States" shall mean the Colorado River Basin States of Colorado, New Mexico, Utah, and Wyoming.

21. "Water Year" shall mean October 1 through September 30 of the following calendar year.

22. "Year" shall mean calendar year.

Section 2. Allocation of Unused Basic Apportionment Water under Article II(B)(6)

A. Introduction

Article II(B)(6) of the Consolidated Decree allows the Secretary to allocate water that is apportioned to one Lower Division State, but is for any reason unused in that State, to another Lower Division State. This determination is made for one Year only, and no rights to recurrent use of the water accrue to the state that receives the allocated water.

B. Application to Unused Basic Apportionment

Before making a determination of a surplus condition under these Guidelines, the Secretary will determine the quantity of apportioned but unused water from the basic apportionments under Article II(B)(6), and will allocate such water in the following order of priority:

1. Meet the Direct Delivery Domestic Use requirements of MWD and Southern Nevada Water Authority (SNWA), allocated as agreed by said agencies;

2. Meet the needs for Off-stream Banking activities in California by MWD and in Nevada by SNWA, allocated as agreed by said agencies; and

3. Meet the other needs for water in California in accordance with the California Seven-Party Agreement as supplemented by the Quantification Settlement Agreement.

Section 3. Coordinated Operation of Lakes Powell and Mead During the Interim Period

A. During the Interim Period, the Secretary shall coordinate the operations of Lake Powell and Lake Mead according to the strategy set forth in this Section 3.

B. The objective of the operation of Lakes Powell and Mead as described herein is to avoid curtailment of uses in the Upper Basin, minimize shortages in the Lower Basin and not adversely affect the yield for development available in the Upper Basin.

C. The August 24-month study projections for the January 1 system storage and reservoir water surface elevations, for the following Water Year, would be used to determine the applicability of the coordinated operation of Lakes Powell and

Mead. Equalization or balancing of storage in Lakes Powell and Mead shall be achieved by the end of each Water Year.

Powell Elevation (feet)	Powell Operation	Powell Live Storage (maf)
3700	Equalize, avoid spills or 8.23 maf	**24.32**
3636 - 3666 (see table below)	8.23 maf; if Mead < 1075 feet, balance contents with a min/max release of 7.0 and 9.0 maf	**15.54 - 19.29** (2008 - 2026)
3575	7.48 maf 8.23 maf if Mead < 1025 feet	**9.52**
3525	Balance contents with a min/max release of 7.0 and 9.5 maf	**5.93**
3370		**0**

4

Lake Powell Equalization Elevation Table

In each of the following Water Years, the Lake Powell Equalization Elevation will be as follows:

Water Year	Elevation (feet)
2008	3636
2009	3639
2010	3642
2011	3643
2012	3645
2013	3646
2014	3648
2015	3649
2016	3651
2017	3652
2018	3654
2019	3655
2020	3657
2021	3659
2022	3660
2023	3662
2024	3663
2025	3664
2026	3666

1. Equalization: In Water Years when Lake Powell content is projected on January 1 to be at or above the elevation stated in the Lake Powell Equalization Elevation Table, an amount of water will be released from Lake Powell to Lake Mead at a rate greater than 8,230,000 acre-feet per Water Year to the extent necessary to avoid spills, or equalize storage in

the two reservoirs, or otherwise to release 8,230,000 acre-feet from Lake Powell.

2. Upper Elevation Balancing: In Water Years when Lake Powell content is projected on January 1 to be below the elevation stated in the Lake Powell Equalization Elevation Table and at or above 3575 feet, the Secretary shall release 8,230,000 acre-feet from Lake Powell if the projected elevation of Lake Mead is at or above 1075 feet. If the projected elevation of Lake Mead is below 1075 feet, the Secretary shall balance the contents of Lake Mead and Lake Powell, but shall release no more than 9,000,000 acre-feet and no less than 7,000,000 acre-feet from Lake Powell.

3. Mid-Elevation Releases: In Water Years when Lake Powell content is projected on January 1 to be below 3575 feet and at or above 3525 feet, the Secretary shall release 7,480,000 acre-feet from Lake Powell if the projected elevation of Lake Mead is at or above 1025 feet. If the projected elevation of Lake Mead is below 1025 feet, the Secretary shall release 8,230,000 acre-feet from Lake Powell.

4. Lower Elevation Balancing: In Water Years when Lake Powell content is projected on January 1 to be below 3525 feet, the Secretary shall balance the contents of Lake Mead and Lake Powell, but shall release no more than 9,500,000 acre-feet and no less than 7,000,000 acre-feet from Lake Powell.

5. When determining lake elevations and contents under this Section 3, no adjustment shall be made for ICS.

Coordinated Operation of Lakes Powell and Mead as described herein will be presumed to be consistent with the Section 602(a) storage requirement contained in the Colorado River Basin Project Act.

Section 4. Determination of Lake Mead Operation during the Interim Period

A. Normal Conditions

In Years when Lake Mead elevation is projected on January 1 to be at or above elevation 1075 feet and below 1145 feet, the Secretary shall determine a normal operating condition, unless there is an ICS Surplus under Section 4.B.5.

B. Surplus Conditions

1. Domestic Surplus (Lake Mead above Elevation 1145 feet and below 70R Strategy) in Effect through December 31, 2015 (through preparation of 2016 Annual Operating Plan for the Colorado River System Reservoirs ("AOP"))

In Years when Lake Mead content is projected to be above elevation 1145 feet, but less than the amount which would initiate a Surplus under Section B.3 70R Strategy or Section B.4 Flood Control Surplus on January 1, the

6

Secretary shall determine a Domestic Surplus. The amount of such Surplus shall equal:

a. For Direct Delivery Domestic Use by MWD, 1.250 million acre-feet (maf) reduced by the amount of basic apportionment available to MWD.

b. For use by SNWA, the Direct Delivery Domestic Use within the SNWA service area in excess of the State of Nevada's basic apportionment.

c. For use in Arizona, the Direct Delivery Domestic Use in excess of Arizona's basic apportionment.

2. Domestic Surplus (Lake Mead above Elevation 1145 feet and below 70R Strategy) in Effect from January 1, 2016 through December 31, 2025 (through preparation of 2026 AOP)

In Years when Lake Mead content is projected to be above elevation 1145 feet, but less than the amount which would initiate a Surplus under Section B.3 70R Strategy or Section B.4 Flood Control Surplus on January 1, the Secretary shall determine a Domestic Surplus. The amount of such Surplus shall equal:

a. For use by MWD, 250,000 acre-feet per Year in addition to the amount of California's basic apportionment available to MWD;

b. For use by SNWA, 100,000 acre-feet per Year in addition to the amount of Nevada's basic apportionment available to SNWA;

c. For use by Arizona, 100,000 acre-feet per Year in addition to the amount of Arizona's basic apportionment available to Arizona contractors.

3. Quantified Surplus (70R Strategy)

In Years when the Secretary determines that water should be released for beneficial consumptive use to reduce the risk of potential reservoir spills based on the 70R Strategy, the Secretary shall determine and allocate a Quantified Surplus sequentially as follows:

a. Establish the volume of the Quantified Surplus. For the purpose of determining the existence, and establishing the volume, of Quantified Surplus, the Secretary shall not consider any volume of ICS as defined in these Guidelines.

b. Allocate and distribute the Quantified Surplus 50% to California, 46% to Arizona and 4% to Nevada, subject to c. through e. that follow.

c. Distribute California's share first to meet basic apportionment demands and MWD's demands, and then to California Priorities 6 and 7 and other surplus contracts. Distribute Nevada's share first to meet basic apportionment demands and SNWA demands. Distribute Arizona's share to surplus demands in Arizona including Off-stream Banking and interstate banking demands. Arizona, California and Nevada agree that Nevada would get first priority for interstate banking in Arizona.

d. Distribute any unused share of the Quantified Surplus in accordance with Section 2, Allocation of Unused Basic Apportionment Water Under Article II(B)(6).

e. Determine whether MWD, SNWA and Arizona have received the amount of water they would have received under Sections 4.B.1 or 4.B.2 if a Quantified Surplus had not been determined. If they have not, then determine and meet all demands provided for in Sections 4.B.1 or 4.B.2.

4. Flood Control Surplus

In Years in which the Secretary makes space-building or flood control releases pursuant to the February 8, 1984 Field Working Agreement between Reclamation and the Army Corps of Engineers, the Secretary shall determine a Flood Control Surplus for the remainder of that Year or the subsequent Year as specified in Section 12. In such Years, releases will be made to satisfy all beneficial uses within the United States, including unlimited Off-Stream Banking. Under current practice, surplus declarations under the Treaty for Mexico are declared when flood control releases are made. Modeling assumptions used in the FEIS are based on this practice. These Guidelines are not intended to identify, or change in any manner, conditions when Mexico may schedule up to an additional 0.2 maf.

5. ICS Surplus

a. In Years in which Lake Mead's elevation is projected on January 1 to be above elevation 1075 feet and ICS has been requested for release, the Secretary shall determine an ICS Surplus.

b. In Years in which a Quantified Surplus or a Domestic Surplus is available to a Contractor, the Secretary shall first deliver the Quantified Surplus or Domestic Surplus before delivering any requested ICS to that Contractor. If Quantified Surplus or Domestic Surplus is insufficient or unavailable to meet a Contractor's demands, the Secretary may release ICS available in that Contractor's ICS Account at the request of the Contractor.

c. The Secretary shall release ICS as described in Section 5.

C. Allocation of Colorado River Water and Forbearance Arrangements

Under these Guidelines, Colorado River water will continue to be allocated for use among the Lower Division States in a manner consistent with the provisions of the Consolidated Decree. It is expected that Lower Division States and individual Contractors for Colorado River water have or will adopt arrangements that will affect utilization of Colorado River water during the Interim Period. It is expected that water orders from Colorado River Contractors will be submitted to reflect forbearance arrangements by Lower Division States and individual Contractors. The Secretary will deliver Colorado River water to Contractors in a manner consistent with these arrangements. Surplus water will be delivered only to entities with contracts that are eligible to receive surplus water. ICS will be delivered pursuant to Section 5.D.6.

D. Shortage Conditions

1. Reductions in deliveries to the Lower Division States during declared shortages shall be implemented in the following manner:

   a. Step One reduction: In Years when Lake Mead content is projected on January 1 to be at or below elevation 1075 feet and at or above 1050 feet, a quantity of 333,000 acre-feet shall not be released or delivered in the Lower Division States.

   b. Step Two reduction: In Years when Lake Mead content is projected on January 1 to be below elevation 1050 feet and at or above 1025 feet, a quantity of 417,000 acre-feet shall not be released or delivered in the Lower Division States.

   c. Step Three reduction: In Years when Lake Mead content is projected on January 1 to be below 1025 feet, a quantity of 500,000 acre-feet shall not be released or delivered in the Lower Division States.

2. In the event projections included in any Bureau of Reclamation monthly 24-Month Study indicate Lake Mead elevations may approach an elevation that would trigger shortages in deliveries of water from Lake Mead in the United States, the Secretary shall consult with the Basin States on how the United States shall reduce the quantity of water allotted to Mexico.

3. Whenever Lake Mead is below elevation 1025 feet, the Secretary shall consult with the Basin States annually to determine whether Colorado River hydrologic conditions, together with the anticipated delivery of water to the Lower Division States and Mexico, will cause the elevation of Lake

9

Mead to fall below 1000 feet. Upon such a determination, the Secretary shall consult with the Basin States to discuss further measures that may be undertaken. If increased reductions are required, the Secretary shall implement the reductions consistent with the law of the river.

4. Subject to the provisions of Section 4.D.3, the Lower Division States shall not take shortages in excess of those provided in Section 4.D.1 Arizona and Nevada have agreed to share all reductions, described in Section 4.D.1 based on the Arizona-Nevada Shortage Sharing Agreement dated February 9, 2007. California shall not be required to share in any reductions described in Section 4.D.1.

5. The Secretary shall consult with the Basin States to evaluate actions at critical elevations that may avoid shortage determinations as reservoir elevations approach critical thresholds.

6. During declared Shortages described in Section 4.D.1, the Secretary may release Developed Shortage Supply, subject to the provisions in Sections 5 and 6.

Section 5. System Efficiency, Extraordinary Conservation, Tributary Conservation and Importation of Non-Colorado River System Water for the Purpose of Developing Intentionally Created Surplus

A. Findings

ICS may be created through projects that create water system efficiency, extraordinary conservation, tributary conservation, and the importation of non-Colorado River System water into the Colorado River Mainstream. ICS is consistent with the concept that the States will take actions to augment storage of water in the Lower Colorado River Basin. The ICS shall be released to the Contractor that created it pursuant to both Article II(B)(2) of the Consolidated Decree and agreements among various Contractors to forbear from taking water that they otherwise would be able to request. Implementation under these Guidelines shall be predicated upon the execution of a Forbearance Agreement and a Delivery Agreement, as further provided for below.

B. Purposes

The purposes of ICS are to:

1. Encourage the efficient use and management of Colorado River water, and to increase the water supply in Colorado River system reservoirs, through the creation, release, and use of ICS;

2. Help avoid shortages to the Lower Basin;

3. Benefit both Lake Mead and Lake Powell;

4. Increase the surface elevations of both Lakes Powell and Mead to higher levels than would have otherwise occurred; and

5. Assure any Contractor that invests in conservation or augmentation to create ICS that no Contractor within another state will claim the ICS created by the Contractor.

C. Statement of Consistency with the Law of the River and Consequential Limitations on ICS Guidelines

In Years in which the Secretary determines that sufficient Mainstream water is available for release to satisfy annual consumptive use in the Lower Division States in excess of 7,500,000 acre-feet, Article II(B)(2) of the Consolidated Decree authorizes the Secretary to apportion surplus Mainstream water 50% for use in California, 46% for use in Arizona, and 4% for use in Nevada. The Boulder Canyon Project Act and Articles II(B)(2) and II(B)(6) of the Consolidated Decree, taken together, authorize the Secretary to apportion surplus water and to release one Lower Division State's unused apportionment for use in another Lower Division State. Pursuant to such authority and for the purpose of increasing the efficiency, flexibility, and certainty of Colorado River management and thereby helping satisfy the regional water demands that exist, the Secretary has the authority to promulgate guidelines to establish a procedural framework for facilitating the creation and release of ICS.

In the absence of forbearance, surplus water is apportioned for use according to the percentages provided in Article II(B)(2) of the Consolidated Decree. The Forbearance Agreement, as approved by the Parties, will provide the basis for such forbearance. The Parties will forbear only with respect to ICS created by projects described in exhibits attached to the Forbearance Agreement or added thereto by written consent of all Parties. It is hereby recognized that the creation, release and use of ICS pursuant to these Guidelines shall not be administered in such a way as to violate the Consolidated Decree, including Articles II(B)(2) and II(B)(6) therein. These Guidelines regarding ICS shall have no force or effect absent the existence and effectiveness of the Forbearance Agreement.

D. Creation and Release of ICS

1. Extraordinary Conservation ICS

A Contractor may create Extraordinary Conservation ICS through the following activities:

a. Fallowing of land that currently is, historically was, and otherwise would have been irrigated in the next Year.

b. Canal lining programs.

c. Desalination programs in which the desalinated water is used in lieu of Mainstream water.

d. Extraordinary conservation programs that existed on January 1, 2006.

e. Extraordinary Conservation ICS demonstration programs pursuant to a letter agreement entered into between the United States Bureau of

Reclamation and the Contractor prior to the effective date of these Guidelines.

f. Tributary Conservation ICS created under Section 5.D.2 and not released in the Year created.

g. Imported ICS created under Section 5.D.4 and not released in the Year created.

h. Other extraordinary conservation measures, including development and acquisition of a non-Colorado River System water supply used in lieu of Colorado River Mainstream water within the same state, in consultation with the Basin States, and as agreed upon by the Parties pursuant to the Forbearance Agreement.

2. Tributary Conservation ICS

A Contractor may create Tributary Conservation ICS by purchasing documented water rights on Colorado River System tributaries upstream of Hoover Dam within the Contractor's state if there is documentation that the water rights have been used for a significant period of Years and that the water rights were perfected prior to June 25, 1929 (the effective date of the Boulder Canyon Project Act). The quantity of Tributary Conservation ICS shall be limited to the quantity of water set forth in Exhibits incorporated in the Forbearance Agreement, and shall in no event be more than the quantity of such water the Secretary verifies actually flows into Lake Mead. Any Tributary Conservation ICS not released pursuant to Section 5.D.6 or deducted pursuant to Section 5.D.5.c in the Year it was created will, at the beginning of the following Year, be converted to Extraordinary Conservation ICS at the request of the Contractor and will thereafter be subject to all provisions applicable to Extraordinary Conservation ICS. Tributary Conservation ICS may be released for Domestic Use only.

3. System Efficiency ICS

A Contractor may make contributions of capital to the Secretary for use in Secretarial projects designed to realize system efficiencies that save water that would otherwise be lost from the Colorado River Mainstream in the United States. An amount of water equal to a portion of the water saved may be made available to contributing Contractor(s) by the Secretary as System Efficiency ICS. System efficiency projects are intended only to provide temporary water supplies. System Efficiency ICS will not be available for permanent use. System Efficiency ICS will be released to the contributing Contractor(s) on a predetermined schedule of annual deliveries for a period of Years as agreed by the Parties. The Secretary, in consultation with the Basin States, will identify potential system efficiency projects, terms for capital participation in such projects, and types and amounts of benefits the Secretary should provide in consideration of non-federal capital contributions to system efficiency projects, including identification of a portion of the water saved by such projects.

4. Imported ICS

A Contractor may create Imported ICS by introducing non-Colorado River System water in that Contractor's state into the Mainstream. Contractors proposing to create Imported ICS shall make arrangements with the Secretary, contractual or otherwise, to ensure no interference with the Secretary's management of Colorado River system reservoirs and regulatory structures. Any arrangement shall provide that the Contractor must obtain appropriate permits or other authorizations required by state law and that the actual amount of water introduced to the Mainstream shall be reported to the Secretary on an annual basis. Any Imported ICS not released pursuant to Section 5.D.6 or deducted pursuant to Section 5.D.5.c in the Year it was created will be converted, at the beginning of the following Year, to Extraordinary Conservation ICS at the request of the Contractor and thereafter will be subject to all provisions applicable to Extraordinary Conservation ICS.

5. Creation of ICS

A Contractor may create ICS subject to the following conditions:

a. A Contractor shall submit a plan for the creation of ICS to the Secretary and the Basin States demonstrating how all requirements of these Guidelines will be met in the Contractor's creation of ICS. Until such plan is reviewed and approved by the Secretary in consultation with the other Basin States, such plan, or any ICS purportedly created through it, shall not be a basis for an ICS Declaration. A Contractor may modify its plan for creation of ICS during any Year, subject to approval by the Secretary in consultation with the Basin States. System Efficiency ICS with an approved multi-Year plan shall not require annual approval by the Secretary or consultation with the Basin States.

b. A Contractor that creates ICS shall submit a Certification Report to the Secretary demonstrating the amount of ICS created and that its creation was consistent with the Forbearance Agreement, these Guidelines, and a Delivery Agreement executed by the Secretary. The Secretary shall verify the information in the Certification Report in consultation with the Basin States, and provide a final written decision to the Contractor, the Parties and the Basin States. The Contractor or any Party or Basin State may appeal the Secretary's verification of the Certification Report through administrative and judicial processes.

c. There shall be a one-time deduction of five percent (5%) from the amount of ICS in the Year of its creation. This deduction results in additional water in storage in Lake Mead for future use in accordance with the Consolidated Decree and these Guidelines. This provision shall not apply to:

(1) System Efficiency ICS created pursuant to Section 5.D.3 because a large portion of the water saved by this type of project will increase the quantity of water in storage.

(2) Extraordinary Conservation ICS created by conversion of Tributary Conservation ICS that was not released in the Year created, pursuant to Section 5.D.1.f because 5% of the ICS is deducted at the time the Tributary Conservation ICS is created.

(3) Extraordinary Conservation ICS created by conversion of Imported ICS that was not released in the Year created, pursuant to Section 5.D.1.g because 5% of the ICS is deducted at the time the Imported ICS is created.

d. The records of any Contractor relating to the creation of ICS shall be open to inspection by the Secretary or any Contractor, Party or Basin State.

e. In addition to the conditions described above, creation of Extraordinary Conservation ICS is subject to the following conditions:

(1) Except as provided in Sections 5.D.2 and 5.D.4, Extraordinary Conservation ICS can only be created if such water would have otherwise been beneficially used.

(2) The maximum total amount of Extraordinary Conservation ICS that can be created during any Year is limited to the following:

(a) 400,000 acre-feet for California Contractors;

(b) 125,000 acre-feet for Nevada Contractors; and

(c) 100,000 acre-feet for Arizona Contractors.

(3) The maximum quantity of Extraordinary Conservation ICS that may be accumulated in all ICS Accounts, at any time, is limited to the following:

(a) 1,500,000 acre-feet for California Contractors;

(b) 300,000 acre-feet for Nevada Contractors; and

(c) 300,000 acre-feet for Arizona Contractors.

(4) Except as provided in Sections 5.D.2 and 5.D.4, no category of surplus water can be used to create Extraordinary Conservation ICS.

(5) The quantity of Extraordinary Conservation ICS remaining in an ICS Account at the end of each Year shall be diminished by annual evaporation losses of 3%. Losses shall be applied

annually to the end-of-the-Year balance of Extraordinary Conservation ICS beginning in the Year after the ICS is created and continuing until no Extraordinary Conservation ICS remains in Lake Mead. No evaporation losses shall be assessed during a Year in which the Secretary has declared a shortage.

(6) Extraordinary Conservation ICS from a project within a state may be credited to the ICS Account of a Contractor within that state that has funded or implemented the project creating ICS, or to the ICS Account of a Contractor within the same state as the funding entity and project and with written agreement of the funding entity.

(7) A Contractor must notify Reclamation by September 15 of the amount of Extraordinary Conservation ICS it wishes to create for the subsequent Year. If conditions during the Year change due to weather or other unforeseen circumstances, a Contractor may request a mid-Year modification of its water order to reduce the amount of ICS created during that Year. A Contractor cannot increase the amount of ICS it had previously scheduled to create during the Year.

6. Release of ICS

The release of ICS shall be pursuant to the terms of a Delivery Agreement entered into among the Secretary, the Parties to the Forbearance Agreement and any Contractor creating ICS. The Secretary shall not release ICS to a Contractor unless that Contractor is a party to a Delivery Agreement. A Contractor that has created ICS may request release of its ICS as is provided within such Delivery Agreement and subject to the following conditions:

a. ICS shall be released pursuant to an ICS Declaration.

b. If a Contractor has an overrun payback obligation, as described in the October 10, 2003 Inadvertent Overrun and Payback Policy or Exhibit C to the October 10, 2003 Colorado River Water Delivery Agreement, the Contractor must pay the overrun payback obligation in full before requesting or receiving a release of any ICS. The Contractor's ICS account shall be reduced by the amount of the overrun payback obligation in order to pay the overrun payback obligation.

c. If more ICS is released to a Contractor than is actually available for release to the Contractor in that Year, then the excess ICS released shall be treated as an inadvertent overrun until it is fully repaid.

d. A Contractor may reduce its request for release of ICS during the Year for any reason, including reduction in water demands. A Contractor may increase its request for release of ICS during the Year only if extraordinary weather conditions or water emergencies occur.

e. In addition to the conditions described above, the release of Extraordinary Conservation ICS is subject to the following conditions:

(1) The total amount of Extraordinary Conservation ICS that may be released in any Year is limited to the following:

(a) 400,000 acre-feet for California Contractors;

(b) 300,000 acre-feet for Nevada Contractors; and

(c) 300,000 acre-feet for Arizona Contractors.

(2) If the May 24-month study for that Year indicates that a shortage condition would be declared in the succeeding Year if the requested amounts for the current Year under Section 5.D.6.e.(1) were released, the Secretary may release less than the amounts of ICS requested to be released.

(3) If the Secretary releases Flood Control Surplus water, Extraordinary Conservation ICS accumulated in ICS Accounts shall be reduced by the amount of the Flood Control Surplus on an acre-foot for acre-foot basis until no Extraordinary Conservation ICS remains. The reductions to the ICS Accounts shall be shared on a pro-rata basis among all Contractors that have accumulated Extraordinary Conservation ICS.

E. Accounting Procedure for ICS

In consultation with the Basin States, the Secretary shall develop a water accounting procedure to annually establish separate ICS Accounts to account for, at a minimum, the following:

1. For each Contractor that creates Extraordinary Conservation ICS:

a. The quantity of Extraordinary Conservation ICS created by the Contractor.

b. The releases of Extraordinary Conservation ICS to the Contractor.

c. The amount of Extraordinary Conservation ICS no longer available for release to the Contractor due to releases for flood control purposes.

d. The amount of Extraordinary Conservation ICS deducted pursuant to Section 5.D.5.c.

e. The amount of Extraordinary Conservation ICS no longer available for release to the Contractor due to annual evaporation losses pursuant to Section 5.D.5.e.(5).

f. The amount of Extraordinary Conservation ICS remaining available for release to the Contractor.

2. For each Contractor that creates Tributary Conservation ICS:

   a. The quantity of Tributary Conservation ICS created by the Contractor.

   b. The releases of Tributary Conservation ICS to the Contractor.

   c. The amount of Tributary Conservation ICS deducted pursuant to Section 5.D.5.c.

   d. The amount of Tributary Conservation ICS converted to Extraordinary Conservation ICS, if any.

3. For each Contractor that creates System Efficiency ICS:

   a. The quantity of System Efficiency ICS created by the Contractor.

   b. The releases of System Efficiency ICS to the Contractor.

   c. The amount of System Efficiency ICS no longer available for release to the Contractor for any reason.

   d. The amount of System Efficiency ICS remaining available for release to the Contractor.

4. For each Contractor that creates Imported ICS:

   a. The quantity of Imported ICS created by the Contractor.

   b. The releases of Imported ICS to the Contractor.

   c. The amount of Imported ICS deducted pursuant to Section 5.D.5.c.

   d. The amount of Imported ICS converted to Extraordinary Conservation ICS, if any.

F. Delivery Agreement

The Secretary shall release ICS to a Contractor only after entering into a Delivery Agreement with the Contractor and the Parties to the Forbearance Agreement. Any Delivery Agreement shall be consistent with these Guidelines and the Forbearance Agreement, and shall include the following:

1. A procedure for the annual schedule for the submission and approval of the plans for the creation of ICS, required by Section 5.D.5.a.

2. Procedures for demonstrating and verifying the creation of ICS, including a description of the contents of the Certification Report, required by Section 5.D.5.b.

3. A procedure for the release of ICS, in accordance with Section 5.D.6.

4. An accounting procedure, pursuant to Section 5.E.

Section 6. Creation and Release of Developed Shortage Supply

A. During any Year in which the Secretary declares a shortage within the United States, Developed Shortage Supply may be created by:

1. Purchasing documented water rights on Colorado River System tributaries upstream of Hoover Dam within the Contractor's state if there is documentation that the water rights have been used for a significant period of Years and that the water rights were perfected prior to June 25, 1929 (the effective date of the Boulder Canyon Project Act), provided that the quantity of such Developed Shortage Supply shall be limited to the quantity of water set forth in Exhibits incorporated in the Forbearance Agreement, and shall in no event be more than the quantity of such water the Secretary verifies actually flows into Lake Mead; and/or

2. Introducing non-Colorado River System water in that Contractor's state into the Colorado River Mainstream, making sufficient arrangements with the Secretary, contractual or otherwise, to ensure no interference with the Secretary's management of Colorado River system reservoirs and regulatory structures. Any arrangement shall provide that the Contractor must obtain appropriate permits or other authorizations required by state law and reporting the actual amount of water introduced to the Colorado River Mainstream to the Secretary on an annual basis.

B. Developed Shortage Supply may only be created by a project that is approved for creation of ICS prior to the declared Shortage.

C. Except as provided in Sections 6.D through 6.F, Developed Shortage Supply is subject to all conditions set forth in Section 5 relating to creation and release of ICS.

D. Any Developed Shortage Supply not released pursuant to Section 6.E in the Year it is created may not be converted to Extraordinary Conservation ICS.

E. The Secretary shall release Developed Shortage Supply during a declared shortage. The following conditions shall apply to the release of Developed Shortage Supply:

1. Developed Shortage Supply shall be released pursuant to a Shortage Declaration.

2. Release of Developed Shortage Supply shall not cause the total deliveries within the Lower Division States to reach or exceed 7.5 million acre-feet in any Year. If the volume of Developed Shortage Supply requested to be released in any Year would cause the total deliveries within the Lower Division States to reach or exceed 7.5 million acre-feet for that Year, the Secretary shall consult with all Contractors requesting the release of Developed Shortage Supply and release so much thereof as will not cause

total deliveries in the Lower Division States to reach or exceed 7.5 million acre-feet in that Year.

F. The Secretary shall account for the creation and release of Developed Shortage Supply through the AOP and the Article V Consolidated Decree accounting processes.

G. Delivery Agreement

For a Contractor seeking to create and use Developed Shortage Supply, the Delivery Agreement for ICS executed by the Secretary, the Contractor and the Parties to the Forbearance Agreement shall also include the following:

1. A procedure for the annual schedule for the submission and approval of the plans for the creation of Developed Shortage Supply, required by Sections 6.C and 5.D.5.a.

2. Procedures for demonstrating and verifying the creation of Developed Shortage Supply, including a description of the contents of the Certification Report, required by Sections 6.C and 5.D.5.b.

3. A procedure for the release of Developed Shortage Supply, in accordance with Sections 6.C, 6.E, and 5.D.6.

4. An accounting procedure, pursuant to Section 6.F.

Section 7. Implementation of Guidelines

During the effective period of these Guidelines the Secretary shall utilize the currently established process for development of the AOP and use these Guidelines to make determinations regarding Normal, Surplus and Shortage conditions for the operation of Lake Mead, allocation of apportioned but unused water, the coordinated operations of Lakes Mead and Powell, and the administration of Developed Shortage Supply and contractor accounts for ICS.

The operation of the other Colorado River System reservoirs and determinations associated with development of the AOP shall be in accordance with the Colorado River Basin Project Act of 1968, these Guidelines, and other applicable federal law.

In order to allow for better overall water management during the Interim Period, the Secretary shall undertake a "mid-Year review" pursuant to Section 1(2) of the LROC, allowing for the revision of the current AOP, as appropriate, if actual runoff conditions are greater than projected or demands are lower than projected. The Secretary shall revise the determination for the current Year only to allow for additional deliveries. Any revision in the AOP, including reductions in the amount of ICS released, may occur only after a re-initiation of the AOP consultation process as required by law.

As part of the AOP process during the effective period of these Guidelines, California shall report to the Secretary on its progress in implementing its California Colorado River Water Use Plan.

The Secretary will base annual determinations of surplus, normal and shortage conditions on these Guidelines, unless extraordinary circumstances arise. Such circumstances could include operations necessary for safety of dams or other emergency situations, or other unanticipated or unforeseen activities arising from actual operating experience.

Section 8. Consultation

In addition to the circumstances described in Section 4.D.2, the Secretary shall consult with the Basin States in the following circumstances:

A. The Secretary will first consult with all the Basin States before making any substantive modification to these Guidelines.

B. Upon a request by a State for modification of these Guidelines, or upon a request by a State to resolve any claim or controversy arising under these Guidelines or under the operations of Lakes Powell and Mead pursuant to these guidelines or any other applicable provision of federal law, regulation, criteria, policy, rule, or guideline, or the Mexican Water Treaty of 1944, the Secretary shall invite the Governors of all the Basin States, or their designated representatives, to consult with the Secretary in an attempt to resolve such claim or controversy by mutual agreement.

Section 9. Effective Period & Termination

A. Effective Period

These guidelines will be in effect 30 days from the publication of the ROD in the Federal Register and will, unless subsequently modified, remain in effect through December 31, 2025 (through preparation of the 2026 AOP), except that during the effective period of the Forbearance Agreement defined in Section 5.C:

1. Any ICS remaining in an ICS Account on December 31, 2025, may be released as provided herein until December 31, 2035.

2. Tributary Conservation ICS described in Section 5.D.2 and Imported ICS described in Section 5.D.4 shall continue in full force and effect until fifty years from the date of the execution of the Forbearance Agreement.

3. Developed Shortage Supply described in Section 6 shall continue in full force and effect until fifty years from the date of the execution of the Forbearance Agreement.

B. Termination of Guidelines

Except as provided in Section 9.A, these Guidelines shall terminate on December 31, 2025 (through preparation of the 2026 AOP). At the conclusion of the effective period of these Guidelines, the operating criteria for Lake Powell and Lake Mead are assumed to revert to the operating criteria used to model baseline conditions in the Final Environmental Impact Statement for the Interim Surplus Guidelines dated December 2000 (i.e., modeling assumptions are based upon a 70R strategy for the period commencing January 1, 2026 (for preparation of the 2027 AOP)).

C. Review of Guidelines

Beginning no later than December 31, 2020, the Secretary shall initiate a formal review for purposes of evaluating the effectiveness of these Guidelines. The Secretary shall consult with the Basin States in initiating this review.

Section 10. California's Colorado River Water Use Plan Implementation Progress

The California agricultural (Palo Verde Irrigation District (PVID), Yuma Project Reservation Division (YPRD), Imperial Irrigation District (IID), and Coachella Valley Water District (CVWD)) usage plus 14,500 acre-feet of Present Perfected Right (PPR) use would need to be at or below the following amounts at the end of the Year indicated in Years of Quantified Surplus (for Decree accounting purposes all reductions must be within 25,000 acre-feet of the amounts stated):

Benchmark Date (Year)	Benchmark Quantity (California Agricultural Usage & 14,500 af of PPR Use in maf)
2009	3.53
2012	3.47

In the event that California has not reduced its use in amounts to equal the above Benchmark Quantities, the surplus determinations under Sections 4.B.1 or 4.B.2 will be suspended and will instead be based upon the 70R Strategy, for up to the remainder of the term of these Guidelines. If however, California meets the missed Benchmark Quantity before the next Benchmark Date, or after 2012, the surplus determinations under Sections 4.B.1 or 4.B.2 shall be reinstated as the basis for the surplus determinations under the AOP for the next following Year(s).

Section 11. Authority

These Guidelines are issued pursuant to the authority vested in the Secretary by federal law, including the Boulder Canyon Project Act of 1928 (28 Stat. 1057) (the "BCPA"), and the Consolidated Decree and shall be used to implement Article III of the Criteria for the Coordinated Long-Range Operation of Colorado River Reservoirs Pursuant to the Colorado River Basin Project Act of September 30, 1968 (Pub. L. No. 90-537), amended March 21, 2005.

Section 12. Modeling and Data

The August 24-Month Study projections for the January 1 system storage and reservoir water surface elevations, for the following Year, will be used to determine the applicability of these Guidelines.

In preparation of the AOP, Reclamation will utilize the 24-Month Study and/or other modeling methodologies appropriate for the determinations and findings necessary in the AOP.

Reclamation will utilize the best available data and information, including National Weather Service forecasting to make these determinations.

Attachment C

Forbearance Agreement

This attachment to Appendix J contains the text of Attachment C to the Revised Basin States' Proposal.

ATTACHMENT C

Lower Colorado River Basin Intentionally Created Surplus Forbearance Agreement

The State of Arizona, acting through the Arizona Department of Water Resources ("ADWR"); the Palo Verde Irrigation District ("PVID"); the Imperial Irrigation District ("IID"); The City of Needles; the Coachella Valley Water District ("CVWD"); The Metropolitan Water District of Southern California ("MWD"); the Southern Nevada Water Authority ("SNWA"); and the Colorado River Commission of Nevada enter into this Lower Colorado River Basin Intentionally Created Surplus Forbearance Agreement ("Forbearance Agreement") as follows:

Recitals

A. The purposes of this Forbearance Agreement are to:

1. Encourage the efficient use and management of Colorado River water, and to increase the water supply in Colorado River system reservoirs, through the creation, release, and use of Intentionally Created Surplus ("ICS");

2. Help avoid shortages to the Lower Basin;

3. Benefit both Lake Mead and Lake Powell; and

4. Increase the surface elevations of both Lakes Powell and Mead to higher levels than would have otherwise occurred.

5. Assure any Contractor that invests in conservation or augmentation to create ICS under this Forbearance Agreement that no Contractor within another state will claim the ICS created by the Contractor.

B. The Parties to the Forbearance Agreement and their respective authority to forbear are as follows:

1. The Arizona Department of Water Resources, through its Director, is the successor to the signatory agency of the State for the 1922 Colorado River Compact, and the 1944 Contract for Delivery of Water with the United States, both authorized and ratified by the Arizona Legislature, A.R.S. §§ 45-1301 and 1311. Pursuant to A.R.S. § 45-107, the Director is authorized and directed, subject to the limitations in A.R.S. § 45-106, for and on behalf of the State of Arizona, to consult, advise and cooperate with the Secretary of the Interior of the United States ("Secretary") with respect to the exercise by the Secretary of Congressionally authorized authority relative to the waters of the Colorado River (including, but not limited to, the Boulder Canyon Project Act of 1928, 43 U.S.C. § 617, and the Colorado River Basin Project Act of 1968, 43 U.S.C. § 1501) and with respect to the development, negotiation and execution of interstate agreements. Additionally, under A.R.S. § 45-105(A)(9), the Director is authorized to "prosecute and defend all rights, claims and privileges of this state respecting interstate streams."

2. SNWA is a Nevada joint powers agency and political subdivision of the State of Nevada, created by agreement dated July 25, 1991, as amended November 17, 1994, and January 1, 1996, pursuant to N.R.S. §§ 277.074 and 277.120. SNWA is authorized by N.R.S. § 538.186 to enter into this Forbearance Agreement and, pursuant to its contract issued under Section 5 of the Boulder Canyon Project Act of 1928, SNWA has the right to divert ICS released by the Secretary for use within the State of Nevada pursuant to the Consolidated Decree.

3. The Colorado River Commission of the State of Nevada (CRCN) is an agency of the State of Nevada, authorized generally by N.R.S. §§ 538.041 and 538.251. CRCN is authorized by N.R.S. § 538.161 (6), (7) to enter into this

2

Agreement. The CRCN, in furtherance of the State of Nevada's responsibility to promote the health and welfare of its people in Colorado River matters, makes this Agreement to supplement the supply of water in the Colorado River which is available for use in Nevada, augment the waters of the Colorado River, and facilitate the more flexible operation of dams and facilities by the Secretary.

4. PVID is an irrigation district created under the Palo Verde Irrigation District Act, codified at Section 33-1 et seq. of the Appendix to the California Water Code, and delivers Colorado River water in Riverside and Imperial Counties, California, pursuant to its contract issued under Section 5 of the Boulder Canyon Project Act of 1928.

5. IID is an irrigation district created under the California Irrigation District Law, codified at Section 20500 *et seq.* of the California Water Code, and delivers Colorado River water in Imperial County, California, pursuant to its contract issued under Section 5 of the Boulder Canyon Project Act of 1928.

6. CVWD is a county water district created under the California County Water District Law, codified at Section 30000 *et seq.* of the California Water Code, and delivers Colorado River water to portions of its service area in Imperial, Riverside, and San Diego Counties, California, pursuant to its contract issued under Section 5 of the Boulder Canyon Project Act of 1928 and the California Quantification Settlement Agreement.

7. MWD is a metropolitan water district created under the California Metropolitan Water District Act, codified at Section 109-1 *et seq.* of the Appendix to the California Water Code; and delivers Colorado River water to portions of its service area in Los Angeles, Orange, Riverside, San Bernardino, San Diego and Ventura Counties, California, pursuant to its contracts issued under Section 5 of the Boulder Canyon Project Act of 1928.

8. The City of Needles is a charter city duly authorized and existing under and by virtue of the laws of the State of California and delivers Colorado River water, either directly or by exchange, to portions of Imperial, Riverside, and San Bernardino Counties, California, pursuant to its contracts issued under Section 5 of the Boulder Canyon Project Act of 1928,

NOW, THEREFORE, in consideration of the mutual covenants herein contained, the Parties hereby agree as follows:

Article 1
Definitions and Term

1.1 Definitions.

The definitions in the Interim Surplus Guidelines ("ISG") described in the Record of Decision dated January 16, 2001, and modified by the ROD are hereby incorporated in this Forbearance Agreement. In addition, each of the following terms shall have the meaning defined here. All defined terms shall be identified by initial letter capitalization.

A. "Certification Report" shall mean the written documentation provided by a Contractor pursuant to Article 2.5(B) that provides the Secretary with sufficient information to verify the quantity of ICS created and that the creation was consistent with the approved project exhibit, this Forbearance Agreement, the Delivery Agreement, and the ROD.

B. "Colorado River System" shall have the same meaning as defined in the 1922 Colorado River Compact.

C. "Consolidated Decree" shall mean the Consolidated Decree entered by the United States Supreme Court in *Arizona v. California*, 126 S.Ct. 1543, 547 U.S. ____ (2006).

D. "Contractor" shall mean a Boulder Canyon Project Act Section 5 Contractor or an entity receiving Mainstream water pursuant to other applicable federal statute or the Consolidated Decree.

E. "Delivery Agreement" shall mean the agreement entered into by the Parties to this Agreement and the Secretary of the Interior contemporaneously with this Forbearance Agreement.

F. "Forbearance Agreement" shall mean this Lower Colorado River Basin Intentionally Created Surplus Forbearance Agreement.

G. "ICS" shall mean intentionally created surplus available for use under the terms and conditions of this Forbearance Agreement and the Delivery Agreement.

1. ICS created through extraordinary conservation, as provided for in Article 2.1 herein, shall be referred to as "Extraordinary Conservation ICS."

2. ICS created through tributary conservation, as provided for in Article 2.2 herein, shall be referred to as "Tributary Conservation ICS."

3. ICS created through system efficiency projects, as provided for in Article 2.3 herein, shall be referred to as "System Efficiency ICS."

4. ICS created through the importation of non-Colorado River System Water, as provided for in Article 2.4 herein, shall be referred to as "Imported ICS."

H. "ICS Account" shall mean a record established by the Secretary under the terms of this Forbearance Agreement, the Delivery Agreement, and the ROD.

I. "ICS Declaration" shall mean a declaration of ICS made by the Secretary pursuant to the ROD, the Delivery Agreement and the provisions of this Forbearance Agreement.

J. "Lower Division States" shall mean the Colorado River Basin States of Arizona, California, and Nevada.

K. "Mainstream" shall have the same meaning as defined in the Consolidated Decree.

L. "Parties" shall mean all of the signatories to this Forbearance Agreement.

M. "ROD" shall mean the Record of Decision issued by the Secretary for the Development of Lower Basin Shortage Guidelines and Coordinated Management Strategies for Lake Powell and Lake Mead, Particularly Under Low Reservoir Conditions, and including the policy for implementation of ICS.

N. "Year" shall mean calendar year.

1.2 <u>Term of the Forbearance Agreement</u>.

This Forbearance Agreement shall commence on the date of execution by all Parties and shall terminate December 31, 2025; provided, however, that any ICS remaining in an ICS

Account on December 31, 2025, may be released as provided herein until December 31, 2035.

1.3 Extended Term for Tributary Conservation ICS and Imported ICS.

Notwithstanding Article 1.2, the provisions of this Forbearance Agreement for creation, and release in the Year of creation, of Tributary Conservation ICS under Article 2.2 and Imported ICS under Article 2.4, shall continue in full force and effect after termination of this Forbearance Agreement until the earlier of (1) the termination of the period provided in the ROD for the creation, release, and use of Tributary Conservation ICS and Imported ICS, or (2) fifty years from the date of execution of this Forbearance Agreement. The amount of Tributary Conservation ICS and Imported ICS that may be created, released, and used through the end of the extended term provided by this Article 1.3 shall not exceed the amount shown in, and shall be consistent with, the attached Exhibits ___ and ___ for Tributary Conservation ICS and Imported ICS. Such ICS may be released during the extended term as provided herein. The obligations of the Parties under Articles 2.5, 2.6, 3, 4, and 5 shall continue with regard to such ICS.

1.4 Seven Colorado River Basin States' Agreement

Notwithstanding Articles 1.2 and 1.3 above, if one or more states withdraw from the agreement dated ____, executed by the seven Colorado River Basin states, the Parties to this Forbearance Agreement shall consult to determine whether to continue this Forbearance Agreement in effect or to amend or terminate this Forbearance Agreement. In such event, the terms of this Forbearance Agreement shall continue in effect until the Parties have consulted and agreed to continue, amend, or terminate this Forbearance Agreement. In the event of termination, all Parties shall be relieved from the terms hereof and this Forbearance Agreement shall be of no further force or effect.

Article 2

Creation and Release of ICS

2.1 Extraordinary Conservation ICS

Pursuant to procedures set forth in the ROD, the Delivery Agreement, and this Forbearance Agreement, Extraordinary Conservation ICS may be created only through the following activities:

A. Fallowing of land that currently is, historically was, and otherwise would have been irrigated in the next Year.

B. Canal lining programs.

C. Desalination programs in which the desalinated water is used in lieu of Mainstream water.

D. Extraordinary conservation programs that existed on January 1, 2006.

E. Demonstration Extraordinary Conservation ICS programs pursuant to a letter agreement entered into between the United States Bureau of Reclamation and the Contractor prior to the effective date of the ROD.

F. Tributary Conservation ICS created under Article 2.2 hereto and not released in the Year created.

G. Imported ICS created under Article 2.4 hereto and not released in the Year created.

H. Other extraordinary conservation measures, including development and acquisition of a non-Colorado River System water supply used in lieu of Mainstream water within the same state, as agreed upon by the Parties pursuant to this Forbearance Agreement.

2.2 Tributary Conservation ICS

Pursuant to procedures set forth in the ROD, a Contractor may create Tributary Conservation ICS by purchasing documented water rights on Colorado River System tributaries within the

8

Contractor's state if there is documentation that the water rights have been used for a significant period of years and that the water rights were perfected prior to June 25, 1929 (the effective date of the Boulder Canyon Project Act of 1928). The quantity of Tributary Conservation ICS that may be created shall be limited to the quantity of water set forth in Exhibits __ and __, and shall in no event be more than the quantity of such water the Secretary verifies actually flows into Lake Mead. Any Tributary Conservation ICS not released or deducted pursuant to Article 2.5(C) in the Year it was created will be converted to Extraordinary Conservation ICS at the request of the Contractor and will be subject to all provisions of this Forbearance Agreement applicable to Extraordinary Conservation ICS.

2.3 System Efficiency ICS

Pursuant to procedures set forth in the ROD, a Contractor may make contributions of capital to the Secretary for use in Secretarial projects designed to realize efficiencies that save water that would otherwise be lost from the Mainstream in the United States. An amount of water equal to a portion of the water saved may be made available to contributing Contractors by the Secretary as System Efficiency ICS. System efficiency projects are only intended to provide temporary water supplies and System Efficiency ICS will not be available for permanent use. The System Efficiency ICS will be released to the capital contributor on a predetermined schedule of annual deliveries for a period of years as agreed by the Parties.

2.4 Imported ICS

Pursuant to procedures set forth in the ROD, a Contractor may create Imported ICS by introducing non-Colorado River System water in that Contractor's state into the Mainstream. Contractors proposing to create Imported ICS shall make sufficient arrangements with the Secretary, contractual or otherwise, to guarantee that the creation of Imported ICS shall cause no harm to the Secretary's management of the Colorado River System. These arrangements shall provide that the Contractor must obtain appropriate permits or other authorizations required by state law and that the actual amount of water introduced to the Mainstream would be reported to the Secretary on an annual basis. Any Imported ICS not released or deducted pursuant to Article 2.5(C) in the Year it was created will be converted to Extraordinary Conservation ICS at the request of the Contractor and will be subject to all provisions of this Forbearance Agreement applicable to Extraordinary Conservation ICS.

2.5 Creation of ICS

A Contractor may create ICS subject to the following conditions:

A. Pursuant to procedures set forth in the ROD, a Contractor shall submit a plan for the creation of ICS to the Secretary and the Lower Division States demonstrating how all requirements of this Forbearance Agreement will be met in the Contractor's creation of ICS. System Efficiency ICS with an approved multi-year plan shall not require annual approval by the Secretary or consultation with the Lower Division States. Until such plan is reviewed and approved by the Secretary annually in consultation with the Lower Division States, such ICS plan, or any ICS purportedly created through it, cannot be a basis for an ICS Declaration. A Contractor may modify its plan for creation of ICS during any Year, subject to approval by the Secretary in consultation with the Lower Division States.

B. Pursuant to procedures set forth in the ROD, a Contractor that creates ICS shall submit a Certification Report to the Secretary demonstrating the amount of ICS created and that its creation was consistent with this Forbearance Agreement and the ROD. The Secretary shall verify the information in the Certification Report in consultation with the Lower Division States, and provide a final written decision to the Parties. Any Party may appeal the Secretary's verification of the Certification Report through administrative and judicial processes.

C. There shall be a one-time deduction of five percent (5%) from the amount of ICS in the Year of its creation. This deduction results in additional water in storage in Lake Mead for future use in accordance with the Consolidated Decree, the Interim Surplus Guidelines, and the ROD. This provision shall not apply to:

1. System Efficiency ICS created pursuant to Article 2.3 of this Forbearance Agreement because a large portion of the water saved by this type of project will increase the quantity of water in storage.
2. Extraordinary Conservation ICS created by conversion of Tributary Conservation ICS that was not released in the Year created, pursuant to Article 2.1(E) of this Forbearance Agreement, because 5% of the ICS is deducted at the time the Tributary Conservation ICS is created.
3. Extraordinary Conservation ICS created by conversion of Imported ICS that was not released in the Year created, pursuant to Article 2.1(F) of this Forbearance Agreement, because 5% of the ICS is deducted at the time the Imported ICS is created.

D. In addition to the conditions described above, creation of Extraordinary Conservation ICS is subject to the following conditions:

1 Except as provided in Articles 2.2 and 2.4, Extraordinary Conservation ICS can only be created if such water would have otherwise been beneficially used.

2. The maximum total amount of Extraordinary Conservation ICS that can be created during any Year is limited to the following:
   a. 400,000 acre-feet for California Contractors;
   b. 125,000 acre-feet for Nevada Contractors; and
   c. 100,000 acre-feet for Arizona Contractors.
3. The maximum quantity of Extraordinary Conservation ICS that may be accumulated in all ICS Accounts, at any time, is limited to the following:
   a. 1,500,000 acre-feet for California Contractors;
   b. 300,000 acre-feet for Nevada Contractors; and
   c. 300,000 acre-feet for Arizona Contractors.
4. Except as provided in Articles 2.2 and 2.4, no category of surplus water can be used to create Extraordinary Conservation ICS.
5. The quantity of Extraordinary Conservation ICS remaining in an ICS Account at the end of each Year shall be diminished by annual

evaporation losses, as determined by the Secretary in consultation with the Lower Division States, provided that such losses shall not exceed three percent (3%). Losses shall be applied annually to the end-of-the-Year balance of Extraordinary Conservation ICS beginning in the Year after the ICS is created and continuing until no Extraordinary Conservation ICS remains in Lake Mead. No evaporation losses shall be assessed during a Year in which the Secretary has declared a shortage.

6. Extraordinary Conservation ICS from a project within a state may only be credited to the ICS Account of a Contractor within that state that has funded or implemented the project creating the ICS, or to the ICS Account of a Contractor within the same state as the funding entity and project and with written agreement of the funding entity.

2.6 Request for Release of ICS

A Contractor that has created ICS may request that the Secretary release its ICS subject to the following conditions:

A. If a Contractor has an overrun payback obligation, as described in the October 10, 2003 Inadvertent Overrun and Payback Policy or Exhibit C to the October 10, 2003 Colorado River Water Delivery Agreement, the Contractor must pay the overrun payback obligation in full before requesting or receiving a release of any ICS. The Contractor may request that the amount of ICS in the Contractor's ICS Account be reduced by the amount of the overrun payback obligation in order to pay the overrun payback obligation.

B. ICS shall only be released pursuant to an ICS Declaration.

C. In addition to the conditions described above, a Contractor's request for release of Extraordinary Conservation ICS is subject to the following conditions:

1. The total amount of Extraordinary Conservation ICS that may be released in any Year is limited to the following:
   a. 400,000 acre-feet for California Contractors;
   b. 300,000 acre-feet for Nevada Contractors; and
   c. 300,000 acre-feet for Arizona Contractors;
2. If the May, 24-month study for that Year indicates that a shortage condition would be declared in the succeeding Year if the requested amounts for the current Year under Article 2.6 were released, the Secretary may release less than the amounts of ICS requested to be released.
3. If the Secretary releases Flood Control Surplus water, Extraordinary Conservation ICS accumulated in ICS Accounts shall be reduced by the amount of the Flood Control Surplus on an acre-foot for acre-foot basis until no Extraordinary Conservation ICS remains. The reductions to the ICS Accounts shall be shared on a pro-rata basis among all Contractors that have accumulated Extraordinary Conservation ICS unless otherwise agreed to by the Contractors.

2.7 Additional Terms Regarding Creation and Release of ICS

It is the specific intent of the Parties that the terms, conditions and procedures regarding the creation and release of ICS contained in this Article 2 will be applied in conformance with additional terms, conditions and procedures governing the creation and release of ICS contained in the Delivery Agreement.

Article 3

Forbearance

3.1 In the absence of forbearance, surplus water is apportioned for use according to the percentages provided in Article II(B)(2) of the Consolidated Decree. The Parties respectively agree as follows:

13

A. ADWR hereby forbears:

1. Any right the State of Arizona may have to delivery of any ICS released in accordance with the terms and conditions set forth in this Forbearance Agreement and the Delivery Agreement for use within the State of California or the State of Nevada.

2. Any right the State of Arizona may have to the release and delivery of water for direct delivery domestic use to entities in California or Nevada under a Domestic Surplus as described in the Delivery Agreement and the ROD.

B. PVID, IID, CVWD, the City of Needles and MWD hereby forbear:

1. Any right they may have to delivery of any ICS released in accordance with the terms and conditions set forth in this Forbearance Agreement and the Delivery Agreement for use within the State of Arizona or the State of Nevada.

2. Any right they may have to the release and delivery of water for direct delivery domestic use to entities in Arizona or Nevada under a Domestic Surplus as described in the Delivery Agreement and the ROD.

C. SNWA and CRCN hereby forbear:

1. Any right SNWA or the State of Nevada may have to delivery of any ICS released in accordance with the terms and conditions set forth in this Forbearance Agreement and the Delivery Agreement for use within the State of Arizona or the State of California.

2. Any right SNWA or the State of Nevada may have to the release and delivery of water for direct delivery domestic use to entities in Arizona or California under a Domestic Surplus as described in the Delivery Agreement and the ROD.

3.2 Notwithstanding the foregoing forbearance of ICS, the Parties only forbear with respect to ICS that is created pursuant to exhibits attached to and incorporated within this Forbearance Agreement. This Forbearance Agreement incorporates Exhibits A through ___as of the date of execution. Additional exhibits may be

14

added to this Forbearance Agreement after written approval of all of the Parties. Such approval shall not be unreasonably withheld.

3.3 The Parties do not forbear any right to the release or delivery of any water that is not described in Article 3.1.

3.4 Forbearance of all Parties is conditioned on the following:

A. The execution, by all of the Parties and the Secretary, of a Delivery Agreement that will be a companion to this Forbearance Agreement.

B. The adoption by the Secretary of a ROD implementing an ICS program in substantial conformance with the provisions of this Forbearance Agreement and its companion Delivery Agreement.

C. The continued implementation of an ICS program that is in substantial conformance with this Forbearance Agreement and its companion Delivery Agreement, including:

1. The availability of the verification and appeal process described in Article 2.5(B);
2. The establishment and use of an ICS accounting procedure by the Secretary consistent with this Forbearance Agreement and the Delivery Agreement;
3. The Secretary's annual declaration of Normal, Surplus (other than Quantified Surplus), or Shortage conditions based on conditions in Lake Mead with consideration of the amount of ICS accumulated by the Parties. The determination of the amount of Quantified Surplus shall not include the volume of accumulated Extraordinary Conservation ICS; and
4. The termination of Partial Domestic Surplus as defined in the Record of Decision dated January 16, 2001, upon issuance of the ROD.

Article 4

General Provisions

4.1 The records of any Party to this Forbearance Agreement that relate to the creation of ICS shall be open to inspection by any other Party.

4.2 The Parties to this Forbearance Agreement are hereby notified of A.R.S. § 38-511.

4.3 The Parties agree to comply with all applicable federal or state laws relating to equal opportunity and non-discrimination.

4.4 Except as provided in Article 3, including additional exhibits agreed upon by the Parties pursuant to Article 3.2, nothing in this Forbearance Agreement shall be deemed to diminish or waive the rights of any Party. The failure of any Party to enforce a provision of this Forbearance Agreement shall not be deemed to constitute a waiver of that provision. The execution of, and forbearance in compliance with, this Forbearance Agreement shall not be admissible against any Party in any action except for an action to enforce the terms of this Forbearance Agreement or the companion Delivery Agreement.

4.5 No Party to this Forbearance Agreement shall be considered to be in default in the performance of any obligations under this Forbearance Agreement when a failure of performance shall be due to uncontrollable forces. The term "uncontrollable force" shall mean any cause beyond the control of the party unable to perform such obligation, including but not limited to failure or threat of failure of facilities, flood, earthquake, storm, fire, lightning, and other natural catastrophes, epidemic, war, civil disturbance or disobedience, strike, labor dispute, labor or material shortage, sabotage, restraint by order of a court or regulatory agency of competent jurisdiction, and action or non-action by, or failure to obtain the necessary authorizations or approvals from, a federal governmental agency or authority, which by exercise of due diligence and foresight such party could not reasonably have been expected to overcome. Nothing contained herein shall be construed to require any party to settle any strike or labor dispute in which it is involved.

Article 5

Notices

5.1 Notices and Requests

A. All notices and requests required or allowed under the terms of this Forbearance Agreement shall be in writing and shall be mailed first class postage paid to the following entities at the following addresses:

CRCN:
Colorado River Commission of Nevada
555 E. Washington Ave., Suite 3100
Las Vegas, NV 89101

Attachment D

Shortage Sharing Agreement between Arizona and Nevada

This attachment to Appendix J contains the text of Attachment D to the Revised Basin States' Proposal.

ATTACHMENT D

Arizona-Nevada Shortage-Sharing Agreement

This Agreement is entered into among the Arizona Department of Water Resources ("Arizona"), the Arizona Water Banking Authority ("AWBA"), the Colorado River Commission of Nevada ("CRC") and the Southern Nevada Water Authority ("SNWA"). For convenience, Arizona, AWBA, CRC and SNWA are at times herein referred to individually as "Party" and collectively as "Parties" and CRC and SNWA are referred to as "Nevada".

Preamble

The 1944 Mexican Water Treaty, the 1964 U.S. Supreme Court Decree in *Arizona v. California*, and the 1968 Colorado River Basin Project Act authorize and guide the Secretary of the Interior ("Secretary") in the determination of water deliveries to the Republic of Mexico and from the mainstream of the Colorado River within the Lower Basin during shortage conditions. However, there remain significant differences of opinion between Arizona and Nevada regarding how much water would be delivered to each state within the Lower Colorado River Basin during a shortage declared by the Secretary. Arizona and Nevada have now, therefore, agreed on how Secretarial shortage declarations of up to 500,000 acre-feet within the United States would be shared between them during an Interim Period. This Agreement is conditioned upon the inclusion of all material terms from the *Seven Basin States' Preliminary Proposal Regarding Colorado River Interim Operations* (Seven States' Proposal) that was forwarded to the Secretary on February 3, 2006, as it may be modified, within the Record of Decision for *Colorado River Reservoir Operations: Development of Lower Basin Shortage Guidelines and Coordinated Management Strategies for Lake Powell and Lake Mead Under Low Reservoir Conditions* ("Record of Decision"). If shortage declarations within the United States exceed 500,000 acre-feet, the Secretary would consult with representatives from the seven Colorado River Basin states before allocating additional shortage reductions. That consultation would be initiated anytime that the water surface elevation of Lake Mead is at or below water surface elevation 1025 feet.

AGREEMENT

Now, therefore, based upon the mutual covenants and promises contained herein, the receipt and sufficiency of which are hereby acknowledged, the Parties hereto do agree as follows:

1. Definitions:

a. Interim Period. The period beginning on the date the Secretary issues a Record of Decision and ending on December 31, 2025 (through preparation of the 2026 Annual Operating Plan).

b. Shortage. Any shortage within the United States declared by the Secretary pursuant to Article II(B)(3) of the Decree during the Interim Period.

1

2. Reduction in Mexican Deliveries. The Parties have entered into this Agreement based on the presumption that the United States will reduce deliveries to Mexico as described in the Seven States' Proposal. In the event that the United States does not reduce deliveries to Mexico in accordance with paragraph (3)(F)(5) of the Seven States' Proposal, the Parties have agreed only to the shortage allocations described in Section 3 of this Agreement.

3. Shortage Sharing Between Arizona and Nevada. During the Interim Period the Parties agree that shortages shall be allocated between Arizona and Nevada in the following quantities:

A. In years when Lake Mead content is projected on January 1 to be at or below elevation 1075 ft. and at or above 1050 ft., then Nevada's share of the shortage within the United States shall equal 13,000 acre-feet and Arizona's share of the shortage within the United States shall equal 320,000 acre-feet.

B. In years when Lake Mead content is projected on January 1 to be below elevation 1050 ft. and at or above 1025 ft., then Nevada's share of the shortage within the United States shall equal 17,000 acre-feet and Arizona's share of the shortage within the United States shall equal 400,000 acre-feet.

C. In years when Lake Mead content is projected on January 1 to be below 1025 ft., then Nevada's share of the shortage within the United States shall equal 20,000 acre-feet and Arizona's share of the shortage within the United States shall equal 480,000 acre-feet.

4. Agreement Limited to Maximum Shortage Volume of 500,000 Acre-feet Within the United States. This Agreement and the Parties relative obligations hereunder are specifically limited to a maximum shortage volume of 500,000 acre-feet within the United States in any year during the Interim Period. Should Lower Basin total shortage volume exceed 500,000 acre-feet within the United States, then the Parties will consult with the Secretary concerning shortage sharing beyond 500,000 acre-feet within the United States.

5. Shortage Assistance. For the purpose of assisting Arizona in offsetting impacts from shortages that may occur during the Interim Period, SNWA agrees to provide to the Arizona Water Banking Authority the sum of $8,000,000.00 (Eight Million Dollars) ("the Funds"). The Arizona Water Banking Authority will use the Funds to purchase and/or store water supplies. This sum shall be paid to Arizona within 60 days of the date the Secretary issues a Record of Decision, unless otherwise agreed in writing by the SNWA and Arizona. Neither the payment nor the use of the Funds are conditioned on the occurrence of a shortage during the Interim Period, and the Funds shall be nonrefundable.

6. Condition Precedent to Effectiveness of Agreement. The Parties agree, as an express condition precedent to the effectiveness and enforceability of this Agreement,

that the Secretary must issue a Record of Decision that is consistent with all material terms included in the Seven States' Proposal, including this Agreement, by July 1, 2008, unless otherwise agreed to in writing by the Parties. If such condition precedent does not occur by the date set forth herein or as extended or modified by written agreement of the Parties, this Agreement shall be of no force or effect among the Parties.

7. Nevada's Use of Tributary Conservation Water and Nevada State Groundwater During Declared Shortage Condition. The Parties anticipate that following the issuance of the Record of Decision, Nevada will be able to create Intentionally Created Surplus ("ICS") by introducing into the Colorado River mainstream Nevada State Groundwater ("Imported ICS") and Virgin and Muddy River water pursuant to Nevada water rights that pre-date the Boulder Canyon Project Act ("Tributary Conservation ICS"). Pursuant to a mutually agreed upon forbearance agreement, the Secretary will deliver such ICS for municipal and industrial uses within Nevada. The Parties have agreed that the water that would be used to create Tributary Conservation ICS and Imported ICS during non-shortage years will be available during declared shortages. It is anticipated by the Parties that the Record of Decision will establish guidelines whereby the Secretary of Interior, through the Bureau of Reclamation, may enter into agreements to verify and deliver ICS to the party that created it.

Arizona agrees that if in any year, pursuant to Article II (B)(3) of the Decree, there is insufficient mainstream water available to satisfy the consumptive use of 7.5 maf in the lower division states, then Arizona will not object to the delivery by the Secretary to Nevada of water that would otherwise qualify for creation and release of Tributary Conservation ICS or Imported ICS during a non-shortage year nor otherwise claim a right to use such water in any form or fashion. Arizona's agreement not to object to any secretarial delivery of and Nevada's diversion of such water shall be binding on Arizona only to the extent that such delivery does not cause the total deliveries within the lower division states to exceed 7.5 maf in any year in which the Secretary has declared a shortage. Furthermore, Arizona's agreement is conditioned on application of the same provisions for verification that would apply to the creation of Tributary Conservation ICS or Imported ICS under the Seven States' Proposal.

8. Reservation of Rights. Notwithstanding the terms of this Agreement, in the event that for any reason this Agreement is terminated, or that the term of this Agreement is not extended, or upon the withdrawal of any Party from this Agreement, the Parties reserve, and shall not be deemed to have waived, any and all rights, including any claims or defenses, they may have as of the date hereof or as may accrue during the term hereof, including specifically the respective legal positions of Nevada and Arizona regarding how the delivery of water under a shortage declaration by the Secretary would be administered within the Lower Colorado River Basin and any other rights, claims or defenses under any existing federal or state law or administrative rule, regulation or guideline, including without limitation the Colorado River Compact, the Decree in *Arizona v. California* (the "Decree"), the Colorado River Basin Project Act of 1968, and any other applicable provision of federal law, rule, regulation, or guideline.

In Witness of this Agreement, the Parties affix their official signatures below, this 9th day of February, 2007.

Herbert R. Guenther

J.2 Preliminary Proposal - Letter to Secretary of the Interior

**The States of Arizona, California, Colorado, Nevada,
New Mexico, Utah and Wyoming
Governor's Representatives on Colorado River Operations**

February 3, 2006

Honorable Gale A. Norton, Secretary
Department of the Interior
1849 C. Street, NW
Washington, D.C. 20240

Re: Development of Lower Basin Shortage Guidelines and Coordinated Management Strategies for the Operation of Lake Mead and Lake Powell Under Low Reservoir Conditions

Dear Secretary Norton:

The materials attached to this letter contain descriptions of the programs that the seven Colorado River Basin States suggest be included within the scope of the environmental impact statement (EIS) for the proposed *Colorado River Reservoir Operations: Development of Lower Basin Shortage Guidelines and Coordinated Management Strategies for Lake Powell and Lake Mead Under Low Reservoir Conditions* (70 Fed. Reg. 57322) (Sept. 30, 2005).

The Basin States, Bureau of Reclamation and others have consulted regularly since our previous correspondence on August 25, 2005 to further discuss and refine recommended management strategies for the Colorado River system. Subsequently, individual entities within the seven Basin States submitted oral and written comments to the Bureau of Reclamation on the above-referenced EIS process. Attachment A, "Seven Basin States' Preliminary Proposal Regarding Colorado River Interim Operations," is submitted as a consensus document on behalf of the seven Basin States. Please recognize that the States are still actively working on the matters addressed in this submission and anticipate further refinement.

Our recommendation is designed to provide input for the Department's consideration as it develops additional operational and water accounting procedures to: 1) delay the onset and minimize the extent and duration of shortages in the Lower Division States; 2) maximize the protection afforded the Upper Division States by storage in Lake Powell against possible curtailment of Upper Basin uses; 3) provide for more efficient, flexible, responsive and reliable operation of the system reservoirs for the benefit of both the Upper and Lower Basins by developing additional system water supplies through extraordinary conservation, system efficiency and augmentation projects; 4) allow the continued development and use of the Colorado River resource in both the Upper and Lower Basins; and 5) allow for development of dedicated water supplies through participation in improvements to system efficiency and clarification of how to proceed with development of non-system water reaching the Lower Basin

S-2006

The Honorable Gale A. Norton
February 3, 2006
Page 2 of 3

mainstream. It is our position that implementation of these operational and accounting procedures can be accomplished without modification of the Long Range Operating Criteria or other elements of the law of the river.

The States' attached proposal incorporates an approach to shortage management. Additionally, the proposal includes modification and extension of the Department's Interim Surplus Guidelines to incorporate operations for all reservoir conditions.

The attached proposal also addresses the States' recommended approach to implementation of shortages pursuant to the U.S.-Mexico Treaty of 1944. We request that the Department of the Interior initiate, at the earliest appropriate time, consultation with the U.S. Section of the International Boundary and Water Commission and the U.S. Department of State on implementation of Treaty shortages. We further request the opportunity to consult with Interior and State Department officials on this issue as the federal government formulates its approach to any bi-national consultation with Mexico.

An agreement between Basin State water managers and users will be necessary to put in place additional terms upon which they have reached common understanding. We intend that this agreement be finalized while Reclamation is preparing the draft EIS, and be executed as soon as practicable. We are including with this letter a draft version of the agreement (Attachment B), to memorialize our current understandings and to provide you the benefits of our thoughts at this time. As with Attachment A, please recognize that the parties are still actively working on the matters addressed in Attachment B, and contemplate additional development and refinement of the agreement. We recognize that timely execution of our agreement is necessary in order to allow funding of certain efficiency projects to go forward.

During the time Reclamation is preparing the draft EIS, the States will move forward with a package of other actions that include implementation of a demonstration program for extraordinary conservation in 2006, system efficiency projects, preparation of an action plan for system augmentation through weather modification, execution of a memorandum of understanding for preparing a Lower Division States interstate drought management plan, development of forbearance agreements among the Lower Division States and the initiation of a study for long-term augmentation of Colorado River system water supplies. The States have already begun the consultant procurement process to support the long-term augmentation study, and intend to complete a weather modification action plan and a memorandum of understanding for interstate drought planning as soon as practicable. The Basin States recognize that Reclamation is undertaking NEPA compliance separately to determine whether to construct a regulating reservoir near Drop 2 of the All-American Canal and urge swift completion of that process.

We appreciate the opportunity you have provided for the Colorado River Basin States to recommend to you a program of reservoir management that considers all their respective concerns and interests. The Basin States look forward to working with you and Reclamation in analyzing and addressing these matters.

Attachment A

Preliminary Proposal Regarding Colorado River Interim Operations

This attachment to Appendix J contains the text of Attachment A to the Preliminary Basin States' Proposal.

ATTACHMENT A
Seven Basin States' Preliminary Proposa Regarding Colorado River Interim Operations

---

The Seven Basin States (States) have worked together to recommend interim operations to the Secretary that should minimize shortages in the Lower Basin and avoid the risk of curtailment in the Upper Basin through conservation, more efficient reservoir operations, and long-term alternatives to bring additional water into the Colorado River community.

The States' recommendation has three key elements. First, the States propose to manage the reservoirs to minimize shortages and avoid curtailments. Second, the States have identified actions in the Lower Basin to conserve water. Third, the States recommend a specific proposal for implementing shortages in the Lower Basin. Finally, the States recognize the need for additional water supplies to meet the current and future needs in the Basin.

Section 1. Allocation of Unused Basic Apportionment Water under Article II(B)(6)

A. Introduction

Article II(B)(6) of the 1964 Decree in *Arizona* v. *California* (Decree) allows the Secretary to allocate water that is apportioned to one Lower Division State, but is for any reason unused in that State, to another Lower Division State. This determination is made for one year only and no rights to recurrent use of the water accrue to the State that receives the allocated water.

B. Application of Unused Basic Apportionment

Before making a determination of a surplus condition under this proposal, the Secretary will determine the quantity of apportioned but unused water under Article II (B)(6), and will allocate such water in the following order of priority.

1. Meet the direct delivery domestic use requirements of the Metropolitan Water District of Southern California, (MWD) and the Southern Nevada Water Authority (SNWA), as allocated between them by agreement.

2. Meet the needs of off stream banking activities by MWD in California and SNWA in Nevada, as allocated between them by agreement.

3. Meet the other needs for water in California in accordance with the California Seven-Party Agreement as supplemented by the Quantification Settlement Agreement.

Section 2. Coordinated Operation of Lakes Powell and Mead

Figure 1 describes the operating strategy that has been agreed to by the Colorado River Basin States.

---

1. Equalization: In years when Lake Powell content is projected on January 1 to be at or above the elevation stated in the Lake Powell Equalization Elevation Table, an amount of water will be released from Lake Powell to Lake Mead at a rate greater than 8,230,000 acre-feet per year to the extent necessary to equalize storage in the two reservoirs, or otherwise to release 8,230,000 acre-feet from Lake Powell.

2. Upper Elevation Balancing: In years when Lake Powell content is projected on January 1 to be below the elevation stated in the Lake Powell Equalization Elevation Table and at or above 3575 ft., the Secretary shall release 8,230,000 acre-feet from Lake Powell if the projected elevation of Lake Mead is at or above 1075 ft. If the projected elevation of Lake Mead is below 1075 ft., the Secretary shall balance the contents of Lake Mead and Lake Powell, but shall release no more than 9,000,000 acre-feet and no less than 7,000,000 acre-feet from Lake Powell.

3. Mid-Elevation Releases: In years when Lake Powell content is projected on January 1 to be below 3575 ft. and at or above 3525 ft., the Secretary shall release 7,480,000 acre-feet from Lake Powell if the projected elevation of Lake Mead is at or above 1025 ft. If the projected elevation of Lake Mead is below 1025 ft., the Secretary shall release 8,230,000 acre-feet from Lake Powell.

4. Lower Elevation Balancing: In years when Lake Powell content is projected on January 1 to be below 3525 ft., the Secretary shall balance the contents of Lake Mead and Lake Powell, but shall release no more than 9,500,000 acre-feet and no less than 7,000,000 acre-feet from Lake Powell.

Coordinated Operation of Lakes Powell and Mead as described herein will be presumed to be consistent with the Section 602(a) storage requirement contained in the Colorado River Basin Project Act.

The objective of the operation of Lakes Powell and Mead as described herein is to avoid curtailment of uses in the Upper Basin, minimize shortages in the Lower Basin and not adversely affect the yield for development available in the Upper Basin.

The August 24-month study projections for the January 1 system storage and reservoir water surface elevations, for the following year, would be used to determine the applicability of the coordinated operation of Lakes Powell and Mead.

Section 3. Determination of Lake Mead Operation during the Interim Period

A. Interim Surplus Guidelines

S-2006

ATTACHMENT A
Seven Basin States' Preliminary Proposa Regarding Colorado River Interim Operations

---

1. The Basin States recommend that the Secretary continue to implement the Interim Surplus Guidelines (ISG) except as modified by this proposal, including the following:
   a. Partial Domestic Surplus would be discontinued upon issuance of the Record Of Decision ("ROD"); and

   b. The ISG effective period would be extended through December 31, 2025.

2. During the years 2017 through 2025 the Secretary shall distribute Domestic Surplus water:

   a. For use by MWD, 250,000 acre-feet per year in addition to the amount of California's basic apportionment available to MWD.

   b. For use by SNWA, 100,000 acre-feet per year in addition to the amount of Nevada's basic apportionment available to SNWA.

   c. For use in Arizona, 100,000 acre-feet per year in addition to the amount of Arizona's basic apportionment available to Arizona contractors.

B. Flood Control Surplus

In years in which the Secretary makes space building or flood control releases pursuant to the Field Working Agreement, the Secretary shall determine a Flood Control Surplus for the remainder of that year or the subsequent year as specified in Section 7 of the ISG. In such years, releases will be made to satisfy all beneficial uses within the United States, including unlimited off-stream banking. Intentionally Created Surplus credits, as defined herein, would be reduced by the amount of any flood control release, if necessary until no credits are remaining. Under current practice, surplus declarations under the Treaty for Mexico are declared when flood control releases are made. Operation under a Flood Control Surplus does not establish any determination relating to implementation of the Treaty, including any potential changes in approach relating to surplus declarations under the Treaty. Such determinations must be addressed in a bilateral fashion with the Republic of Mexico.

C. Quantified Surplus
(70R Strategy)

In years when the Secretary determines that water should be released for beneficial consumptive use to reduce the risk of potential reservoir spills based on the 70R Strategy, the Secretary shall determine and allocate Quantified Surplus sequentially as follows:

1. Establish the volume of the Quantified Surplus. For the purpose of determining the existence, and establishing the volume, of Quantified

S-2006

4

ATTACHMENT A
Seven Basin States' Preliminary Proposa Regarding Colorado River Interim Operations

---

Surplus, the Secretary would not consider the volume of Intentionally Created Surplus credits, as defined herein.

2. Allocate and distribute the Quantified Surplus 50% to California, 46% to Arizona and 4% to Nevada, subject to 3. through 5. that follow.

3. Distribute California's share first to meet basic apportionment demands and MWD's demands. Then distribute to California Priorities 6 and 7 and other surplus contracts. Distribute Nevada's share first to meet basic apportionment demands and SNWA's demands. Distribute Arizona's share to surplus demands in Arizona including off stream banking and interstate banking demands. Arizona, California and Nevada agree that Nevada would get first priority for interstate banking in Arizona.

4. Distribute any unused share of the Quantified Surplus in accordance with Section 1, Allocation of Unused Basic Apportionment Water Under Article II (B)(6).

5. Determine whether MWD, SNWA and Arizona have received the amount of water they would have received under Section 3 D of this proposal, Domestic Surplus, if a Quantified Surplus had not been declared. If they have not, then determine and meet all demands provided for in Section 3 D, Domestic Surplus.

D. Domestic Surplus

In years when Lake Mead elevation is projected on January 1 to be above 1145 ft and below 70R Strategy elevation determination, the Secretary would determine a Domestic Surplus in accordance with Section 2(B)(2) of the ISG between the effective date of the ROD and December 31, 2016 and in accordance with Section 3(A) (2) of this proposal between January 1, 2017 and December 31, 2025.

E. Normal Conditions

In years when Lake Mead elevation is projected on January 1 to be above elevation 1075 ft. and below 1145 ft., the Secretary would determine a normal operating condition. In any year when Lake Mead elevations are in this range, the Secretary may determine that Intentionally Created Surplus ("ICS") as described in Section 4 of this proposal is available. ICS credits may then be delivered pursuant to the provisions of Section 4.

F. Shortage Conditions

Shortages would be implemented in the Lower Division States and Mexico under the following conditions and in the following manner:

1. 400,000 acre foot shortage: In years when Lake Mead content is projected on January 1 to be at or below elevation 1075 ft. and at or above 1050 ft.,

ATTACHMENT A
Seven Basin States' Preliminary Proposa Regarding Colorado River Interim Operations

a quantity of 400,000 acre-feet shall not be released or delivered in the Lower Division States and Mexico.

2. 500,000 acre foot shortage: In years when Lake Mead content is projected on January 1 to be below elevation 1050 ft. and at or above 1025 ft. a quantity of 500,000 acre-feet shall not be released or delivered in the Lower Division States and Mexico.

3. 600,000 acre foot shortage: In years when Lake Mead content is projected on January 1 to be below 1025 ft., a quantity of 600,000 acre-feet shall not be released or delivered in the Lower Division States and Mexico.

4. The three conditions described above are illustrated in Figure 2.

Figure 2

Lake Mead Step Shortage		
Mead Elevation (ft)	Stepped Shortage	Mead Live Storage
1075 to 1050	400 kaf	9.37 to 7.47 maf
<1050 to 1025	500 kaf	7.47 to 5.80 maf
<1025 to 1000	600 kaf	5.80 to 4.33 maf
<1000	Increased reductions to be consistent with consultation(s)	<4.33 maf

5. The United States, through the appropriate mechanisms, should implement a shortage pursuant to Article 10 of the 1944 Treaty in any year in which the Secretary has declared that a shortage condition exists pursuant to Art. II(B)(3) of the Decree. The total quantity of water that will not be released or delivered to Mexico shall be based on Lower Basin water deliveries during normal water supply conditions. The proportion of the shortage that shall be borne by Mexico will be 17% (1.5 maf / 9 maf x 100% = 17%).

6. Arizona and Nevada will share shortages based on a shortage sharing agreement. In the event that no agreement has been reached, Arizona and Nevada will share shortages in accordance with the 1968 Colorado River Basin Project Act, the Decree, other existing law as applicable, and the Interstate Banking Agreement between Arizona and Nevada parties.

7. Whenever Lake Mead reaches elevation1025 ft., the Secretary will consult with the States to determine whether Colorado River hydrologic conditions, together with the delivery of 8.4 million acre-feet of Colorado River water to Lower Basin users and Mexico, will cause the elevation of Lake Mead to fall below 1000 ft. Upon such a determination, the

Secretary shall consult with the states to discuss further measures that may be undertaken to avoid or reduce further increases in shortage determinations. If increased reductions are required, the Secretary shall implement the reductions consistent with the law of the river.

8. The States will evaluate factors at critical elevations that may avoid shortage determinations as reservoir elevations approach critical thresholds. The States may provide operational recommendations surrounding the critical elevations at some later date.

Section 4. System Efficiency, Extraordinary Conservation and Augmentation Projects

The States propose that the Secretary develop a policy and accounting procedure concerning augmentation, extraordinary conservation, and system efficiency projects, including specific extraordinary conservation projects, tributary conservation projects, introduction of non-Colorado River System water, system efficiency improvements and exchange of non-Colorado River System water. The accounting and recovery process would be referred to as "Intentionally Created Surplus" consistent with the concept that the States will take actions to augment storage of water in the Lower Colorado River Basin. The water would be distributed pursuant to Section II(B)(2) of the Decree and forbearance agreements between the States. The ICS credits may not be created or released without such forbearance agreements.

A. The purposes of the Lake Mead Intentionally Created Surplus ("ICS") program are to:

1. Help avoid shortages to the Lower Basin. For the purposes of determining calendar year declarations of Domestic Surplus, Normal and Shortage conditions, any ICS credits would be considered system water;

2. Benefit both Lake Mead and Lake Powell; and

3. Increase the surface elevations of both Lakes Powell and Mead to higher levels than would have otherwise occurred.

B. Extraordinary Conservation Storage Credits

1. Users of Colorado River water may create ICS credits through extraordinary conservation under the following conditions:

a. A Boulder Canyon Project Act Section 5 Contractor ("Contractor") shall repay all outstanding system payback obligations before it can create ICS credits.

b. ICS credits can only be created if such water could have otherwise been beneficially used.

S-2006

ATTACHMENT A
Seven Basin States' Preliminary Proposa Regarding Colorado River Interim Operations

c. A Contractor notifies Reclamation by September 15 of the amount of ICS credits it wishes to create for the subsequent year.

2. ICS credits may be created only through extraordinary conservation activities. These activities include:

a. Fallowing of land that currently is, historically was, and otherwise would have been in the next year, irrigated.

b. Canal lining programs

c. Desalination programs

d. Extraordinary conservation programs existing as of January 1, 2006

e. Other extraordinary conservation measures as agreed upon by the States

3. If conditions during the year change due to weather or other unforeseen circumstances, a Contractor may request a mid-year modification of its water order to reduce the amount of ICS credits created during that year. A Contractor cannot increase the amount of ICS credits it had previously scheduled to create during the year.

4. Any ICS credits would be used first to offset any overrun for that year or future year(s).

5. The maximum amount of ICS credits that can be created during any year through extraordinary conservation is limited to each state as listed below.

a. California: 400,000 acre-feet per year

b. Nevada: 125,000 acre-feet per year

c. Arizona: 100,000 acre-feet per year

6. The maximum cumulative amount of ICS credits created through extraordinary conservation that would be available at any one time is:

a. 1,500,000 acre-feet for California;

b. 300,000 acre-feet for Nevada; and

c. 300,000 acre-feet for Arizona.

7. No category of surplus water can be used to create ICS credits.

S-2006

ATTACHMENT A
Seven Basin States' Preliminary Proposa Regarding Colorado River Interim Operations

---

8. At the time the ICS credits are created by extraordinary conservation, the Contractor will dedicate 5% of the ICS credits to the system on a one-time basis to provide a water supply benefit to the system. Additionally, ICS credits will be subject to annual evaporation loss (estimated to be no more than 3% annually) during each year in which no shortage has been declared. The Secretary will not assess any other charge for creating ICS credits.

9. Contractors that have created ICS credits may recover them under the following conditions:

   a. A Contractor may request delivery of ICS credits it has created at the time it submits its annual water order for the following year. The ICS credits would be added to the Contractor's approved water order for that year upon approval by Reclamation.
   b. The amount of ICS credits that may be recovered by California in any one year is limited to 400,000 acre-feet, by Nevada 300,000 acre-feet and Arizona 300,000 acre-feet; provided that the May 1, 24-month study for that year does not indicate that a shortage condition would be declared in the current or succeeding year.

   c. If extraordinary weather conditions or water emergencies occur, a Contractor may request that Reclamation increase its use of ICS credits for that year.

   d. A Contractor may request to reduce its use of ICS credits during the year for any reason, including reduction in water demands.

   e. If Reclamation releases water for flood control purposes, ICS credits shall be reduced on a pro-rata basis among all holders of ICS credits-- if necessary until no credits remain. In determining the amount of Quantified Surplus, Reclamation shall not consider the volume of ICS credits that will be available.

10. Contractors may begin to create ICS through extraordinary conservation 1) beginning in 2006 as a pilot program (which may be lost if the Secretary does not adopt an extraordinary conservation program as part of the Coordinated Operation of Lakes Powell and Mead) or 2) after adoption of the Coordinated Operation for Lakes Powell and Mead until 2025. Any ICS credits under this program remaining at the end of the program would remain available for recovery for up to 10 years following termination of the Program.

C. Tributary Conservation

The Secretary should develop procedures in consultation with the States that would permit Contractors to purchase and fallow annual or permanent water rights on tributaries within the Lower Division States that have been used for a significant period of years and were created prior to Congress' adoption of the Boulder Canyon Project Act that, when retired, and verified by the Secretary, contribute water to the Colorado River mainstream for diversion by the Contractor. The water recovered by the Contractor may be used for municipal and industrial purposes only. This water would be in addition to the State's basic apportionment and would be available during declared shortages.

It is intended that the water would be taken on a real-time basis and that not more than 95% of such water will be recovered; however, if storage were required, such stored water would be subject to all provisions applicable to ICS credits created through extraordinary conservation.

D. System Efficiency Projects

A Contractor may make contributions of capital to the Secretary for use in Secretarial projects designed to realize efficiencies that save water that would otherwise be lost from the Colorado River System in the United States. The Secretary in consultation with the States will identify system efficiency projects, terms for capital participation in such projects, and types and amounts of benefits the Secretary would provide in consideration of non-federal capital contributions to system efficiency projects, including a portion of the water saved by the project. Water made available to Contractors by the Secretary would be considered Intentionally Created Surplus. System efficiency projects are only intended to provide temporary water supplies and would not be available for permanent use.

Benefits to the total water available within the Colorado River System in the United States should be substantial, taking into account any benefit provided to any non-federal capital contributor. In those cases in which benefits are provided to a non-federal capital contributor in the form of a portion of the water saved by the system efficiency project, the water provided to the capital contributor should be characterized as Colorado River surplus water intentionally created by the system efficiency project. The ICS credits should be provided to the capital contributor pursuant to its BCPA § 5 surplus contract. The Secretary should first obtain the waiver or forbearance of any other BCPA § 5 surplus contractor(s) that may possess any right to the delivery of the same water, so that the Secretary may deliver it to the capital contributor pursuant to Article II (B)(6) of the Decree. The ICS credits should be provided to the capital contributor on a predetermined schedule of annual deliveries for a period of years as agreed by the Secretary and Contractor. The ICS credits would not be stored, and therefore would not spill from system reservoirs. Delivery of ICS credits during shortage conditions will be determined on a project-by-project basis.

E. Introduction and Recovery of Non-Colorado River System Water

The Secretary should develop procedures, in consultation with the States, that would prospectively allow non-Colorado River System water in a Lower Division State to be introduced into, conveyed through, and diverted from system reservoirs, or otherwise through the Colorado River System. The non-Colorado River System water may be

ATTACHMENT A
Seven Basin States' Preliminary Proposa Regarding Colorado River Interim Operations

introduced either (1) directly from the non-Colorado River System source, or (2) as effluent resulting from use of the non-Colorado River System water in the introducing entity's service area, assuming water quality concerns are adequately addressed by the Contractor introducing the water. This water is in addition to a state's basic apportionment and may be used during declared shortages.

Contractors proposing to introduce, convey and recover such non-Colorado River System water should make sufficient arrangements, contractual or otherwise, with the Secretary so as to guarantee that any such action causes no harm to the Secretary's management of the Colorado River System. Such arrangements would provide that the introduction, conveyance and recovery of such water be done pursuant to appropriate permits or other authorizations as required by state law, that the actual amount of water introduced, conveyed and recovered would be reported to the Secretary on an annual basis, and that no more than 95% of such water introduced will be recovered. The non-Colorado River System water would be intended to be taken on a real-time basis, and hence would not spill from system reservoirs. However, if storage were required such stored water would be subject to all provisions applicable to ICS created through extraordinary conservation. Any agreements made with the Secretary to introduce and recover this water will survive the termination of the Coordinated Operations of Lakes Powell and Mead.

Weather modification projects should be pursued as a means of augmenting Colorado River System water supplies. However, increases in water supply that result from weather modification projects are not included within the projects defined in this Section and would not create any additional supply for a Contractor or State that engages in a weather modification project.

Section 5. Non-Colorado River System Water Exchanges

Contractors in Arizona, California, or Nevada may secure an additional water supply by funding the development of a non-Colorado River System water supply in one Lower Division State for use in another State by exchange. The new water supply developed would be consumptively used in the State in which it was developed by a Contractor and that Contractor would intentionally reduce its consumptive use of Colorado River water. This would allow the Contractor(s) in the other Lower Division State(s) that provided the funding to consumptively use the Colorado River water that was intentionally unused through an agreement with the Secretary of the Interior. Through the cooperation of the International Boundary and Water Commission, United States and Mexico, similar agreements could be established by which non-Colorado River System water supplies in Mexico could be developed for use in the United States by exchange.

It could be necessary for a State or other lower priority Contractors in the State in which consumptive use was intentionally reduced to agree to forebear their use of such water depending on the then-existing priority system to use of Colorado River water, to avoid a claim against the water being delivered to the Contractor that funded the new water supply. As an alternative to forbearance, an offer by the Contractor developing the non-Colorado River System water to allow the lower priority Contractor to pay the cost of developing a portion or all of the non-

ATTACHMENT A
Seven Basin States' Preliminary Proposa Regarding Colorado River Interim Operations

Colorado River System water supplies to be developed, would be utilized to protect such a lower priority Contractor's position in the then-existing priority system. A refusal of an offer to pay the cost of developing a portion or all of the non-Colorado River System water supplies to be developed would constitute the lower-priority Contractor's waiver of a right to challenge the exchange.

Section 6. Accounting Mechanisms

The operating alternatives discussed in Sections 4 and 5 will require new or modified Colorado River accounting mechanisms. No specific accounting mechanism to allow these types of operations is proposed for evaluation in Reclamation's current NEPA process. However, the description and evaluation of such accounting mechanisms would provide Contractors with the assurance that if such accounting mechanism were adopted in the Record of Decision, funds spent to propose such an arrangement in the future would not be spent in vain.

Section 7. Effective Period

The proposed interim operations will be in effect 30 days from the publication of the Secretary's Record of Decision in the Federal Register. The proposed interim operations will, unless subsequently modified, remain in effect through December 31, 2025 (through preparation of the 2026 AOP), subject to a formal review of their effectiveness beginning no later than 2020.

Attachment B

Draft Agreement

This attachment to Appendix J contains the text of Attachment B to the Preliminary Basin States' Proposal.

ATTACHMENT B DRAFT AGREEMENT

AGREEMENT

The [name parties] hereby enter into this Agreement effective as of ______________.

RECITALS

A. Parties.

1. Arizona

   a. The Arizona Department of Water Resources, through its Director, is the successor to the signatory agency of the State for the 1922 Colorado River Compact, and the 1944 Contract for Delivery of Water with the United States, both authorized and ratified by the Arizona Legislature, A.R.S. §§ 45-1301 and 1311. Pursuant to A.R.S. §§ 45-107, the Director is authorized and directed, subject to the limitations in A.R.S. §§ 45-106, for and on behalf of the State of Arizona, to consult, advise and cooperate with the Secretary of the Interior of the United States with respect to the exercise by the Secretary of Congressionally authorized authority relative to the waters of the Colorado River (including but not limited to the Boulder Canyon Project Act, 43 U.S.C. § 617, and the 1968 Colorado River Basin Project Act, 43 U.S.C. § 1501) and with respect to the development, negotiation and execution of interstate agreements. Additionally, under A.R.S. § 45-105(A)(9), the Director is authorized to "prosecute and defend all rights, claims and privileges of this state respecting interstate streams."

   b. Under A.R.S. § 11-951 *et. seq.*, the Director is authorized to enter into Intergovernmental Agreements with other public agencies, which includes another state; departments, agencies, boards and commissions of another state; and political subdivisions of another state.

2. California. The chairman of the Colorado River Board of California, acting as the Colorado River Commissioner pursuant to California Water Code section 12525, has the authority to exercise on behalf of California every right and power granted to California by the Boulder Canyon Project Act, and to do and perform all other things necessary or expedient to carry out the purposes of the Colorado River Board.

3. Colorado

   a. Section 24-1-109, Colorado Revised Statutes (2005) provides that "Interstate compacts authorized by law shall be administered under the direction of the office of the governor." This includes the Colorado River Compact and the Upper Colorado River Basin Compact. Section 37-60-109 provides that "the governor from time to time, with approval of the

1

S-2006

board, shall appoint a commissioner, who shall represent the state of Colorado upon joint commissions to be composed of commissioners representing the state of Colorado and another state or other states for the purpose of negotiating and entering into compacts or agreements between said states…" By Executive Order _____, issued __________, 2006, attached hereto as Exhibit _______ and incorporated herein by reference, the Governor appointed Upper Colorado River Commissioner Scott Balcomb to represent the State of Colorado.

b. Section 37-60-106, subsections (e) and (i), C.R.S. (2005), authorize the Colorado Water Conservation Board to "cooperate with the United States and the agencies thereof, and with other states for the purpose of bringing about the greater utilization of the water of the state of Colorado and the prevention of flood damages," and "to confer with and appear before the officers, representatives, boards, bureaus, committees, commissions, or other agencies of other states, or of the federal government, for the purpose of protecting and asserting the authority, interests, and rights of the state of Colorado and its citizens with respect to the waters of the interstate streams in this state." By resolution dated ______________, attached hereto as Exhibit __, and incorporated herein by reference, the Colorado Water Conservation Board authorized and directed its Director to negotiate with and enter into agreements with other state entities within the Colorado River Basin.

4. Nevada

a. The Colorado River Commission of the State of Nevada (CRCN) is an agency of the State of Nevada, authorized generally by N.R.S. §§ 538.041 and 538.251. CRCN is authorized by N.R.S. § 538.161 (6), (7) to enter into this Agreement. The CRCN, in furtherance of the State of Nevada's responsibility to promote the health and welfare of its people in Colorado River matters, makes this Agreement to supplement the supply of water in the Colorado River which is available for use in Nevada, augment the waters of the Colorado River, and facilitate the more flexible operation of dams and facilities by the Secretary of the Interior of the United States. The Chairman of the Commission, signatory hereto, serves as one of the Governor's representatives as contemplated by Section 602(b) of the 1968 Colorado River Basin Project Act, 43 U.S.C. § 1552(b) and the Criteria for Coordinated Long-Range Operation of Colorado River Reservoirs Pursuant to the Colorado River Basin Project Act.

b. The Southern Nevada Water Authority (SNWA) is a Nevada joint powers agency and political subdivision of the State of Nevada, created by agreement dated July 25, 1991, as amended November 17,1994 and January 1,1996, pursuant to N.R.S. §§ 277.074 and 277.120. SNWA is authorized by N.R.S. § 538.186 to enter into this Agreement and, pursuant

286 U.S. 494 (1922). *See Hinderlider v. La Plata River & Cherry Creek Ditch Co.,* 304 U.S. 92 (1938). In signing this Agreement, the State Engineer intends that this Agreement be mutually and equally binding between the Parties.

B. Background

1. Federal law and practice (including Section 602(b) of the 1968 Colorado River Basin Project Act, 43 U.S.C. § 1552(b), and the Criteria for Coordinated Long-Range Operation of Colorado River Reservoirs Pursuant to the Colorado River Basin Project Act), contemplate that in the operation of Lakes Powell and Mead, the Secretary of the Interior consults with the States through Governors' Representatives, who represent the Governors and their respective States. Through this law and practice, the Governors' Representatives have in the past reached agreements among themselves and with the Secretary on various aspects of Colorado River reservoir operation. This Agreement is entered into in furtherance of this law and practice.

2. On January 16, 2001, the Secretary adopted Colorado River Interim Surplus Guidelines (ISG) based on an alternative prepared by the Colorado River Basin States, for the purposes of determining annually the conditions under which the Secretary would declare the availability of surplus water for use within the states of Arizona, California and Nevada in accordance with and under the authority of the Boulder Canyon Project Act of 1928 (45 Stat. 1057) and the Decree of the United States Supreme Court in *Arizona v. California*, 376 U.S. 340 (1964). The ISG are effective through calendar year 2015 (through preparation of the 2016 Annual Operating Plan).

3. In the years following the adoption of the ISG, drought conditions in the Colorado River Basin caused a significant reduction in storage levels in Lakes Powell and Mead, and precipitated discussions by and among the Parties, and between the Parties and the United States through the Department of the Interior and the Bureau of Reclamation. The Parties recognize that the Upper Division States have not yet developed their full apportionment under the Colorado River Compact. Although the Secretary has not imposed any shortage in the Lower Basin, the Parties also recognize that with additional Upper Basin development and in drought conditions, the Lower Division States may be required to suffer shortages in deliveries of water from Lake Mead. Therefore, these discussions focused on ways to improve the management of water in Lakes Powell and Mead so as to enhance the protection afforded to the Upper Basin by Lake Powell, and to delay the onset and minimize the extent and duration of shortages in the Lower Basin.

4. Shortages in the Lower Basin will also trigger shortages in the delivery of water to Mexico pursuant to the Mexican Water Treaty of 1944, February 3, 1944, U.S.-Mex., 59 Stat. 1219, T.S. 994, 3 U.N.T.S. 313.

286 U.S. 494 (1922). *See Hinderlider v. La Plata River & Cherry Creek Ditch Co.,* 304 U.S. 92 (1938). In signing this Agreement, the State Engineer intends that this Agreement be mutually and equally binding between the Parties.

B. Background

1. Federal law and practice (including Section 602(b) of the 1968 Colorado River Basin Project Act, 43 U.S.C. § 1552(b), and the Criteria for Coordinated Long-Range Operation of Colorado River Reservoirs Pursuant to the Colorado River Basin Project Act), contemplate that in the operation of Lakes Powell and Mead, the Secretary of the Interior consults with the States through Governors' Representatives, who represent the Governors and their respective States. Through this law and practice, the Governors' Representatives have in the past reached agreements among themselves and with the Secretary on various aspects of Colorado River reservoir operation. This Agreement is entered into in furtherance of this law and practice.

2. On January 16, 2001, the Secretary adopted Colorado River Interim Surplus Guidelines (ISG) based on an alternative prepared by the Colorado River Basin States, for the purposes of determining annually the conditions under which the Secretary would declare the availability of surplus water for use within the states of Arizona, California and Nevada in accordance with and under the authority of the Boulder Canyon Project Act of 1928 (45 Stat. 1057) and the Decree of the United States Supreme Court in *Arizona v. California*, 376 U.S. 340 (1964). The ISG are effective through calendar year 2015 (through preparation of the 2016 Annual Operating Plan).

3. In the years following the adoption of the ISG, drought conditions in the Colorado River Basin caused a significant reduction in storage levels in Lakes Powell and Mead, and precipitated discussions by and among the Parties, and between the Parties and the United States through the Department of the Interior and the Bureau of Reclamation. The Parties recognize that the Upper Division States have not yet developed their full apportionment under the Colorado River Compact. Although the Secretary has not imposed any shortage in the Lower Basin, the Parties also recognize that with additional Upper Basin development and in drought conditions, the Lower Division States may be required to suffer shortages in deliveries of water from Lake Mead. Therefore, these discussions focused on ways to improve the management of water in Lakes Powell and Mead so as to enhance the protection afforded to the Upper Basin by Lake Powell, and to delay the onset and minimize the extent and duration of shortages in the Lower Basin.

4. Shortages in the Lower Basin will also trigger shortages in the delivery of water to Mexico pursuant to the Mexican Water Treaty of 1944, February 3, 1944, U.S.-Mex., 59 Stat. 1219, T.S. 994, 3 U.N.T.S. 313.

5. On May 2, 2005, the Secretary announced her intent to undertake a process to develop Lower Basin shortage guidelines and explore management options for the coordinated operation of Lakes Powell and Mead. On June 15, 2005, the Bureau of Reclamation published a notice in the *Federal Register*, announcing its intent to implement the Secretary's direction. The Bureau of Reclamation has proceeded to undertake scoping and develop alternatives pursuant to the National Environmental Policy Act (the NEPA Process), which the Parties anticipate will form the basis for a ROD to be issued by the Secretary by December 2007.

6. On August 25, 2005, the Governors' Representatives for the seven Colorado River Basin States wrote a letter to the Secretary expressing conceptual agreement in the development and implementation of three broad strategies for improved management and operation of the Colorado River: Coordinated Reservoir Management and Lower Basin Shortage Guidelines; System Efficiency and Management; and Augmentation of Supply.

7. On February 3, 2006, the Governors' Representatives transmitted to the Secretary their recommendation for the scope of the NEPA Process, which refined many of the elements outlined in the August 25, 2005 letter.

8. At the request of the Secretary, the Parties have continued their discussions relative to the areas of agreement outlined in the letters of August 25, 2005 and February 3, 2006.

9. In furtherance of the letters of August 25, 2005 and February 3, 2006, the Parties have reached agreement to take additional actions for their mutual benefit, which are designed to augment the supply of water available for use in the Colorado River System and improve the management of water in the Colorado River.

C. Purpose. The Parties intend that the actions by them contemplated in this Agreement will: improve cooperation and communication among them; provide additional security and certainty in the water supply of the Colorado River System for the benefit of the people served by water from the Colorado River System; and avoid circumstances which could otherwise form the basis for claims or controversies over interpretation or implementation of the Colorado River Compact and other applicable provisions of the law of the river.

AGREEMENT

In consideration of the above recitals and the mutual covenants contained herein, and other good and valuable consideration, the receipt and sufficiency of which is hereby acknowledged, the Parties agree as follows:

1. Recitals. The Recitals set forth above are material facts that are relevant to and form the basis for the agreements set forth herein.

2. Definitions. As used in this Agreement, the following terms have the following meanings:

A. Colorado River System. This term shall have the meaning as defined in the Colorado River Compact.

B. ISG. The Colorado River Interim Surplus Guidelines adopted by the Secretary on January 16, 2001.

C. NEPA Process. The decision-making process pursuant to the National Environmental Policy Act, 42 U.S.C. §§ 4321 through 47, beginning with the Bureau of Reclamation's Notice to SolicitComments and Hold Public Meetings, 70 Fed. Reg. 34794 (June 15, 2005) and culminating in a Record of Decision.

D. Party or Parties. Any party or parties to this Agreement.

E. Parties' Recommendation. The Seven Basin States' Preliminary Proposal Regarding Colorado River Interim Operations, a copy of which is attached hereto and incorporated herein by this reference, presented by the Parties to the Secretary in furtherance of the States' letters of August 25, 2005 and February 3, 2006, and any modification of the Parties' Recommendation adopted by the Parties pursuant to this Agreement.

F. ROD. The Record of Decision anticipated to be issued by the Secretary after completion of NEPA Process, pursuant to her letter of May 2, 2005, and the Notice published in the Federal Register on September 30. 2005, 70 Fed. Reg. 57322.

G. Secretary. The Secretary of the Interior or the Bureau of Reclamation, as applicable.

H. State or States. Any of the states of Arizona, California, Colorado, Nevada, New Mexico, Utah or Wyoming, as context requires.

3. Support for Parties' Recommendation. After considering a number of alternatives, each Party has determined that the Parties' Recommendation is in the best interests of that Party, and promotes the health and welfare of that Party and of the Colorado River Basin States. In the NEPA Process, the Parties shall support the Secretary's adoption of the Parties' Recommendation in a ROD. If during the course of the NEPA Process any new information becomes available which causes any Party, in its sole and absolute discretion, to reassess any provision of the Parties' Recommendation, that Party shall immediately notify all other Parties in writing. The Parties shall jointly confer and, if they agree to any modification of the Parties' Recommendation, shall consult with the Secretary to advise her of such modification and request the adoption thereof in the ROD. If after such conference and consultation it is apparent there is an

S-2006

irreconcilable conflict between the Parties as to such modification, then any Party may upon written notice to the other Parties withdraw from this Agreement, and in such event this Agreement shall no longer be effective or binding upon such withdrawing Party. All withdrawing Parties hereby reserve all rights upon withdrawal from this Agreement to take such actions, including support of or challenges to the ROD, as they in their sole and absolute discretion deem necessary or appropriate. In the event of the withdrawal of any one or more Parties from this Agreement, this Agreement shall continue in full force and effect as to the remaining Parties. The remaining Parties may confer to determine whether to continue this Agreement in effect, to amend this Agreement, or to terminate this Agreement. In the event of termination, all Parties shall be relieved from the terms hereof, and this Agreement shall be of no further force or effect.

4. <u>ROD Consistent with the Parties' Recommendation</u>. In the event the Secretary adopts a ROD in substantial conformance with the Parties' Recommendation, the Parties shall take all necessary actions to implement the terms of the ROD, including the approval and execution of agreements necessary for such implementation.

5. <u>ROD Inconsistent with the Parties' Recommendation</u>. In the event the Secretary adopts a ROD that any Party, in its sole and absolute discretion, determines is not in substantial conformance with the Parties' Recommendation, such Party shall immediately notify all other Parties of such determination in writing. The Parties shall jointly confer, and consult with the Secretary as necessary, in order to determine whether the ROD is in substantial conformance with this Agreement, or whether any action, including the amendment of this Agreement, may resolve such concern. If after such conference and consultation it is apparent there is an irreconcilable conflict between the ROD and the concerns of such Party, then such Party may upon written notice to the other Parties withdraw from this Agreement, and in such event this Agreement shall no longer be effective or binding upon such withdrawing Party. All withdrawing Parties hereby reserve all rights upon withdrawal from this Agreement to take such actions, including support of or challenges to the ROD, as they in their sole and absolute discretion deem necessary or appropriate. In the event of the withdrawal of any one or more Parties from this Agreement, this Agreement shall continue in full force and effect as to the remaining Parties. The remaining Parties may confer to determine whether to continue this Agreement in effect, to amend this Agreement, or to terminate this Agreement. In the event of termination, all Parties shall be relieved from the terms hereof, and this Agreement shall be of no further force or effect.

6. <u>Additions to the ROD</u>. The Parties hereby request that the Secretary recognize the specific provisions of this Agreement as part of the NEPA Process and, if appropriate, include in the ROD specific provisions that reference this Agreement as a basis for the ROD. The Parties also hereby request that the Secretary include in the ROD specific provision that the Secretary will first consult with all the States, through their designated Governor's Representatives, before making any substantive modification to the ROD. Finally, the Parties hereby request that the Secretary include in the ROD specific provision that upon a request by any State for modification of the ROD, or upon any request by any State to resolve any claim or controversy arising under this Agreement or

under the operations of Lakes Powell and Mead pursuant to the ROD, the ISG, or any other applicable provision of federal law, regulation, criteria, policy, rule or guideline, the Secretary shall invite all of the Governors, or their designated representatives, to consult with the Secretary in an attempt to resolve such claim or controversy by mutual agreement.

7. Consultation on Operations. After the Secretary commences operating Lakes Powell and Mead pursuant to the ROD, the Parties shall confer among themselves as necessary, but at least annually, to assess such operations. Any Party may request consultation with the other Parties on a proposed adjustment or modification of such operations, based on changed circumstances, unanticipated conditions, or other factors. Upon such request, the Parties shall in good faith confer to resolve any such issues, and based thereon may request consultation by the States with the Secretary on adjustments to or modifications of operations under the ROD. In any event, the Parties shall confer before December 31, 2020, to determine whether to extend this Agreement and recommend that the Secretary continue operations under the ROD for an additional period, or modify this Agreement and recommend that the Secretary modify operations under the ROD, or terminate this Agreement and recommend that the Secretary not continue operations under the ROD after the expiration thereof.

8. Development of System Augmentation. The Parties agree to diligently pursue system augmentation within the Colorado River System including but not limited to the determination of the feasibility of projects to increase precipitation in the basin or to augment available supplies through desalination. Additionally, the Parties agree to cooperatively pursue an interim water supply of at least a cumulative amount of 280,000 acre-feet for use in Nevada while long-term augmentation projects are being pursued. It is anticipated that this interim water supply will be made available in return for Nevada's funding of the Drop 2 Reservoir currently proposed for construction by the Bureau of Reclamation. Annual recovery of this interim water supply by Nevada will not exceed 40,000 acre-feet. All water available to Nevada in consideration for funding the Drop 2 Reservoir would remain available during all shortage conditions declared by the Secretary.

In consideration of the Parties' diligent pursuit of long-term augmentation and the availability of the interim water supply, the Southern Nevada Water Authority (SNWA) agrees that it will withdraw right-of-way Application No. N-79203 filed with the Bureau of Land Management on October 1, 2004 for the purpose of developing Permit No. 58591 issued by the Nevada State Engineer in Ruling No. 4151.

The SNWA will not re-file such right-of-way application or otherwise seek to divert the water rights available under Permit No. 58591 from the Virgin River prior to 2014 so long as Nevada is allowed to utilize its pre-Boulder Canyon Project Act Virgin and Muddy River rights in accordance with section 4(C) of the Parties' Recommendation in the form forwarded to the Secretary on February 3, 2006, and the interim water supply made available to Nevada is reasonably certain to remain available. The SNWA will not re-file such right-of-way application or otherwise seek to divert the water rights available under Permit No. 58591 from the Virgin River after 2014 so long as diligent pursuit of system augmentation is proceeding to provide Nevada an annual supply of 75,000 acre-feet by the year 2020. Prior to re-filing any applications with the Bureau of Land Management, SNWA and Nevada will consult with the other Basin States.

This agreement is without prejudice to any Party's claims, rights or interests in the Virgin or Muddy River systems.

9. Consistency with Existing Law. The Parties' Recommendation is consistent with existing law. The Parties expressly agree that the storage of water in and release of water from Lakes Powell and Mead pursuant to a ROD issued by the Secretary in substantial conformance with the Parties' Recommendation and this Agreement, and any agreements, rules and regulations adopted by the Secretary or the parties to implement such ROD, shall not constitute a violation of Article III(a)-(e) inclusive of the Colorado River Compact, or Sections 601 and 602(a) of the Colorado River Basin Project Act of 1968 (43 U.S.C. §§ 1551 and 1552(a)), and all applicable rules and regulations promulgated thereunder.

10. Resolution of Claims or Controversies. The Parties recognize that litigation is not the preferred alternative to the resolution of claims or controversies concerning the law of the river. In furtherance of this Agreement, the Parties desire to avoid litigation, and agree to pursue a consultative approach to the resolution of any claim or controversy. In the event that any Party becomes concerned that there may be a claim or controversy under this Agreement, the ROD, Article III(a)-(e) inclusive of the Colorado River Compact, or Sections 601 and 602(a) of the Colorado River Basin Project Act of 1968 (43 U.S.C. §§ 1551 and 1552(a)), and all applicable rules and regulations promulgated thereunder, such Party shall notify all other Parties in writing, and the Parties shall in good faith meet in order to resolve such claim or controversy by mutual agreement prior to any litigation. No Party shall initiate any judicial or administrative proceeding against any other Party or against the Secretary under Article III(a)-(e) inclusive of the Colorado River Compact, or Sections 601 and 602(a) of the Colorado River Basin Project Act of 1968 (43 U.S.C. §§ 1551 and 1552(a)), or any other applicable provision of federal law, regulation, criteria, policy, rule or guideline, and no claim thereunder shall be ripe, until such conference has been completed. In addition, all States shall comply with any request by the Secretary for consultation in order to resolve any claim or controversy. In addition, any State may invoke the provisions of Article VI of the Colorado River Compact. Notwithstanding anything in this Agreement to the contrary, the terms of this Paragraph 10 shall survive for a period of five years following the termination or expiration of this Agreement, and shall apply to any withdrawing Party after withdrawal for such period.

11. Reservation of Rights. Notwithstanding the terms of this Agreement and the Parties' Recommendation, in the event that for any reason this Agreement is terminated, or that the term of this Agreement is not extended, or upon the withdrawal of any Party from this Agreement, the Parties reserve, and shall not be deemed to have waived, any and all rights, including any claims or defenses, they may have as of the date hereof or as

may accrue during the term hereof, under any existing federal or state law or administrative rule, regulation or guideline, including without limitation the Colorado River Compact, the Upper Colorado River Basin Compact, the Decree in *Arizona v. California*, the Colorado River Basin Project Act of 1968, and any other applicable provision of federal law, rule, regulation, or guideline.

12. No Third-Party Beneficiaries. This Agreement is made for the benefit of the Parties. No Party to this Agreement intends for this Agreement to confer any benefit upon any person or entity not a signatory upon a theory of third-party beneficiary or otherwise.

13. Joint Defense Against Third Party Claims. In the event the Secretary adopts a ROD in substantial conformance with the Parties' Recommendation as set forth herein, they will have certain common, closely parallel, or identical interests in supporting, preserving and defending the ROD and this Agreement. The nature of this interest and the relationship among the Parties present common legal and factual issues and a mutuality of interests. Because of these common interests, the Parties will mutually benefit from an exchange of information relating to the support, preservation and defense of the ROD and this Agreement, as well as from a coordinated investigation and preparation for discussion of such interests. In furtherance thereof, in the event of any challenge by a third party as to the ROD or this Agreement (including claims by any withdrawing Party), the Parties will cooperate to proceed with reasonable diligence and to use reasonable best efforts in the support, preservation and defense thereof, including any lawsuit or administrative proceeding challenging the legality, validity or enforceability of any term of the ROD or this Agreement, and will to the extent appropriate enter into such agreements, including joint defense or common interest agreements, as are necessary therefor. Each Party shall bear its own costs of participation and representation in any such defense.

14. Reaffirmation of Existing Law. Nothing in this Agreement or the Parties' Recommendation is intended to, nor shall this Agreement be construed so as to, diminish or modify the right of any Party under existing law, including without limitation the Colorado River Compact, the Upper Colorado River Basin Compact, or the Decree in *Arizona v. California*. The Parties hereby affirm the entitlement and right of each State under such existing law to use and develop the water of the Colorado River System.

15. Term. This Agreement shall be effective as of the date of the first two signatories hereto, and shall be effective as to any additional Party as of the date of execution by such Party. Unless earlier terminated, this Agreement shall be effective for so long as the ROD and the ISG are in effect, and shall terminate upon the termination of the ROD and the ISG.

16. Authority. The persons and entities executing this Agreement on behalf of the Parties are recognized by the Parties as representing the respective States in matters concerning the operation of Lakes Powell and Mead, and as those persons and entities authorized to bind the respective Parties to the terms hereof. Each person executing this

Agreement has the full power and authority to bind the respective Party to the terms of this Agreement. No Party shall challenge the authority of any person or Party to execute this Agreement and bind such Party to the terms hereof, and the Parties waive the right to challenge such authority.

Appendix K

Conservation Before Shortage II Proposal

A consortium of environmental non-governmental organizations (NGO) developed and submitted the Conservation Before Shortage II proposal to the Secretary of the Department of the Interior in a letter dated July 7, 2006. This proposal supplemented the original proposal (Conservation Before Shortage proposal) submitted by the consortium of NGOs to the Secretary on July 18, 2005. The consortium of NGOs includes: Defenders of Wildlife, Environmental Defense, National Wildlife Federation, Pacific Institute, Sierra Club, the Nature Conservancy, Rivers Foundation of the Americas, and the Sonoran Institute. The full text of the Conservation Before Shortage II proposal, supplemental information submitted therein, and the full text of the original Conservation Before Shortage proposal are provided in this appendix.

K.1 Conservation Before Shortage II: Proposal for Colorado River Operations

Defenders of Wildlife * Environmental Defense * National Wildlife Federation
The Nature Conservancy * Pacific Institute * Sierra Club * Sonoran Institute

July 7, 2006

The Honorable Dirk Kempthorne
Secretary, U.S. Department of the Interior
1849 C Street, NW
Washington, DC 20240

via email: strategies@lc.usbr.gov

Dear Secretary Kempthorne:

With this letter, we submit our proposal "Conservation Before Shortage II" for your consideration in the "Development of Lower Basin Shortage Guidelines and Coordinated Management Strategies for Lake Powell and Lake Mead, Particularly Under Low Reservoir Conditions."

A year ago, we submitted our original proposal "Conservation Before Shortage" in anticipation of Reclamation's work to develop new shortage rules for the Colorado River. Since then, the Colorado River Basin States significantly changed the scope of Reclamation's deliberations with the submission of their own proposal. The new flexibility they propose with Intentionally Created Surplus (ICS), administered appropriately, could provide a framework for improving environmental conditions on the Colorado. We have therefore combined the ICS concept with a slightly modified version of our original proposal.

The original Conservation Before Shortage was a proposal to manage shortages in the Colorado River by asking water users to voluntarily engage in predictable, small-scale reductions in use – and receive compensation for those reductions – rather than face large-scale, involuntary, and uncompensated disruptions in water deliveries that could cut into municipal and agricultural water supplies and create unmitigated economic impacts. Conservation Before Shortage II combines such voluntary, market-based water conservation to protect against shortages on the Lower Colorado River with a voluntary, market-based mechanism to protect or enhance flow dependent environmental values.

With this letter, we submit a description of Conservation Before Shortage II (including relevant background, a description of the proposal itself, a rationale for the proposal, and the identification of several additional issues), as well as the original Conservation Before Shortage proposal, and an additional proposal to expand the ICS program to include Mexico.

1 of 2

We appreciate the effort Reclamation staff have made to help us understand the hydrologic impacts of our proposals through the use of their expertise in river operations modeling. We hope to continue this dialogue about management of Colorado River shortages with Interior and Reclamation, as well as the Colorado River Basin States, the International Boundary and Water Commission and representatives of the Republic of Mexico.

Thank you for your consideration, and please do not hesitate to contact any one of us if you have questions.

Sincerely,

Kara Gillon

Conservation Before Shortage II:

Proposal for Colorado River Operations

I. Background/Context

In August of 2005, various non-governmental conservation organizations introduced the "Conservation Before Shortage" proposal into the U.S. Bureau of Reclamation's (Reclamation) process for the "Development of Lower Colorado River Basin Shortage Guidelines and Coordinated Management Strategies for Lakes Powell and Mead Under Low Reservoir Conditions" (Shortage Guidelines). The "Conservation Before Shortage" proposal suggested an approach to the management of shortages in the Lower Colorado through the implementation of a tiered program of voluntary and compensated water conservation, tied to the surface elevation of Lake Mead.

Since the time of that proposal, the seven Basin States have reached agreement on a far-reaching proposal to transform management of Colorado River system water through conjunctive management of Lakes Mead and Powell, modification and extension of the existing Interim Surplus Criteria, and the adoption of shortage guidelines. Perhaps most significantly, the Basin States' proposal introduces a series of new mechanisms to increase flexibility within the Lower Basin delivery system and water allocations, including the creation of a new category of water: "Intentionally Created Surplus" (ICS). ICS can be generated through extraordinary conservation measures, funding of system efficiency improvements, and recognition of water exchanges.

As currently constituted, the Basin States' proposal is largely concerned with water deliveries between and among the Basin States, with ICS programs and related mechanisms confined to the states of the Lower Basin. While these programs will clearly benefit water management on the Colorado River system, we suggest that significant benefits for U.S. water users, Mexican water users, and the environment could be gained by expanding portions of the Basin States' proposal to include additional potential domestic water users, provide for direct federal participation, and leave the door open to potential international implementation of ICS programs.

In addition, we strongly suggest that there remain significant potential advantages to some of the concepts expressed in the original "Conservation Before Shortage" proposal, particularly the use of voluntary, market-based conservation as a method to mitigate involuntary shortages. By combining that proposal with an expanded ICS program we believe that "Conservation Before Shortage II" is a powerful tool for mitigating against shortages and helping to meet the federal government's bypass flow replacement obligations under the Colorado River Basin Salinity Control Act.

Conservation Before Shortage II meets the purposes identified in the Basin States' original proposal: delaying and minimizing the onset of shortage in the Lower Basin and the risk of curtailment in the Upper Basin through conservation, more efficient reservoir operations and water supply augmentation. It also meets multiple federal objectives on the Colorado River, including the watermaster's continued federal oversight and management of the river, the protection of important environmental resources, and replacement of the bypass flow.

Over the past several months, the conservation organizations that developed the original Conservation Before Shortage proposal have, with technical assistance from Reclamation's modeling staff, developed a revised version of the proposal (hereafter referred to as "CBS II"). This document describes the essential elements of the CBS II proposal, the rationale behind these elements, its relationship to the states' proposal, and the significant potential benefits associated with the CBS II approach.

II. Elements of Conservation Before Shortage II

A. Shortage Guidelines to Reduce Deliveries/Releases from Lake Mead

Shortage Conditions

At elevations below 1000 feet, the Secretary would impose involuntary shortage conditions to the extent necessary to maintain an elevation of 1000 feet (absolute protection of elevation 1000 feet).[1]

Conservation Conditions

In years when the August 24-month study projects the elevation of Lake Mead on January 1 will fall within the elevation ranges for "conservation conditions" identified below, on behalf of the Secretary of the Interior (Secretary), Reclamation will engage in a program to purchase ICS credits in the amounts corresponding to those ranges. To the extent permitted by law and through the appropriate authorities, Reclamation will also seek to generate such ICS credits by purchasing water from users in Mexico (temporarily reducing deliveries of Colorado River water to Mexico). Federal ICS creation requirements would follow identical triggers and reductions to the involuntary shortages proposed under the Basin States' alternative:

- Elevation greater than 1050 to 1075 feet: 400,000 acre-feet
- Elevation greater than 1025 to 1050 feet: 500,000 acre-feet
- Elevation greater than 1000 to 1025 feet: 600,000 acre-feet

Reclamation would maintain an accounting system to track cumulative Main Outlet Drain Extension bypass flow replacement obligations (to the extent not otherwise satisfied via other mechanisms) and banked federal ICS credits. ICS credits created when the elevation of Lake Mead is at or below 1075 feet would first be credited against the cumulative bypass flow "deficit." Federal ICS credits created in excess of this deficit would be credited to the federal ICS account up to the amount of the federal cap of 1.5 million acre feet (see below). Federal ICS credits created in excess of the federal cap would become system water.

---

[1] In the event that a shortage is declared when Lake Mead is at or below elevation 1000 feet, and a bi-lateral determination of an extraordinary drought is also made under the 1944 Treaty, deliveries to Mexico would be reduced in the same proportion as consumptive uses in the Lower Basin are reduced.

All funding for creation of federal ICS up to the amount of the 1.5 million acre foot cap would be provided by the federal government in recognition of the bypass flow replacement and environmental benefits. Thereafter, 50% of funding would be provided by the federal government, with the remaining 50% derived from fees assessed against Lower Basin water and power users using the mechanisms described in the original CBS proposal (see Attachment A).

B. Coordinated Reservoir Operations (Lake Mead and Lake Powell).

CBS II does not address coordinated reservoir operations. However, for the purpose of highlighting the differences between CBS II and the Basin States' alternative in Reclamation's modeling exercise, reservoir operations at Lakes Mead and Powell would be coordinated as described in the Basin States Alternative.

C. Lake Mead Storage and Delivery of Conserved and Non-system Water

ICS credits generated via extraordinary conservation activities, tributary conservation, system efficiency projects, and other mechanisms would be handled under rules identical to the Basin States Alternative, except as follows:

- ICS credits could be generated by entities that are not current Colorado River delivery contract holders (although a delivery contract with the Secretary would be required for the storage and delivery of ICS credits). Entities eligible for participation in the ICS program would include:
    - U.S. federal agencies
    - State agencies
    - Private entities, including U.S. non-governmental organizations
    - Mexican federal agencies
    - Mexican water users
- All participating entities would follow the Basin States rules for storage and withdrawal of ICS credits (including restrictions on creation and use of ICS credits during shortage and surplus conditions, 5% system set-aside for creation of ICS[2], and reductions to stored ICS to account for evaporation losses), except:

[2] The Basin States' proposal provides that at the time ICS credits are created by extraordinary conservation, the entity creating the credits will dedicate 5% of the ICS credits to the system on a one-time basis to provide a water supply benefit to the system, while 10% of the ICS credits would be set aside under the Reservoir Storage Alternative. Quite possibly, the set-aside rate of 10% may be too modest. We suggest that Reclamation analyze the benefits and costs of a larger set-aside.

- U.S. federal government would be permitted to purchase or create and bank ICS credits during Conservation Conditions (see below), but would be subject to the same rules for delivery and use of ICS credits as other users.

- Mexico would be permitted to create, bank, and deliver ICS credits during "Normal," "Full Domestic Surplus," and 70(r) surplus conditions but not during Conservation, Shortage or Flood Control Surplus conditions. Same-year ICS reallocations within Mexico that do not result in system storage would not be subject to the 5% system set-aside (as this would not alter Treaty deliveries). Water banked by Mexico in Lake Mead would be subject to the 5% system set-aside as well as evaporative loss charges. Mexico's participation in the ICS program would operate under a Treaty minute reflecting procedures to alter delivery schedules to accommodate transfers of ICS within Mexico, as well as procedures for temporary reductions and corresponding increases in Treaty deliveries to allow for banking in Lake Mead.

- The maximum amount of ICS credits that could be created in any one year would be limited to 950,000 acre-feet per year, allocated among the participants as follows:
  - California contractors: 400,000 acre-feet per year (state proposal)
  - Nevada contractors: 125,000 acre-feet per year (state proposal)
  - Arizona contractors: 100,000 acre-feet per year (state proposal)
  - United States: 100,000 acre-feet per year (except during Conservation Conditions, see above) (potentially allowing use of water for environmental projects)
  - Mexico (government/users): 125,000 acre-feet per year (enough water to bank and deliver 200,000 acre-feet of a 250,000 acre-foot flood flow every 5 years with the last 50,000 acre-feet scheduled as part of Mexico's annual delivery in the year of the flood flow release, plus allow for other environmental, municipal, industrial, and other uses, accounting for the 5% system set-aside and up to 5% annual evaporation loss for banked water)
  - All other users: 100,000 acre-feet per year

- The maximum cumulative amount of ICS credits that would available at any one time would be 4,200,000 acre-feet, allocated as follows:
  - California contractors: 1,500,000 acre-feet (state proposal)
  - Nevada contractors: 300,000 acre-feet (state proposal)
  - Arizona contractors: 300,000 acre-feet (state proposal)

4

- United States: 1,500,000 acre-feet (3-5 years of Conservation Conditions acquisitions, 15 years of ICS recovery)
- Mexico: 400,000 acre-feet (enough water to bank 200,000 acre-feet of a 250,000 acre-foot flood flow every 5 years with the last 50,000 acre-feet scheduled as part of Mexico's annual delivery in the year of the flood flow release, plus approximately 2-3 years cumulative storage for other uses)
- All other: 200,000 acre-feet (2 years storage to allow for purchase and storage of water during cheaper market conditions)

- The maximum amount of ICS credits that could be recovered in any one year would be limited to 1.6 million acre-feet per year, allocated as follows:
  - California contractors: 400,000 acre-feet (state proposal)
  - Nevada contractors: 300,000 acre-feet (state proposal)
  - Arizona contractors: 300,000 acre-feet (state proposal)
  - United States: 100,000 acre-feet (maximum volume of federally-banked ICS that could be recovered each year for environmental use, including MSCP, at Mead elevations above 1075 feet) (10 years worth of recovery)
  - Mexico: 400,000 acre-feet (enough to provide for unlikely confluence of 250,000 acre-feet flood flow plus significant non-environmental use in one year)
  - All other: 100,000 acre-feet (enough to implement restoration in the limitrophe reach, plus water available for additional projects).
- During Conservation Conditions, the federal government is required to acquire ICS from U.S. and/or Mexican users pursuant to shortage guidelines in volumes of 400,000, 500,000, and 600,000 acre-feet (see II.*A*, above).

D. Interim Surplus Guidelines for deliveries/releases from Lake Mead and all other operation criteria

CBS II does not address the Interim Surplus Guidelines or other operating criteria. However, for the purpose of highlighting the differences between CBS II and the Basin States' alternative in Reclamation's modeling exercise, all other river operation criteria, including operation of the Interim Surplus Guidelines, would be the same as proposed in the Basin States Alternative.

III. Rationale for Conservation Before Shortage II

Conservation Before Shortage II is founded on the principle that the Secretary should take greater responsibility to operate the Colorado River in a manner that minimizes shortages in the Lower Basin and avoids the risk of curtailment in the Upper Basin through conservation, more efficient reservoir operations, and increased flexibility in the management of river resources, while protecting or enhancing environmental values associated with the Colorado River. Three elements of CBS II highlight this principle:

> (1) voluntary, market-based water conservation as an alternative to and mitigation mechanism against involuntary, uncompensated shortages on the Lower Colorado River;
>
> (2) voluntary, market-based mechanisms to protect or enhance flow dependent environmental values, in close alignment with applying such mechanisms to mitigate against involuntary, uncompensated shortages; and
>
> (3) potential expansion of ICS programs (pending appropriate diplomatic consultations) to include water users in Mexico and to improve the management of Colorado River water supplies in both countries.

A. Voluntary, Market-Based Conservation as an Alternative to Involuntary Shortage

As discussed in the original Conservation Before Shortage proposal (see Attachment A), we believe that there are significant potential advantages to the use of voluntary, market-based conservation as an alternative to and as a means of mitigating against involuntary shortages.

- Based on extensive modeling performed for the Lower Basin states, reductions of 400,000, 500,000 and 600,000 acre-feet at Lake Mead elevations 1075 feet, 1050 feet and 1025 feet, respectively, appear to provide optimal results in preventing larger involuntary shortages that perform better than the 200,000, 400,000, and 600,000 acre-foot reductions proposed in the original CBS proposal.

- It is desirable to protect the elevation of Lake Mead at no less than 1000 feet under any condition to protect Southern Nevada Water Authority's lower intake structures, as well as the new minimum power pool if proposed low-pressure turbines are installed at Hoover Dam.

- It is preferable for Lower Basin water users to voluntarily engage in predictable, small-scale reductions in use – and receive compensation for those reductions – rather than face large-scale, involuntary and uncompensated disruptions in water deliveries that could cut into municipal and agricultural water supplies and create unmitigated economic impacts.

- There is a large volume of Colorado River water which could be temporarily conserved through voluntary, market-based mechanisms such as part-year fallowing or forbearance agreements, dry year options, or other similar arrangements to reduce Lower Basin consumptive use on an occasional, temporary basis as an alternative to involuntary shortages to low-priority users.[3]

- Users of Colorado River water in Mexico may wish to participate in short-term, voluntary and compensated conservation agreements, to reduce the probability of larger, uncompensated future reductions due to a declaration of shortage under the 1944 Treaty with Mexico.[4]

The ICS program suggested in the Basin States' proposal will likely result in the identification of numerous opportunities for extraordinary conservation activities that could be used to accomplish reductions in water use in the Lower Basin. These mechanisms could not be utilized by other water users when the elevation of Lake Mead is at or below 1075 feet, creating a readily available supply of ICS credit-eligible water that could instead be utilized by the federal government as a means of temporarily reducing water use on a voluntary, compensated basis.

CBS II would also create an obvious means of implementing a significant portion of the federal government's bypass flow replacement obligation. The recently published report led by the Central Arizona Water Conservancy District "Balancing Water Needs on the Lower Colorado River: Recommendations of the Yuma Desalting Plant/Cienega de Santa Clara Workgroup," includes recognition that replacement of the MODE bypass flow is primarily necessary during shortage conditions to ensure that accumulated system water deficits resulting from the bypass flow do not result in shortages to Lower Basin users. One of the primary recommendations in the report is the creation of a "shortage alleviation trust fund" which would be used, in combination with fallowing programs or other conservation mechanisms, to provide replacement water to compensate for accumulated bypass flow deficits during shortage conditions. The recommendations of the workgroup have been widely circulated among Lower Basin water users and have received significant support among both water users, water managers, and environmental interests.

Use of the ICS mechanism by the federal government when Lake Mead elevation is at or below 1075 feet would provide an ideal means of implementing this recommendation of the YDP/Cienega de Santa Clara workgroup. ICS credits that the federal government would be required to purchase when Lake Mead elevation is at or below 1075 feet could be retired for the benefit of the system to the extent necessary to eliminate any accumulated bypass flow replacement deficit; only after this deficit is extinguished would ICS credits accrue to the federal government for other uses.

---

[3] Some 4.5 million acre-feet of Colorado River water are used to irrigate crops in the Lower Basin states, and more than 1 million acre-feet are used to irrigate crops in Mexico. Conservation of between 400,000 and 600,000 acre-feet through the use of part-year fallowing programs, dry year options, or other similar arrangements would constitute only 7-11% of total Lower Basin agricultural use in the United States and Mexico. (However, as even small-scale reductions in agricultural water use may have third-party impacts, provision should be made to support community economic development in affected areas.) Conversely, even under the Basin States' tiered shortage proposal, involuntary shortages could have significant economic consequences, disrupting water banking plans in Arizona and cutting low-priority municipal and agricultural use in the U.S. and Mexico (resulting in unpredictable loss of farm income, economic disruptions from municipal shortfalls, or requiring expensive municipal conservation efforts or efforts to secure agricultural water to support hardened municipal demand).

[4] Such an agreement would likely require a new Minute to the 1944 Treaty with Mexico. Fallowing agreements in Mexico would have to be administered by the appropriate authorities.

B. Voluntary, Market-Based Conservation to Protect or Enhance Environmental Flows.

This proposal suggests two mechanisms for protecting and enhancing environmental flows in close alignment with the mechanisms to mitigate involuntary and uncompensated shortages, although other mechanisms may also be appropriate for consideration. First, extending the ICS program to include a broader range of participants than current Colorado River contractors provides an opportunity to ensure that some portion of the water developed via extraordinary conservation activities could be dedicated to environmental uses, via the participation of interested parties (such as conservation organizations) in ICS creation. There are several proposed restoration efforts in the United States – such as a restoration proposal for the limitrophe reach of the Colorado River – which could potentially benefit from access to ICS water supplies during normal conditions.

Second, direct participation of the federal government in the ICS program could be an excellent mechanism for purchasing water for environmental purposes or other public benefit uses by the federal government. Although these credits would only be available for use when the elevation of Lake Mead is greater than 1075 feet, they could be used to provide "bridge" supplies for restoration projects, run pilot restoration projects, or meet other interim water supply needs.

C. ICS for Mexico

As discussed in detail in a draft proposal entitled *Taking ICS to Mexico: International Opportunities in the Seven States Agreement* (see Attachment B), ICS credits could be used to firm urban water supplies in both countries, implement long-studied environmental restoration projects in the Colorado River Delta, and increase flexibility in Mexico's agricultural sector – creating economic, environmental, and social benefits in both countries while offering the United States and Mexico a venue for cooperation in the otherwise contentious area of water management at the border. In addition, during shortage conditions, extension of the ICS program to include Mexico would expand the pool of participants who could provide voluntary, compensated reductions in water use as an alternative to involuntary shortages in the United States.

An extension of the ICS program to include Mexico would likely require the adoption of a new Minute to the Treaty of 1944, and would obviously require diplomatic discussions and negotiations likely to occur in a different venue than Reclamation's domestic process to develop Shortage Guidelines. However, we strongly suggest that the current federal process should leave the door open to the eventual approval of a binational extension of the ICS program, to limit the costs of future review of such a program and encourage the initiation of binational discussions about such a program. Since critical elements of the Basin States' proposal – most notably the proposed shortage policy and proposed policies for water exchanges – will already require consultation with Mexico and/or the adoption of a new Minute, these opportunities could be considered in the same diplomatic process

IV. Additional Issues

To characterize the impact that these concepts would have on river management outcomes, we have attempted to minimize the differences (and thus the number of modeling variables at play) between CBS II and the Basin States' proposal. While we do not necessarily agree with or endorse all of the approaches suggested in the Basin States' proposal, we have not attempted to alter many of its basic elements, including the proposed modification and extension of the Interim Surplus Guidelines, new conjunctive management of Lakes Mead and Powell, or the imposition of Shortage Criteria only through 2026. However, CBS II incorporates these elements of the Basin States' proposal for comparative and analytical purposes only.

We do not assume the various proposals under consideration, including CBS II and the Basin States' proposals, are consistent with the existing law. Reclamation should clarify, during the environmental review process, how or whether these proposals would function within existing laws.

Attachment A

Conservation Before Shortage Proposal

This attachment to Appendix K contains the text of the Conservation Before Shortage proposal submitted on July 18, 2005.

Conservation Before Shortage

Proposed Shortage Criteria for
Colorado River Operations

I. Background/Context

The effects of a multi-year drought have had a tremendous impact on storage in the Colorado River basin. Although above-average precipitation in the Lower Basin has led to small recoveries in system storage over the winter of 2004-2005, total system storage on the Colorado River has decreased by more than 40% over the past several years. As a result, there is a real possibility that the Secretary of the Interior will declare an actual shortage on the lower Colorado River in the near future. A shortage declaration would reduce deliveries to the Central Arizona Project (CAP) and to southern Nevada (which are among the first in line for cuts in the event of a shortage).

The surface elevation of Lake Mead dropped more than 80 feet from the end of 2000 through the end of 2004; Lake Powell dropped by more than 115 feet in this period. The Bureau of Reclamation's (Reclamation's) Riverware model of the Colorado, based on historic flow records, projects that reservoir levels at Lake Powell could head quickly towards the minimum power pool if the drought continues, and reservoir levels at Lake Mead could fall below the elevation of southern Nevada's upper intakes or remain in a long-term decline that will be difficult to reverse until Powell begins to re-fill. In addition, the model predicts that even if precipitation levels returned to average today, it could take 10-20 years for the Colorado River reservoir system to recover fully (during which time continued development of water supplies in the Upper Basin will further shrink available supplies). As a result, it is time to begin a long-delayed discussion about the method for defining, mitigating, and sharing shortages on the Colorado River.

Although the Secretary of the Department of the Interior (Secretary) has the authority to declare a shortage on the Colorado River, thereby reducing deliveries to some Lower Colorado River contractors, to date no criteria exist for determining when such a shortage will be declared. In June 2005, the Department of the Interior (DOI) noticed its intent to begin a public scoping process for the development of "Lower Basin Shortage Guidelines," (70 Fed.Reg. 34794). In 2004, DOI initiated a series of technical meetings with the Colorado Basin states to discuss drought issues, and the seven Basin states met frequently among themselves throughout the winter of 2004-2005 to discuss potential shortage criteria. Non-governmental organizations (NGOs) were not invited to participate in these discussions; however, several NGOs with interest and expertise in Colorado River issues began meeting over the winter to develop an alternative shortage proposal. These organizations met with Reclamation staff to review the results of technical modeling runs developed in support of the states' discussions, and Reclamation has provided additional modeling data to these interested NGOs in response to their inquiries and to evaluate potential shortage criteria.

These meetings led to the development of this document, which proposes an approach to the management of shortages in the Lower Colorado through the implementation of a tiered conservation program that is tied to the surface elevation of Lake Mead.

II. Rationale for this Proposal

The basic rationale behind this "Conservation Before Shortage" proposal is that shortage criteria should attempt to maximize the reliability and predictability of water deliveries on the Lower Colorado by introducing increased flexibility into the management of river resources when shortage conditions are imminent.

Principles:

- It is desirable to protect the elevation of Lake Mead at 1050 feet (the current minimum power pool) to the extent feasible without implementing shortages that would involuntarily curtail deliveries to Lower Basin users.
- It is desirable to protect the elevation of Lake Mead at no less than 1000 feet under any condition in order to protect Southern Nevada Water Authority's lower intake structures, as well as the new minimum power pool if proposed low-pressure turbines are installed at Hoover Dam.
- It is desirable to avoid shortages in the Lower Basin above 500,000 acre-feet whenever possible (the approximate level at which shortages would cut into CAP's deliveries beyond those currently utilized for water banking).
- It is preferable for Lower Basin water users to voluntarily engage in predictable, small-scale reductions in use – and receive compensation for those reductions – rather than face large-scale, involuntary, and uncompensated disruptions in water deliveries that could cut into municipal and agricultural water supplies and create unmitigated economic impacts.
- Minimizing large, forced disruptions to normal deliveries as a result of shortage declarations will minimize the threat of unmitigated environmental impacts in the Lower Colorado River and Delta as a result of significantly decreased deliveries to low-priority users and corresponding return flows that support environmental values.
- Market-based programs, with low transaction costs and appropriate mitigation of third-party impacts, can offer a reasonable mechanism for minimizing the risk and impacts of shortage.[1]
- Users of Colorado River water in Mexico may wish to participate in short-term conservation agreements, to reduce the probability of larger, uncompensated future reductions due to a declaration of shortage under the 1944 Treaty with Mexico.
- Water can be obtained from agricultural users in the United States, and could be obtained in Mexico with an appropriate agreement,[2] through the use of voluntary, market-based forbearance programs. Economic studies of Lower Basin agricultural use, as well as recent leases of water from farmers in this area, suggest that there is a large volume of water in the basin that could be obtained for $20 - 100 per acre-foot (see Figure 9).

---

[1] Some 4.5 million acre-feet of Colorado River water are used to irrigate crops in the Lower Basin states, and more than 1 million acre-feet are used to irrigate crops in Mexico. Conservation of between 200,000 and 600,000 acre-feet through the use of part-year fallowing programs, dry year options, or other similar arrangements would constitute only 4-11% of total Lower Basin agricultural use in the United States and Mexico. (However, as even small-scale reductions in agricultural water use may have third-party impacts, some portion of funds accrued for the purchase of water should be set aside to support community economic development in affected areas.) Conversely, without these small-scale reductions, water users would likely be faced with the need to curtail large amounts of water quite abruptly, with significant economic consequences. (Shortages of nearly 2 million acre-feet in a single year are predicted by Reclamation's model when the 1000 feet elevation is protected at Lake Mead without conservation measures).

[2] Such an agreement would likely require a new Minute to the 1944 Treaty with Mexico. Fallowing agreements in Mexico would have to be administered by the appropriate authorities.

III. Conservation Before Shortage Policy

The "Conservation Before Shortage" policy essentially consists of two sets of criteria tied to projected elevations at Lake Mead on January 1 of a given year, according to the Bureau of Reclamation's August 24-month study. These criteria consist of three "conservation triggers," which impose progressively increasing conservation goals as lake levels drop from 1100 feet to 1050 feet, and a "shortage trigger," which imposes involuntary shortages in the Lower Basin as are necessary to accomplish absolute protection of Lake Mead at a minimum elevation of 1000 feet.

(A) Normal Conditions

In years when the 24-month study projects the elevation of Lake Mead on January 1 will be at or above 1100 feet, the Secretary of the Interior (Secretary) shall determine a Normal or Surplus (as defined by the Interim Surplus Guidelines) year.

(B) Conservation Triggers

First Conservation Trigger: Below 1100 Feet at Lake Mead

In years when the 24-month study projects the elevation of Lake Mead on January 1 will be at or above 1075 feet but below 1100 feet, the Secretary will seek to conserve 200,000 acre-feet of water. On behalf of the Secretary, Reclamation will preferentially seek to achieve this 200,000 acre-feet of savings by means of voluntary conservation agreements (including forbearance agreements) with Lower Basin delivery-contract holders. Additionally, Reclamation will, to the extent permitted by law and through the appropriate authorities, seek forbearance or other such water conservation agreements with Colorado River users in Mexico. In the case of such agreements, U.S. deliveries of Colorado River water to Mexico at the Northerly International Boundary will be reduced by the total volume indicated by these binational agreements.

Second Conservation Trigger: Below 1075 Feet at Lake Mead

In years when the 24-month study projects that the elevation of Lake Mead on January 1 will be at or above 1050 feet but below 1075 feet, the Secretary will seek to conserve 400,000 acre-feet of water. Reclamation will preferentially seek to achieve this 400,000 acre-feet of savings by means of voluntary conservation agreements (including forbearance agreements) with Lower Basin delivery-contract holders. Additionally, Reclamation will, to the extent permitted by law and through the appropriate authorities, seek forbearance or other such water conservation agreements with Colorado River users in Mexico. In the case of such agreements, U.S. deliveries of Colorado River water to Mexico at the Northerly International Boundary will be reduced by the total volume indicated by these binational agreements.

Third Conservation Trigger: Below 1050 Feet at Lake Mead

In years when the 24-month study projects that the elevation of Lake Mead on January 1 will be below 1050 feet (minimum power pool absent the installation of low-pressure turbines), the Secretary will seek to conserve 600,000 acre-feet of water. Reclamation will preferentially seek to achieve this 600,000 acre-feet of savings by means of voluntary conservation agreements (including forbearance agreements) with Lower Basin delivery-contract holders. Additionally, Reclamation will, to the extent permitted by law and through the appropriate authorities, seek forbearance or other such water conservation agreements with Colorado River users in Mexico. In the case of such agreements, U.S. deliveries of Colorado River water to Mexico at the Northerly International Boundary will be reduced by the total volume indicated by these binational agreements.

(C) Shortage Trigger

Absolute Protection of Lake Mead Elevation 1000 Feet

The Secretary shall not permit the elevation of Lake Mead to drop below elevation 1000 feet (minimum low-pressure power pool and Southern Nevada Water Authority intakes) at any time. Shortages to Colorado River contractors shall be implemented in the Lower Basin and in Mexico[3] to the extent necessary to prevent such declines.

(D) Funding Mechanisms

In recognition of the federal government's continuing national obligation to replace the MODE bypass flow to Mexico, 43 U.S.C. § 1571(c), the federal government will assume responsibility for the cost of all conservation agreements up to the volume of the bypass flow that the Secretary has not otherwise replaced in the year that a conservation trigger becomes effective. Given the national interest in minimizing both environmental impacts and economic disruptions resulting from the involuntary curtailment of deliveries to Colorado River users, the federal government would also assume responsibility for half of the cost of any additional agreements required to generate conserved water for the "Conservation Before Shortage" policy, pursuant to the Secretary's authority under the Reclamation States Emergency Drought Relief Act of 1991 (Drought Relief Act),[4] conservation authorities in the Farm Bill, or other appropriate authority that may be granted by Congress.

To the extent that conservation of water is required beyond that to be funded by the federal government in the manner described above, conservation activities would be funded through one or both of the following:

Power Pool Protection Fund

The priority of water used for power generation is considered to be tertiary to that of irrigation and domestic use under the Law of the River. As a result, Hoover and Glen Canyon Dams are operated to maintain deliveries to water users regardless of the impact of declining reservoir levels on power production. However, one of the more significant corollary benefits of the conservation program described in this proposal, beyond the primary benefit of protecting water users from involuntary and uncompensated shortages, would be the preservation of power production at Hoover Dam at higher levels and for longer durations by reducing deliveries for irrigation, domestic use, and underground storage in a manner that would not otherwise occur under current practices.

[3] In the event that a shortage is declared and is also considered to be an extraordinary drought under the 1944 Treaty, deliveries to Mexico will be reduced in the same proportion as consumptive uses in the United States are reduced.
[4] The Reclamation States Emergency Drought Relief Act of 1991, 43 U.S.C. §§ 2201 *et seq.*, provides the Secretary of Interior the authority to purchase water "from willing sellers, including, but not limited to, water made available by Federal Reclamation project contractors through conservation or other means with respect to which the seller has reduced the consumption of water." 43 U.S.C. § 2211(c).

Given the significant loss in generating capacity that has already occurred as a result of declines in power pool elevations,[5] and the even more significant impacts that would be associated with a total loss of generating capacity, the implementation of "Conservation Before Shortage" would clearly benefit power purchasers and consumers. As such, it would seem reasonable to derive a percentage of the funding for the proposed voluntary conservation program from a modest, conditional surcharge on power rates under existing or renewed contracts for hydropower produced at Hoover Dam as a means to mitigate against the loss of power head and stave off the complete loss of power production at Hoover Dam.[6] This surcharge could be imposed in years when Reclamation's August 24-month study projects that the storage in Lake Mead falls below fifty percent of its active capacity. The revenues generated by this surcharge could be collected in a "power pool protection fund," to be maintained by Reclamation for expenditure when and if lake elevations reach a conservation "trigger."

Temporary Cost Recovery/Delivery Surcharges

Pursuant to the Drought Relief Act, the Secretary of Interior is authorized to engage in water purchases from willing sellers and to seek cost recovery for water delivered from the users of that water under temporary contracts. 43 U.S.C. §2211(c), §2212(a),(c). Reclamation could utilize this authority to purchase water through temporary, part-year fallowing arrangements, dry-year options, or similar mechanisms, and would seek cost recovery from Colorado River users. In recognition of the Basin-wide interest in alleviating the impacts of drought and reducing uncertainty on the Lower Colorado, and in the interests of encouraging extraordinary conservation to minimize the likelihood of significant delivery interruptions, the cost of some portion of conservation agreements, including those with Colorado River users in Mexico, could be funded through a conservation surcharge imposed on a per-acre-foot basis on all Lower Basin contractors.

Anticipated Cost of Conservation

Current short-term leasing agreements between farmers and irrigation districts or municipal water agencies, as well as recent research on the net returns per acre-foot of irrigation water, suggest that "Conservation Before Shortage" water could be obtained for $20 - 100 per acre-foot. To ensure that such water remains available in times of increased scarcity (when market forces might otherwise increase the cost), the Secretary should be granted the authority to enter into "Conservation Before Shortage option agreements," similar to existing dry-year leasing agreements/interruptible supply agreements that have been enacted within the basin states.

[5] Largely as a result of declining reservoir elevations, power production at Hoover and Glen Canyon has declined steadily since the onset of drought conditions in the Colorado River Basin. Annual power production at Hoover fell from 5,697 gigawatt-hours (GWh) in 1998 to 4,094 GWh in 2003, according to Western Area Power Administration (WAPA) Annual Reports, 1998 – 2003. A portion of hydropower revenues currently supports the two Upper Basin endangered fish recovery programs, the Glen Canyon Adaptive Management Program, and the Colorado River Salinity Control Program; alternative sources of revenue should be identified and implemented to fully fund these recovery programs. The Department of the Interior should also work proactively with WAPA to identify alternative sources of power for those Indian tribes that have experienced power shortages, or drastic increases in power costs, due to the declining production associated with falling reservoir levels.

[6] The rates for power produced at Hoover Dam have increased as reservoir levels and power production have declined, but may still remain well below open market rates. Although annual revenues tend to vary from year to year, revenues from Hoover Dam power production have generally been in the range of $50 million annually.

IV. Analysis: Benefits of Conservation Before Shortage Policy

To date, actual shortage criteria for the Colorado River have not been defined. For the purposes of comparison, a ‘baseline’ was defined as the current operating conditions for the Colorado River, with the addition of a policy requiring the absolute protection of Lake Mead at 1000 feet (that is, Hoover Dam would not release any water to cause the elevation of Lake Mead to drop below 1000 feet). The baseline policy does *not* provide for the implementation of conservation measures. These ‘baseline’ conditions, reflecting current operating conditions, are depicted in the following figures.

Analysis of the “Conservation Before Shortage” policy suggests that this policy could produce significant benefits for Basin water users by:

- Consistently maintaining reservoir storage and power head above baseline conditions in average to low flow conditions, resulting in increased power production and improved power revenues;
- Significantly reducing the likelihood of involuntary, uncompensated shortages in the Lower Basin and corresponding, unmitigated economic impacts;
- Significantly reducing the likelihood of involuntary and uncompensated shortages in the Lower Basin at levels above 500,000 acre-feet (the approximate level at which a shortage imposed by the Secretary would cut into CAP deliveries, by exceeding the ability of the Arizona Water Bank to readily buffer the shortage); and
- Eliminating the risk that elevations at Lake Mead will drop below minimum power head, improving the reliability of power production and associated revenues.

The analyses below show the impacts of the “Conservation Before Shortage” (CBS) policy on reservoir operations based on historic flows in the Colorado River Basin.

Modeling Assumptions

The proposed “Conservation Before Shortage” policy was modeled using Reclamation’s Riverware model, which is based on historical records of flows in the Colorado River Basin over approximately the past century. Conservation triggers, as described in Section III, were implemented at 1100 feet, 1075 feet and 1050 feet, with the assumption that required measures to reduce Lower Basin consumptive use by 200,000, 400,000, and 600,000 acre-feet, respectively, would be implemented in years when the January 1 elevation at Lake Mead is below the triggers. An absolute protection trigger was implemented at Lake Mead elevation 1000 feet, with releases from Lake Mead to meet delivery obligations to Lower Basin users reduced as necessary to maintain that level. To avoid even modestly under-predicting the elevations of Mead and Powell pools, particularly in the near term, this modeling has assumed that the schedule of Upper Basin depletions will effectively begin with the last reported actual level for CY 2000, will increase at a slower rate than projected by the Upper Colorado River Basin Commission through CY 2009, and will increase at the rate projected by the Commission thereafter.[7]

For purposes of the model, the minimum objective release out of Lake Powell was assumed to be 8.23 maf per year (reflecting current operating conditions).[8] Alternative scenarios for conjunctive management were not modeled, and the protection of a minimum power pool at Lake Powell was not incorporated into this proposal; either or both of these assumptions would affect the elevation of Lake Powell. Model runs used end-of-year 2004 elevations at Lake Mead and Lake Powell to establish initial conditions for 2005, and were run through year 2025.

Protection of Lake Mead

Figures 1 -3 show the potential value of implementing the CBS policy, under a range of average to extremely low flow conditions. **These and following figures show that the CBS policy would greatly benefit the elevation of Lake Mead.**

As shown in Figure 1 below, under average conditions, the CBS policy would maintain reservoir elevations at Mead approximately 30 feet above the baseline policy. As shown by Figures 2 and 3, the CBS policy would significantly reduce the rate of decline in the lower 25th and in the very low 10th percentile reservoir elevations for Mead and maintain even these lower reservoir elevations above the 1000 foot protection level. Model runs showed essentially no impact of the CBS on the higher 90th percentile Mead elevations, so no figure is provided.

[7] *See* "Estimates of Future Depletions in the Upper Division States," Upper Colorado River Commission Memorandum, December 23, 1999. This schedule predicts a 440,000 acre-foot increase in Upper Basin depletions between 2000 and 2010 and a 542,000 acre-foot increase over actual CY2000 depletions, as reported in Reclamation's Consumptive Uses and Losses 1996-2000 report (see Tables UC-1 & UC-6). Actual increases in Upper Basin depletions water may not keep pace with this schedule, because water that would otherwise have been utilized has been and may continue to be physically unavailable for depletion in the Upper Basin due to drought conditions, and in other cases, projects that were proposed to have been constructed during this period may not yet have been or will not be completed through CY 2009. A slower rate of increase from 2000 to 2009 was modeled by subtracting four increments of 100,000 acre-feet from the Commission's schedule from CY 2005 to 2009. This and all other Riverware modeling exercises should be revised to reflect actual increases in Upper Basin depletions as soon as more current information becomes available.

[8] This assumption is not intended to endorse or reject the Secretary's current use of 8.23 maf as the minimum release objective for Powell, the protection of a minimum power pool at Powell, or proposals for the conjunctive management of the combined storage of Mead and Powell. Alternative release scenarios should be incorporated into the modeling for this proposal as they are developed. As a general matter, none of the assumptions used in this proposal should be construed as an interpretation of the 1922 Colorado River Compact, the 1944 Treaty with Mexico, or any other aspect of the Law of the River.

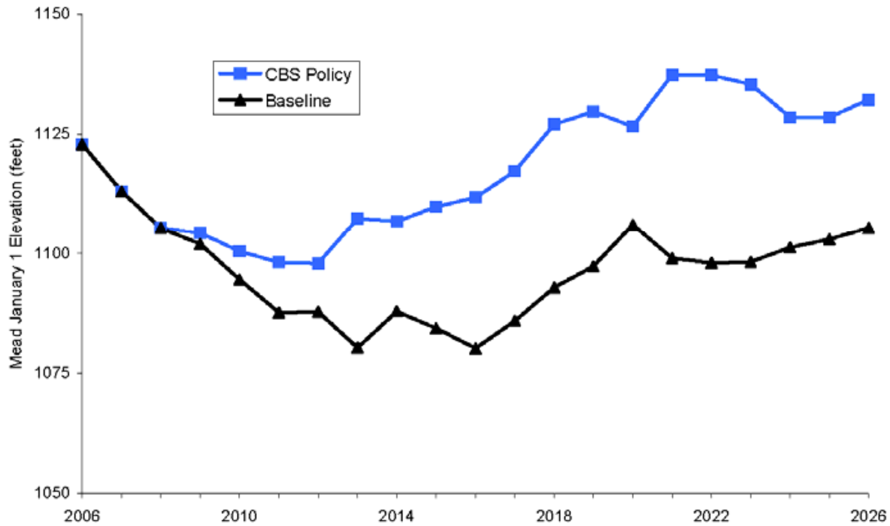

Figure 1. Impact of CBS policy on elevations at Lake Mead, at 50th percentile elevation.

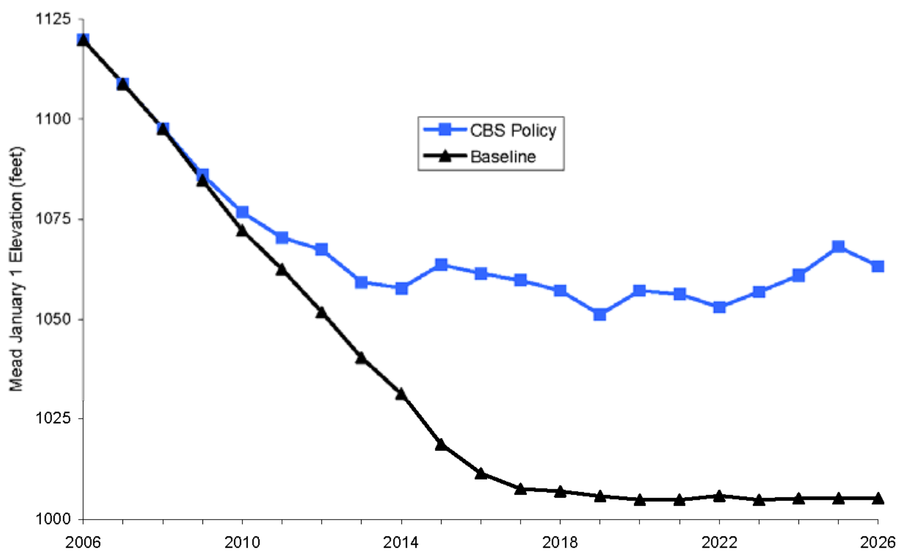

Figure 2. Impact of CBS policy on elevations at Lake Mead, at 25th percentile elevation.

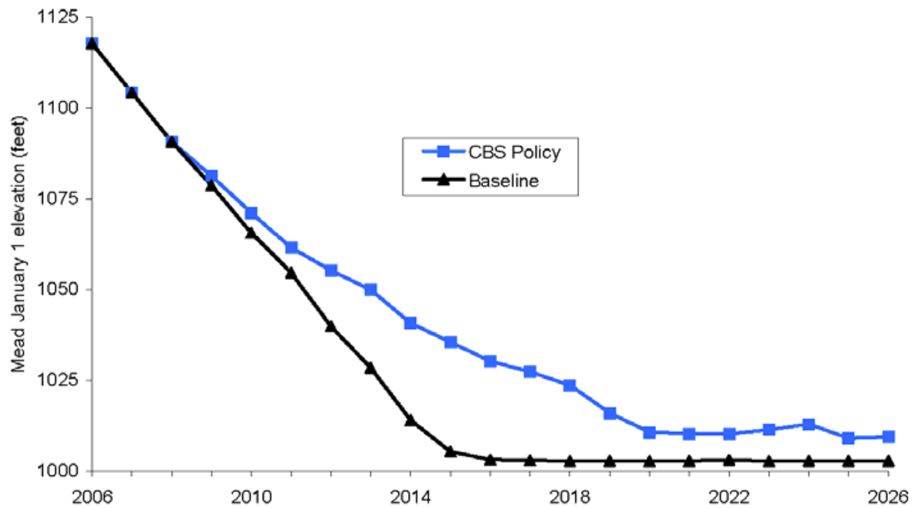

Figure 3. Impact of CBS policy on Lake Mead elevation, at 10[th] percentile elevation.

Probability of Shortages

As noted above, a primary goal of the CBS policy is to significantly reduce the probability of an involuntary, uncompensated shortage in excess of 500,000 acre-feet (the approximate level at which CAP deliveries would be reduced beyond that currently utilized for water banking). **As shown in Figure 4, below, the probability of shortages exceeding 500,000 acre-feet is reduced to 5% or less through the entire modeled period under the CBS policy. By contrast, the probability of shortage under the baseline policy rapidly approaches 30% during this same period. Furthermore, as shown in Figure 5, below, the CBS policy reduces the probability of any involuntary shortage by approximately 20% over the next 20 years.**

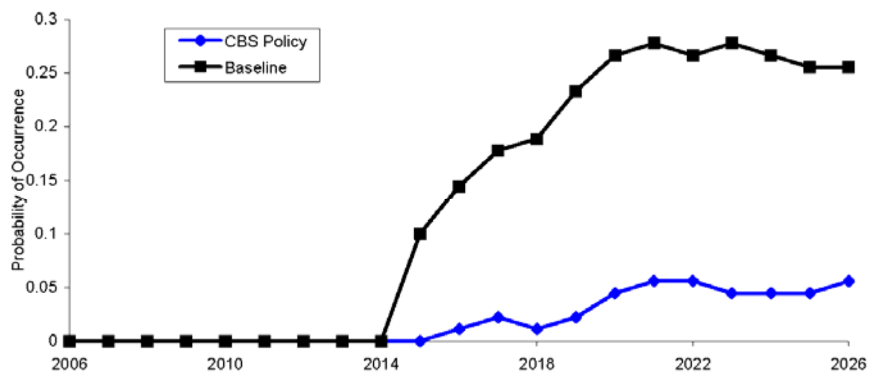

Figure 4. Impact of CBS policy on probability of involuntary Lower Basin shortage greater than 500,000 acre-feet.

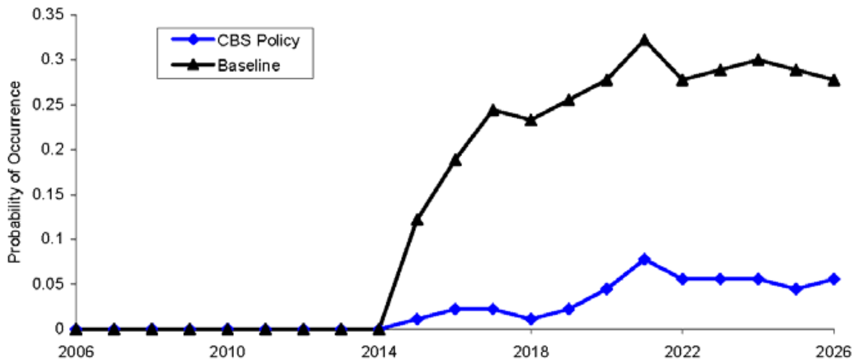

Figure 5. Impact of CBS policy on probability of any involuntary shortage in the Lower Basin.

Probability of Reaching Conservation Triggers

Figures 6 - 8, below, show the relative probability of reaching or exceeding any of the proposed conservation triggers at 1100 feet, 1075 feet and 1050 feet. As one might expect, the probability of reaching the first two triggers is highest in the earlier years of the modeled period, while the probability of reaching the third trigger is higher towards the end of the modeled period. However, the probability of reaching and continuing to remain below a given trigger for an extended period of time appears to be low because of the conservation measures tied to the triggers. For obvious reasons, trigger levels are most likely to be reached under low or very low flow conditions, and are rarely (if ever) reached under high flow conditions.

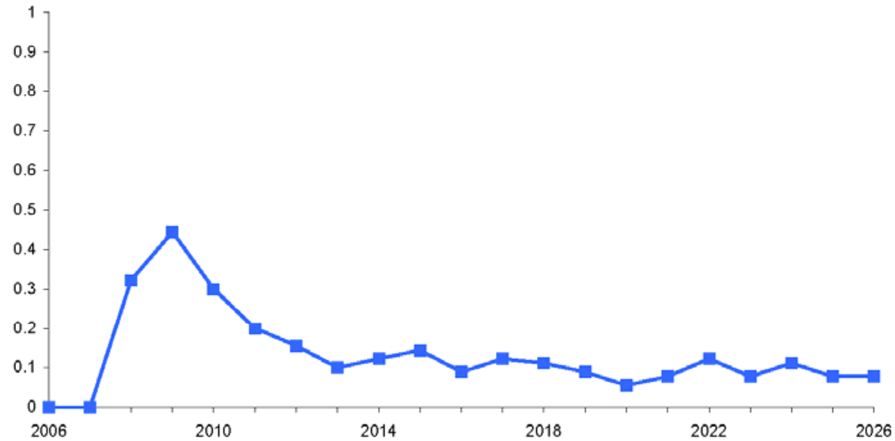

Figure 6. Probability of Lake Mead January 1 elevation occurring in a bounded range of 1100 feet to 1075 feet, with CBS policy in place.

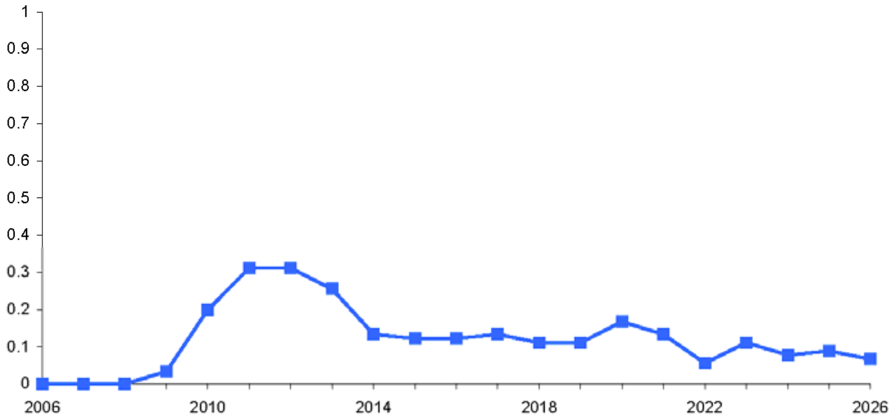

Figure 7. Probability of Lake Mead January 1 elevation occurring in a bounded range of 1075 feet to 1050 feet, with CBS policy in place.

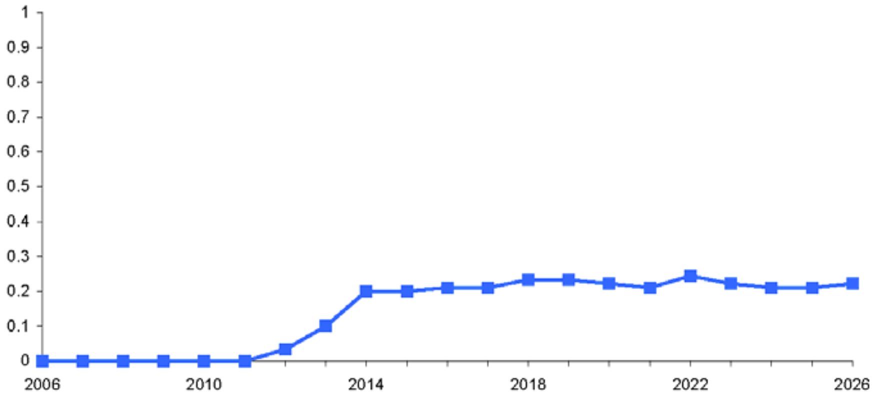

Figure 8. Probability of Lake Mead January 1 elevation occurring below 1050 feet, with CBS policy in place.

Cost of Implementing Conservation Triggers

The cost of implementing conservation triggers is directly related to the cost of obtaining water using the proposed voluntary, market-based conservation mechanisms. Recent purchases of water from farmers in the Lower Basin, as well as analysis of agricultural production in this area, suggest that there is a substantial volume of water used for irrigation which could potentially be obtained on a temporary basis for $20 - 100 per acre-foot. For example, in 2004, the Imperial Irrigation District acquired water from its farmers for less than $60 per acre-foot.

As shown in Figure 9, a recent economic study by Environmental Defense into the profits returned by field crops suggests that slightly more than 2.3 million acre-feet of agricultural water is being used by Lower Basin farmers in California and Arizona to produce profits of less than $100 per acre-foot; more than one million acre-feet of agricultural water is being used to produce profits of less than $20 per acre-foot. (Figures are based on the average volume of water applied to produce a crop unit and market rates for each crop, less costs of production.)

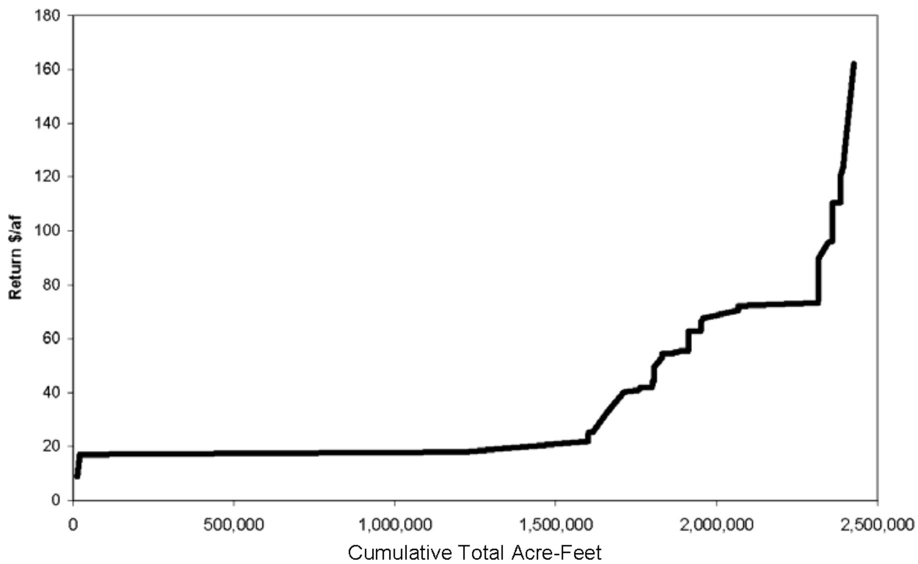

Figure 9. Profits per acre-foot returned on Colorado River water used in the production of selected crops in the Lower Colorado River Basin. [9]

While these figures do not necessarily reflect the amount at which any given water user would be willing to take part in a part-year fallowing program or agree to a dry-year option, they do suggest that if an open, market-based approach is used to identify potential participants, a number of water users in the Lower Basin would probably be willing to temporarily reduce or forgo the use of water for agricultural production in a price range between $20 and $100 per acre-foot (as the sale of water in this range would produce equal or greater monetary returns to the user than the use of water to irrigate crops).

In order to mitigate third-party impacts of fallowing, the federal government could establish a drought economic adjustment fund that would provide economic development grants to affected communities in the counties of origin. These funds preferentially would go to established county-based farm labor assistance programs to the extent that such programs exist, and could include lump sum payments to displaced workers based on a percentage of foregone annual income.

[9] This graph has not been published elsewhere. For methodology, please contact Jennifer Pitt at jpitt@environmentaldefense.org. A study using similar methodology, but limited to crop values in the Wellton-Mohawk Irrigation and Drainage District, has been published previously (Pitt et al., New Water for the Colorado River: Replacing the Bypass Flow, 6 U. Denver Water L. Rev. 68 (2002)). The study found a range of prices similar to that represented here for profits derived from water use in that area.

Using these assumptions for water acquisition costs, Table 1 suggests the approximate range of costs for implementing each of the conservation triggers under the CBS policy.

Table 1. Approximate federal and power/water user cost of implementation of CBS policy conservation trigger levels (assumes that water can be acquired temporarily for $20 - $100/acre-foot, and that the annual federal bypass obligation of 110,000 acre-feet has not otherwise been satisfied).

Trigger	Conservation required	Federal obligation (bypass + 50%)	Federal cost (millions)	Remaining Obligation	Water user cost (millions)	Power Surcharge (millions)	User cost per af (all Lower Basin users)
1075-1100	200,000 af	155,000 af	$3 - $15.4	45,000 af	$0.45 - $2.3	$0.45 - $2.3	$0.06 - $0.30
1050-1075	400,000 af	255,000 af	$5 - $25.4	145,000 af	$1.5 - $7.3	$1.5 - $7.3	$0.19 - $0.97
Below 1050	600,000 af	355,000 af	$7 - $35.4	245,000 af	$2.5 - $12.3	$2.5 - $12.3	$0.33 - $1.63

Cost of Not Implementing "Conservation Before Shortage" Policy

Although the "Conservation Before Shortage" policy would impose notable costs on water and power users, and on taxpayers generally, these costs should be compared with the much larger financial costs that would occur if the Secretary were to impose involuntary, uncompensated shortages, as well as the costs due to the lack of certainty and reliability that would exist without the CBS policy. The recent drought and decrease in power production at both Hoover Dam and Glen Canyon Dam point to the dramatic costs imposed by the loss of reservoir storage.

If Lake Mead falls to 1050 feet, power rates will need to be increased to an approximate composite rate of 2.31 cents/kWh, which is a 44.3% increase over current rates. Replacement power purchases would be (depending on the user) 2.9 to 3.7 times the Hoover rate. In FY03, replacement power may have cost customers an additional $24 million.

Attachment B

Taking ICS to Mexico: International Opportunities in the Seven States Agreement

This attachment to Appendix K contains the text of a proposal to expand the ICS mechanism to include Mexico.

Taking ICS to Mexico:
International Opportunities in the Seven States Agreement

Introduction

The Seven Basin states recently reached agreement on a far-reaching proposal to improve the management of Colorado River system water through conjunctive management of Lakes Mead and Powell, modification and extension of the existing interim surplus guidelines, and the adoption of shortage guidelines. Perhaps most significantly, this agreement introduces of a series of new mechanisms to increase flexibility within the Lower Basin delivery system and water allocations, including the creation of a new category of water: "Intentionally Created Surplus," which can be generated through extraordinary conservation measures or the funding of system efficiency improvements, and the recognition of water exchanges.

At the present time, the states' proposal is largely concerned with operations between and among the Basin states, particularly the states of the Lower Basin, although some elements of the proposal (such as water exchanges) have apparently contemplated Mexican participation. However, it would appear that significant benefits for U.S. water users, Mexican water users, and the environment could also be derived from expressly extending portions of the proposed agreement to water users in Mexico – while helping Mexican users to more readily bear burdens that could otherwise be imposed by the alterations proposed in the states' accord.

In particular, an extension of proposed policies related to Intentionally Created Surplus (ICS), system efficiency improvements, and water exchanges to include water users in Mexico could provide significant assistance in resolving difficult issues related to urban, agricultural, and environmental water supplies in Mexico, while opening enormous opportunities for both U.S. and Mexican water users to obtain water supplies via funding of irrigation efficiency improvements, the construction of urban water infrastructure, water supply replacement or enhancement, desalination, and other projects. These credits could be used to firm up urban water supplies in both countries, engage in long-studied environmental restoration projects in the Delta, and increase flexibility in Mexico's agricultural sector – creating economic, environmental, and social benefits in both countries while offering the United States and Mexico a venue for cooperation in the otherwise contentious area of water management at the border.

These outcomes would meet all three of the purposes identified in the Basin States' original proposal: improving cooperation and communication, providing additional security and certainty in the water supply of the Colorado River System, and avoiding circumstances which could otherwise form the basis for claims or controversies over the Colorado River Compact and other applicable provisions of the Law of the River.

While an extension of this agreement to include Mexico would likely need to occur on a different timeframe than for the domestic implementation of the agreement, the domestic process should at least not close the door on an international program, and would preferably encourage the initiation of binational discussions on the issue. Since critical elements of the states' current proposal – most notably the proposed shortage policy and proposed policies for unilateral water exchanges – will already require consultation with Mexico and/or the adoption of a new Minute, these opportunities could be considered in the same diplomatic process.

Binational Challenges for the Seven States' Agreement

Mexico has no storage system for Colorado River water, and as such, is effectively dependent on the U.S. reservoir system to guarantee water deliveries to meet municipal and agricultural demands. In addition, although the Mexicali Valley has significant groundwater resources, Mexico does not currently operate a water bank or other shortage mitigation program comparable to those in place in the United States (e.g., the Arizona Water Bank). At the same time, the lack of storage in Mexico effectively prevents Mexico from accumulating reserve supplies that could be used to meet environmental needs in Mexico (such as pulse flooding the in Delta region, which has been identified as a necessary precondition to effective restoration of key riparian areas). In the face of a rapidly growing population, ongoing efficiency and water accounting issues in its agricultural sector, and increasing pressure to protect and restore critical environmental resources in the Delta, Mexico faces a uniquely challenging situation with regard to the management of its water resources.

Of particular concern for Mexico in the states' proposal could be the provisions related to the implementation of shortages on the Lower Colorado. Although the Treaty of 1944 provides that Mexico is to share "proportionately" with U.S. users in times of "extraordinary drought," the precise meaning of this provision remains unclear, and it has never been invoked since the time of the Treaty's execution. The states' agreement, for the first time, unilaterally and precisely defines a set of proposed parameters under which shortages would be implemented against the Mexican allocation. Because Mexico has no readily available mechanisms to reduce or mitigate against shortage impacts on its users (such as reservoir storage or water banking), the potential for shortages will cause understandable concern for Mexican water users – similar to those that have arisen among low-priority users in the U.S.

Similarly, although conjunctive management of Lakes Mead and Powell as proposed in the states' agreement will doubtless help to reduce the probability that such shortages will actually occur, this will potentially come at the cost of decreasing the probability of future spills from these reservoirs in the future, since reservoirs may be drawn down further in the event of drought, increasing available capacity to absorb flood events in the future. The states' proposal also appears likely to create incentives to further increase the efficiency of U.S. water delivery systems by providing opportunities to receive ICS credits for the funding of these projects (e.g., Southern Nevada Water Authority's proposed funding of the Drop 2 reservoir); these projects will further reduce normal-year deliveries to Mexico. Combined with gradually increasing efficiency in agricultural water use, this will continue to pose challenges for the maintenance of critical environmental values in the Delta, which receive virtually all of their current water supplies from agricultural return flows, excess deliveries, canal leakage, and occasional flood events.

However, the states' proposal also offers a potential opportunity to promote binational solutions to these concerns as well as a broader suite of water issues in the border region – particularly insofar as it could be used to promote improvements in agricultural efficiency, water infrastructure, and municipal water quality and supply in Mexico. A brief discussion of these opportunities is provided below, together with examples of how particular programs might work. Of course, any projects undertaken would require the review, approval, and continuing oversight of both countries. However, it is critical to note that each of these programs could be undertaken without altering Mexico's basic Treaty entitlement to Colorado River water; any decrease (or increase) in Treaty deliveries would be matched by a mutually agreed-to compensation program or a proportionate increase (or decrease) in water deliveries in a later year. None of these programs would change Mexico's right to Colorado River water deliveries under the 1944 Treaty.

Expanding Three Elements of the States' Proposal to Mexico: How It Could Work

Intentionally-Created Surplus (ICS)

Under the states' proposal, a contractor could generate "ICS credits" by engaging in extraordinary conservation activities that have the effect of reducing the use of Colorado River water. These activities could include land fallowing, canal lining, desalination, or other extraordinary conservation measures agreed to by the states, so long as they result in the savings of water that would otherwise have been beneficially used as a part of a state's basic entitlement (surplus water cannot be used), the contractor plans and identifies the intended savings in advance (by September 15 of the preceding year), and the credits are first used to offset any delivery overruns.

These ICS credits would then be stored in Lake Mead for use by the contractor at some future time, subject to annual reductions to account for storage losses to reservoir evaporation, and a 5% "system tax" that would accrue to the benefit of the river system as a whole.The remaining credits could then be used during any year with "normal" operating conditions. During shortage or surplus conditions, the credits could not be used, and they would be reduced on a pro-rata basis in the event of a spill. However, for the purposes of determining calendar year declarations of surplus, normal, and shortage conditions, stored water that is subject to ICS credits would be considered system water – helping to keep reservoir levels higher in Powell and Mead and avoid shortages in the Lower Basin.

ICS credits would be subject to both yearly and cumulative maximums for each state, with California limited to no more than 400,000 acre-feet per year and a total credit of 1.5 million acre-feet, and Arizona and Nevada to 100,000 and 125,000 acre-feet per year, respectively, and total credits of 300,000 acre-feet. Recovery of ICS credits is similarly limited to 400,000 acre-feet annually for California and 300,000 acre-feet annually for Arizona and Nevada.

- How it could work in Mexico:[1]
    - Mexican users could engage in extraordinary conservation activities in Mexico with the effect of reducing actual beneficial use such that deliveries to Mexico under the Treaty could be temporarily reduced below 1.5 million acre-feet in any one year. This would generate ICS credits that would be available for delivery to Mexico in later years, under the same rules applicable to U.S. users, resulting in temporary increases in deliveries above the 1.5 million acre-foot Treaty obligation.
        - Example: Pronatura Sonora pays to temporarily fallow low-productivity lands in the Mexicali Valley, saving 30,000 acre-feet of water a year over a period of years. Treaty deliveries in each year are accordingly reduced below 1.5 million acre-feet, resulting in increased storage in Lake Mead. Pronatura receives an ICS credit which it can deliver to Mexico in a future year as a pulse flow for a riparian restoration project (after reducing the ICS credit for reservoir evaporation and paying the 5% system tax).

System Efficiency Projects

In addition to creating ICS through extraordinary conservation activities for existing uses of Colorado River water, the states' proposal allows for Colorado River users to receive ICS credits in exchange for making capital contributions to projects that would increase the overall efficiency of the Colorado River delivery system. The credits would comprise a portion of the water saved through the efficiency project, and would not be stored, but would rather be provided to the user that developed the credit on a predetermined schedule for some period of years.

- How it could work in Mexico: Mexican or U.S water users could fund delivery system efficiency improvements and receive proportionate amounts of temporary ICS credits for their investments that could be used under the same rules applicable under the states' proposal. These temporary credits would have the effect of either increasing (if funded by a Mexican user) or reducing (if funded by a U.S. user) Treaty deliveries to Mexico for an agreed period of time. After the temporary ICS credits expired, the system efficiency improvement would accrue to the country in which the project was undertaken.
    - Example: Metropolitan Water District develops a cooperative program with CNA and the U.S. federal government to invest in upgrades to the Mexicali Valley irrigation system, including canal lining and water

[1] The legal mechanism for implementing the extension of ICS and water exchanges to Mexico is discussed below.

accounting infrastructure, resulting in significant savings of water that would otherwise have been lost in the delivery system while improving or at least maintaining agricultural productivity. MWD receives a fixed amount of ICS credits for a period of years that can be used as a "bridge" supply until permanent water transfers from U.S. agricultural sources are completed. After the expiration of that period, all ICS credits revert to Mexico. Mexico, in turn, commits to dedicate a portion of the water saved to natural habitat restoration in the Colorado River Delta. With the approval of the U.S. Fish and Wildlife Service and appropriate international agreements, this could even result in some partial credit under the Multi-Species Conservation Program. Mexico uses the bulk of efficiency savings from the program to improve urban and agricultural water supplies, including offsetting expected impacts from the lining of the All-American Canal.

Water Exchanges

Finally, the states' proposal allows Colorado River users in the Lower Basin to secure additional water supplies by funding the development of a non-Colorado River System water supply in one state for use in another state by exchange. The new water supply would be used in place of the Colorado River water supply, allowing the user that provided the funding to use the Colorado River water that is no longer used through and agreement with the Secretary of the Interior. The states' proposal expressly contemplates exchanges with Mexico, albeit only unilateral exchanges in which non-Colorado River System supplies would be developed in Mexico, with the savings used in the United States.

- How it could work in Mexico: This program could be extended to a bilateral program in which water could be exchanged in either direction, with exchanges resulting in commensurate increases or decreases in Treaty deliveries (indeed, it is unclear why Mexico would agree to a purely unilateral program as proposed by the states).

Opportunities in Mexico

The examples cited above suggest just a few of the opportunities which could be explored if the states' proposal could be extended to users in Mexico - opportunities that could help not only to offset the impacts of the states' proposal, but also to meaningfully improve the tools available to meet human and environmental needs in the border region.

Over the years, there have been a number of proposals suggesting means by which the United States and Mexico might cooperate to improve both agricultural efficiency and municipal water quality in the border region. Notably, in 1991, the United States Bureau of Reclamation (BOR) and the Comisón Nacional del Agua (CNA) released a joint proposal entitled "International Cooperative Water Conservation and Irrigation Efficiency Improvement Program between the Republic of Mexico and the United States of America" that was championed by Dennis Underwood. This proposal noted similarities between cropping patterns and irrigation methods in the Imperial and Mexicali Valleys, and based on the experience of municipal and industrial users in California with investment in efficiency improvements (that were otherwise beyond the means of farmers in the region), suggested that similar investments in the Mexicali Valley could produce significant short and long-term water supply benefits.

Observations of water management in the Mexicali Valley suggest that there remain significant opportunities for improving water delivery and use through system automation, operational changes to improve the timing and quantity of deliveries, conversion to high capacity farm turnouts, canal lining, spill interception, land leveling, installation of canal turnouts for rapid delivery, improved cropping patterns, changed field irrigation practices and adaptation to low water-use technologies, improvements to drainage, and improved maintenance procedures. Water conserved from these efforts could be beneficial in terms of providing replacement supplies in the face of shortages, reducing dependence of local farmers on groundwater supplies, and providing environmental benefits.

For example, the Mexicali Irrigation District (DDR 0014) reports approximately 645,000 af/yr (800 mcm/yr) in conveyance losses that are recoverable (as opposed to conveyance losses that recharge groundwater supply[2]). Based on some extremely rough estimates, of this total conveyance loss, approximately 150,000 af/yr (200 mcm/yr) may be attributable to seepage from major canals. Much of this latter seepage apparently occurs along approximately 70 kilometers of unlined canal sections, which could potentially be lined, by one estimate, for around $600 million pesos (US $56 million). These include the Reforma canal (28 km, estimated lining cost $150 million pesos or US $13.7 million), the Revolución canal (20 km, no lining estimate available), the Alimenta del Sur canal (5.5 km, no lining estimate available), and the Nuevo Delta canal (16 km, lining cost $300 million pesos or US$27.4 million).[3] None of these sections reportedly cross or recharge aquifers from which significant amounts of groundwater are recovered or that support river flows or wetlands. The total estimated costs of all of these lining projects would likely be comparable to the $80-$90 million construction cost for the Drop 2 storage reservoir, but could potentially produce a far larger quantity of savings at a much lower cost per acre-foot.

The opportunities associated with an international expansion of the seven states proposal are not limited to agricultural water use. Mexico is currently experiencing increasing risks of shortages to municipal and industrial water supplies in the Mexicali Valley and the major communities to the west of the Valley – as well as significant concerns related to water quality due to high water salinity in the Mexicali Valley region and water

[2] The extent to which the aquifers are interconnected and to which such losses are recoverable without impacting groundwater recharge that is pumped for irrigation or that supports river flows or wetlands should be verified by geo-hydrologic investigation, modeling, and monitoring.

[3] These figures are rough estimates based on informal discussions with a former employee of CONAGUA and are provided for illustrative purposes only. The estimated costs for lining the Nuevo Delta canal reach are apparently high due the location of this reach over a geologic fault.

pollution. These concerns create a significant opportunity for the use of tools such as ICS and system efficiency investments to improve these supplies – and perhaps just as significantly, opportunities to invest in desalination or other technologies to replace low-quality Colorado River supplies or otherwise improve water quality for municipal use.

Creating a Delta Water Supply

These proposals would necessarily require consideration of environmental needs in the Colorado River Delta. As numerous studies have pointed out, the remaining Delta ecosystem largely depends on “system inefficiencies” for its water supply – such as return flows from agriculture, effluent flows, canal leakage, and releases in excess of Treaty requirements from the U.S. These proposals would create inevitable incentives to reduce these inefficiencies in Mexico (just as the states’ proposal creates incentives to reduce inefficiencies in the United States). As such, it is essential that any program in Mexico provide a mechanism for replacing (or improving) the Delta’s water supplies while meeting critical agricultural and municipal needs.

To a certain extent, this issue could be addressed through implementation of an ICS mechanism in Mexico. Several recent studies, including a recent Packard Report, “Immediate Options for Augmenting Water Flows to the Colorado River Delta in Mexico,” have investigated options related to taking existing, marginal agricultural lands in Mexico out of production and utilizing the water associated with those lands for environmental purposes. The Sonoran Institute and Pronatura Noroeste-Sonora, together with other NGO partners, are currently in the process of exploring just such an option, focusing on highly marginal lands in the southern portions of the Mexicali Valley where salt buildup and shallow groundwater create economic challenges for agricultural production. Although funding for these efforts has not yet been secured, mechanisms have been identified for holding water derived from these lands via water trusts, wheeling water to appropriate locations, and designating protected receiving areas in the riparian corridor to ensure that water is used for environmental benefit.

Nevertheless, reliance on non-governmental organizations alone will not guarantee the continued availability of water to support key ecosystem values in the Delta. To ensure the continued viability of the Delta ecosystem – and to avoid ongoing uncertainties for U.S. and Mexican water users associated with environmental challenges to water allocations – any international program should include a process for securing necessary environmental flows, such as the dedication of a portion of the proceeds of various water-saving programs to provide a permanent, reliable supply of water to replace current supplies and support environmental uses in the Delta.

Making a Binational Proposal Work: Changes to the States’ Proposal and the Treaty of 1944

Implementation of a binational program for Intentionally-Created Surplus, efficiency improvements, and water exchanges would of course require an alteration to the current framework of the Treaty of 1944 between the United States and Mexico. Currently, the

Treaty requires the delivery of 1.5 million acre-feet of water to Mexico annually, absent surplus or extraordinary drought.

It should be noted that none of the proposals discussed above would have the result of altering the basic entitlements of either the United States or Mexico under the Treaty; regardless of the program developed, Mexico would continue to have the same 1.5 million acre-foot entitlement to Colorado River water even if the precise timing (or the place) of the delivery of that entitlement was altered). As such, the implementation of such programs should not result in any conflict with other provisions of the Law of the River, and in particular the Colorado River Compact, since no change in position between the U.S. and Mexico would occur.

However, the implementation of the proposals discussed above would require temporary reductions or increases in deliveries above or below this basic number to the extent that water was stored or released from Lake Mead in response to programs generating ICS via extraordinary conservation or investment in system efficiency improvements, or else via water exchanges between parties in the U.S. and Mexico. As such, an appropriate alteration to the delivery rules under the Treaty would be required.

This could be effectively accomplished via the addition of a new Minute to the Treaty of 1944, adopted through the International Boundary and Water Commission (IBWC). Pursuant to the Treaty of 1944, IBWC is authorized to build and manage waterworks, to resolve problems and negotiate further agreements regarding international waters, and to settle treaty-interpretation disputes.[4] The Treaty grants broad jurisdiction to IBWC to "plan, build, and manage water works; to enter into further agreements regarding international waters," and to "settle all differences that may arise between the two Governments with respect to the interpretation or application of this Treaty, subject to the approval of the two Governments."[5] Assuming appropriate approvals could be obtained from the U.S. and Mexican federal governments, IBWC should thus have appropriate authority under the Treaty to implement a binational program for ICS, water efficiency improvements, and water exchanges based on the same rules applicable to the other Lower Basin states. In addition, any international agreement would need to address a number of technical issues that would be associated with these programs, including the development of appropriate accounting methods for water conservation, and the identification of conservation priorities and opportunities to which water generated for ecosystem use might be put.

Such a new Minute could be modeled after the new regulations or guidelines that would need to be adopted to implement the states' proposal in the U.S. As the shortage criteria for deliveries to Mexico and the states' existing proposal for unilateral water exchanges would also likely require implementation via a new Minute, these issues could be explored under the same diplomatic process.

---

[4] *See* Mexico-U.S. Water Treaty of 1944, Art. 24, 59 Stat. at 1255-1257.
[5] *See* Mexico-U.S. Water Treaty of 1944, Art. 24(d).

Obviously, these proposals would require diplomatic discussions between the U.S. and Mexico before they could be appropriately implemented, which would place the implementation of an international ICS program on a different timeframe than that anticipated for the adoption of a domestic program. However, as the operation of such a program would likely require consideration of environmental concerns under the National Environmental Policy Act, as well as appropriate recognition in any guidelines that may be adopted by the Secretary to implement the states' agreement. For example, the rules used to guide the storage and release of ICS credit water would need to recognize the potential for delivery of ICS to Mexico pursuant to the Treaty of 1944, rather than solely by reference to Section II(B)(2) of the Decree and forbearance agreements between the states. Similarly, rules defining the maximum amount of ICS credits that could be generated in any one year, and the cumulative amount that could be subject to storage in Lake Mead, would also need to reference the potential for Mexican use of this system.

To ensure that a potential international program could be eventually implemented in conjunction with the states' proposed program, and assuming that there is interest among Mexican water users in such an international program, we suggest that the proposals discussed above should be appropriately considered as a part of the U.S. Bureau of Reclamation's ongoing public process for the "Development of Lower Colorado River Basin Shortage Guidelines and Coordinated Management Strategies for Lakes Powell and Mead Under Low Reservoir Conditions."

BILLING CODE 4310–JA–P

DEPARTMENT OF THE INTERIOR

Bureau of Reclamation

Colorado River Reservoir Operations: Development of Management Strategies for Lake Powell and Lake Mead Under Low Reservoir Conditions

AGENCY: Bureau of Reclamation, Interior.

ACTION: Notice to solicit comments and hold public meetings on the development of management strategies for Lake Powell and Lake Mead, including Lower Basin shortage guidelines, under low reservoir conditions.

SUMMARY: The Secretary of the Interior (Secretary) has directed the Bureau of Reclamation (Reclamation) to develop additional Colorado River management strategies to address operations of Lake Powell and Lake Mead under low reservoir conditions. It is anticipated that, among other potential elements, these strategies could identify those circumstances under which the Department of the Interior (Department) would reduce annual water deliveries, and the manner in which annual operations would be modified.

DATES AND ADDRESSES: Two public meetings will be held to solicit comments on the content, format, mechanism, and analysis to be considered during the development of management strategies for Lake Powell and Lake Mead under low reservoir conditions. Oral and written comments will be accepted at the public meetings to be held at the following locations:

- *Tuesday, July 26, 2005*–10 a.m. to 12 noon, Henderson Convention Center, Grand Ballroom, 200 South Water Street, Henderson, Nevada.
- *Thursday, July 28, 2005*–10 a.m. to 12 noon, Hilton Salt Lake City Center, Topaz Room, 255 South West Temple, Salt Lake City, Utah.

Written comments on the proposed development of these strategies may be sent by close of business on *Wednesday, August 31, 2005,* to: Regional Director, Bureau of Reclamation, Lower Colorado Region, Attention: BCOO–1000, P.O. Box 61470, Boulder City, Nevada 89006–1470, fax at 702–293–8156, or e-mail at *strategies@lc.usbr.gov;* and/or Regional Director, Bureau of Reclamation, Upper Colorado Region, Attention: UC–402, 125 South State Street, Salt Lake City, Utah 84318–1147, fax at 801–524–3858, or e-mail at *strategies@uc.usbr.gov.*

FOR FURTHER INFORMATION CONTACT: Terrance J. Fulp, Ph.D., at 702–293–8500 or e-mail at *strategies@lc.usbr.gov;* and/or Randall Peterson at 801–524–3633 or e-mail at *strategies@uc.usbr.gov.* If special assistance is required regarding accommodations for attendance at either of the public meetings, please call Nan Yoder at 702–293–8495, fax at 702–293–8156, or e-mail at *nyoder@lc.usbr.gov* no less than 5 working days prior to the applicable meeting(s).

SUPPLEMENTARY INFORMATION: In recent years the Department has undertaken a number of initiatives to improve the efficient and coordinated operation and management of the Colorado River. For example, a number of Indian water rights settlements have been enacted and implemented, while additional settlements are under active negotiation. Important programs have been developed in the Upper and Lower Basins to address conservation of endangered species. Scientific investigations are proceeding under the framework of the Glen Canyon Adaptive Management Program to study the impacts to and improve the values for which the Grand Canyon National Park and the Glen Canyon National Recreation Area were established. In 2003, water users in California executed agreements that will assist California to limit its use of water from the Colorado River to its normal year apportionment of 4.4 million acre-feet (maf).

More recently a new management challenge has emerged on the Colorado River. The Colorado River Basin has experienced the worst five-year drought in recorded history. Drought in the Basin has impacted system storage, while demands for Colorado River water supplies have continued to increase. During the period from October 1, 1999, to October 1, 2004, storage in Colorado River reservoirs fell from 55.7 maf to 29.7 maf.

In the future, low reservoir conditions may not be limited to drought periods as additional development of Colorado River water occurs. The Colorado River is of strategic importance in the southwestern United States for water supply, hydropower production, recreation, fish and wildlife habitat, and other benefits. In addition, the Republic of Mexico has an allocation to the waters of the Colorado River pursuant to a 1944 treaty with the United States.

In a May 2, 2005, letter to the Governors of the Colorado River Basin States, issued in the context of the 2005 Annual Operating Plan mid-year review, the Secretary directed Reclamation to develop additional strategies to improve coordinated management of the reservoirs in the Colorado River system. Pursuant to that direction, Reclamation conducted a public consultation workshop on May 26, 2005, in Henderson, Nevada, and has prepared this **Federal Register** notice. In order to assure the continued productive use of the Colorado River into the future, Reclamation is soliciting public comments on, at a minimum, the development of management strategies for the operation of Lake Powell and Lake Mead under low reservoir conditions.

It is the Department's intent that the development of additional management strategies, including Lower Basin Shortage Guidelines, will provide guidance to the Secretary's Annual Operating Plan decisions, and provide more predictability to water users throughout the Basin, particularly those in the Lower Division States of Arizona, California, and Nevada. For example, in 2001 the Department adopted Interim Surplus Guidelines (66 FR 7772) that are used by the Secretary in making annual determinations regarding ''Normal'' and ''Surplus'' conditions for the operation of Lake Mead. Among other provisions, these Guidelines have allowed the Department and entities in Arizona, California, and Nevada that rely on the Colorado River greater predictability in identifying when Colorado River water in excess of 7.5 maf will be available for use within these three states. In contrast, at this time the Department does not have detailed guidelines in place for annual determinations of releases from Lake Mead of less than 7.5 maf to water users in the three Lower Division States (often referred to as a ''shortage'' condition on the lower Colorado River). Therefore, water users who rely on the Colorado River in these states are not currently able to identify particular reservoir conditions under which the Secretary would release less than 7.5 maf for use on an annual basis. Nor are these water users able to identify the amount of any potential future annual reductions in water deliveries. By developing additional management strategies, these users would be better able to plan for periods of less than full water deliveries. Additional operational tools may also facilitate conservation of reservoir storage, thereby minimizing the adverse effects of long-term drought or low-reservoir conditions in the Colorado River Basin.

Over the past year, the seven Colorado River Basin States have been proactively discussing strategies to address the current system-wide drought in the Colorado River Basin. In addition, Reclamation has conducted detailed briefings for stakeholders in the Colorado River Basin and other interested entities regarding future scenarios for Colorado River operations. Reclamation will integrate available technical information in the upcoming development of additional management strategies for Colorado River operations.

Reclamation intends to utilize a public process during the development of management strategies for Lake Powell and Lake Mead under low reservoir conditions. By this notice, Reclamation invites all interested members of the general public, including the seven Colorado River Basin States, Indian Tribes, water and power contractors, environmental organizations, representatives of academic and scientific communities, representatives of the recreation industry, and other organizations and agencies to present oral and written comments concerning the content, format, mechanism, and analysis to be considered during the development of these proposed strategies.

Reclamation has not yet determined the appropriate level of National Environmental Policy Act (NEPA) documentation for the upcoming development of additional management strategies. However, to ensure timely consideration of technical information and public comment, Reclamation is proceeding, at this time, as if the development of additional management strategies would require preparation of an Environmental Impact Statement. Information received by Reclamation pursuant to this **Federal Register** notice and the upcoming public meetings will be analyzed in order to define the nature of any proposed federal actions, the level of appropriate NEPA documentation, and the need, if any, for additional scoping activities. In addition to NEPA documentation, other compliance activities, as appropriate, will be undertaken pursuant to applicable Federal law.

Public Disclosure

Written comments, including names and home addresses of respondents, will be made available for public review. Individual respondents may request that their home address be withheld from public disclosure, which will be honored to the extent allowable by law. There may be circumstances in which respondents' identity may also be withheld from public disclosure, as allowable by law. If you wish to have your name and/or address withheld, you must state this prominently at the beginning of your comment. All submissions from organizations, business, and from individuals identifying themselves as representatives or officials of organizations or businesses, will be made available for public disclosure in their entirety.

Dated: June 6, 2005.

Darryl Beckmann,

Deputy Regional Director—UC Region, Bureau of Reclamation.

Dated: June 7, 2005.

Robert W. Johnson,

Regional Director—LC Region, Bureau of Reclamation.

DEPARTMENT OF JUSTICE

Office of Community Oriented Policing Services, Agency Information Collection Activities: Proposed Collection; Comments Requested

ACTION: 60-day notice of information collection under review: Annual Report to Congress—Expired COPS Awards Exceeding $5 Million.

The Department of Justice (DOJ) Office of Community Oriented Policing Services (COPS) has submitted the following information collection request to the Office of Management and Budget (OMB) for review and approval in accordance with the Paperwork Reduction Act of 1995. The proposed information collection is published to obtain comments from the public and affected agencies. The purpose of this notice is to allow for 60 days for public comment until August 15, 2005. This process is conducted in accordance with 5 CFR 1320.10.

If you have comments especially on the estimated public burden or associated response time, suggestions, or need a copy of the proposed information collection instrument with instructions or additional information, please contact Rebekah Dorr, Department of Justice Office of Community Oriented Policing Services, 1100 Vermont Avenue, NW., Washington, DC 20530.

Written comments and suggestions from the public and affected agencies concerning the proposed collection of information are encouraged. Your comments should address one or more of the following four points:

—Evaluate whether the proposed collection of information is necessary for the proper performance of the functions of the agency, including whether the information will have practical utility;
—Evaluate the accuracy of the agency's estimate of the burden of the proposed collection of information, including the validity of the methodology and assumptions used;
—Enhance the quality, utility, and clarity of the information to be collected; and
—Minimize the burden of the collection of information on those who are to respond, including through the use of appropriate automated, electronic, mechanical, or other technological collection techniques or other forms of information technology, *e.g.*, permitting electronic submission of responses.

Overview of This Information Collection

(1) *Type of Information Collection:* New Collection.

(2) *Title of the Form/Collection:* Annual Report to Congress—Expired COPS Awards Exceeding $5 Million.

(3) *Agency form number, if any, and the applicable component of the Department sponsoring the collection:* Form Number: None. Office of Community Oriented Policing Services.

(4) *Affected public who will be asked or required to respond, as well as a brief abstract:* Primary: State, Local, or Tribal Government. Law enforcement agencies that are recipients of COPS grants over $5,000,000 that are programmatically and financially closed out or that otherwise ended in the immediately preceding fiscal year.

(5) *An estimate of the total number of respondents and the amount of time estimated for an average respondent to respond/reply:* It is estimated that approximately 10 respondents annually will complete the form within one hour.

(6) *An estimate of the total public burden (in hours) associated with the collection:* There are approximately 10 total annual burden hours associated with this collection.

BILLING CODE 4312–51–P

DEPARTMENT OF THE INTERIOR

Bureau of Reclamation

Colorado River Reservoir Operations: Development of Lower Basin Shortage Guidelines and Coordinated Management Strategies for Lake Powell and Lake Mead Under Low Reservoir Conditions

AGENCY: Bureau of Reclamation, Interior.

ACTION: Notice of intent to prepare an environmental impact statement (EIS) and notice to solicit comments and hold public scoping meetings on the development of Lower Basin shortage guidelines and coordinated management strategies for the operation of Lake Powell and Lake Mead under low reservoir conditions.

SUMMARY: Pursuant to the National Environmental Policy Act (NEPA), the Bureau of Reclamation (Reclamation) proposes to conduct public scoping meetings and prepare an EIS for the development of Lower Colorado River Basin Shortage Guidelines and Coordinated Management Strategies for Operation of Lake Powell and Lake Mead Under Low Reservoir Conditions. The Secretary of the Interior (Secretary) has directed Reclamation to develop additional Colorado River management strategies to address operations of Lake Powell and Lake Mead under low reservoir conditions.

The proposed action is to develop these guidelines and strategies. Through the NEPA process initiated by this **Federal Register** notice, Reclamation is considering development of: (1) Specific guidelines that will identify those circumstances under which the Department of the Interior (Department) would reduce annual water deliveries from Lake Mead to the Lower Basin States below the 7.5 million acre-feet (maf) Lower Basin apportionment and the manner in which those deliveries would be reduced, and (2) coordinated management strategies for the operation of Lake Powell and Lake Mead.

Alternatives to be analyzed in the EIS have not been developed at this time and will be developed through the NEPA process, including through the upcoming EIS scoping meetings.

DATES AND ADDRESSES: Four public meetings will be held to solicit comments on the scope of specific shortage guidelines and other coordinated management strategies and the issues and alternatives that should be analyzed. Oral and written comments will be accepted at the public meetings to be held at the following locations:

- Tuesday, November 1, 2005—6 p.m. to 8 p.m., Hilton Salt Lake City Center, Topaz Room, 255 South West Temple, Salt Lake City, Utah.
- Wednesday, November 2, 2005—6 p.m. to 8 p.m., Adam's Mark Hotel, Tower Court D, 1550 Court Place, Denver, Colorado.
- Thursday, November 3, 2005—6 p.m. to 8 p.m., Arizona Department of Water Resources, Third Floor, Conference Rooms A&B, 500 North Third Street, Phoenix, Arizona.
- Tuesday, November 8, 2005—6 p.m. to 8 p.m., Henderson Convention Center, Grand Ballroom, 200 South Water Street, Henderson, Nevada.

Written comments on the proposed development of these strategies may be sent by close of business on *Wednesday, November 30, 2005*, to: Regional Director, Bureau of Reclamation, Lower Colorado Region, Attention: BCOO–1000, PO Box 61470, Boulder City, Nevada 89006–1470, faxogram at (702) 293–8156, or e-mail at *strategies@lc.usbr.gov*; and/or Regional Director, Bureau of Reclamation, Upper Colorado Region, Attention: UC–402, 125 South State Street, Salt Lake City, Utah 84318–1147, faxogram at (801) 524–3858, or e-mail at *strategies@uc.usbr.gov*.

FOR FURTHER INFORMATION CONTACT: Terrance J. Fulp, PhD., at (702) 293–8500 or e-mail at *strategies@lc.usbr.gov*; and/or Randall Peterson at (801) 524–3633 or e-mail at *strategies@uc.usbr.gov*. If special assistance is required regarding accommodations for attendance at any of the public meetings, please call Nan Yoder at (702) 293–8495, faxogram at (702) 293–8156, or e-mail at *nyoder@lc.usbr.gov* no less than 5 working days prior to the applicable meeting(s).

SUPPLEMENTARY INFORMATION: In recent years the Colorado River Basin experienced the worst five-year drought

in recorded history. Drought in the Basin has impacted system storage, while demands for Colorado River water supplies have continued to increase. In the future, low reservoir conditions may not be limited to drought periods as additional development of Colorado River water occurs. The Colorado River is of strategic importance in the southwestern United States for water supply, hydropower production, recreation, fish and wildlife habitat, and other benefits. In addition, the Republic of Mexico has an allocation to the waters of the Colorado River pursuant to a 1944 treaty with the United States.

In 2001, the Department adopted Interim Surplus Guidelines (66 FR 7772) that are used by the Secretary in making annual determinations regarding ''Normal'' and ''Surplus'' conditions for the operation of Lake Mead. Since adoption, these Guidelines have, among other operational and management benefits, allowed the Department and entities in Arizona, California, and Nevada that rely on the Colorado River greater predictability in identifying when Colorado River water in excess of 7.5 maf will be available for use within these three States. In contrast, at this time the Department does not have detailed guidelines in place for annual determinations of releases from Lake Mead of less than 7.5 maf to water users in the three Lower Division States of Arizona, California, and Nevada (often referred to as a ''shortage'' condition on the lower Colorado River). Therefore, water users who rely on the Colorado River in these States are not currently able to identify particular reservoir conditions under which the Secretary would release less than 7.5 maf for use on an annual basis. Nor are these water users able to identify the amount of any potential future annual reductions in water deliveries.

Over the past year, the seven Colorado River Basin States have been proactively discussing strategies to address the recent period of system-wide drought in the Colorado River Basin. In addition, Reclamation has conducted detailed briefings for stakeholders in the Colorado River Basin and other interested entities regarding future scenarios for Colorado River operations.

Currently, each year, the Secretary establishes an Annual Operating Plan (AOP) for the Colorado River Reservoirs. The AOP describes how Reclamation will manage the reservoirs over a 12-month period, consistent with the Criteria for Coordinated Long-Range Operation of Colorado River Reservoirs Pursuant to the Colorado River Basin Project Act of September 30, 1968 (Long-Range Operating Criteria), the Decree entered by the U.S. Supreme Court in the *Arizona* v. *California* litigation, and other provisions of applicable Federal law. Reclamation consults annually with the Colorado River Basin States, Indian tribes, and other interested parties in the development of the AOP. Further, as part of the AOP process, the Secretary makes annual determinations under the Long-Range Operating Criteria regarding the availability of Colorado River water for deliveries to the Lower Division States. To meet the consultation requirements of Federal law, Reclamation also consults with the Colorado River Basin States, Indian tribes, and other interested parties during the five-year periodic reviews of the Long-Range Operating Criteria.

During the mid-year review of the 2005 AOP conducted this past spring, the Department received conflicting recommendations from the Colorado River Basin States regarding operations of Glen Canyon Dam for the remainder of the 2005 water year. In a May 2, 2005, letter to the Governors of the Colorado River Basin States, issued to complete the 2005 AOP mid-year review, the Secretary directed Reclamation to develop additional strategies to improve coordinated management of the reservoirs in the Colorado River system. Pursuant to that direction, Reclamation conducted a public consultation workshop on May 26, 2005, in Henderson, Nevada; issued a **Federal Register** notice soliciting public comments on June 15, 2005; and conducted public meetings on July 26 and July 28, 2005, in Henderson, Nevada, and Salt Lake City, Utah, respectively. Reclamation received a broad range of public comments and suggestions from these discussions, not all of which can be addressed in this proposed process. In addition, some suggestions may be part of ongoing or future efforts.

In order to assure the continued productive management and use of the Colorado River into the future, Reclamation is now soliciting public comments on the development of Lower Basin shortage guidelines and coordinated management strategies for the operation of Lake Powell and Lake Mead under low reservoir conditions. Reclamation will utilize a public process pursuant to NEPA. By this notice, Reclamation provides notice of its intent to prepare an EIS on this action, and provides notice of its upcoming EIS scoping meetings. Reclamation invites all interested members of the general public, including the seven Colorado River Basin States, Indian tribes, water and power contractors, environmental organizations, representatives of academic and scientific communities, representatives of the recreation industry, and other organizations and agencies to present oral and written comments concerning the format and scope of specific shortage guidelines and coordinated management strategies, and the issues and alternatives to be considered during the development of these proposed guidelines and strategies. Reclamation anticipates publishing a ''scoping report'' after completion of the public scoping meetings identified in this **Federal Register** notice.

All comments received will be considered as Reclamation develops formal alternatives under NEPA. Similar to the surplus guidelines referenced above, it is likely that these shortage guidelines will be interim in nature. It is the Department's intent that these guidelines and coordinated management strategies will provide guidance to the Secretary's AOP decisions, and provide more predictability to water users and the public throughout the Colorado River Basin, particularly those in the Lower Division States. The Department does not intend to evaluate the decommissioning of Glen Canyon Dam.

Public Disclosure

Written comments, including names and home addresses of respondents, will be made available for public review. Individual respondents may request that their home address be withheld from public disclosure, which will be honored to the extent allowable by law. There may be circumstances in which respondents' identity may also be withheld from public disclosure, as allowable by law. If you wish to have your name and/or address withheld, you must state this prominently at the beginning of your comment. All submissions from organizations, business, and from individuals identifying themselves as representatives or officials of organizations or businesses, will be made available for public disclosure in their entirety.

Dated: September 22, 2005.

Rick L. Gold,

Regional Director—UC Region, Bureau of Reclamation.

Dated: September 22, 2005.

Jayne Harkins,

Deputy Regional Director—LC Region, Bureau of Reclamation.

[FR Doc. 05–19607 Filed 9–29–05; 8:45 am]

BILLING CODE 4310–MN–P

L.3 Federal Register Volume 71, Number 62

respondents will be available for public review at the Ely Field Office during regular business hours 7:30 a.m. to 4:30 p.m., Monday through Friday, except holidays. Individual respondents may request confidentiality. If you wish to withhold your name and address from public review or disclosure under the Freedom of Information Act, you must state this prominently at the beginning of your comments. Such requests will be honored to the extent allowed by law. All submissions from organizations or businesses, and from individuals identifying themselves as representatives or officials of organizations or business, will be made available for public inspection in their entirety.

FOR FURTHER INFORMATION CONTACT: Penny Woods, BLM Nevada State Office, (775) 861–6466. You may also contact Ms Woods to have your name added to the EIS mailing list.

SUPPLEMENTARY INFORMATION: The LCLA Groundwater Development Project is being proposed by the Lincoln County Water District (LCWD) and would be located in southeastern Lincoln County. The proposed project would develop and convey groundwater in the Tule Desert and Clover Valley hydrographic basins to land recently sold by the BLM that is approximately 2 miles north of Mesquite, Nevada. This private land comprises the LCLA development area and consists of approximately 13,000 acres. The volume of water to be transported through the proposed facilities would be approximately 23,824 acre-feet per year. The water would be used to support development in the LCLA development area.

The proposed facilities include approximately 8 groundwater production wells (16 inch diameter) located in the Tule Desert and Clover Valley hydrographic basins, a 23-mile long water transmission pipeline (24 inch diameter), and lateral pipelines (12 inch diameter) to connect the transmission pipeline to the productions wells. The proposed width of the right-of-way for the transmission pipeline would be 30 feet with a temporary width of 60 feet during construction. The proposed width of the right-of-way for the lateral pipelines would be 20 feet with a temporary width of 60 feet during construction. The productions well site rights-of-way would be 100 feet × 100 feet with a temporary construction area of 100 feet × 200 feet. Access roads approximately 12 feet in width would be needed from existing roads in the Tule Desert area to each well site.

The proposed production wells would be located in the well field area authorized for the Toquop Energy Project, which is a 1100 MW gas-fired power plant. The proposed transmission pipeline would follow the same alignment as the approved water pipeline for the power plant. From the power plant, the transmission pipeline would proceed to the LCLA development area.

Electric lines, communication lines, and a natural gas pipeline would be located within the proposed transmission pipeline right-of-way. A pipeline bringing reclaimed water from the LCLA development area to the already authorized Toquop Energy Project site would also be in the proposed right-of-way.

The facilities would be located within and/or across the following public lands north of Mesquite, Nevada:

Mount Diablo Meridian

Tps. 6 to 12 S., Rgs. 69 and 71 E., various sections.

A map of the proposed project is available for viewing at the Bureau of Land Management, Ely Field Office, 702 North Industrial Way, Ely NV 89301.

Dated: March 21, 2006.

Amy Lueders,

Associate State Director, Nevada.

BILLING CODE 4310–HC–P

DEPARTMENT OF THE INTERIOR

National Park Service

Notice of Proposed National Natural Landmark Designation for the Irvine Ranch Land Reserve, CA

AGENCY: National Park Service, Interior.

ACTION: Notice of proposed National Natural Landmark designation.

SUMMARY: The National Park Service has evaluated and determined that the Irvine Ranch Land Reserve, located forty-five miles south of downtown Los Angeles, in Orange County, California appears to meet the criteria for national significance and proposes to recommend the site for designation as a National Natural Landmark. The public is invited to comment on this recommendation. The proposal will be considered by the National Park System Advisory Board at a meeting to be held on June 8, 2006 at Zion National Park, in the Majestic View Lodge, 2400 Zion Park Blvd., Springdale, Utah.

DATES: Written comments will be accepted until May 30, 2006.

ADDRESSES: Written comments should be sent to Steve Gibbons, National Natural Landmarks Coordinator, North Cascades National Park, 810 State Route 20, Sedro Woolley, Washington 98284, or to his Internet address: *Steve_Gibbons@nps.gov.*

FOR FURTHER INFORMATION CONTACT: Steve Gibbons at 360–856–5700, extension 306.

SUPPLEMENTARY INFORMATION: The Irvine Ranch Land Reserve represents significant biological resources of Mediterranean shrublands, including extensive areas of chaparral and coastal sage scrub associations. These chaparral and coastal sage scrub areas present one of the largest extant areas of this association remaining in the South Pacific Border Province. It is the presence of these large and relative undisturbed ecosystems and their inherent biological diversity that provide the uniqueness of this area. In commensurate with its biological significance the Irvine Ranch Land Reserve geologically represents a remarkably unique, long time-range stratigraphic succession that shows the linkage between tectonic framework, provenances, sedimentology, paleoenvironments, paleontology, paleoclimate, landscape evolution and geologic history. In this regard it is not only outstanding, but represents one of the most critical time intervals and locations in the evolution of the South Pacific Border Province.

Information on the National Natural Landmarks Program can be found in 36 CFR Part 62 or on the Internet at *http://www.nature.nps.gov/nnl.*

Dated: March 28, 2006.

Fran Mainella,

Director, National Park Service.

BILLING CODE 4312–HJ–P

DEPARTMENT OF THE INTERIOR

Bureau of Reclamation

Colorado River Reservoir Operations: Development of Lower Basin Shortage Guidelines and Coordinated Management Strategies for Lake Powell and Lake Mead, Particularly Under Low Reservoir Conditions

AGENCY: Bureau of Reclamation, Interior.

ACTION: Notice of public availability of a Scoping Summary Report on the development of Lower Basin shortage guidelines and coordinated management strategies for the operation of Lake

16342 Federal Register / Vol. 71, No. 62 / Friday, March 31, 2006 / Notices

Powell and Lake Mead, particularly under low reservoir conditions.

SUMMARY: Pursuant to the National Environmental Policy Act (NEPA) of 1969, as amended, and the Council on Environmental Quality's Regulations for Implementing the Procedural Provisions of NEPA, the Department of the Interior (Department) has issued a Scoping Summary Report on the development of Lower Basin shortage guidelines and coordinated management strategies for the operation of Lake Powell and Lake Mead, particularly under low reservoir conditions. The Scoping Summary Report provides a summary of the issues raised during the scoping process and describes the Department's current assessment of the proposed scope of the environmental analysis to be included in the draft environmental impact statement (EIS). The Department anticipates that the Draft EIS will be published in December 2006. The report also includes a summary of the issues raised and comments received during the scoping process. Among other things, the report identifies how the Department anticipates addressing these issues.

Dates and Addresses: The Department will accept, review, and incorporate, as appropriate, any additional public comments on the information contained in the Scoping Summary Report as part of the development of the Draft EIS, which the Department anticipates will be published in December 2006. The Department would prefer that any such comments be received by May 1, 2006, in order to allow full consideration during the development of the Draft EIS. Send written comments to: Regional Director, Bureau of Reclamation, Lower Colorado Region, Attention: BCOO–1000, P.O. Box 61470, Boulder City, Nevada 89006–1470; faxogram at (702) 293–8156; or e-mail at *strategies@lc.usbr.gov.*

The Scoping Summary Report is available on the Bureau of Reclamation's Web site at *http://www.usbr.gov/lc/region/g4000/strategies/index.html.* If you would like a printed copy of the report, please contact Nan Yoder at telephone (702) 293–8500; facsimile (702) 293–8156; e-mail: *strategies@lc.usbr.gov.*

FOR FURTHER INFORMATION CONTACT: Terrance J. Fulp, Ph.D., at (702) 293–8500 or e-mail at *strategies@lc.usbr.gov;* and/or Randall Peterson at (801) 524–3633 or e-mail at *strategies@lc.usbr.gov.*

SUPPLEMENTARY INFORMATION: The Department is publishing the Scoping Summary Report as a voluntary effort to assist in public understanding of this important process. Based upon information presented in the report and all information submitted to the Department as part of this process, the Department is now undertaking preparation of a Draft EIS.

Proposed Federal Action

The Bureau of Reclamation, acting on behalf of the Secretary of the Interior (Secretary), proposes to take action to adopt specific Colorado River Lower Basin shortage guidelines and coordinated reservoir management strategies to address operations of Lake Powell and Lake Mead, particularly under low reservoir conditions. This action will provide a greater degree of certainty to all water users and managers in the Colorado River Basin by providing more detailed objective guidelines for the operation of Lake Powell and Lake Mead and by allowing water users in the Lower Basin to know when, and by how much, water deliveries will be reduced in drought and other low reservoir conditions. In addition, this action is designed to delay the onset and magnitude of shortages and maximize the protection afforded to water supply, hydropower production, recreation, and environmental benefits by water storage in Lakes Powell and Mead. As a result of analysis of comments and public input received to date, the Department anticipates that the elements of the proposed action will include:

(1) Adoption of guidelines that will identify those circumstances under which the Secretary would reduce the annual amount of water available for consumptive use from Lake Mead to the Lower Division states (Arizona, California, and Nevada) below 7.5 million acre-feet (maf) (a "Shortage") pursuant to Article II(B)(3) of the Supreme Court Decree in *Arizona* v. *California*; [1]

(2) adoption of guidelines for the coordinated operation of Lake Powell and Lake Mead that are designed to provide improved operation of the two reservoirs, particularly under low reservoir conditions;

(3) adoption of guidelines for the storage and delivery of water in Lake Mead to increase the flexibility to meet water use needs from Lake Mead, particularly under low reservoir conditions. These guidelines are anticipated to address the storage and delivery of non-system water, exchanges, and water conserved by extraordinary measures; and

(4) modification of the substance and term of the existing Interim Surplus Guidelines, published in the **Federal Register** on January 25, 2001 (66 FR 7772–7782), from 2016 to coincide with the proposed new guidelines described above.

The Secretary proposes that these guidelines will be interim in nature and will extend through 2025. Adoption of new guidelines along with modification of existing operational guidelines for a consistent interim period will provide the opportunity to gain valuable experience for operating the reservoirs under the modified operations and should improve the basis for making additional future operational decisions, whether during the interim period or thereafter.

It is the intent of the Department to adopt and implement the above proposed action in a manner that is consistent with applicable Federal law,[2] and further, in a manner that does not require any additional statutory authorization. In this regard, Reclamation proposes to implement the proposed action consistent with the Colorado River Compact of 1922, the Decree entered by the United States Supreme Court in the case of *Arizona* v. *California,* and other provisions of applicable Federal law. It is the intent of the Department that the proposed action will be consistent with and provide implementing guidance that would be used each year by the Department in implementing the Criteria for Coordinated Long-Range Operation of Colorado River Reservoirs Pursuant to the Colorado River Basin Project Act of September 30, 1968 (Long-Range Operating Criteria or LROC).

Purpose and Need for the Proposed Federal Action

The purpose of the proposed action is to adopt additional operational strategies to improve the Department's annual management and operation of key Colorado River reservoirs while also providing mainstream users of Colorado River water, particularly those in the Lower Division states of Arizona, California, and Nevada, a greater degree

[1] The Department intends to meet any consultation requirements identified in Article II(B)(3) of the Supreme Court Decree in *Arizona* v. *California* through the ongoing NEPA process initiated by the **Federal Register** Notice of September 30, 2005 (70 FR 57322–57323).

[2] The treaties, compacts, decrees, statutes, regulations, contracts, and other legal documents and agreements applicable to the allocation, appropriation, development, exportation, and management of the waters of the Colorado River Basin are often referred to as the "Law of the River." There is no single, universally-agreed upon definition of the "Law of the River," but it is useful as a shorthand reference to describe this longstanding and complex body of legal agreements governing the Colorado River.

of predictability with respect to the amount of annual water deliveries in future years, particularly under low reservoir conditions.

The need for the proposed action is based on a number of important considerations including the following reasons:

• The Colorado River flows through the driest portion of the continental United States and is the primary source of water to a region that has experienced continued population growth over recent decades.

• The Colorado River is of strategic importance in the southwestern United States for water supply, hydropower production, flood control, recreation, fish and wildlife habitat, and other benefits. In addition, the United States has a delivery obligation to the Republic of Mexico for certain waters of the Colorado River pursuant to the 1944 U.S.-Mexico Water Treaty.

• The Colorado River Basin experienced the worst five-year drought in recorded history in 2000 through 2004. This drought has impacted system storage, while demands for Colorado River water supplies have continued to increase. During the period from October 1, 1999, to October 1, 2004, storage in Lakes Powell and Mead fell from 47.6 maf (approximately 95% of capacity) to 23.1 maf (approximately 46% of capacity). This drought was also the worst sustained drought experienced in the Colorado River Basin at a time when all major storage facilities were in place, and when use by the Lower Division states met or exceeded the annual "normal" apportionment of 7.5 maf pursuant to Article II(B)(1) of the Decree. Moreover, entering the five year drought period with Lake Powell and Lake Mead reservoir storage capacity at 95% fortuitously provided for sufficient water supplies to meet basin demands. This may not be the case in the future. Among other factors, these conditions led the Department to conclude that additional management guidelines are necessary and desirable for the efficient, and coordinated, management of the major mainstem Colorado River reservoirs.

• In the future, low reservoir conditions will likely not be limited to drought periods because of anticipated future demands on Colorado River water supplies. Projected future increases in Colorado River water demands are expected to increase the frequency and magnitude that Colorado River reservoirs are drawn down to low reservoir conditions.

• As a result of actual operating experience and through reviews of the LROC and preparation of Annual Operating Plans, particularly during recent drought years, the Secretary has determined a need for more specific guidelines, consistent with the Decree and other applicable provisions of Federal law, to assist in the Secretary's determination of annual water supply conditions in the Lower Basin. The increased level of predictability is needed by the entities that receive Colorado River water to better plan for and manage available water supplies, and to allow such entities to better integrate the use of Colorado River water with other water supplies that they rely on. To date, storage of water and flows in the Colorado River Basin have been sufficient so that it has not been necessary to reduce Lake Mead annual releases below 7.5 maf; nor has the Department yet identified when water supplies would be reduced, by how much, or who would experience specified reductions.

• After public consultation meetings held in the summer of 2005, the Secretary has also determined the desirability of developing additional operational guidelines that will provide for releases greater than or less than 8.23 maf from Lake Powell.

• To further enhance this coordinated reservoir approach, the Secretary has also determined a need for guidelines that provide water users with the opportunity to conserve, store, and take delivery of water in and from Lake Mead for the purposes of enhancing existing water supplies, particularly under low reservoir conditions.

• Lastly, the Secretary has determined the need to modify and extend the Interim Surplus Guidelines to coincide with the duration of the proposed new guidelines. This will provide an integrated approach for reservoir management and more predictability for future Colorado River Basin water supplies.

Results of Scoping Input

The description of the Proposed Federal Action and the Purpose and Need for the Proposed Federal Action described in this Notice and in the Scoping Summary Report available at Reclamation's Web site noted above, was refined to reflect information and comments received during the scoping meetings and in written and oral scoping comments submitted to the Department.[3] The Proposed Federal Action has been crafted to reflect, among others, three important considerations that were identified by commentors:

(1) *Importance of Encouraging Conservation of Water:* Many comments submitted to the Department focused on the importance of encouraging and utilizing water conservation as an important tool to better manage limited water supplies and therefore minimize the likelihood and severity of potential future shortages. *See e.g.*, comment G–0003, "Conservation Before Shortage" proposal submitted to the Department on July 18, 2005, which is available in its entirety in Appendix W of the Scoping Summary Report. Water conservation can occur through a number of approaches that will be identified in the Draft EIS, including: Extraordinary conservation, forbearance, financial incentives to maximize conservation, dry-year options, and associated storage and recovery methodologies and procedures to address conservation actions by particular parties.

(2) *Importance of Consideration of Reservoir Operations at all Operational Levels:* Comments submitted to the Department urged the Department to consider and analyze management and operational guidelines for the full range of operational levels at Lake Powell and Lake Mead. *See e.g.*, comment S–2006, "Basin States' Preliminary Proposal Regarding Colorado River Interim Operations" submitted to the Department on February 3, 2006, which is available in its entirety in Appendix Q of the Scoping Summary Report. It was suggested that this approach is integral to the prudent development of new low-reservoir operational guidelines, as the approach and management of these reservoirs at higher elevations has a direct impact on available storage, thereby affecting the likelihood and severity of potential future shortages.

(3) *Term of Operational Guidelines:* Comments submitted to the Department urged the Department to consider interim, rather than permanent, additional operational guidelines. *See e.g.*, comment letters L–2002 through 2006 submitted to the Department by several Arizona municipalities which are available in their entirety in Appendix W of the Scoping Summary Report. In this manner, the Department would have the ability to use actual operating experience for a period of years, thereby facilitating a better understanding of the operational effects of the new guidelines; modifications would then be made, if necessary, during or preferably at the end of the interim period. In particular, the

[3] The Scoping Summary Report also addresses in Section 5.0 those issues raised during scoping that have been determined to be beyond the proposed scope of the EIS.

Department was also urged to consider adopting additional operational guidelines for both low and higher reservoir elevations for a consistent period of years. At this time, it is important to note, the Department has detailed operational guidelines for declaration of surplus conditions at higher elevations of Lake Mead through 2016, but does not have similar detailed operational guidelines for either Lake Powell or the lower operational levels of Lake Mead.

Public Disclosure

Written comments, including names and home addresses of respondents, will be made available for public review. Individual respondents may request that their home address be withheld from public disclosure, which will be honored to the extent allowable by law. There may be circumstances in which respondents' identity may also be withheld from public disclosure, as allowable by law. If you wish to have your name and/or address withheld, you must state this prominently at the beginning of your comment. All submissions from organizations, business, and from individuals identifying themselves as representatives or officials of organizations or businesses, will be made available for public disclosure in their entirety.

Dated: March 18, 2006.

Robert W. Johnson,

Regional Director, Lower Colorado Region, Bureau of Reclamation.

Dated: March 16, 2006.

Rick L. Gold,

Regional Director, Upper Colorado Region, Bureau of Reclamation.

BILLING CODE 4310–MN–P

DEPARTMENT OF THE INTERIOR

Office of Surface Mining Reclamation and Enforcement

Notice of Proposed Information Collection for 1029–0025, 1029–0040 and 1029–0104

AGENCY: Office of Surface Mining Reclamation and Enforcement.

ACTION: Notice and request for comments.

SUMMARY: In compliance with the Paperwork Reduction Act of 1995, the Office of Surface Mining Reclamation and Enforcement (OSM) is announcing its intention to request renewed approval for the collections of information for 30 CFR 733, Maintenance of state programs and procedures for substituting federal enforcement of state programs and withdrawing approval of state programs; 785, Requirements for permits for special categories of mining; and 876, Acid mine drainage treatment and abatement program.

DATES: Comments on the proposed information collection activities must be received by May 30, 2006, to be assured of consideration.

ADDRESSES: Comments may be mailed to John A. Trelease, Office of Surface Mining Reclamation and Enforcement, 1951 Constitution Ave., NW., Room 202—SIB, Washington, DC 20240. Comments may also be submitted electronically to *jtreleas@osmre.gov.*

FOR FURTHER INFORMATION CONTACT: To request a copy of the information collection request, explanatory information and related forms, contact John A. Trelease, at (202) 208–2783 or via e-mail at the address listed above.

SUPPLEMENTARY INFORMATION: The Office of Management and Budget (OMB) regulations at 5 CFR 1320, which implement provisions of the Paperwork Reduction Act of 1995 (Pub. L. 104–13), require that interested members of the public and affected agencies have an opportunity to comment on information collection and recordkeeping activities [see 5 CFR 1320.8(d)]. This notice identifies information collections that OSM will be submitting to OMB for approval. These collections are contained in (1) 30 CFR 733, Maintenance of state programs and procedures for substituting federal enforcement of state programs and withdrawing approval of state programs; (2) 30 CFR 785, Requirements for permits for special categories of mining; and (3) 30 CFR 876, Acid mine drainage treatment and abatement program. OSM will request a 3-year term of approval for each information collection activity.

Comments are invited on: (1) The need for the collection of information for the performance of the functions of the agency; (2) the accuracy of the agency's burden estimates; (3) ways to enhance the quality, utility and clarity of the information collection; and (4) ways to minimize the information collection burden on respondents, such as use of automated means of collection of the information. A summary of the public comments will accompany OSM's submission of the information collection request to OMB.

The following information is provided for the information collection: (1) Title of the information collection; (2) OMB control number; (3) summary of the information collection activity; and (4) frequency of collection, description of the respondents, estimated total annual responses, and the total annual reporting and recordkeeping burden for the collection of information.

Title: Maintenance of state programs and procedures for substituting federal enforcement of state programs and withdrawing approval of state programs, 30 CFR 733.

OMB Control Number: 1029–0025.

Summary: This part provides that any interested person may request the Director of OSM to evaluate a State program by setting forth in the request a concise statement of facts that the person believes establishes the need for the evaluation.

Bureau Form Number: None.

Frequency of Collection: Once.

Description of Respondents: Any interested person (individuals, businesses, institutions, organizations).

Total Annual Responses: 1.

Total Annual Burden Hours: 100.

Title: Requirements for permits for special categories of mining, 30 CFR 785.

OMB Control Number: 1029–0040.

Summary: The information is being collected to meet the requirements of section 507, 508, 510, 515, 701 and 711 of Public Law 95–87, which requires applicants for special types of mining activities to provide descriptions, maps, plans and data of the proposed activity. This information will be used by the regulatory authority in determining if the applicant can meet the applicable performance standards for the special type of mining activity.

Bureau Form Number: None.

Frequency of Collection: Once.

Description of Respondents: Applicants for coalmine permits and State Regulatory Authorities.

Total Annual Responses: 228.

Total Annual Burden Hours: 16,146.

Title: Acid mine drainage treatment and abatement program, 30 CFR 876.

OMB Control Number: 1029–0104.

Summary: This part establishes the requirements and procedures allowing states and Indian tribes to establish acid mine drainage abatement and treatment programs under the Abandoned Mine Land fund as directed through Public Law 101–508.

Bureau Form Number: None.

Frequency of Collection: Once.

Description of Respondents: State governments and Indian tribes.

Total Annual Responses: 1.

Total Annual Burden Hours: 350.

Dated: March 27, 2006.

Kathryn S. O'Toole,

Acting Chief, Division of Regulatory Support.

L.4 Federal Register Volume 72, Number 39

9026 Federal Register / Vol. 72, No. 39 / Wednesday, February 28, 2007 / Notices

Procedure will now read "Describe the records sought."

Dated: February 22, 2007.

Robert Roudabush,

Acting Assistant Director, Renewable Resources and Planning, Bureau of Land Management.

INTERIOR/LLM–2

SYSTEM NAME:

Range Management System—Interior, LLM–2.

SYSTEM LOCATION:

U.S. Department of the Interior, Bureau of Land Management, Denver Federal Center, Bldg. 50, Denver, Colorado 80225.

CATEGORIES OF INDIVIDUALS COVERED BY THE SYSTEM:

Individuals to whom BLM issues grazing permits or leases.

CATEGORIES OF RECORDS IN THE SYSTEM:

The records, paper and electronic, contain the lessee's or permittee's name, address, the Bureau's assigned case file number, grazing allotment descriptions, grazing applications, grazing preference summary and history, copies of the grazing permit or lease, grazing fee billing statements, grazing exchange-of-use agreement, evidence of ownership or control of base property, notice of lienholder interest in base property, corporate or partnership documentation, affiliate documentation, notice of authorized representative, livestock control agreements, copies of brand registration, closed unauthorized use case records, Cooperative Range Improvement Agreements, Range Improvement Permits, Assignment of Range Improvements, grazing decisions, and correspondence to, or received from, the permittee or lessee.

AUTHORITY FOR MAINTENANCE OF THE SYSTEM:

43 U.S.C. 315, et seq.

ROUTINE USES OF RECORDS MAINTAINED IN THE SYSTEM, INCLUDING CATEGORIES OF USERS AND THE PURPOSES OF SUCH USES:

The primary uses of the records are (a) to identify the permittees and lessees authorized to graze lands administered by the Bureau of Land Management, (b) to print statements of grazing preference, grazing authorizations, billings for grazing fees due, and other reports, (c) to maintain the information required to administer livestock grazing on public rangelands in accordance with applicable laws and regulations, and (d) to provide information concerning the grazing permittees and lessees for administrative use.

Disclosures outside the Department of the Interior may be made: (1) To the Department of Justice, or to a court, adjudicative or other administrative body, or to a party in litigation before a court or adjudicative or administrative body, when (a) the Department or any component of the Department, any Departmental employee acting in his or her official capacity, or any Departmental employee acting in his or her individual capacity where the Department of Justice has agreed to represent the employee is a party in the suit and (b) we deem the disclosure to be relevant and necessary to the proceeding, and compatible with the purpose for which we compiled the information; (2) to Federal, State, or local agencies to manage their activities related to BLM's grazing program; and (3) to a congressional office from the record of an individual in response to a written inquiry the individual has made to the congressional office.

DISCLOSURE TO CONSUMER REPORTING AGENCIES:

Disclosures pursuant to 5 U.S.C. 552a(b)(12): Disclosures may be made to consumer reporting agencies as defined in the Fair Credit Reporting Act (15 U.S.C. 1681a(f)) or the Federal Claims Collection Act of 1966 (31 U.S.C. 3701(a)(3)).

POLICIES AND PRACTICES FOR STORING, RETRIEVING, ACCESSING, RETAINING, AND DISPOSING OF RECORDS IN THE SYSTEM:

STORAGE:

Computer magnetic tape and/or manual index. Paper case records are maintained in locking filing cabinets at BLM field offices.

RETRIEVABILITY:

Indexed by name of permittee or lessee and grazing authorization number.

SAFEGUARDS:

Maintained with safeguards meeting the requirements of 43 CFR 2.51 for manual and automated records. Access to records in the system is limited to authorized personnel whose official duties require such access. Paper records are maintained in locked file cabinets and/or in secured rooms. Electronic records conform to Office of Management and Budget and Departmental guidelines reflecting the implementation of the Federal Information Security Management Act. The electronic data will be protected through user identification, passwords, database permissions, and software controls. Such security measures will establish access levels for different types of users. A Privacy Impact Assessment was completed on the system to ensure that privacy protection measures were in place.

RETENTION AND DISPOSAL:

BLM Manual(s) 1220, Records and Information Management, Appendix II, GRS/BLM Combined Records Schedule, Schedule 20, Item 42. Destroyed when superseded or no longer needed for administrative purposes.

SYSTEM MANAGER(S) AND ADDRESS:

Chief, Division of Rangeland Management, U.S. Department of the Interior, Bureau of Land Management, (WO–220), 1849 C St., NW., Washington, DC 20240.

NOTIFICATION PROCEDURE:

To determine whether records are maintained on you in this system, write to the System Manager. See 43 CFR 2.60.

RECORD ACCESS PROCEDURES:

To see your records, write to the System Manager. Describe the records sought. If copies are desired, indicate the maximum you are willing to pay. See 43 CFR 2.63.

CONTESTING RECORD PROCEDURES:

To request corrections or the removal of material from your files, write the System Manager. See 43 CFR 2.71.

RECORD SOURCE CATEGORIES:

Grazing Permittees or Lessees

EXEMPTIONS CLAIMED FOR THE SYSTEM:

None.

DEPARTMENT OF THE INTERIOR

Bureau of Reclamation

[DES–07–05]

Colorado River Interim Guidelines for Lower Basin Shortages and Coordinated Operations for Lake Powell and Lake Mead

AGENCY: Bureau of Reclamation, Interior.

ACTION: Notice of Availability and Notice of Public Hearings for the Draft Environmental Impact Statement for the Colorado River Interim Guidelines for Lower Basin Shortages and Coordinated Operations for Lake Powell and Lake Mead.

SUMMARY: Pursuant to the National Environmental Policy Act (NEPA) of 1969, as amended, and the Council on Environmental Quality's Regulations for Implementing the Procedural Provisions

of NEPA, the Department of the Interior (Department), acting through the Bureau of Reclamation (Reclamation), has prepared a draft environmental impact statement (Draft EIS) on the proposed adoption of specific Colorado River Lower Basin shortage guidelines and coordinated reservoir management strategies to address operations of Lake Powell and Lake Mead, particularly under low reservoir conditions. This action is proposed in order to provide a greater degree of certainty to U.S. Colorado River water users and managers of the Colorado River Basin by providing detailed and objective guidelines for the operations of Lake Powell and Lake Mead, thereby allowing water managers and water users in the Lower Basin to know when, and by how much, water deliveries will be reduced in drought and other low reservoir conditions. The Department proposes that these guidelines be interim in duration and extend through 2026.

Cooperating agencies are the Bureau of Indian Affairs, the U.S. Fish and Wildlife Service, the National Park Service (NPS), the Western Area Power Administration (Western), and the United States Section of the International Boundary and Water Commission.

DATES AND ADDRESSES: A public review period commences with the publication of this notice. Comments on the Draft EIS must be submitted no later than Monday, April 30, 2007, to: Regional Director, Lower Colorado Region, Bureau of Reclamation, *Attention:* BCOO–1000, P.O. Box 61470, Boulder City, Nevada 89006–1470; faxogram at (702) 293–8156; or e-mail at *strategies@lc.usbr.gov*.

Reclamation will conduct three public hearings to receive written or oral comments from the public on the Draft EIS at the following locations:

- Tuesday, April 3, 2007—6 p.m. to 9 p.m., Henderson Convention Center, Sierra Room, 200 South Water Street, Henderson, Nevada.
- Wednesday, April 4, 2007—6 p.m. to 9 p.m., Phoenix Airport Marriott, Buckhorn Room, 1101 North 44th Street, Phoenix, Arizona.
- Thursday, April 5, 2007—6 p.m. to 9 p.m., Hilton Salt Lake City Center, Canyon Room A & B, 255 South West Temple, Salt Lake City, Utah.

If special assistance is required regarding accommodations for attendance at any of the public hearings, please contact Nan Yoder at (702) 293–8495, faxogram at (702) 293–8156, or e-mail at *nyoder@lc.usbr.gov* no less than 5 working days prior to the applicable meeting(s).

The Draft EIS is electronically available for viewing and copying at Reclamation's project Web site at: *http://www.usbr.gov/lc/region/programs/strategies.html*. Alternatively, a compact disc or hard copy is available upon written request to: Regional Director, Lower Colorado Region, Bureau of Reclamation, Attention: BCOO–1000, P.O. Box 61470, Boulder City, Nevada 89006–1470; faxogram at (702) 293–8156; or e-mail at *strategies@lc.usbr.gov*.

Copies of the Draft EIS are available for public inspection and review at the following locations:

- Bureau of Reclamation, Lower Colorado Regional Office, 400 Railroad Avenue, Boulder City, Nevada.
- Bureau of Reclamation, Upper Colorado Regional Office, 125 South State Street, Room 7220, Salt Lake City, Utah.
- Bureau of Reclamation, Phoenix Area Office, 6150 West Thunderbird Road, Glendale, Arizona.
- Bureau of Reclamation, Yuma Area Office, 7301 Calle Agua Salada, Yuma, Arizona.
- Bureau of Reclamation Library, Denver Federal Center, 6th Avenue and Kipling, Building 67, Room 167, Denver, Colorado.
- Department of the Interior, Natural Resources Library 1849 C Street NW., Washington, DC.
- Yuma County Library, 185 South Main Street, Yuma, Arizona.
- Palo Verde Valley Library, 125 West Chanslor Way, Blythe, California.
- Mohave County Library, 1170 Hancock Road, Bullhead City, Arizona.
- Laughlin Library, 2840 South Needles Highway, Laughlin, Nevada.
- Las Vegas Clark County Library, 833 Las Vegas Boulevard N, Las Vegas, Nevada.
- James I. Gibson Library, 280 Water Street, Henderson, Nevada.

FOR FURTHER INFORMATION CONTACT: Terrance J. Fulp, Ph.D., at (702) 293–8500 or e-mail at *strategies@lc.usbr.gov*; and/or Randall Peterson at (801) 524–3633 or e-mail at *strategies@lc.usbr.gov*.

SUPPLEMENTARY INFORMATION: During the period from 2000–2006, the Colorado River has experienced the worst drought conditions in approximately one hundred years of recorded history. During this period, storage in Colorado River reservoirs has dropped from nearly full to less than 60 percent of capacity at the end of 2006. Currently, the Department does not have specific operational guidelines in place to address the operation of Lake Mead and Lake Powell during drought and low reservoir conditions.

Accordingly, the Department proposes the adoption of specific interim guidelines for Lower Basin shortages and coordinated operations of Lake Powell and Lake Mead. The proposed federal action will be implemented through the adoption of interim guidelines in effect through 2026 that would be used each year by the Department in implementing the Criteria for Coordinated Long-Range Operation of Colorado River Reservoirs Pursuant to the Colorado River Basin Project Act of September 30, 1968, through issuance of the Annual Operating Plan for Colorado River Reservoirs.

The proposed federal action considers four operational elements that collectively are designed to address the purpose and need for the proposed federal action. These elements are addressed in each of the alternatives described and analyzed in the Draft EIS. The interim guidelines would be used by the Secretary of the Department of the Interior (Secretary) to:

- Determine those circumstances under which the Secretary would reduce the annual amount of water available for consumptive use from Lake Mead to the Colorado River Lower Division states (Arizona, California, and Nevada) below 7.5 million acre-feet (a "Shortage") pursuant to Article II(B)(3) of the United States Supreme Court in the case of *Arizona* v. *California*, 547 U.S.____(2006);
- Define the coordinated operation of Lake Powell and Lake Mead to provide improved operation of these two reservoirs, particularly under low reservoir conditions;
- Allow for the storage and delivery, pursuant to applicable federal law, of conserved Colorado River system and non-system water in Lake Mead to increase the flexibility of meeting water use needs from Lake Mead, particularly under drought and low reservoir conditions; and
- Determine those conditions under which the Secretary may declare the availability of surplus water for use within the Lower Division states. The proposed federal action would modify the substance of the existing Interim Surplus Guidelines (ISG), published in the **Federal Register** on January 25, 2001 (66 FR 7772), and the term of the ISG from 2016 to 2026.

The purpose of the proposed federal action is to: (1) Improve Reclamation's management of the Colorado River by considering the trade-offs between the frequency and magnitude of reductions of water deliveries, and considering the effects on water storage in Lake Powell and Lake Mead, water supply, power production, recreation, and other environmental resources; (2) provide mainstream U.S. users of Colorado River water, particularly those in the Lower Division states, a greater degree of predictability with respect to the amount of annual water deliveries in future years, particularly under drought and low reservoir conditions; and, (3) provide additional mechanisms for the storage and delivery of water supplies in Lake Mead.

The Draft EIS presents four possible action alternatives for implementation, plus a ''No Action Alternative.'' Reclamation has not identified a preferred alternative in this Draft EIS. The preferred alternative will be identified following public comments on the Draft EIS and will be expressed in the Final EIS. The action alternatives reflect input from Reclamation staff, the cooperating agencies, stakeholders, and other interested parties. Reclamation received two written proposals for alternatives that met the purpose and need of the proposed federal action, one from the Basin States and another from a consortium of environmental organizations. These proposals were used and refined by Reclamation to formulate two of the alternatives considered and analyzed in this Draft EIS: the Basin States Alternative and the Conservation Before Shortage Alternative. A third alternative (Water Supply Alternative) was developed by Reclamation and a fourth alternative (Reservoir Storage Alternative) was developed in coordination with the NPS and Western.

The Basin States Alternative proposes a coordinated operation of Lake Powell and Lake Mead that would minimize shortages in the Lower Basin and avoid the risk of curtailments of use in the Upper Basin. This alternative also provides a mechanism, Intentionally Created Surplus (ICS), for promoting water conservation in the Lower Basin.

The Conservation Before Shortage Alternative includes voluntary, compensated reductions in water use to minimize involuntary shortages in the Lower Basin and avoid risk of curtailments of use in the Upper Basin. This alternative also provides a mechanism for promoting water conservation in the Lower Basin by expanding the ICS mechanism.

The Water Supply Alternative is intended to maximize water deliveries at the expense of retaining water in storage in the reservoirs for future use. This alternative would implement shortages only when insufficient water to meet entitlements is available in Lake Mead.

The Reservoir Storage Alternative would keep more water in storage in Lake Powell and Lake Mead by reducing water deliveries and increasing shortages to benefit power and recreational interests; and this alternative also provides a mechanism for promoting water conservation in the Lower Basin.

Public Disclosure

It is our practice to make comments, including names, home addresses, home telephone numbers, and e-mail addresses of respondents, available for public review. Individual respondents may request that we withhold their names and/or home addresses, etc., but if you wish us to consider withholding this information you must state this prominently at the beginning of your comments. In addition, you must present a rationale for withholding this information. This rationale must demonstrate that disclosure would constitute a clearly unwarranted invasion of privacy. Unsupported assertions will not meet this burden. In the absence of exceptional, documentable circumstances, this information will be released. We will always make submissions from organizations or businesses, and from individuals identifying themselves as representatives or officials of organizations or businesses, available for public inspection in their entirety.

Dated: February 2, 2007.

Willie R. Taylor,

Director, Office of Environmental Policy and Compliance.

BILLING CODE 4310–MN–P

DEPARTMENT OF LABOR

Employment and Training Administration

[TA–W–60,281]

Airtex Products LP, Including On-Site Leased Workers of Staffmark and Aid Temporary Services, Inc.; Marked Tree, Arkansas; Notice of Revised Determination on Reconsideration of Alternative Trade Adjustment Assistance

By letter dated February 8, 2007, a company official requested administrative reconsideration regarding Alternative Trade Adjustment Assistance (ATAA) applicable to workers of the subject firm. The negative determination was signed on January 24, 2007, and was published in the **Federal Register** on February 14, 2007 (72 FR 7087).

The workers of Airtex Products LP, including on-site leased workers of Staffmark and Aid Temporary Services, Inc., Marked Tree, Arkansas were certified eligible to apply for Trade Adjustment Assistance (TAA) on January 24, 2007.

The initial ATAA investigation determined that there was not a significant number of workers in the workers' firm that are 50 years of age or older, and that the skills of the subject worker group are easily transferable to other positions in the local area.

In the request for reconsideration, the company official resubmitted correct employment numbers which show that a significant number or proportion of the worker group of the subject firm are fifty years of age or older. The company official also provided new information confirming that the skills of the workers at the subject firm are not easily transferable in the local commuting area.

Additional investigation has determined that the workers possess skills that are not easily transferable. A significant number or proportion of the worker group are age fifty years or over. Competitive conditions within the industry are adverse.

Conclusion

After careful review of the additional facts obtained on reconsideration, I conclude that the requirements of Section 246 of the Trade Act of 1974, as amended, have been met for workers at the subject firm.

In accordance with the provisions of the Act, I make the following certification:

All workers of Airtex Products LP, including on-site leased workers of Staffmark and Aid Temporary Services, Inc., Marked Tree, Arkansas, who became totally or partially separated from employment on or after October 20, 2005 through January 24, 2009, are eligible to apply for trade adjustment assistance under Section 223 of the Trade Act of 1974 and are also eligible to apply for alternative trade adjustment assistance under Section 246 of the Trade Act of 1974.

Signed in Washington, DC, this 21st day of February, 2007.

Elliott S. Kushner,

Certifying Officer, Division of Trade Adjustment Assistance.

Modeling Assumptions: Lake Mead Storage and Delivery of Conserved System and Non-system Water

Four of the action alternatives assume some form of a Lake Mead storage and delivery mechanism for conserved system and non-system water (the Basin States, Conservation Before Shortage, and Reservoir Storage alternatives, and the Preferred Alternative). This appendix describes the modeling assumptions used in the CRSS model to represent the creation and delivery of storage credits. At this time, the specific entities that may participate in the storage and delivery mechanism and the magnitude and timing of the storage and delivery of the conserved water are unknown. However, modeling assumptions with respect to the entities that might participate and their respective level of participation were needed to enable the evaluation of the mechanisms considered under each alternative and their potential effects on environmental resources. These assumptions are a reasonable and appropriate representation of potential conservation activities and the storage and delivery of water under the alternatives for purposes of environmental analyses.

M.1 Introduction

As described in the Draft EIS, the proposed federal action is comprised of four key elements, one of which is a mechanism for "Lake Mead Storage and Delivery of Conserved System or Non-system Water" (Section 1.2 and Section 2.1). Four of the five action alternatives in the Final EIS (Basin States, Conservation Before Shortage, and Reservoir Storage alternatives and the Preferred Alternative) included some expression of a storage and delivery mechanism. Intentionally Created Surplus (ICS), as proposed by the Basin States and Conservation Before Shortage alternatives, is one way to implement this element and is the mechanism proposed by the Preferred Alternative. Reclamation has published draft guidelines in the Final EIS that describe the proposed administration of the ICS mechanism (Appendix S). In this appendix, however, the storage and delivery mechanism is described in more general terms for modeling purposes only.

At this time, it is unknown which entities might participate in a Lake Mead mechanism that allows the storage and delivery of conserved system and non-system water. Furthermore, the timing and magnitude of the storage and delivery of conserved water is unknown. However, modeling assumptions with respect to the entities that might participate and their respective level of participation were needed to enable the evaluation of the mechanism and its potential effects on environmental resources, particularly to reservoir storage and river flows downstream of Lake Mead.

The proposed federal action is for the purpose of adopting additional operational guidelines to improve the Department's annual management and operation of key Colorado River reservoirs for an interim period through 2026. However, in order to assess the potential effects of the proposed federal action in this Final EIS, certain modeling assumptions are used that display projected water deliveries to Mexico. Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 Treaty or to represent current United States policy or a determination of future United States policy regarding deliveries to Mexico. The United States will conduct all necessary and appropriate discussions regarding the proposed federal action and implementation of the 1944 Treaty with Mexico through the IBWC in consultation with the Department of State. [1]

For two of the action alternatives (the Conservation Before Shortage Alternative and the Reservoir Storage Alternative), it was assumed that storage credits would be generated and used

---

[1] Notwithstanding the lack of an existing mechanism to implement such modeling assumptions, Reclamation utilized these assumptions for a number of reasons, including the following: (1) a larger volume of potential storage in Lake Mead is identified; (2) the maximum potential impacts on river flows downstream of Hoover Dam are identified; (3) the alternative proponent's recommendations as to participating entities and levels of participation are modeled; (4) the arbitrary assignment of water conservation amounts to entities in the Lower Basin states is avoided; and (5) the modeling impacts of a program of potential future cooperation between the United States and Mexico are identified.

for environmental purposes. These modeling assumptions were utilized in this Final EIS in order to analyze the potential impacts to environmental resources of the storage and delivery mechanism, particularly with regard to reservoir elevations and river flow impacts. The use of these modeling assumptions does not represent any determination by Reclamation as to whether, or how, these releases could be made under current management of the river.

M.2 General Modeling Assumptions

Four alternatives assume some form of a Lake Mead storage and delivery mechanism for conserved system and non-system water (the Basin States, Conservation Before Shortage and Reservoir Storage alternatives, and the Preferred Alternative). This section explains the general modeling assumptions regarding how storage credits are generated and delivered within the CRSS model. Examples of the accounting of storage credits within the model are also presented below.

M.2.1 Generation of Storage Credits

When storage credits are created, the model assumes either a delivery from Lake Mead is decreased or a new gain to the system is introduced, resulting in an increase to Lake Mead storage. If the reduced delivery is located downstream of Lake Mead, creation of the storage credit results in a reduction in the release from Lake Mead and river flow downstream.

At the beginning of each year, the model assumes that storage credits will be generated based on annual schedules and that the scheduled amount does not change throughout the year. The ability to store conservation credits in Lake Mead is assumed to be in effect from 2008 through 2026 (i.e., conserved water is assumed to not be stored in Lake Mead after 2026).

The activity resulting in the creation of credits is assumed to originate from a point on the Colorado River located furthest downstream in order to evaluate the maximum effects of the storage and delivery mechanism on river flows. In general, water conserved for use by a particular state is assumed to be generated by an entity within that state that had an annual depletion schedule sufficiently large enough to accommodate the reductions. In the case of the Conservation Before Shortage and Reservoir Storage alternatives, which assume unassigned storage and delivery activities and/or storage and delivery activities for Mexico and the federal government, and the Preferred Alternative, which analyzes additional activities to disclose the environmental impacts of a larger ICS program, these activities were assumed to occur within Mexico because this is the last major user in the lower part of the river and again, this permitted evaluation of the potential effects on river flow reductions[2].

[2] Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 Treaty or to represent current United States policy or a determination of future United States policy regarding deliveries to Mexico. The United States will conduct all necessary and appropriate discussions regarding the proposed federal action and implementation of the 1944 Treaty with Mexico through the IBWC in consultation with the Department of State.

A one-time system assessment is assumed to be dedicated to the system upon the creation of a storage credit. The system assessment is assumed to be five percent of the volume of water conserved for the Basin States and Conservation Before Shortage alternatives and for the Preferred Alternative. For the Reservoir Storage Alternative, the system assessment is assumed to be ten percent of the volume of water conserved. For example, if an entity wishes to receive credit for 100 kaf, then the credits that must be generated become:
100 kaf / (1 - system assessment).

The model assumes that the accounting of storage credits occurs annually, at the end of the calendar year. Storage credits in Lake Mead are assumed to be subject to the following rules:

- an annual three percent deduction for evaporation. The deduction is applied at the end of the year and is based on the available credits at the end of the previous year. Therefore, evaporation reductions are assumed to not apply to ICS credits created and delivered within the same year;
- no evaporation deductions occur during shortage conditions;
- under the Basin States and Conservation Before Shortage alternatives and the Preferred Alternative, if flood control releases occur, storage credits would be reduced on a pro-rata basis among all entities with stored water until no credits remain. For these alternatives and the Reservoir Storage Alternative, a reasonable approximation of this operation was made whereby storage credits were assumed to be eliminated and stored water reverted to system water when flood control releases are made;
- the total volume of storage credits in Lake Mead at any given time is not included in the determination of a Quantified Surplus using the 70R Strategy; and
- the amount of storage credits that may be generated in a single year is constrained by assumed maximum annual and maximum total limits. These assumed limits vary by alternative and are presented in Section M.3.

M.2.2 Delivery of Storage Credits

When storage credits are delivered from Lake Mead, the model assumes that a delivery from Lake Mead was increased for that year, resulting in a decrease in Lake Mead storage. If the increased delivery is located downstream of Lake Mead, delivery of the storage credit results in an increase in the release from Lake Mead and downstream river flows.

At the beginning of each year, the model assumes that storage credits will be delivered based on annual schedules and that the scheduled delivery amount does not change throughout the year. Although the ability to store conservation credits in Lake Mead is assumed to be in effect from 2008 through 2026 (i.e., conserved water may not be stored in Lake Mead after 2026), a ten-year period (2027 through 2036) was assumed for entities to take any storage credits remaining after the end of the interim period.

After 2026, some conservation activities assumed to be undertaken by Nevada are assumed to continue through 2060 (tributary conservation, groundwater return flows, and system augmentation described further in Section M.3.1). The model assumes delivery of that water to Nevada in the year that the conservation occurs.

M.2.3 Examples of Storage Credit Accounting

Table M-1 provides an example of storage credit accounting in CRSS. A Put refers to the creation of credits. A Take is the delivery of credits. Although most calculations in CRSS occur on a monthly basis, the model calculates available storage credits annually, at the end of the year. At the end of year n, the balance of storage credits is determined as,

$$Balance_n = Balance_{n-1} + Put(1 - Assessment\%) - Take - Evap\%(Balance_{n-1})$$

Table M-1
Example of Storage Credit Accounting (af)

Year	Put	Assessment[1]	Put Adjusted for Assessment	Requested Take	Actual Take	Evaporation	Balance
1	0	0	0	0	0	0	0
2	200,000	10,000	190,000	0	0	0	190,000
3	100,000	5,000	95,000	50,000	50,000	5,700	229,300
4	0	0	0	200,000	200,000	6,879	22,421
5	0	0	0	50,000	21,748	673	0

1 Assuming a system assessment of five percent.

Year 1: The storage credit balance is zero and there is no activity for this year.

Year 2: A put of 200 kaf is scheduled for this year. There is a 200 kaf reduction in delivery for this year. Assuming a system assessment of five percent, 190 kaf of storage credits are generated for this year and ten kaf (five percent of 200 kaf) is credited to the system. There are no takes scheduled. Evaporation is counted as three percent of the previous year's balance. Because the balance in Year 1 is 0, there is no evaporation loss deducted in Year 2.

Year 3: Applying the scheduled put and take values to the equation above, a storage credit balance of 229,300 af is created.

$$229{,}300 = 190{,}000 + 100{,}000(1 - 0.05) - 50{,}000 - 0.03(190{,}000)$$

Year 4: Applying the scheduled put and take values to the equation above, a storage credit balance of 22,421 af is created.

$$22{,}421 = 229{,}300 + 0(1 - 0.05) - 200{,}000 - 0.03(229{,}300)$$

Year 5: The requested take is higher than the available storage credits. Therefore the actual take is constrained by the available storage credits and is therefore limited to 21,748 af.

M.3 Modeling Assumptions Specific to Alternatives

Modeling assumptions with respect to the entities that might participate and their respective level of participation were needed to enable the evaluation of the potential effects of the mechanism for each alternative. These assumptions include the maximum amount of storage credits that may be created during any year, the maximum amount of storage credits that may be recovered during any year, and the maximum total amount of storage credits that may be available at any one time. In addition, assumptions with regard to the timing and magnitude of the storage and delivery of conserved water are needed. The assumptions made for each alternative are detailed in the following sections.

M.3.1 Basin States Alternative

The Basin States Alternative proposes the Intentionally Created Surplus (ICS) mechanism and assumes the levels of participation as shown in Table M-2 (Section 2.3).

Table M-2
Basin States Alternative
Volume Limitations of ICS

Entity	Maximum Annual ICS Creation (kaf)	Maximum Cumulative ICS (kaf)	Maximum Annual ICS Delivery (kaf)
Arizona	100	300	300
California	400	1,500	400
Nevada	125	300	300
Total	625	2,100	1,000

These volume limitations are recognized in CRSS as are other rules that specify under which water supply conditions ICS may be delivered or accounted for as summarized in Section M.3.5. The schedules for Arizona, California and Nevada were provided by the Arizona Department of Water Resources (ADWR), the Metropolitan Water District of Southern California (MWD) and the Southern Nevada Water Authority (SNWA), respectively, and are detailed below.

M.3.1.1 Arizona

In order to analyze the maximum effects on river flows, the model assumes that Arizona ICS is generated through extraordinary conservation by the Yuma County Water Users Association and are delivered to CAP. According to the schedules provided by ADWR, the creation of ICS begins in 2017, as shown in Table M-3. It was assumed that ICS is created and delivered during a Normal Condition.

M.3.1.2 California

In order to analyze the maximum effects on river flows, the model assumes that California ICS is generated through extraordinary conservation by the Imperial Irrigation District and are delivered to MWD. Schedules for the creation and delivery of ICS were provided by MWD. One hundred (100) schedules were provided, corresponding to the 100 hydrologic traces used in the ISM simulations (Section 4.2). As an example, one of these schedules is presented in Table M-3. In 2008, California is assumed to begin with an ICS account of 100 kaf due to pilot programs in place in 2006 and 2007. It was assumed that storage credits are created and delivered during a Normal Condition.

M.3.1.3 Nevada

As provided by SNWA, four different conservation activities are assumed to be undertaken by Nevada to generate ICS credits. Each activity is subject to different assumptions as to when ICS credits may be generated and used as described below. The schedules provided by SNWA are shown in Table M-3.

Tributary Conservation. It was assumed that water from extraordinary conservation on the Virgin River and Muddy River would generate ICS credits. This activity is assumed to be in place during the period 2009 through 2060. In the CRSS model, a gain to Lake Mead was introduced as the source of this ICS and it is assumed that delivery is taken by SNWA from Lake Mead. In general, it was assumed that credits may be created during all water supply conditions (except the Flood Control Surplus Condition) and may be delivered during a Normal Condition and a Shortage Condition. However, it was also assumed that SNWA would take ICS during a Full Domestic Surplus Condition, if needed, to avoid exceeding the maximum total amount of ICS. After 2026, it is assumed that the tributary conservation ICS would continue to be created each year and would be used in the same year. The system assessment is assumed to be in effect through 2060.

Groundwater. Nevada state groundwater introduced into Lake Mead or wastewater produced from Nevada state groundwater, are assumed to be available to SNWA during the period 2009 through 2060. In the CRSS model, a gain to Lake Mead was introduced as the source of groundwater and it was assumed that delivery is taken by SNWA from Lake Mead. It was assumed that such ICS may be created and delivered during a Normal Condition and a Shortage Condition. After 2026, it is assumed that such flows would continue to be created each year and would be used in the same year. The system assessment is assumed to be in effect through 2060.

System Augmentation. SNWA is assumed to receive water generated from future system augmentation projects (e.g., desalinization) beginning in 2020 through 2060. To account for water created through system augmentation, a gain was introduced to the system downstream of Imperial Dam. System augmentation water is assumed to be generated and taken during all water supply conditions except during a Flood Control Surplus Condition. After 2026, it is assumed that the system augmentation water would continue to be created each year and would be used in the same year. The system assessment for system augmentation is assumed to be in effect through 2060.

Drop 2 Storage Reservoir. The proposed Drop 2 Storage Reservoir Project is assumed to be in operation beginning in 2010 and assumed to conserve an average of 69 kafy, reducing the average delivery of non-storable flows to Mexico from 77 kafy to 8 kafy under all alternatives (Section 4.2). Under the four action alternatives that assume a storage and delivery mechanism, SNWA is assumed to use water conserved by the Drop 2 Storage Reservoir beginning in 2013 during a Surplus Condition (excluding the Flood Control Surplus Condition) and a Normal Condition. A system assessment is not applied to Drop 2 Storage Reservoir water. Nevada is assumed to take Drop 2 Storage Reservoir water at a maximum rate of 40 kaf each year until a total of 300 kaf has been taken. Thereafter, water conserved by the Drop 2 Reservoir is assumed to be system water.

Table M-3
Assumed Creation and Delivery Schedules for ICS Under the Basin States Alternative[1]

Year	Arizona		California2		Nevada					
	Extraordinary Conservation (af)		Extraordinary Conservation (af)		Tributary Conservation (af)		Groundwater (af)		System Augmentation (af)

1 *Actual modeled delivery amounts may be less depending on availability, system assessment, and evaporation losses.*

2 *Reclamation was provided 100 distinct storage and delivery schedules by MWD to be used with the Index Sequential Method. The schedule in this table is an example of one schedule corresponding to one hydrologic sequence.*

M.3.2 Conservation Before Shortage

The Conservation Before Shortage Alternative assumes the levels of participation shown in Table M-4 (Section 2.4).

Table M-4
Conservation Before Shortage Alternative
Volume Limitations of ICS

Entity	Maximum Annual ICS Creation (kaf)	Maximum Cumulative ICS (kaf)	Maximum Annual ICS Delivery (kaf)
Arizona	100	300	300
California	400	1,500	400
Nevada	125	300	300
Unassigned	825	2,100	600
Total	1,450	4,200	1,600

These volume limitations are recognized in CRSS as are other rules that specify under which water supply conditions conserved system or non-system water may be delivered or stored as summarized in Section M.3.5. The schedules for the Conservation Before Shortage Alternative for the participation of the Lower Division states were assumed to be identical to those used in the Basin States Alternative (Table M-3). The schedules for the expanded participation by other entities (Unassigned in Table M-4) were provided by the non-governmental organizations (NGOs) and are detailed below.

The Conservation Before Shortage proposal includes voluntary, compensated reductions in water use prior to the imposition of involuntary shortages (Section 2.4). To model this proposal, it was assumed that storage credits of 400, 500 and 600 kafy would be created when Lake Mead was at specific elevations within the range of 1,075 feet msl and 1,025 feet msl (Section 2.4). For modeling purposes and to maximize river flow effects, these storage credits were assumed to be generated via extraordinary conservation within Mexico. The system assessment is applied when these storage credits are created and evaporation losses are applied to the account balance at the end of each year. The maximum positive volume for the account is assumed to be 1.5 maf and any additional water that is conserved above that amount is assumed to convert to system water.

It was assumed that these storage credits would remain in Lake Mead and would be counted toward the replacement of the bypass flows to the Cienega de Santa Clara in Mexico. The model maintains an accounting for the bypass flow replacement. In each year, the model releases 109 kaf (Section 4.2) for the bypass flows and deducts that amount from the bypass flow replacement account. Any deficit that accumulates in the account is tracked and offset at a later time when Lake Mead is below elevation 1,075 feet msl and storage credits are created.

The NGOs also postulated that storage credits would be generated by Mexico and be used for the purpose of environmental flows and other purposes in Mexico. These credits would be subject to the system assessment and evaporation losses and would be stored and delivered during a Surplus Condition or a Normal Condition, but not during a Flood Control Surplus Condition or a Shortage Condition. Two sets of flows are assumed to occur. The first are pulse flows to the Colorado River Delta flowing into the Gulf of California, assumed to occur every five years after the last flood control release, with the first flow scheduled for 2012 (referred to as Delta Pulse Flows in Table M-5). Each year, storage credits of 50 kaf are assumed to be generated. Delta pulse flows are of magnitude 250 kaf; however, in the fifth year, the storage credit of 50 kaf is assumed to be stored and delivered in the same year and a system assessment is not applied. The model assumes that Delta pulse flows would flow past the Northerly International Border (NIB) and are counted as an additional delivery to Mexico. The second set of flows (termed Other Flows Below NIB in Table M-5) are assumed also to occur every five years, with the first scheduled for 2010 at a volume of 80 kaf. Each year 40 kaf of storage credits is scheduled to be created for these flows. After 2010, these flows increase to a volume of 200 kaf and similar to the Delta Pulse Flows, in the fifth year the 40 kaf is assumed to be stored and delivered in the same year. The model also assumes that this water would flow past the NIB and is counted as an additional delivery to Mexico.

The NGOs postulated an additional activity to create 100 kafy of storage credits for environmental uses within the United States (termed Additional Environmental Uses in Table M-5). It was assumed that these credits would be created and delivered during a

Normal Condition and a Surplus Condition and would be subject to the system assessment and evaporation losses. For modeling purposes and to maximize river flow effects, this water was also a assumed to be generated via extraordinary conservation within Mexico.

The assumed schedules for these activities are presented in Table M-5.

Table M-5
Assumed Storage and Delivery Schedules for
Other Conservation Activities Under the Conservation Before Shortage Alternative[1] (af)

Year	Delta Pulse Flows		Other Flows Below NIB		Additional Environmental Uses	
	STORE	DELIVER	STORE	DELIVER	STORE	DELIVER
2008	52,632	0	42,105	0	105,263	100,000
2009	52,632	0	42,105	0	105,263	100,000
2010	52,632	0	0	80,000	105,263	100,000
2011	52,632	0	42,105	0	105,263	100,000
2012	50,000	250,000	42,105	0	105,263	100,000
2013	52,632	0	42,105	0	105,263	100,000
2014	52,632	0	42,105	0	105,263	100,000
2015	52,632	0	40,000	200,000	105,263	100,000

M.3.3 Reservoir Storage Alternative

The Reservoir Storage Alternative assumes the levels of participation as shown in Table M-6 (Section 2.6).

Table M-6
Reservoir Storage Alternative
Volume Limitations of Storage and Delivery Mechanism

Entity	Maximum Annual Storage of Conserved System or Non-system Water (kaf)	Maximum Total Storage of Conserved System or Non-system Water (kaf)	Maximum Annual Delivery of Conserved System or Non-system Water (kaf)
Arizona	100	300	300
California	400	1,500	400
Nevada	125	300	300
Unassigned	475	950	950
Total	1,100	3,050	1,950

These volume limitations are recognized in CRSS as are other rules that specify under which water supply conditions conserved system or non-system water may be delivered or stored as summarized in Section M.3.5. The schedules for the Reservoir Storage Alternative for the participation of the Lower Division states were assumed to be identical to those used in the Basin States Alternative (Table M-3). The schedules for the expanded participation by other entities (Unassigned in Table M-6) are detailed below.

Some of the activities assumed in the Conservation Before Shortage Alternative were also assumed for the Reservoir Storage Alternative. In particular, the schedules for the Delta Pulse Flows and Other Flows Below NIB (Table M-5) were assumed to be identical. Other additional activities were assumed for the Reservoir Storage Alternative in order to assess the potential effects of a storage and delivery mechanism with limits different from either the Basin States or the Conservation Before Shortage alternatives.

During all water supply conditions, except the Flood Control Surplus condition, storage credits are assumed to be created to replace bypass flows to the Cienega de Santa Clara in Mexico. The model assumes that 109 kafy is released from Lake Mead for the bypass flows (Section 4.2). Because the system assessment for the Reservoir Storage Alternative is assumed to be ten percent, storage credits of 121 kafy are assumed to be created each year to replace the bypass flows (termed Bypass Flow Replacement in Table M-7). For modeling purposes and to maximize river flow effects, this water was assumed to be generated via extraordinary conservation within Mexico.

It was also assumed that storage credits of 55 kafy would be created for environmental purposes (in the amount of 50 kafy after the system assessment) in the United States (termed Environmental Uses in Table M-7). These credits are assumed to be created and delivered during all conditions (except the Flood Control Surplus Condition). For modeling purposes and to maximize river flow effects, this water was assumed to be generated via extraordinary conservation within Mexico.

During a Normal Condition and a Surplus Condition, an additional 150 kafy is assumed to be created each year with a delivery of 100 kafy (termed "Additional Conservation Activities" in Table M-7). For modeling purposes and to maximize river flow effects, this water was assumed to be generated via extraordinary conservation within Mexico and delivered to SNWA at Lake Mead.

The assumed schedules for these activities are shown in Table M-7.

2060	0	0	0	0	0	0

[1] *Storage amounts are adjusted for system assessment. Actual modeled delivery amounts may be less depending on availability and evaporation losses.*

M.3.4 Preferred Alternative

The Preferred Alternative assumes the levels of participation as shown in Table M-8 (Section 2.7).

Table M-8
Preferred Alternative
Volume Limitations of ICS

Entity	Maximum Annual ICS Creation (kaf)	Maximum Cumulative ICS (kaf)	Maximum Annual ICS Delivery (kaf)
Arizona	100	300	300
California	400	1,500	400
Nevada	125	300	300
Total[1]	625	2,100	1,000
Additional Amounts	625	2,100	1,000
Total[2]	1,250	4,200	2,000

1 *It is anticipated that the ICS mechanism will be implemented to allow a maximum cumulative amount of ICS credits that would be available at any one time of up to 2.1 maf.*

2 *The analysis of potential effects in this Final EIS includes a maximum cumulative amount of ICS credits that would be available at any one time of up to 4.2 maf.*

These volume limitations are recognized in CRSS as are other rules that specify under which water supply conditions conserved system or non-system water may be delivered or stored as summarized in Section M.3.5. The schedules for the Preferred Alternative for the participation of the Lower Division states were assumed to be identical to those under the Basin States Alternative (Table M-3). The schedules for the expanded participation by other entities (Additional Amounts in Table M-9) are detailed below.

In order to analyze the maximum effects on river flows, the model assumed that additional amounts of storage credits are generated through extraordinary conservation within Mexico and delivered to Mexico[3]. It was assumed that these credits are stored and delivered during a Normal Condition.

[3] Notwithstanding the lack of an existing mechanism to implement such modeling assumptions, Reclamation utilized these assumptions for a number of reasons, including the following: (1) a larger volume of potential storage in Lake Mead is identified; (2) the maximum potential impacts on river flows downstream of Hoover Dam are identified; (3) the alternative proponent's recommendations as to participating entities and levels of participation are modeled; (4) the arbitrary assignment of water conservation amounts to entities in the Lower Basin states is avoided; and (5) the modeling impacts of a program of potential future cooperation between the United States and Mexico are identified.

Table M-9
Assumed Storage and Delivery Schedules for Other Conservation Activities Under the Preferred Alternative[1]

[1] *Actual modeled delivery amounts may be less depending on availability, system assessment and evaporation losses.*

M.3.5 Summary of Assumed Storage and Delivery Activities

A summary of the activities assumed to occur under the various water supply conditions (Surplus Condition, Normal Condition, and Shortage Condition) for each alternative is presented in Table M-10.

Table M-10
Modeling Assumptions for Storage and Delivery of Conserved System and Non-System Water

Water Supply Condition		BS, CBS, RS & PA [1]						CBS & RS	CBS	RS	PA
		California	Arizona	Nevada				Mexico[6]	Federal	Federal	Additional Amounts
		Extraordinary Conservation	Extraordinary Conservation	Tributary Conservation	Groundwater	System Augmentation	Drop 2 Reservoir [4]	Extraordinary Conservation	Extraordinary Conservation	Extraordinary Conservation	Extraordinary Conservation
Flood Control Surplus	Store	no	no	no	no	no	no	no	no	no	no
	Deliver	no	no	no	no	no	no	no	no	no	no
Quantified (70R) Surplus	Store	no	no	yes	no	yes	yes	yes	yes	yes	no
	Deliver	no	no	no	no	yes	yes	yes	yes	yes	no
Full Domestic Surplus	Store	no	no	yes	no	yes	yes	yes	yes	yes	no
	Deliver	no	no	yes	no	yes	yes	yes	yes	yes	no
Normal	Store	yes	yes	yes	yes	yes	yes	yes	yes	yes	yes
	Deliver	yes	yes	yes	yes	yes	yes	yes	yes	yes	yes
Shortage (involuntary and voluntary compensated reductions)	Store	no	no	yes	yes	yes	no	no	no [5]	yes	no
	Deliver	no	no	yes	yes	yes	no	no	no	yes	no
System Assessment		yes	yes	yes	yes	yes	no	yes	yes	yes	yes
Period of Activity		2006-2026	2017-2026	2009-2060	2009-2060	2020-2060	Temporary	2008-2026	2008-2026	2008-2026	2008-2026

Notes:

1. *BS = Basin States Alternative, CBS = Conservation Before Shortage Alternative, RS = Reservoir Storage Alternative, PA = Preferred Alternative*
2. *yes = activity assumed to occur*
3. *no = activity assumed to not occur*
4. *Beginning in 2013, Nevada is assumed to receive 40 kafy of the water conserved by the Drop 2 Storage Reservoir during Normal Condition and Surplus Condition years until a total of 300 kaf has been credited to Nevada. Thereafter, water conserved by the Drop 2 Storage Reservoir is assumed to be system water.*
5. *Under the Conservation Before Shortage Alternative, extraordinary conservation is assumed to be undertaken by the federal government during voluntary compensated reductions but not during involuntary shortage conditions.*
6. *These modeling assumptions do not reflect policy decisions and are not intended to constitute interpretation or application of the 1944 Treaty.*

Appendix N

Analysis of Hydrologic Variability Sensitivity

This appendix contains a description of the analysis performed to evaluate the potential effects to the hydrologic resources of alternative hydrologic inflow sequences. Two methods for generating future hydrologic inflow sequences with increased hydrologic variability relative to the historical record are described, both using information derived from the most recently published (2007) streamflow reconstructions from tree-ring data. The modeling results using the alternative hydrologic inflow scenarios are compared to the results from the current method used by Reclamation, which is based on the 100-year historical record.

This appendix also includes an attachment, which was an appendix originally published in the Draft EIS of February 2007. The attachment documents the comparison of the same methods as described above applied to streamflow reconstructions from tree-ring data published in 2006. In addition, a third technique was compared at that time that was based on parametric stochastic models. The latter is also included in the attachment.

N.1 Introduction

This appendix presents the analysis of the sensitivity of the hydrologic resources to alternative hydrologic inflow scenarios. As explained in Section 4.2 of this Final EIS, hydrologic variability was incorporated into the hydrologic modeling using the Index Sequential Method (ISM) (Reclamation 1985; Ouarda et al. 1997) applied to the 100-year natural flow[1] record (1906 to 2005). Two methods were used to generate future hydrologic inflow sequences with increased hydrologic variability relative to the historical record. Although these methods do not explicitly incorporate forecasts of future climate variability, the resulting sequences show a wider range of hydrologic variability, particularly with respect to longer wet and dry periods.

N.2 Development of Two Alternative Hydrologic Inflow Scenarios to Compare with the 1906 to 2005 Natural Flow Record using ISM

In its current configuration, the CRSS model requires monthly natural flows at 29 sites throughout the Colorado River system. There are 20 sites in the Upper Basin (above and including the Lees Ferry Gaging Station in Arizona) and nine sites in the Lower Basin. Natural flows for each of the 29 sites are needed in order simulate the future hydrologic conditions for each alternative hydrologic scenario.

N.2.1 Index Sequential Method Applied to the 1906 to 2005 Natural Flow Record

Under Reclamation current practice, the ISM is used to generate streamflows for input into CRSS. This stochastic method entails a sequential block bootstrap of the observed data, where the block size is determined by the simulation horizon. The ISM cycles through each year in the historic record generating 100 hydrologic sequences (or traces), assuming that the record "wraps around" at the end (i.e., 2005, 1906, 1907). Throughout this appendix, the ISM technique as applied to the 1906 to 2005 natural flow record is referred to as Direct Natural Flow Record (DNF).

Strengths of this method are that it is based on the best available measured data, provides the basis for a quantification of the uncertainty and an assessment of risk with respect to future inflows, and has been widely accepted by stakeholders on the Colorado River. Unfortunately, each trace will only consist of annual and monthly flow magnitudes and sequences that have occurred in the observed record, with the exception of new sequences being generated as a result of the wrap. Therefore, a wider range of plausible future streamflows (including flow magnitudes and wet and dry sequences not seen in the observed record) are not modeled with the ISM method.

[1] Natural flow is the observed flow adjusted for the effects of diversions and the operation of reservoirs upstream of the flow gage. The natural flow record is unbiased by past human development.

N.2.2 Direct Paleo (DP)

This technique uses streamflow reconstructions from tree-ring chronologies directly to generate future hydrologic sequences. The paleo-reconstruction of streamflow is typically based on a model derived from a multiple-linear regression analysis of the tree-ring chronologies that overlap the historical natural flow record. For this study, the sequence 1 paleo-reconstruction from Meko et al. (2007) was used. This paleo-reconstruction provides annual water year flows from year 762 to 2005 on the Colorado River at Lees Ferry. This sequence is of particular interest because it extends into the Medieval Climate Anomaly, a period of time (900 to 1300) when various paleoclimate data indicate hydrologic droughts in the western United States were abnormally widespread (Meko et al. 2007). Remnant preserved wood (tree-rings) were utilized to extend this reconstruction beyond the recent reconstruction described in Woodhouse et al. (2006), which was limited to the period 1492 to 1997.

The major strength of this method is that new sequences not seen in the observed, gaged record are available. One difficulty associated with preparation of tree-ring chronologies and the multiple-linear regression models used for the paleo reconstructions is the accurate representation of the magnitudes of the flows, particularly at the extremes, e.g., at the higher and the lower flows (Woodhouse and Brown 2001). In addition, reconstructions can vary based on the tree-ring samples used as well as the data processing techniques used to generate the streamflows from the tree-ring chronologies. For example, the Meko et al. (2007) paelo reconstruction used in this study is not the first reconstruction completed for Lees Ferry. At least four other streamflows reconstructions (Stockton and Jacoby, 1976; Hildalgo et al., 2000; Hirschboeck and Meko, 2005 and, Woodhouse et al., 2006) are available (see the Attachment A to this appendix) and each reconstruction has a different mean flow for the reconstructed period and each captures differing levels of hydrologic variability. Unfortunately, this makes choosing a particular reconstruction a non-trivial task.

The annual flows at Lees Ferry Gaging Station (site 20) were disaggregated, spatially and temporally, throughout the Colorado River Upper Basin using a nonparametric disaggregation method (Prairie 2006; Prairie et al. 2006). The disaggregation scheme ensures that the flows generated throughout the Upper Colorado River basin are spatially and temporally consistent among the 20 locations that characterize natural flow. The disaggregation method relies on the observed natural flow record (1906 to 2005) to model the spatial and temporal distribution properties of the monthly and annual flow at the 20 locations. From an annual flow at Lees Ferry, the disaggregation scheme temporally disaggregates this annual flow to a monthly time scale then the monthly flow is spatially disaggregated among the 20 Upper Basin sites. During the first step (temporal disaggregation) an annual flow is provided from the Meko et al. reconstruction. This annual flow is ranked among the first K nearest observed natural flows, where K is determined as the square root of the number of years in the observed record (e.g., 100 years). These K nearest observed flows are weighted such that the closed neighbor has the greatest weight and the farthest has the least weight. One of the weighted neighbors is randomly chosen and its corresponding year (termed an “analogue” year) is saved for use during the spatial disaggregation and selection of the Lower Basin flows. The monthly observed flows from the selected year along with the annual flow provided from the reconstruction are incorporated in a conditional probability function that ensures the disaggregated monthly flows sum to the original reconstructed flow. These steps are repeated for each annual flow in the Meko et al. reconstruction. A similar method used for the spatial disaggregation though the analogue year is also used to choose the representative year instead of picking from the K nearest observed flows.

Flows for the nine gages downstream of site 20 were taken from the observed natural flows (1906 to 2005) based on the analogue year that was chosen for the conditional probability function during the Upper Basin disaggregation. For example, if year 1954 was the analogue year chosen during the disaggregation of a given flow in the Upper Basin, then the associated monthly flows for each of the nine downstream sites are resampled from 1954 observed monthly natural flows. This method ensures the downstream sites are both temporally and spatially correlated with each other and with the upstream sites.

These disaggregated flows (1244 years of monthly flows at 29 sites) are chosen with the ISM generating 1244 traces each 53 years in length. As ISM sequentially block bootstraps the disaggregated streamflow data, the generated traces will consist of annual flow magnitudes and sequences that are present in the paleo reconstructed streamflows, with the exception of the sequences created as a result of the wrap.

N.2.3 Nonparametric Paleo Conditioning (NPC)

As previously mentioned, flow magnitudes vary significantly across multiple reconstructions for a particular site (Stockton and Jacoby 1976; Hildalgo et al. 2000; Hirschboeck and Meko 2005, and Woodhouse et al. 2006). However, the paleo-hydrologic state information (i.e., wet or dry), is similar across different reconstructions (Woodhouse et al. 2006). The nonparametric paleo-conditioning technique capitalizes on these observations by first extracting the paleo-hydrologic state information from the streamflow reconstruction and then generating flow magnitudes by conditionally choosing from the historical record (i.e., from historical flows from a wet or dry sequence corresponding to the type of sequence derived from the paleo record).

In essence, this technique combines the strengths of the DNF and Direct Paleo methods. The main drawbacks are that magnitudes not observed in the observed, gaged record can not be generated and the technique is complex and not easily understood by all stakeholders.

For example, to generate a trace, a Markov model fit to the paleo reconstruction is first used to generate a sequence of wet and dry spells over the trace that are representative of spell lengths seen in the paleo reconstruction. The observed record is split into four categories defined by the current and next year’s hydrologic state. These categories include being in a dry state one year and staying in a dry state the next year, or being in a dry state and moving to a wet state, or being in a wet state and moving to a dry state, or lastly being in a wet state and staying in a wet the next year. To choose a flow magnitude for the state sequence, first a flow from the observed record is randomly chosen and its state is determined. The next state is taken from the first value in the state sequence. With these two states the category, from which to choose a flow magnitude is defined. Within the appropriate category all the flows in the category are weighted such that the closest flow magnitude is weighted most and the farthest is weighted least. Then one of the weighted flows is randomly chosen and the flow for the next year is chosen to ensure preservation of the lag-1 correlation observed in the record flows. This chosen flow becomes the next flow and the next state value from the state sequence is used to choose the next flow magnitude. This process is repeated until the end of the state sequence for a given trace is reached. Prairie (2006) provides a detailed description of the conditional choosing technique and its mathematical basis.

For this study, the paleo hydrologic state information was derived from the sequence 1 paleo reconstruction and coupled with the conditional choosing technique to generate annual water year flows at Lees Ferry were generated. These flows are disaggregated, spatially and temporally, throughout the Colorado River Upper Basin with the nonparametric disaggregation method described in the Section N.2.2. The nine lower sites are resampled as described in Section N.2.2.

The traces generated for the Upper Basin sampling sites can produce monthly flows and sequences that were not seen before and reflect a blend of the hydrologic variability seen in the observed and reconstructed data. The downstream sites 21 to 29 contribute significantly less flow (eight percent of the total calendar year flow) than the upper sites; therefore, choosing from the direct observed natural flows does not adversely affect the ability to model unique and probable flows in the basin as a whole.

As a result of using the hydrologic state information from the paleo reconstruction data the flow sequences in the generated paleo conditioned hydrologies will reflect sequence properties (i.e., wet or dry) characteristic of the paleo reconstruction. The magnitudes of generated flow on a water year basis match the magnitudes in the observed record (1906 to 2005). The inability to generate flow magnitudes beyond those in the observed record can be a shortcoming of this technique although the increased variety of flow sequences is an advantage of this method when compared to some other stochastic hydrologic generation methods.

For these nonparametric paleo conditioned hydrologies, 125 traces, each 53 years in length, were generated for the 29 sites throughout the Colorado River Basin.

N.2.4 Comparison of the Inflow Scenarios

Basic statistics from the three inflow scenarios are shown in Figure N-1. Also presented are the two scenarios based on the Woodhouse et al. 2006 reconstructions analyzed in the Draft EIS and presented in Attachment A to this Appendix N. The statistics are computed from total calendar year flow at Lees Ferry Gaging Station on the Colorado River and include the mean, standard deviation, skew, lag-1 autocorrelation, maximum and minimum. The observed statistic (1906 to 2005) is shown as a blue triangle.

The statistics are shown as “box and whisker” plots that display the inter-quartile range as a box (where 25 percent to 75 percent of the values lie), with the median represented as a vertical line within the box. The five percent to 95 percent range of the values is also shown by the dashed lines typically extending outside the box (i.e., the “whiskers”). One measure of performance of a particular method is its ability to capture the observed statistic within the inter-quartile range. It is not always preferable to capture the observed statistic when considering climate variability. Modeling statistics other than what are exhibited by the observed data allows representation of scenarios that have not occurred in the gauged record but are plausible based on paleo reconstructions.

Each inflow scenario is presented in a row and the six statistics are presented in each column. The observed mean is reproduced well by the DNF and the Meko et al. and Woodhouse et al. NPC as expected. The Meko et al. and Woodhouse et al. Direct-Paleo (DP) scenarios underestimate the observed mean, as expected, because these paleo reconstructions have a lower mean (14.7 and 14.6 million acre-feet [maf], respectively) than the observed period (15.0 maf). The standard deviation which measures the spread of the flow magnitudes is similar to the observed standard deviation for all scenarios except the Meko et al. DP scenario, which has a reduced standard deviation. This most likely results from limited tree-ring data available before A.D. 1200 reducing the variability in the tree ring chronologies. The skew, which measures the overall shift of the flows, is shifted towards lower flows for the DP scenarios while the remaining scenarios exhibit a similar skew to the observed flows. The lag-1 autocorrelation is similar to the observed flow for all inflow scenarios. The observed maximum is not exceeded by the DP scenarios and only slightly exceeded by the Non-parametric Paleo Conditioning (NPC) scenarios. The observed minimum flow is not exceeded by the NPC scenarios while the DP scenarios result in lower minimums. The Meko et al. and Woodhouse et al. DP are able to generate much lower flows than observed, approximately two maf and 3.7 maf lower, respectively, five percent of the time. It was expected the DP would generate lower flows than observed as these are characteristic of Lees Ferry streamflow reconstructions. Paleo reconstructions have consistently shown that the recent period (1906 to 2005) has been a relatively wet period compared with results from multiple reconstructions completed for Lees Ferry. The DP scenarios demonstrate the impact these lower flow magnitudes in the paleo record, which are not seen in the recent observed period, may have on reservoir operations. Information from flow magnitudes is just one aspect of each scenarios statistical properties.

From the hydrologic perspective, the probabilities and durations of wet and dry periods is of interest and a further measure of variability. The probability of wet and dry periods of a given length for the DNF inflow and the two Meko et al., based alternative inflow scenarios are shown in Figure N-2 and Figure N-3 as histograms. Each bar in the histogram depicts the probability for the wet or dry period of a given length. A dry period was defined as consecutive years when the flow in each year is below the median (50th percentile) flow. Similarly, a wet period was defined as consecutive years when the flow in each year is above the median observed flow. In both cases, the length of the period was given by the number of consecutive years in each state.

The DNF inflow scenario contains wet and dry periods of maximum length of five and four years, respectively. The DP scenario based on Meko et al. has an increased variability of wet and dry periods where the maximum lengths are eight and 12 years, respectively. The NPC based on Meko et al. scenario displays the greatest variability with a maximum wet and dry length of 22 and 21 years, respectively.

Figure N-3
Histograms of Wet Periods for the Inflow Scenarios
(a) Direct Natural Flow; (b) Direct Paleo – Meko 2007;
and (c) Nonparametric Paleo Conditioning – Meko 2007

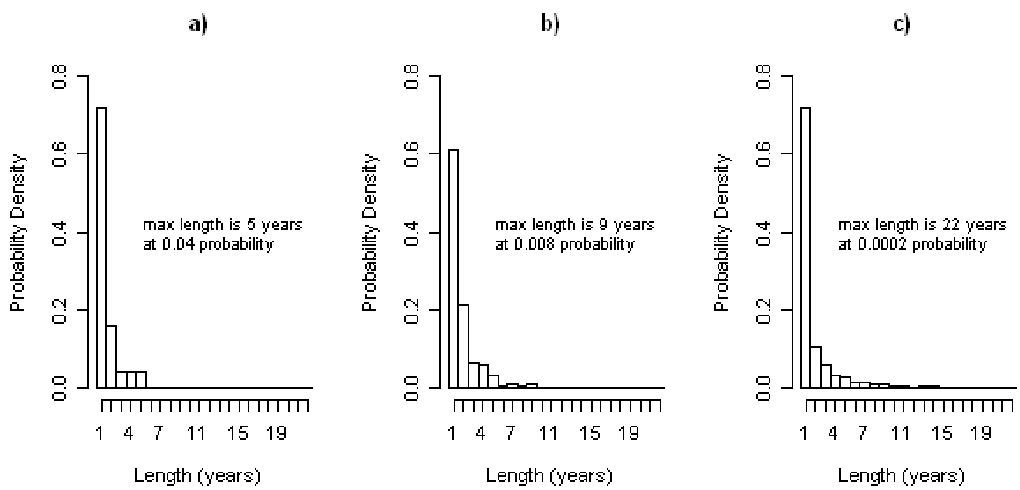

Table N-1 and Table N-2 further present the probability for all dry and wet spells, respectively, for the DNF inflow and the two Meko et al., based alternative inflow scenarios. Spell lengths range from one to 21 years for dry spells or one to 22 years for wet spells. The DNF is developed from the observed record for which the longest dry spell was four years with a 0.125 percent probability. The four-year dry spell has a 0.0697 percent probability with the DP scenario and a 0.0416 percent probability with the NPC scenario. The DP and NPC scenarios exhibit a reduced four-year dry spell as compared with DNF but display a probability of drought lengths beyond the four-year drought. The DP scenario has a 0.0820 percent probability of droughts five years or longer in length. The NPC scenario has a 0.1270 percent probability of droughts five years or longer in length.

19	0.0000	0.0000	0.0000
20	0.0000	0.0000	0.0004
21	0.0000	0.0000	0.0002

The longest wet spells for the DNF scenario are five years in length with a 0.04 percent probability. The DP and NPC again exhibit a slightly reduced five-year wet spell as compared with DNF but display a probability of wet spells beyond five years. The DP scenario has a 0.0245 percent probability of wet spells six years or longer and the NPC scenario has a 0.0627 percent probability of wet spells six years or longer in length.

These dry and wet spell lengths are beyond those exhibited in the observed natural flows and demonstrate the additional hydrologic variability beyond that seen in the recent gaged record that can been attributed to climate variability.

N.3 Results

This section describes the sensitivity of the No Action Alternative and Preferred Alternative to the hydrologic variability provided by the two alternative hydrologic inflow scenarios described in Section N.2. As described in Section 4.2, the modeling assumptions for the Preferred

Alternative are assumed to revert to the assumptions used for the No Action Alternative after 2026.

N.3.1 Percentile Elevations

Figure N-4 presents a comparison of the 90th, 50th, and 10th percentile plots of Lake Powell elevations obtained for DNF and the two alternative hydrologic inflow scenarios, under the No Action Alternative and the Preferred Alternative.

The 90th percentile range of the three hydrologic methods shows smaller variation between the scenarios, largely because Lake Powell is at or near its maximum reservoir capacity.

At the 50th percentile range, the No Action Alternative and Preferred Alternative show little difference except from 2016 to 2030 when the Preferred Alternative is elevated. The DNF and DP track closely throughout the run while the NPC begins lower than either DNF or DP until 2012 when it slightly exceeds both, then drops lower again until the end of the run in 2048.

Variation between the various hydrologic inflow methods is highest at the 10th percentile range because Lake Powell is most sensitive to variations in inflow at lower elevations. The higher variability from year to year at the 10th percentile level for the NPC scenario is a result of the different resampling technique used. The DNF and DP hydrologic inflow scenarios are resampled with the ISM, which guarantees year to year hydrologic inflow scenario statistics that are nearly identical. The year to year variation seen in these scenarios results mostly from reservoir operations. The NPC hydrologic inflow scenario is generated with stochastic methods that do not generate identical hydrologic inflow scenario statistics on a year to year basis; although with increased sample size, these scenarios will produce an average year to year statistic which is similar but not identical. This property is present in most stochastic techniques other than ISM.

The No Action alternative produces lower reservoir elevations for all the hydrologic inflow scenarios in the early part of the run from 2009 to 2020. The NPC alternative shows a significant drop in reservoir elevation after 2030 that is not displayed by either the DNF or DP scenarios.

Because Lake Powell is able to make reduced releases at lower reservoir elevations, the Preferred Alternative has the effect of keeping Lake Powell higher (especially through 2017) compared to the No Action Alternative.

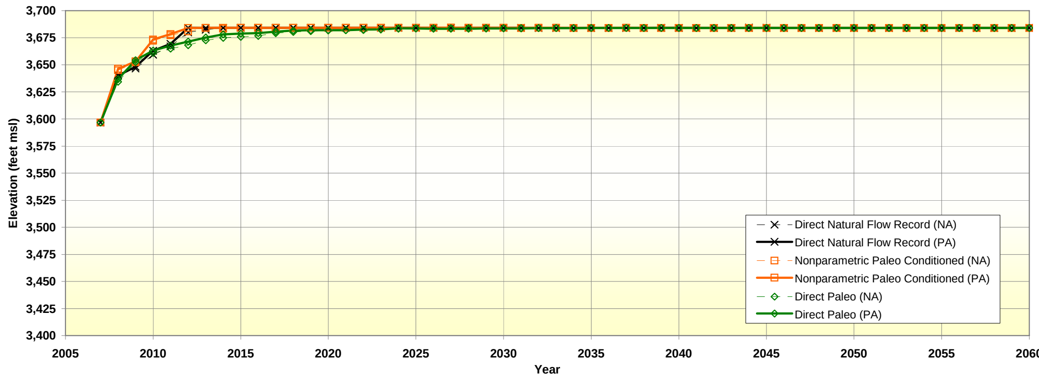
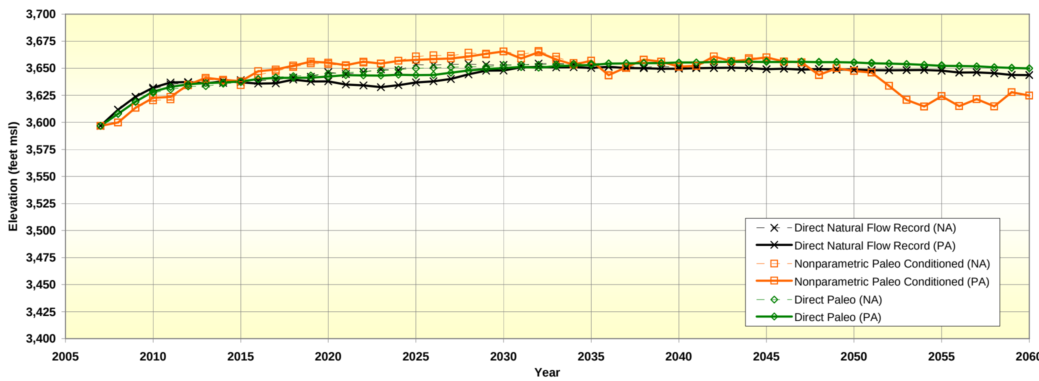
No Action Alternative (NA) and Preferred Alternative (PA)
90th, 50th and 10th Percentile Values

90th Percentile



50th Percentile



10th Percentile

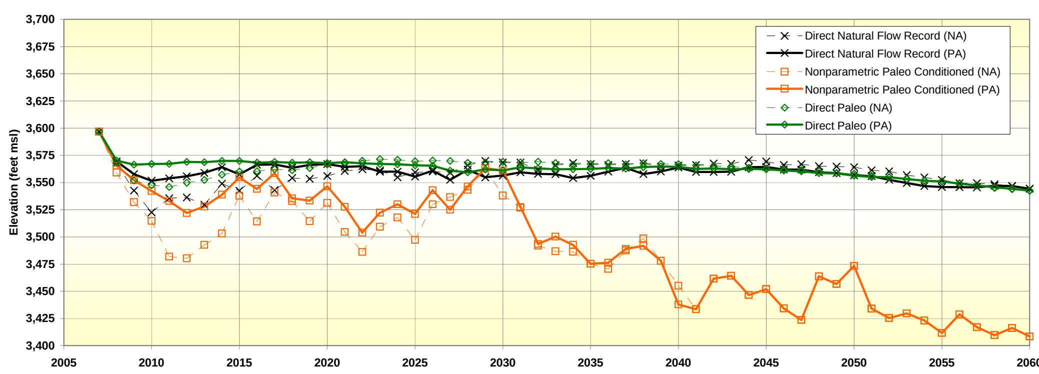


Figure N-5 presents a comparison of the 90th, 50th, and 10th percentile plots of Lake Mead elevations obtained for DNF and the two alternative hydrologic inflow scenarios, operated under the No Action Alternative and the Preferred Alternative. At the 90th and 50th percentiles, DP is generally consistently lower than DNF even though both utilized the same sampling technique because the DP hydrology set has a higher magnitude and droughts of longer duration. At the 90th and 50th percentiles, NPC is generally higher than DNF due to higher magnitude and longer duration wet cycles in the two data sets.

At the 90th percentile, the No Action Alternative is generally lower until 2020 when the two alternatives track similarly. At the 50th percentile, the No Action Alternative is again generally lower through the interim period. From 2027 to 2045, the No Action Alternative is higher than the Preferred Alternative after which the two alternatives track similarly. At the 10th percentile, the Preferred Alternative is the lowest compared to the No Action Alternative with the NPC hydrologic inflow scenario through about 2020. This behavior is due to the low inflows into Lake Powell under this scenario of which the effect can be seen at the Lake Powell 10th percentile in Figure N-4. In contrast to the NPC and DNF scenarios, under the DP scenario the Lake Powell elevation is generally higher under the Preferred Alternative than under the No Action Alternative during the interim period. Lake Powell elevation is highest at the 10th percentile under the DP scenario, and more significantly the Preferred Alternative is closest to elevation 3,575 feet msl. Above this elevation, Lake Powell must release 8.23 maf or for balancing (resulting in higher Lake Mead elevations) and below this elevation, Lake Powell reduces releases to 7.48 maf.

N.3.2 Extreme Drought Single Trace Analysis

Figure N-6 presents the 25-year running mean from sequence 1 of the paleo reconstruction published by Meko et al. (2007). The lowest 25-year period in the paleo reconstruction extends from A.D. 1130 to 1154. During this period the mean flow is 84 percent of the mean observed natural flow from 1906 to 2005. The lowest 25-year period in the observed flow (1953 to 1977) is 87 percent of the observed mean.

Figure N-6
Annual Natural Flow at Lees Ferry
Meko et al. sequence 1 Reconstruction
25 Year Running Mean

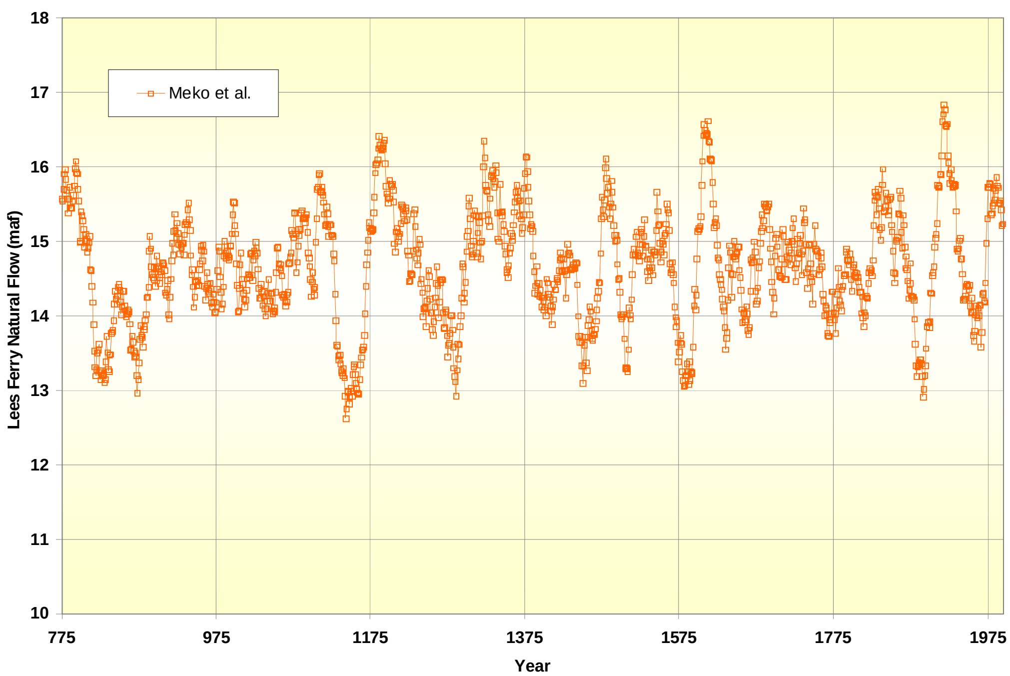

Figure N-7 presents the annual natural flow at Lees Ferry from trace 369 for DP. This trace is an identical input to both the No Action Alternative and the Preferred Alternative simulations. This trace is resampled directly from the Meko et al. paleo reconstruction and begins with the A.D. 1130 to 1154 lowest 25-year period thereby, including the flow sequence with the most extreme 25-year drought exhibited in the paleo reconstruction. This period falls within the timeframe of the Medieval Climate Anomaly, a period when many paleoclimate records have demonstrated severe hydrologic droughts in the western United States (Meko et al. 2007). During the first 25 years of trace 369, not all flows are below the mean observed flow (15.1 maf). Multiple years are above the mean observed flow, though the majority of years are below the mean in these first 25 years.

Figure N-7

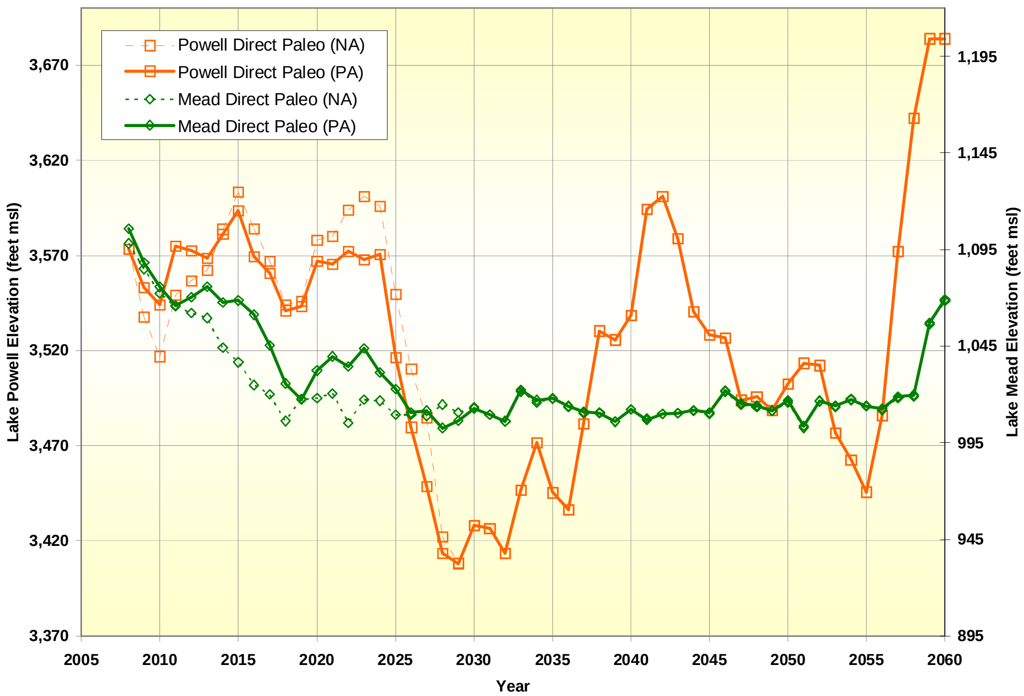
Figure N-8 presents end-of-December elevations of Lake Powell and Lake Mead resulting from trace 369 for DP.

Figure N-8
End-of-December Elevations
Comparison of Single Trace using Meko et al. Reconstruction for
No Action Alternative (NA) and Preferred Alternative (PA)
Hydrology Start Year is 1130 from Meko et al. Reconstruction



Given the current initial conditions a continuing drought further draws down Lake Mead though the Preferred Alternative maintains higher elevations at Lake Mead as a result of balancing releases from Lake Powell. Under the Preferred Alternative, Lake Powell is initially higher due to the ability to reduce releases below 8.23 maf. However, as Lake Mead's elevation is drawn down, Lake Powell provides water through balancing releases and is also eventually drawn down near the end of the interim period. During the higher Lake Powell reservoir elevations centered on 2042 and 2059 the natural flows were substantially increased, thereby building reservoir storage at Lake Powell.

Figure N-9 presents the annual natural flow at Lees Ferry from trace 50 for NPC. This trace is an identical input to both the No Action Alternative and the Preferred Alternative simulations. This trace is not directly resampled from the paleo reconstruction but uses the reconstruction to conditionally choose the observed natural flows generating dry spells not seen before but statistically plausible given the paleo reconstruction's spell length properties. The trace begins with the lowest 25-year period generated from the NPC hydrologic inflow scenarios. During this period the mean flow is 80 percent of the mean observed natural flow from 1906 to 2005. In this trace the natural flows exhibit increased variability of extreme low flows compared to the single trace presented in Figure N-7. In Figure N-7, the lowest annual flow is 8.6 maf while in Figure N-9, the lowest flow is 5.7 maf. The lower flows exhibited by the NPC trace allow further understanding of the impacts that periods of extreme low flows may have on reservoir operations.

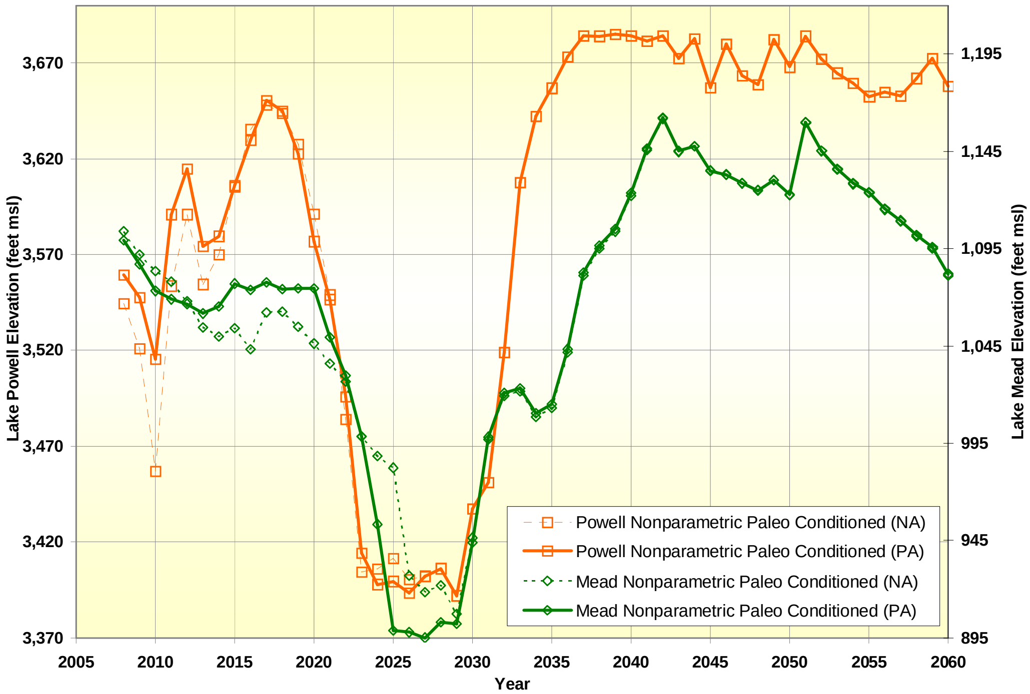
Figure N-10
End-of-December Elevations
Comparison of Single Trace using Nonparametric Paleo Conditioning with
Meko et al. Reconstruction for No Action Alternative (NA) and Preferred Alternative (PA)



The initial natural flows shown in Figure N-10 are low but increase above the mean observed flow by 2011 increasing elevations at both Lake Powell and Lake Mead. Beginning in 2018, natural flows are below the mean observed flow and remain below until 2032. Under this sustained dry spell, Lake Mead is drawn down to dead pool (895 feet msl) by 2027 and Lake Powell is taken to 3,392 feet msl by 2029 under the Preferred Alternative. The increased drawdown seen under the Preferred Alternative is a result of the modeling assumption that includes a maximum shortage amount of 600 kaf[2] while the No Action Alternative includes absolute protection of Lake Mead at elevation 1,000 feet msl[3], which can result in shortages as large as 3,300 kaf which prevent the reservoirs from dropping to the elevations seen under the Preferred Alternative. When natural flows rebound above the mean observed flow again in 2032, both reservoirs recover.

N.3.3 Probability of Being Below Key Elevations

Figure N-11 presents a comparison of the likelihood of Lake Powell end-of-December elevations being at or below the minimum power pool (elevation 3,490 feet msl) for DNF and for the two alternative hydrologic inflow scenarios. DNF shows nearly no chance of

---

[2] As noted in Section 2.7, the Preferred Alternative includes a provision for appropriate consultations regarding additional shortages when Lake Mead is below 1,025 feet msl. For modeling purposes, it was assumed that shortages of 600 kaf would continue to be applied for Lake Mead elevations below 1,025 feet msl.

[3] Modeling assumptions used in the Preferred Alternative allowed a maximum shortage of approximately 3,300 kaf, resulting in the inability to absolutely protect Lake Mead elevation 1,000 feet msl.

Lake Powell elevations falling below minimum power pool. NPC indicates the highest likelihood of occurrence at 26 percent, followed by the DP (five percent), and DNF (one percent). During the interim period, for all inflow scenarios, the probability of Lake Powell falling below elevation 3,490 feet msl is less under the Preferred Alternative due to the ability of Lake Powell to make reduced releases at lower reservoir elevations.

Figure N-11
Lake Powell End-of-December Elevations
Comparison of Direct Natural Flow Record to Meko et al. Reconstruction
No Action Alternative (NA) and Preferred Alternative (PA)
Percent of Values Less Than or Equal to Elevation 3,490 feet msl

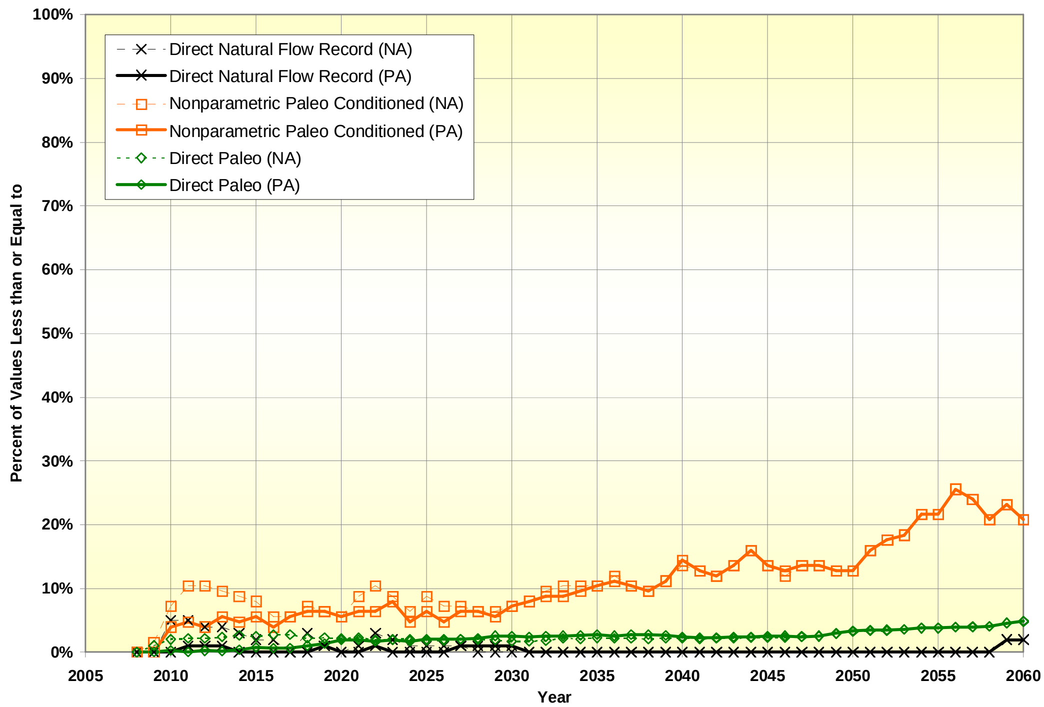


Figure N-12 presents a comparison of the likelihood of Lake Mead end-of-December elevations being at or below the minimum power pool (elevation 1,050 feet msl) for DNF and for the two alternative hydrologic inflow scenarios. NPC generally shows the highest chance of being below minimum power pool until 2017, when the No Action Alternative with DP and DNF indicate a higher likelihood. After 2028, the NPC generally indicates the lowest likelihood for most years.

The Preferred Alternative generally shows a lower likelihood for both the DNF and DP inflow scenarios until 2028 when these scenarios show the highest likelihood for most years.

Figure N-12
Lake Mead End-of-December Elevations
Comparison of Direct Natural Flow Record to Meko et al. Reconstruction
No Action Alternative (NA) and Preferred Alternative (PA)
Percent of Values Less Than or Equal to Elevation 1,050 feet msl

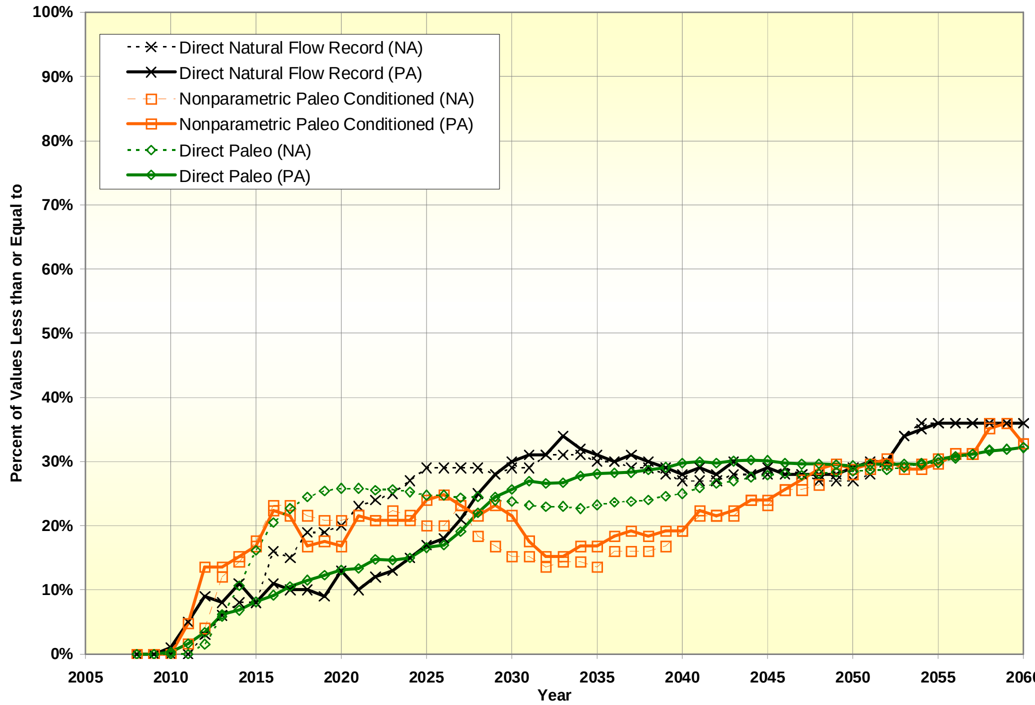

Figure N-13 presents a comparison of the likelihood of Lake Mead end-of-December elevations being at or below 1,025 feet msl for DNF and for the two alternative hydrologic inflow scenarios. NPC generally shows the highest likelihood of falling below elevation 1,025 feet msl until 2020, when the No Action Alternative with DP and DNF indicate a higher likelihood. After 2028, the NPC generally indicates the lowest likelihood until 2050, when NPC again shows the highest likelihood.

The Preferred Alternative generally shows a lower likelihood for both the DNF and DP hydrologic inflow scenarios until 2033, when these scenarios show slightly higher likelihood until 2050, when NPC generally shows a higher likelihood.

Figure N-13
Lake Mead End-of-December Elevations
Comparison of Direct Natural Flow Record to Meko et al. Reconstruction
No Action Alternative (NA) and Preferred Alternative (PA)
Percent of Values Less than or Equal to Elevation 1,025 feet msl

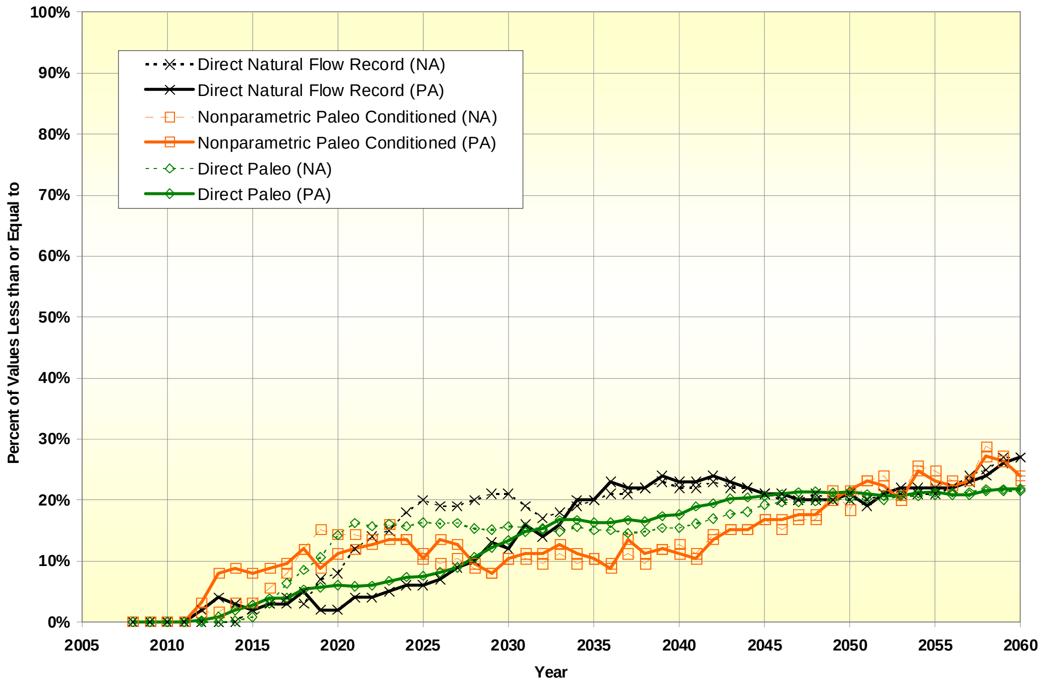

Figure N-14 presents a comparison of the likelihood of Lake Mead end-of-December elevations being at or below 1,000 feet msl (the elevation of Southern Nevada Water Authority's lower intake) for DNF and for the two alternative hydrologic inflow scenarios. DNF shows no chance of Lake Mead elevations being below 1,000 feet msl. NPC indicates the highest likelihood of occurrence at nine percent in 2023 under the Preferred Alternative, followed by the No Action Alternative (eight percent), and the DP Preferred Alternative (two percent).

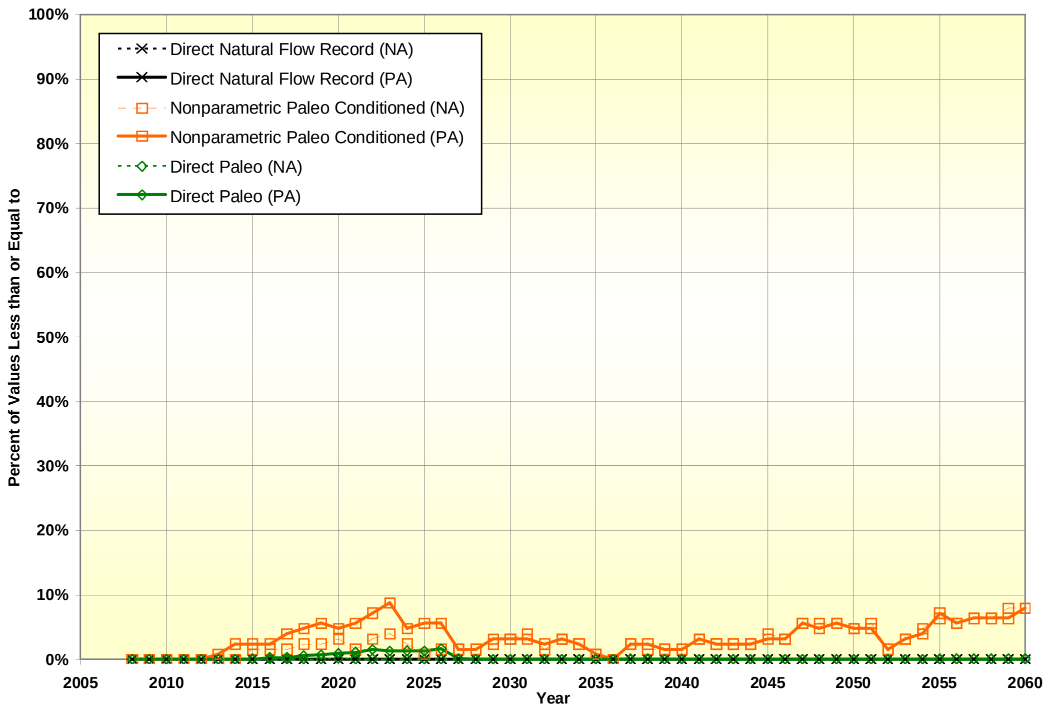
Figure N-14
Lake Mead End-of-December Elevations
Comparison of Direct Natural Flow Record to Meko et al. Reconstruction
No Action Alternative (NA) and Preferred Alternative (PA)
Percent of Values Less Than or Equal to Elevation 1,000 feet msl



N.3.4 Lower Basin Shortage

Figure N-15 shows the probability of shortage in the Lower Basin under the No Action Alternative and the Preferred Alternative obtained for DNF and the two alternative hydrologic inflow scenarios. The higher variability observed with the NPC method is a function of the resampling technique. The Preferred Alternative exhibits a lower probability of shortage until 2026 when the No Action Alternative has a generally lower probability. The highest probability of shortage for each alternative occurs after 2055 with the following approximate values: DNF, 69 percent; DP, 82 percent; and NPC, 78 percent.

Figure N-15
Lower Basin Shortages
Comparison of Direct Natural Flow Record to Meko et al. Reconstruction
No Action Alternative (NA) and Preferred Alternative (PA)
Probability of Occurrence

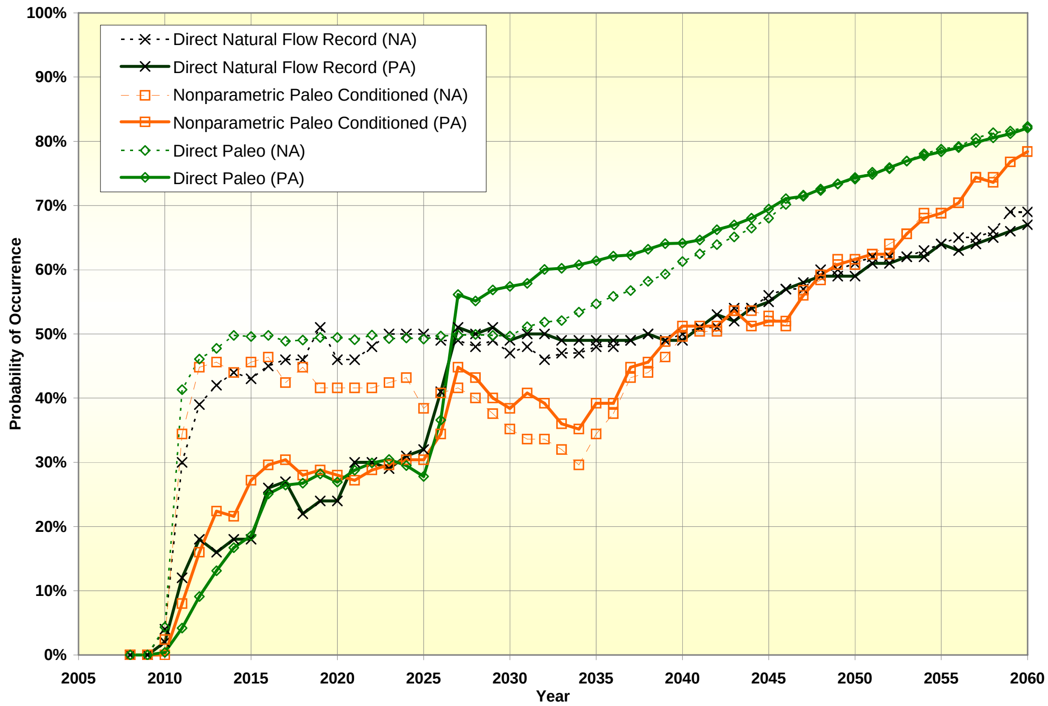


Figure N-16 shows the cumulative distribution of shortages over the interim period. Under the No Action Alternative, for all inflow scenarios, the magnitude of most shortages is about 500 kaf. Under the Preferred Alternative, for the DNF and DP scenarios, most shortages are about 400 kaf. With the NPC scenario, about fifty percent of the shortage amounts are 400 kaf while fifty percent are 500 kaf and above, up to 859 kaf. A shortage of 859 kaf under the Preferred Alternative indicates that Lake Mead elevation was below 1,000 feet msl for the entire year resulting in no delivery to SNWA. The No Action Alternative with both the DP and NPC scenarios reaches a maximum shortage of 3.3 maf, the maximum shortage using current modeling assumptions. With the DNF scenario, the maximum shortage in the No Action Alternative is much lower at about 1.9 maf.

Figure N-16
Cumulative Distribution of Lower Basin Shortages
Comparison of Direct Natural Flow Record to Meko et al. Reconstruction
No Action Alternative (NA) and Preferred Alternative (PA)
2008 to 2026

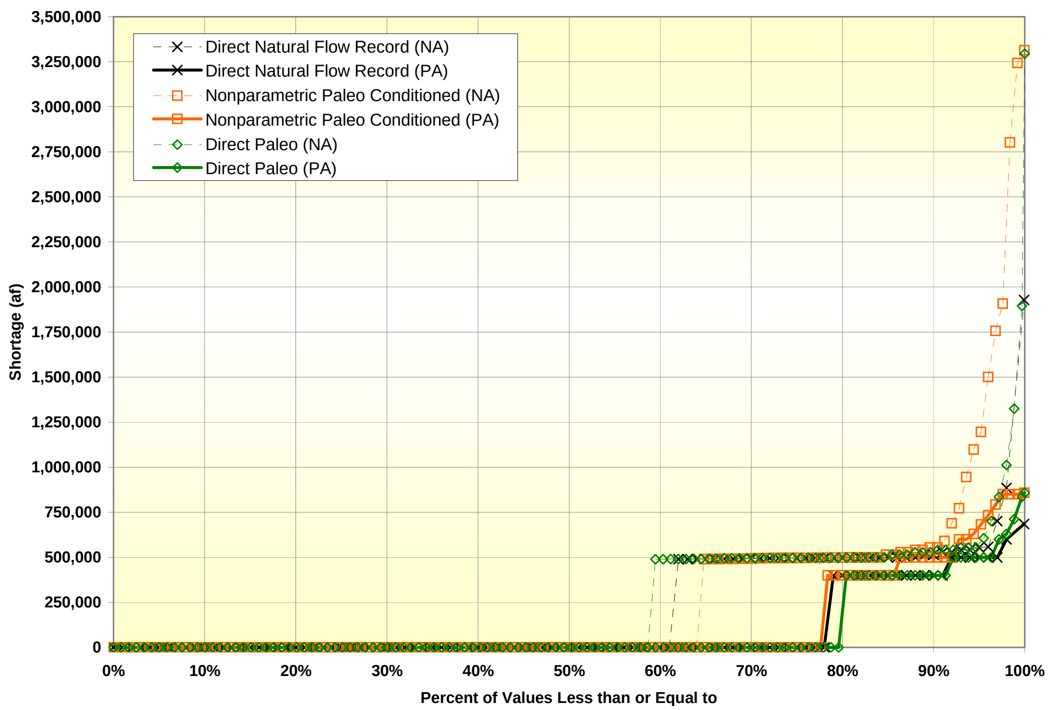

Figure N-17 shows the cumulative distribution of shortages from 2027 through 2060. During this period the shortage strategy for both the No Action Alternative and the Preferred Alternative is identical and includes absolute protection of Lake Mead elevation 1,000 feet msl. For all inflow scenarios most of the shortages are about 500 kaf, however shortages of this amount occur approximately fifteen percent more often with the DP inflow scenario. Shortages above 500 kaf occur about ten percent more often under the NPC scenario. Both the DP and NPC scenarios reach a maximum shortage of 3.3 maf, while the DNF scenario reaches a maximum shortage much lower at about 1.9 maf.

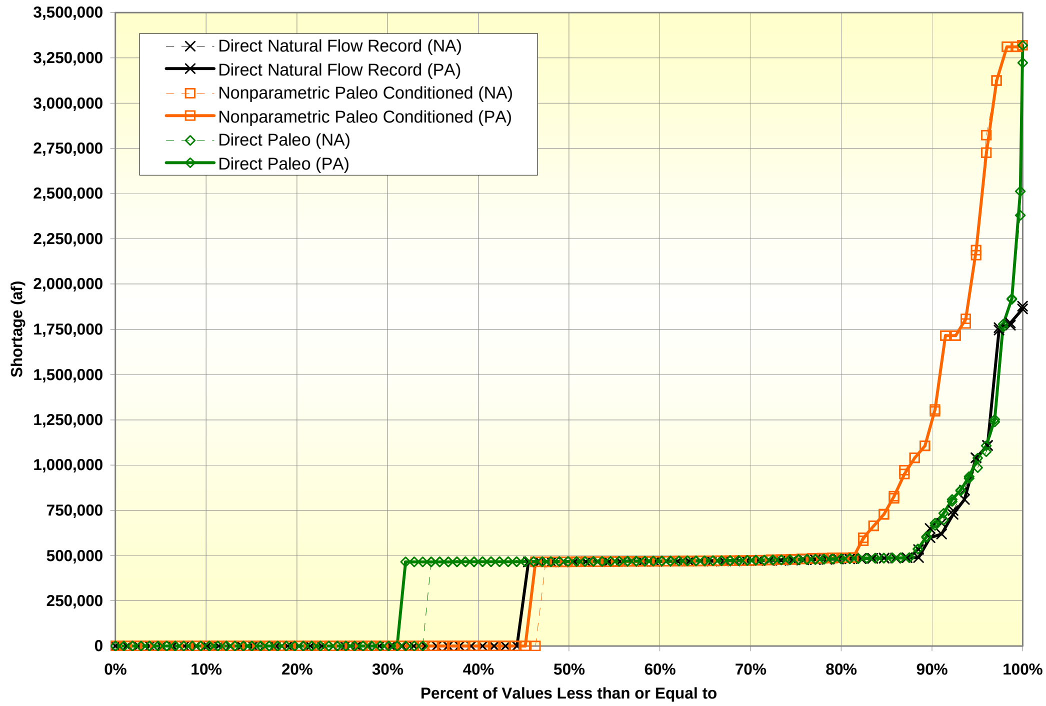
Figure N-17
Cumulative Distribution of Lower Basin Shortages
Comparison of Direct Natural Flow Record to Meko et al. Reconstruction
No Action Alternative (NA) and Preferred Alternative (PA)
2027 to 2060



N.3.5 Lower Basin Surplus

Figure N-18 shows the probability of any surplus to the Lower Division states under the No Action Alternative and the Preferred Alternative obtained for DNF and the two alternative hydrologic inflow scenarios. This plot includes the probability of Flood Control surplus under which condition Mexico would also receive up to 1.7 mafy. The higher variability observed with the NPC is a function of the resampling technique. Under both alternatives, NPC has a higher probability of surplus than DNF from 2015 to 2030 due to the extended wet periods in the data set. The highest probability of surplus for each inflow scenario occurs around 2026 under the Preferred Alternative with the following approximate values: DP, 30 percent; DNF, 40 percent; and NPC, 46 percent. Beginning in 2017, under the No Action Alternative, only 70R and Flood Control surpluses occur, which reduces the probability of surplus to below 25 percent.

Figure N-18

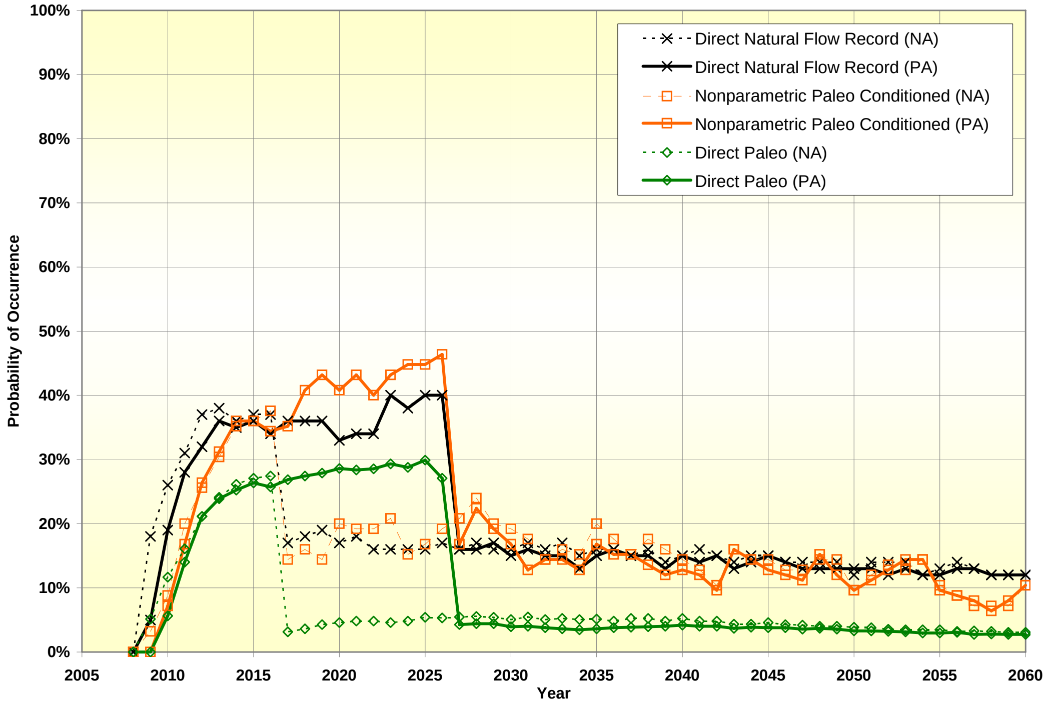
Probability of Occurrence



N.3.6 Releases from Glen Canyon Dam

Figure N-19 presents a comparison of 10-year running total of water-year release volumes from Glen Canyon Dam for DNF and the two alternative hydrologic scenarios. The largest differences in the frequency of release volumes are observed at the highest and lowest volumes, where the NPC hydrologic sequence shows the lowest low and highest high extreme values. DP shows the lowest high extreme values and has depressed high values as compared to the other two hydrologic inflow scenarios as a result of the reduced standard deviation discussed in Section 2.3 of this Final EIS.

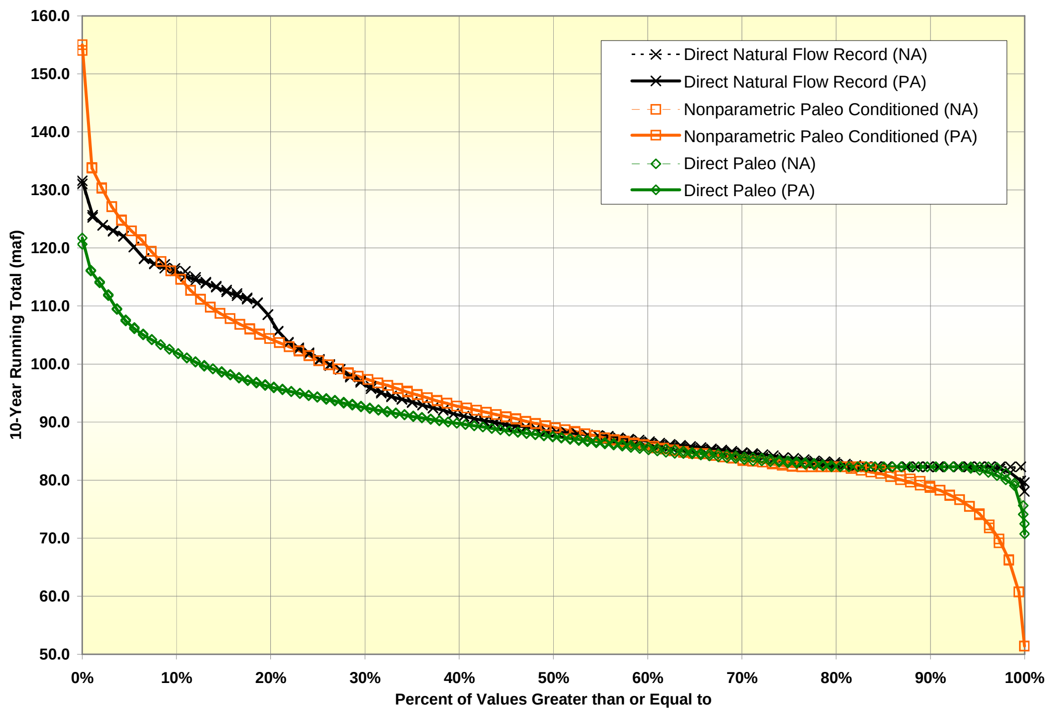
No Action Alternative (NA) and Preferred Alternative (PA)
Water Years 2009 to 2060



N.3.7 Natural Flow at Lees Ferry

Figure N-20 presents a comparison of annual natural flow volumes past Lees Ferry Gaging Station for DNF and the two alternative hydrologic scenarios. The largest differences in the frequency of natural flow volumes are observed at the highest volumes, where the DP hydrologic sequence again shows depressed high flows. The DP hydrologic sequence also shows the lowest volume at 2.9 maf compared to the DNF and NPC scenarios at 5.5 maf and 5.1 maf, respectively.

Attachment A
(Appendix N from the Draft EIS dated February 2007)

Analysis of Hydrologic Variability Sensitivity

This attachment to Appendix N was first published as Appendix N in the Draft EIS. Although no substantial changes have been made, some minor errors were fixed. This attachment contains descriptions of the analyses performed to evaluate the potential effects of using alternative hydrologic inflow scenarios when performing modeling simulations in CRSS. This sensitivity analysis compares three accepted scientific methods for providing hydrologic variability. These alternative hydrologic inflow scenarios use hydrologic inflow data derived from Nonparametric Paleo Hydrologic State information, Parametric Stochastic Natural Flow Records, and Direct Paleo methods. The alternative hydrologic inflow scenarios are compared to the current method used by Reclamation which uses the Index Sequential Method (ISM) for stochastic streamflow reconstruction.

A.1 Introduction

This appendix was developed to explore the potential effects of using alternative hydrologic inflow scenarios when performing modeling simulations in CRSS. As explained previously in Section 4.2.4 of the Draft EIS hydrologic variability was incorporated in the hydrologic modeling using the Index Sequential Method (ISM) (USBR 1985; Ovarda, et al. 1997) on the 99-year natural flow record from 1906 to 2004. This sensitivity analysis will compare three other accepted scientific methods for providing hydrologic variability. The three methods used do not incorporate forecasts of future climate variability, but do provide a wider range of hydrologic variability than the application of ISM to the natural flow record, including longer wet and dry periods than seen in the observed record.

A.2 Development of Three Alternative Hydrologic Inflow Scenarios to Compare with the 1906 – 2004 Natural Flow Record using ISM

The CRSS model requires natural flow inputs at 29 sites throughout the Colorado River system. There are 20 sites above and including the Lees Ferry site on the Colorado River. Below the Lees Ferry site are an additional 9 sites. Generation of stochastic natural flows throughout the 29 sites is a critical step towards understanding the impact of natural streamflow variability on model results.

As stated before, Reclamation currently uses the ISM for stochastic streamflow generation. This stochastic method entails a sequential block bootstrap of the observed data, where the block size is determined by the simulation horizon. The ISM cycles through each year in the historic record generating 99 traces, assuming that the record wraps around at the end (i.e., 2004, 1906, 1907, etc.). Each trace will only consist of annual and monthly flow magnitudes and sequences that have occurred in the observed record, with the exception of new sequences being generated as a result of the wrap. This limits the ISM's ability to model a wide range of plausible future streamflows including flow magnitudes and sequences not seen in the observed record. Strengths of this method are it is easy to implement, understandable, and has been widely accepted by stakeholders on the Colorado River.

To address these drawbacks three alternative methods to generate stochastic natural flows were applied and three alternative hydrology scenarios were generated. These methods were chosen to sample a range of techniques available to generate stochastic flows. Each method has strengths and weaknesses that are described below along with the basic concept of the method.

Throughout this appendix the ISM technique as applied to the 1906 to 2004 natural flow record is referred to as Direct Natural Flow Record (DNF).

A.2.1 Nonparametric Paleo Conditioning (NPC)

This technique conditionally resamples historic data based on paleo hydrologic state information (i.e., wet or dry). Hydrologic state sequences are modeled based on the "Lees-B" paleo reconstruction (1490-1997) and flow magnitudes from the observed natural flows (1906-2004) are conditionally resampled generating annual water year flows at Lees Ferry on the Colorado River (Lee, et al. 2006). Prairie (2006) provides a detailed description of the conditional resampling technique.

The annual flows at Lees Ferry (site 20) are disaggregated, spatially and temporally, throughout the Upper Colorado River Basin using a nonparametric disaggregation method (Prairie, 2006; Prairie et al., 2006). The disaggregation scheme ensures that the flows generated throughout the Upper Colorado River basin are spatially and temporally consistent among the 20 locations that characterize natural flow.

Flows for the 9 gauges below site 20 are resampled from the observed natural flows (1906-2004) based on the analogue year resampled from the observed natural flows when conditionally generating monthly flows. For example, if year 1954 was the analogue year chosen during the disaggregation then the associated monthly flows for each of the 9 lower sites are resampled from 1954 observed monthly natural flows. This method ensures the lower sites are both temporally and spatially correlated with each other and the upper sites. The lower sites 21-29 contribute significantly less flow (eight percent of the total calendar year flow) than the upper sites; therefore, resampling the direct observed natural flows does not adversely affect the ability to model unique and probable flows in the basin as a whole.

For these nonparametric paleo conditioned hydrologies, 125 traces, each 53 years in length, were generated for the 29 sites throughout the Colorado River basin. The traces generated for the upper 20 sites will produce annual calendar year flow sequences that were not seen before. As a result of using the hydrologic state information from the paleo reconstruction data the flow sequences in the generated paleo conditioned hydrologies will reflect sequence properties (i.e., wet or dry) characteristic of the paleo reconstruction. The magnitudes of generated flow on a water year basis match the magnitudes in the observed record (1906-2004). The inability to generate flow magnitude beyond those in the observed record can be a shortcoming of this technique though the increased variety of flow sequences is an advantage of this method when compared to some other stochastic hydrologies.

A.2.2 Parametric Stochastic Natural Flow Record (PS)

This technique uses parametric stochastic methods to fit the observed natural flows (1906-2003) to an appropriate set of stochastic models for streamflow generation and disaggregation. A parameter fitting procedure, hence the name parametric methods, is applied to fit the observed natural flow to the appropriate parametric models. For this project the observed natural flows at two key sites (Lees Ferry and at Imperial Dam on the Colorado River) were fit to a contemporaneous autoregressive order 1 (CAR[1]) model (Salas, 1985). Annual flows at both sites were simultaneously generated producing 100 traces each 53 years in length. The generated flows where then spatially and temporally disaggregated to the 29 sites at a monthly time scale with appropriate parametric disaggregation techniques. Lee et al., 2006 provides a detailed description of the model selection and fitting procedure for the generation and disaggregation of flows. Scheme 2 from Lee et al., (2006) was found to best preserve both the monthly and annual statistical properties of the observed natural flow and was selected for generation of the parametric hydrologies applied in this study.

Note these parametric hydrologies were developed with natural flows only including up to 2003 while the preceding two stochastic methods used observed natural flows though 2004. At the time these parametric hydrologies were developed the 2004 data was not yet available. A Kolmogorov-Smirnov test (KS-test) was performed for each site to determine if the data distribution has significantly changed between these two datasets. This test found no significant differences at any sites at a 95 percent significance level. Therefore, there should be no reason the parametric hydrologies cannot be compared along side the other two alternative hydrologies.

The parametric techniques can generate both flow magnitudes and sequence not seen in the observed record but statistically similar to the observed record A drawback of the parametric methods are they have the ability to generate values must larger or smaller than those in the observed record and can be difficult to justify. They also have difficulty representing non-Gaussian data distribution features.

A.2.3 Direct Paleo (DP)

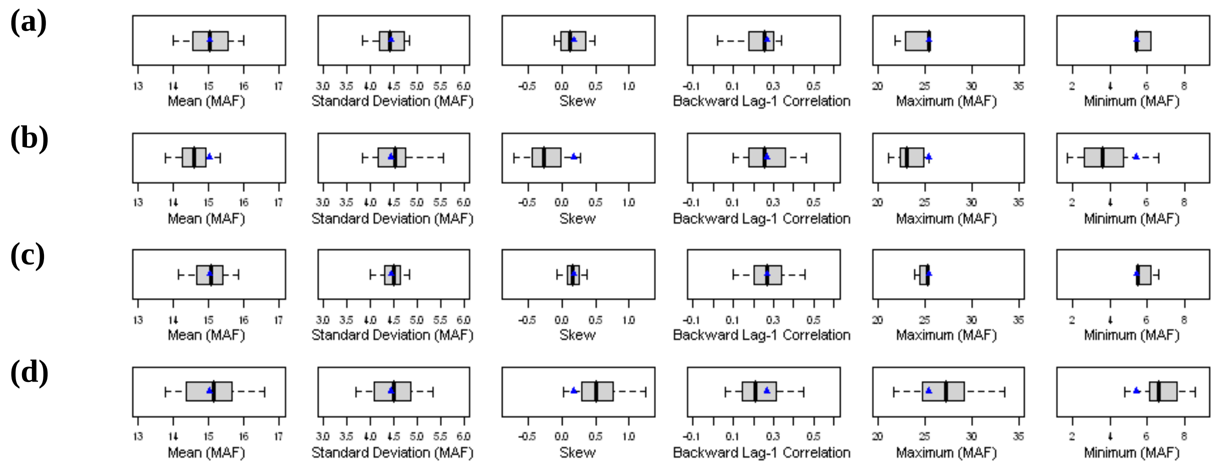
This technique uses the “Lees-B” paleo-reconstruction from Woodhouse et al. (2006). This paleo-reconstruction provides annual water year flows from 1490-1997 on the Colorado River at Lees Ferry. The annual water year flows are disaggregated, spatially and temporally, throughout the Upper Colorado River Basin with the nonparametric disaggregation method (Prairie et al., 2006); the same disaggregation method described in the Section A.2.1 Nonparametric Paleo Conditioned. The nine lower sites are resampled as described in Section A.2.1.

These disaggregated flows (508 years of monthly flows at 29 sites) are resampled with the ISM generating 508 traces each 53 years in length. As ISM sequentially block bootstraps the disaggregated streamflow data, the generated traces will consist of annual flow magnitudes and sequences that are present in the paleo reconstructed streamflows, with the exception of the sequences created as a result of the wrap.

A.2.4 Comparison of Three Alternative Inflow Scenarios

Basic statistics from the DNF inflow and the three alternative inflow scenarios are shown in Figure Att. A-1. The statistics are computed from total calendar year flow at Lees Ferry on the Colorado River. These statistics include the mean, standard deviation, skew, lag-1 autocorrelation, maximum and minimum. The observed statistic (1906-2004) is shown as a blue triangle. While the statistics based on the inflow scenario are shown as boxplots. The boxplots display the interquartile range (IQR), where 25 percent to 75 percent of the values lie, with the median represented as a vertical line within the IQR. The whiskers extend to the five percent to 95 percent range of the values. Performance is generally judged as appropriate when the observed statistics is captured within the IQR.

Figure Att. A-1
Boxplots of Basic Statistics for
(a) Direct Natural Flow Record, (b) Nonparametric Paleo Conditioned,
(c) Parametric Stochastic Natural Flow Record, and (d) Direct Paleo



Each inflow scenario is presented in a row and the six statistics are presented in each column. The observed mean is reproduced well by the first three scenarios (DNF, NPC and PS) as expected. The DP scenario underestimates the observed mean, as expected, because this paleo reconstruction has a lower mean (14.6 million acre-feet [maf]) than the observed period (15.0 maf). The standard deviation is well reproduced by all scenarios. The skew is over estimated by the PS, a difficult statistic for parametric techniques to capture, while the DP underestimates the skew. The lag-1 autocorrelation is captured by all inflow scenarios. The observed maximum is not exceeded by the DNF or DP scenarios and only slightly exceeded by the NPC but the PS scenario is able to reproduce much higher flows than observed, approximately 8.0 maf higher five percent of the time. The observed minimum flow is not exceeded by the ISM or NPC, while the PS generates a few lower values. The DP is able to generate much lower flows than observed, approximately 3.7 maf lower five percent of the time. It was expected the DP would generate lower flows than observed as these are characteristic of Lees Ferry streamflow reconstructions.

A.3 Results

This section is separated into two parts. Section A.3.1 examines the effects of the alternative hydrologic inflow scenarios by holding constant the alternative and varying the hydrologic inflow sequences. Section A.3.2 examines the performance of each alternative under the alternative hydrologic inflow scenarios by holding constant the inflow scenario while varying the alternative.

A.3.1 Effects of Alternative Hydrology on No Action Alternative

This section describes the sensitivity of the No Action Alternative to the hydrologic variability provided by the three alternative hydrologic inflow scenarios described in the previous sections. This will be done through comparing the No Action Alternative, simulated using ISM and the 99-year natural flow record (DNF) to the No Action Alternative simulated with three alternative hydrologic inflow scenarios.

A.3.1.1Percentile Elevations

Figure N-19 presents a comparison of the 90th, 50th, and 10th percentile lines of Lake Powell elevations obtained for DNF and the three alternative hydrologic inflow scenarios, operated under the No Action Alternative.

The 90th percentile range of the four hydrologic methods shows smaller variation between the scenarios, largely because Lake Powell is at or near its maximum reservoir capacity.

At the 50th percentile range the DP hydrologic inflow scenario consistently produces the lowest elevations, while the NPC and the PS hydrologic inflow scenarios generally produce higher median elevations than DNF.

Variation between the various hydrologic inflow methods is highest at the 10th percentile range. The higher variability from year to year at the 10th percentile level for the NPC and the PS hydrologic inflow scenarios is a result of sample size. The DNF and DP hydrologic inflow scenarios are resampled with the ISM, which guarantees year to year hydrologic inflow scenario statistics that are identical. The year to year variation seen in these scenarios only results from reservoir operations. The NPC and PS hydrologic inflow scenarios are generated with stochastic methods that do not generate identical hydrologic inflow scenario statistics on a year to year basis; although with increased sample size, these scenarios will produce an average year to year statistic which is similar but not identical. This property is present in most stochastic techniques other than ISM.

90th, 50th and 10th Percentile Values

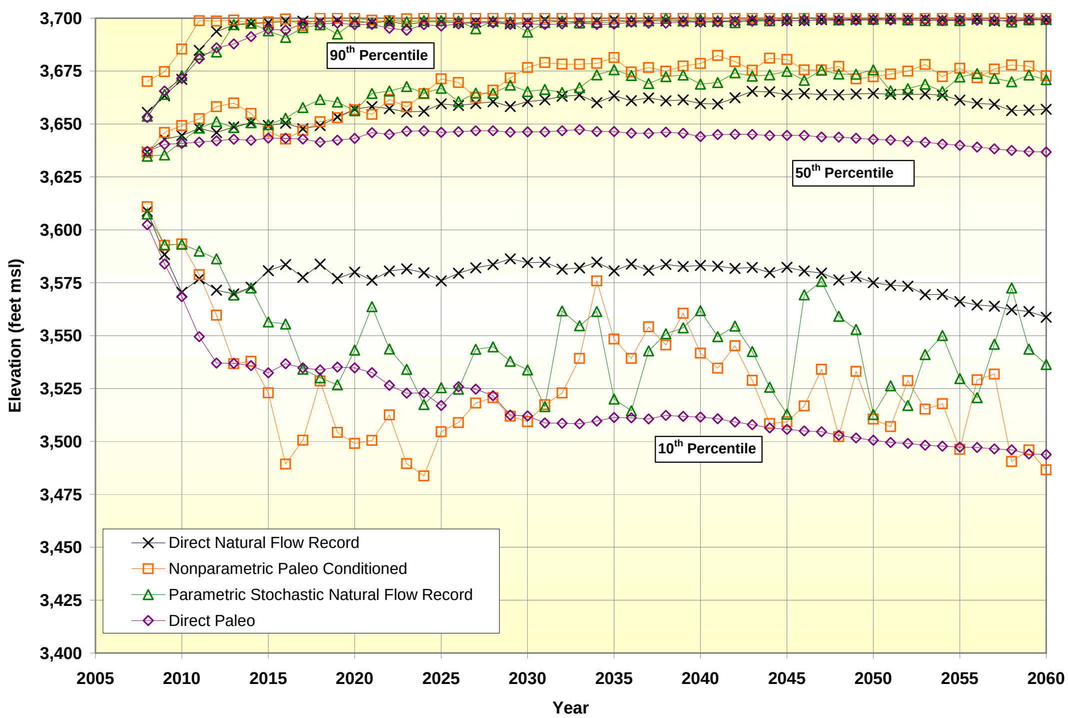

Figure Att. A-3 presents a comparison of the 90th, 50th, and 10th percentile lines of Lake Mead elevations obtained for DNF and the three alternative hydrologic inflow scenarios, operated under the No Action Alternative. At each percentile, DP is consistently lower than DNF even though both utilized the same sampling technique because the DP hydrology set has a higher magnitude and droughts of longer duration. At the 90th and 50th percentile, NPC and PS are generally higher than DNF due to higher magnitude and longer duration wet cycles in the two data sets.

A.3.1.2 Probability of Being Below Key Elevations

Figure Att. A-4 presents a comparison of the likelihood of Lake Powell end-of-July elevations being at or below the minimum power pool for DNF and for the three alternative hydrologic inflow scenarios. DNF shows nearly no chance of Lake Powell elevations falling below minimum power pool. NPC indicates the highest likelihood of occurrence at 14 percent, followed by the DP (nine percent), PS (nine percent), and DNF (one percent).

Figure Att. A-4
Lake Powell End-of-July Elevations
Comparison of Direct Natural Flow Record to Three Alternative Hydrologic Sequences
No Action Alternative
Percent of Values Less Than or Equal to 3,490 feet msl

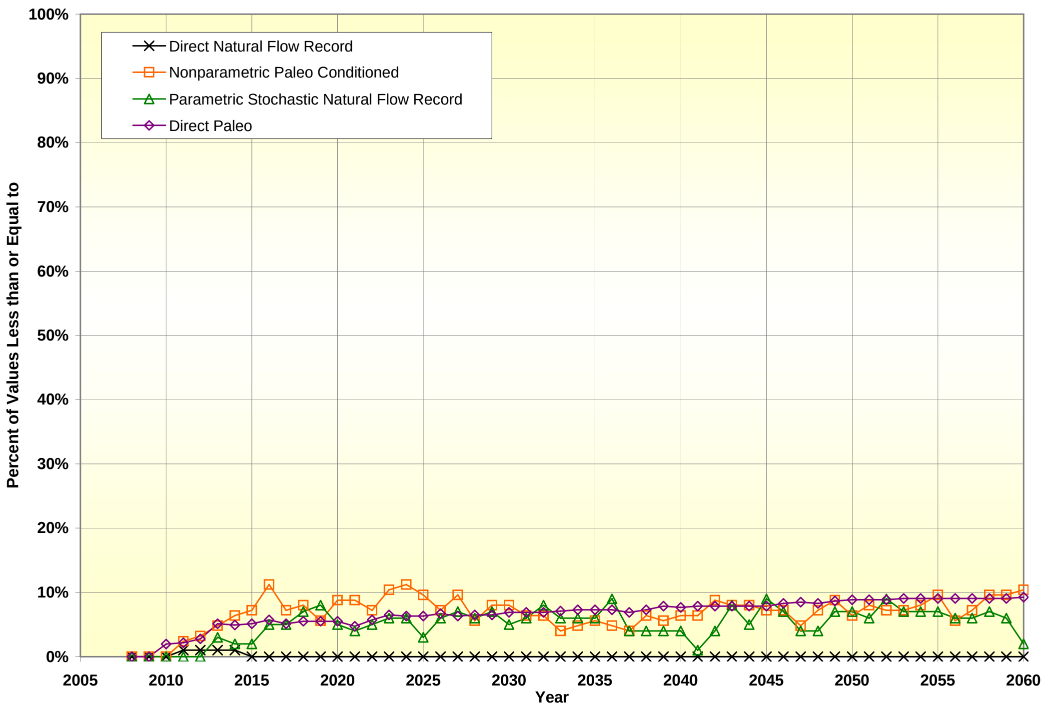

Figure Att. A-5 presents a comparison of the likelihood of Lake Mead end-of-December elevations being at or below the minimum power pool for DNF and for the three alternative hydrologic inflow scenarios. PS shows the lowest chance for all years of Lake Mead elevations falling below minimum power pool. DP and DNF indicate the highest likelihood for most years.

Figure Att. A-5
Lake Mead End-of-December Elevations
Comparison of Direct Natural Flow Record to Three Alternative Hydrologic Sequences
No Action Alternative
Percent of Values Less Than or Equal to 1,050 feet msl

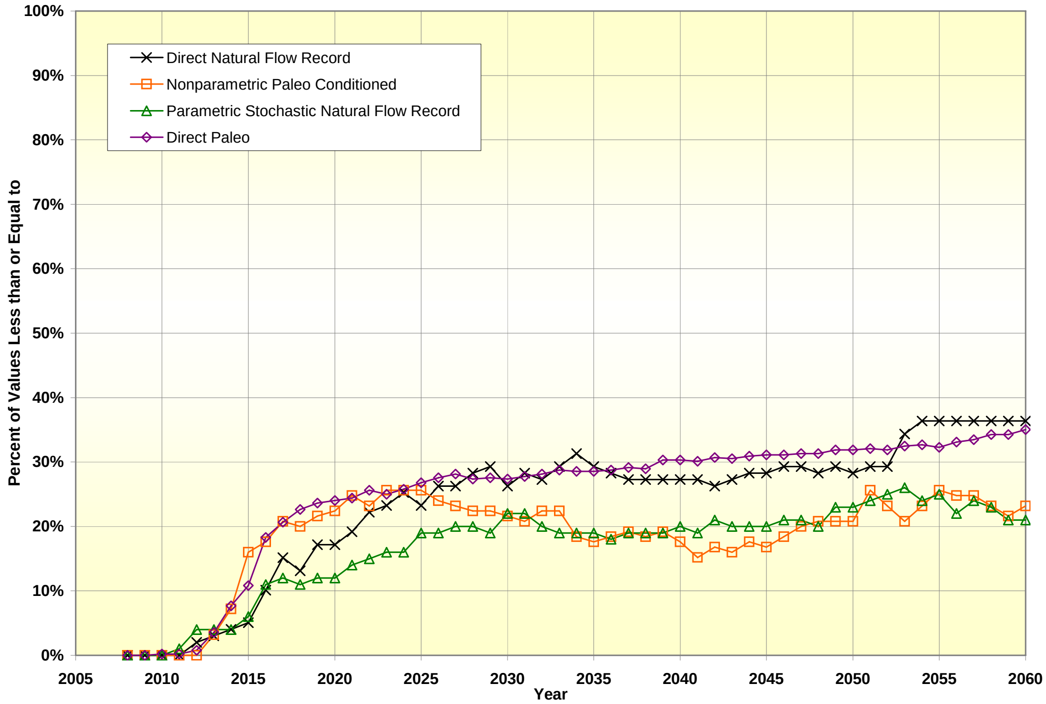

Figure Att. A-6 presents a comparison of the likelihood of Lake Mead end-of-December elevations being at or below 1,000 feet msl for DNF and for the three alternative hydrologic inflow scenarios. DNF shows no chance of Lake Mead elevations falling below 1,000 feet msl. NPC indicates the highest likelihood of occurrence at six percent in 2022, followed by the PS (four percent), and DP (one percent).

Figure Att. A-6

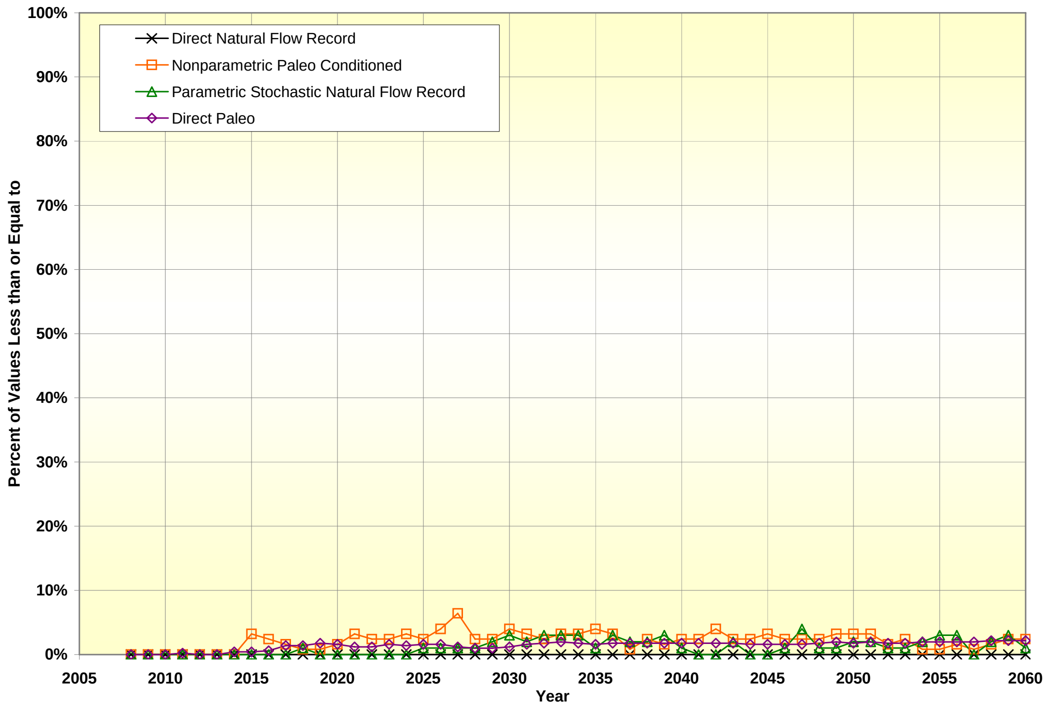
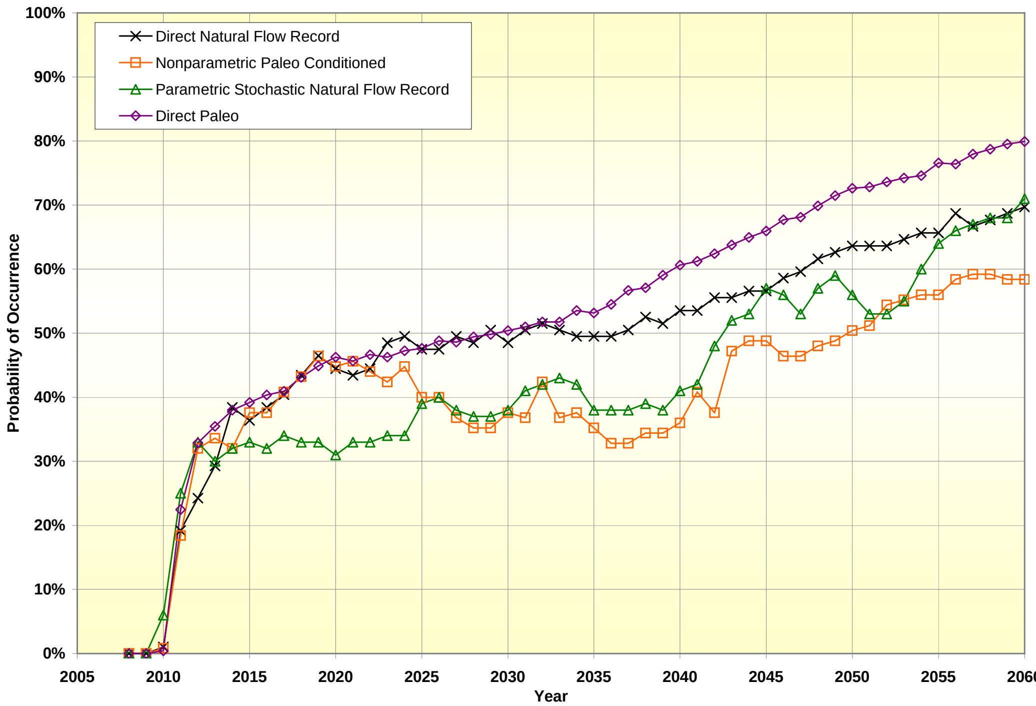
Comparison of Direct Natural Flow Record to Three Alternative Hydrologic Sequences
No Action Alternative
Percent of Values Less Than or Equal to 1,000 feet msl



A.3.1.3 Lower Basin Shortage

Figure Att. A-7 shows the probability of shortage to the Lower Basin and Mexico under the No Action Alternative obtained for DNF and the three alternative hydrologic inflow scenarios. The higher variability observed with the NPC and PS methods are a function of sample size, as described under Section A.3.1.1. NPC and PS have a lower probability of shortage than DNF for most of the period of analysis due to the extended wet periods in both data sets. The highest probability of shortage for each alternative occurs after 2055 with the following approximate values: DNF, 69 percent; DP, 80 percent; NPC, 62 percent; and PS, 71 percent.

Figure Att. A-7
Lower Basin Shortage
Comparison of Direct Natural Flow Record to Three Alternative Hydrologic Sequences
No Action Alternative
Probability of Occurrence



A.3.1.4 Lower Basin Surplus

Figure Att. A-8 shows the probability of any surplus to the Lower Division states under the No Action Alternative obtained for DNF and the three alternative hydrologic inflow scenarios. Note: this plot includes the probability of Flood Control surplus where Mexico would also receive surplus water. The higher variability observed with the NPC and PS methods are a function of sample size. NPC and PS have a higher probability of surplus than DNF for most of the period of analysis due to the extended wet periods in both data sets. The highest probability of surplus for each alternative occurs before 2017 with the following approximate values: DNF, 44 percent; DP, 42 percent; NPC, 44 percent; and PS, 48 percent. Beginning in 2017, under the No Action Alternative, only 70R and Flood Control surpluses occur, which reduces the probability of surplus to below 25 percent.

Figure Att. A-8

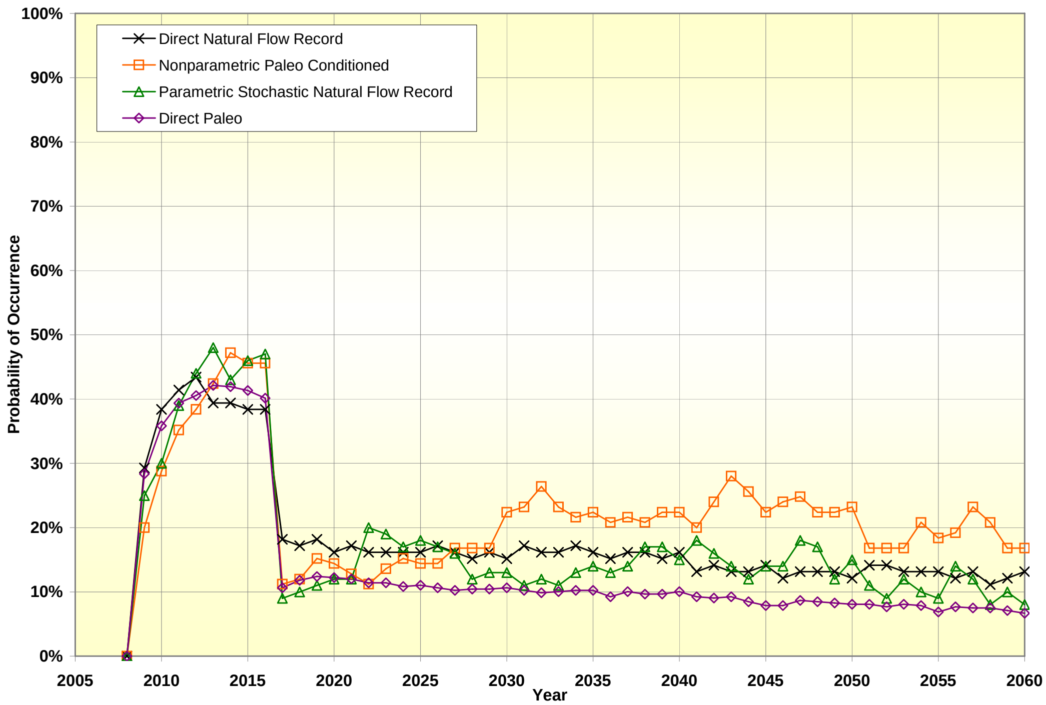
Probability of Occurrence



A.3.1.5 Releases from Glen Canyon Dam

Figure Att. A-9 presents a comparison of 10-year release volumes from Glen Canyon Dam for DNF and the three alternative hydrologic scenarios. The largest differences in the frequency of flow volumes are observed at the highest and lowest volumes, where the NPC hydrologic sequence shows the lowest low extreme values and DNF shows the lowest high extreme values. The PS hydrologic sequence "fills the gaps" in the data resulting in the smoothest curve and the highest extreme value.

Figure Att. A-9

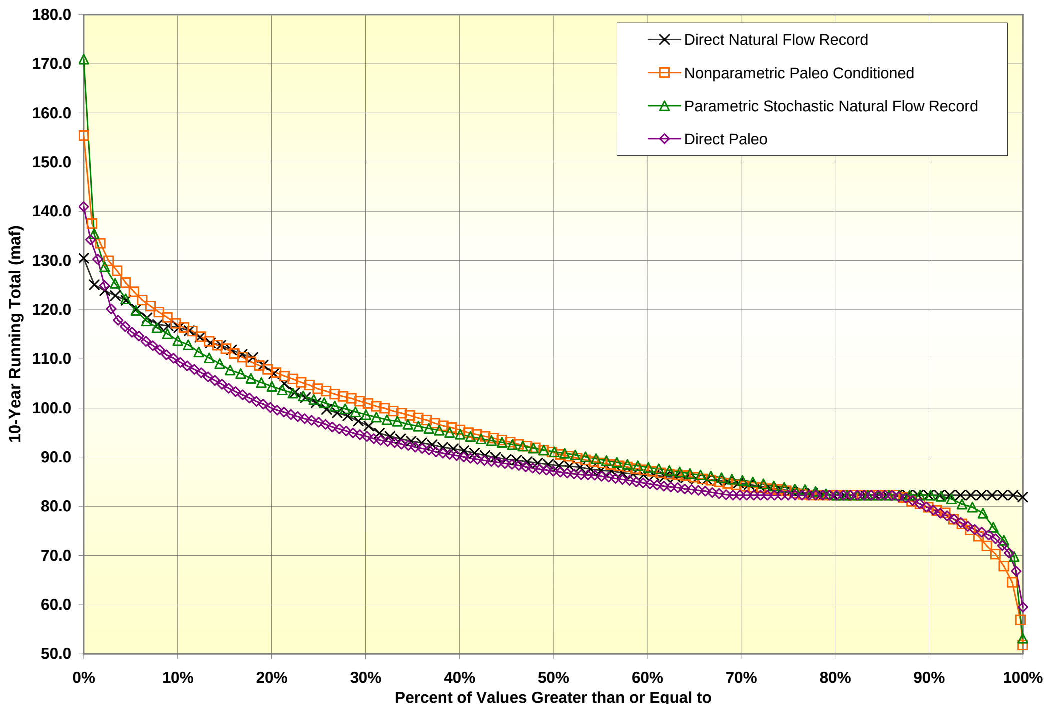
Percent of Values Greater than or Equal to (Years 2008 to 2060)



A.3.1.6 Natural Flow at Lees Ferry

Figure Att. A-10 presents a comparison of annual natural flow volumes past Lees Ferry for DNF and the three alternative hydrologic scenarios. The largest differences in the frequency of flow volumes are observed at the highest and lowest volumes, where the DP hydrologic sequence shows the lowest extreme values. The PS hydrologic sequence "fills the gaps" in the data resulting in the smoothest curve and the highest extreme value. The maximum flows produced under the PS scenario are much higher than the maximum flows by any other method in this analysis.

A.3.3 Nonparametric Paleo Conditioned – Reservoir Levels

Figure Att. A-13 and Table Att. A-3 presents a comparison of the 90th, 50th, and 10th percentile lines obtained for the No Action and action alternatives under the NPC hydrologic inflow scenario. The NPC inflow hydrology method is explained in detail in Section A.2.1.

Median Lake Powell elevations as depicted on the 50th percentile lines are consistently lower under the Water Supply Alternative than the No Action Alternative until year 2038, with a maximum difference of 32 feet in year 2026.

At the 10th percentile, elevations under the Water Supply Alternative drop below elevations under the No Action Alternative in year 2016, reaching a maximum difference of 39 feet below the No Action Alternative in year 2020. Elevations at the 10th percentile under the Basin States, Conservation Before Shortage and Reservoir Storage alternatives remain above No Action Alternative elevations for most years before year 2033, and thereafter the differences are minimal.

Nonparametric Paleo Conditioned
90th, 50th, and 10th Percentile Values

Alternative	Year 2026			Year 2060		
	90th Percentile	50th Percentile	10th Percentile	90th Percentile	50th Percentile	10th Percentile
No Action	3,700.00	3,669.57	3,508.94	3,700.00	3,672.76	3,486.56
Basin States	3,700.00	3,667.27	3,524.31	3,700.00	3,672.76	3,486.56
Conservation Before Shortage	3,700.00	3,668.01	3,541.49	3,700.00	3,672.76	3,486.56
Water Supply	3,699.06	3,659.05	3,505.77	3,700.00	3,672.76	3,486.56
Reservoir Storage	3,700.00	3,673.14	3,522.48	3,700.00	3,672.76	3,486.56

Figure Att. A-14 and Table Att. A-4 present a comparison of the 90th, 50th, and 10th percentile elevations at Lake Mead. The relationship between alternatives is maintained under NPC hydrologic sequences at Lake Mead 50th and 90th percentiles as both percentiles lie in the same elevation range as under DNF. Because the 10th percentile is lower in the reservoir (ranging from 25 to 100 feet through 2026), whether or not an alternative includes the absolute protection of 1,000 feet msl is important. For example, the Conservation Before Shortage and Basin States alternatives are very similar at the 10th percentile under DNF. The absolute protection of 1,000 feet msl as part of the Conservation Before Shortage Alternative and not the Basin States Alternative results in keeping Lake Mead higher at the 10th percentile. The Water Supply, Basin States and Conservation Before Shortage alternatives are lower than the No Action Alternative at the 10th percentile due to reduced releases from Lake Powell. Using the NPC inflow hydrology the Water Supply Alternative reaches the lowest 10th percentile values compared to the other action alternatives.

A.3.3.1 Parametric Stochastic – Reservoir Levels

Figure Att. A-15 and Table Att. A-5 present a comparison of the 90th, 50th, and 10th percentile lines obtained for the No Action and the action alternatives under the PS hydrologic inflow scenario. The PS inflow hydrology method is explained in detail in Section A.2.2.

Median Lake Powell elevations as depicted on the 50th percentile lines are consistently lower under the Water Supply Alternative than the No Action Alternative until year 2036, with a maximum difference of eight feet in year 2029.

At the 10th percentile, elevations under the Water Supply Alternative drop below elevations under the No Action Alternative in year 2011, reaching a maximum difference of 46 feet below the No Action Alternative in year 2028. Following year 2035, these differences are minimal. Elevations at the 10th percentile under the Basin States, Conservation Before Shortage and Reservoir Storage alternatives remain above the No Action Alternative elevation until year 2030.

Comparison of Action Alternatives to No Action Alternative
Parametric Stochastic Natural Flow Record
90th, 50th and 10th Percentile Values

Alternative	Year 2026			Year 2060		
	90th Percentile	50th Percentile	10th Percentile	90th Percentile	50th Percentile	10th Percentile
No Action	3,698.61	3,660.60	3,524.76	3,699.46	3,670.91	3,536.35
Basin States	3,698.34	3,659.99	3,549.06	3,699.46	3,670.91	3,536.35
Conservation Before Shortage	3,698.36	3,659.99	3,549.93	3,699.46	3,670.91	3,536.35
Water Supply	3,698.36	3,657.22	3,501.62	3,699.46	3,670.91	3,536.35
Reservoir Storage	3,698.90	3,667.34	3,542.31	3,699.46	3,670.91	3,536.35

Figure Att. A-16 and Table Att. A-6 present a comparison of the 90th, 50th, and 10th percentile elevations at Lake Mead. As with the NPC hydrologic sequences, the relationship between alternatives is maintained at Lake Mead 50th and 90th percentiles. The 50th percentile is about 25 feet higher in the reservoir compared to DNF. The 10th percentile is lower in the reservoir (about 15 feet) than with DNF but not as low as with NPC. Whether or not an alternative includes the absolute protection of 1,000 feet msl is not as dominate here as with NPC as seen by the smaller difference between the Conservation Before Shortage and Basin States alternatives. The Water Supply Alternative drops lower than under DNF due to the possible more extreme droughts resulting in lower Lake Powell inflow. The position of the Reservoir Storage Alternative remains almost unchanged compared to DNF at the 10th percentile.

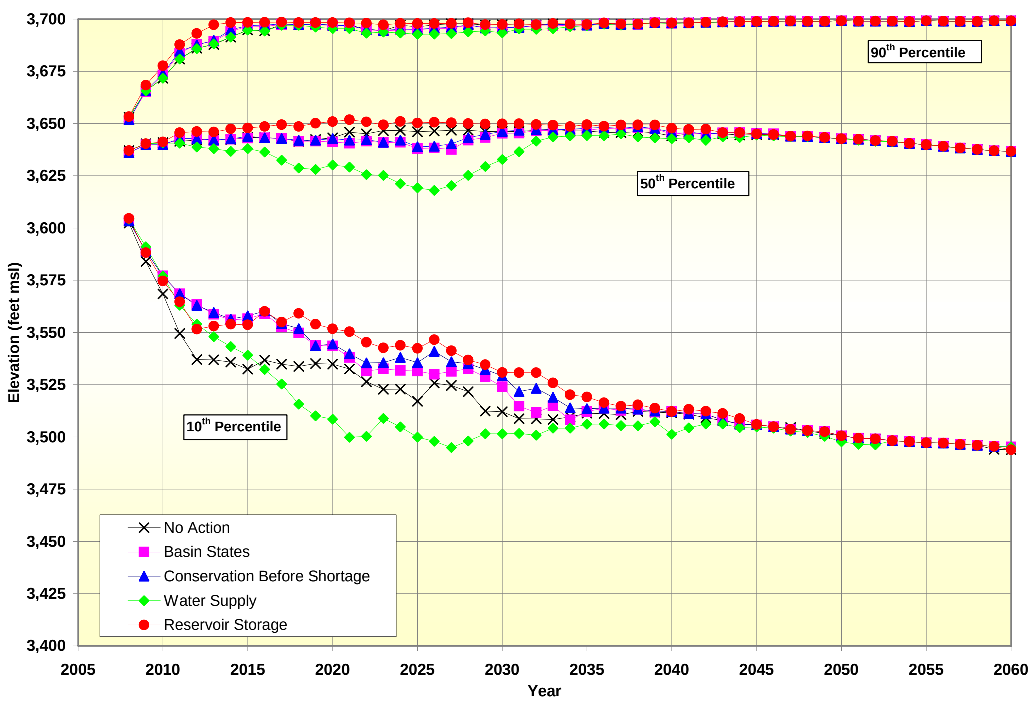
A.3.3.2 Direct Paleo – Reservoir Levels

Figure Att. A-17 and Table Att. A-7 present a comparison of the 90th, 50th, and 10th percentile lines obtained for the No Action and action alternatives under the DP hydrologic inflow scenario. The DP inflow hydrology method is explained in detail in Section 2.3

The median Lake Powell elevation for all five scenarios generally declines over the period of analysis, due to increasing Upper Basin depletions. Figure Att. A-7 also illustrates that median Lake Powell elevations as depicted on the 50th percentile lines are consistently lower under the Water Supply Alternative until year 2047, with a maximum difference of 33 feet in year 2026. These differences are insignificant by year 2047.

Figure Att. A-17
Lake Powell End-of-July Elevations
Comparison of Action Alternatives to No Action Alternative
Direct Paleo Inflow Hydrology
90th, 50th and 10th Percentile Values



At the 10th percentile, elevations under the Water Supply Alternative drop below those of the No Action Alternative in year 2016, reaching a maximum difference of 33 feet below the No Action Alternative in year 2021. Elevations at the 10th percentile from the Basin States, Conservation Before Shortage and Reservoir Storage alternatives remain above No Action Alternative elevations until 2038.

Table Att. A-7

Comparison of Action Alternatives to No Action Alternative
Direct Paleo
90th, 50th and 10th Percentile Values

Alternative	Year 2026			Year 2060		
	90th Percentile	50th Percentile	10th Percentile	90th Percentile	50th Percentile	10th Percentile
No Action	3,697.24	3,646.33	3,525.79	3,699.17	3,636.71	3,493.86
Basin States	3,695.52	3,638.28	3,529.95	3,699.17	3,636.71	3,495.25
Conservation Before Shortage	3,695.62	3,639.13	3,540.96	3,699.17	3,636.71	3,495.25
Water Supply	3,692.83	3,617.99	3,497.83	3,699.17	3,636.71	3,495.25
Reservoir Storage	3,697.89	3,650.61	3,546.57	3,699.17	3,636.71	3,493.86

Figure Att. A-18 and Table Att. A-8 present a comparison of the 90th, 50th, and 10th percentile elevations at Lake Mead. The position of these percentiles is most similar to DNF with DP. All relationships are preserved with the exception of the Water Supply Alternative and No Action Alternative at the 10th percentile. The Basin States and Conservation Before Shortage Alternatives remain below the No Action Alternative from 2012 to 2019 as Lake Powell makes reduced releases. The same is true for the Water Supply Alternative. This alternative drops almost 40 feet lower in 2026 at the 10th percentile compared to DNF. Lake Powell is unable to provide balancing releases that benefit Lake Mead due to lower inflow sequences.

A.3.3.3 All Inflow Scenarios – Shortage Magnitude and Frequency

Tables Att. A-9 and Att. A-10 compare the probabilities of shortages occurring between 0 and 500 kaf, 500 and 750 kaf, 750 and 1.0 maf, 1.0 and 1.5 maf, 1.5 and 2.0 maf, 2.0 and 2.5 maf and above 2.5 maf for the years 2010, 2017, 2026 and 2060. The upper range of the shortage increment is inclusive. These years and shortage ranges are compared for all alternatives and inflow scenarios.

2010. The earliest occurrence of shortage, for all alternatives and inflow scenarios, is 2010. Most of these occurrences are under the Reservoir Storage Alternative due to the highest trigger elevation of the alternatives at 1,100 feet msl. The probability of these occurrences is within 4 percent except for DNF which is the highest.

2017. In 2017, about halfway through the interim period, the majority of the shortages are less than 1.0 maf. Deeper shortages occur with NPC under all alternatives. With NPC there is a 5 percent occurrence of a 1.2 maf shortage under the Reservoir Storage Alternative which never occurs under DNF. The 15 percent chance of a shortage under the Water Supply Alternative with NPC indicates that Lake Mead is lowest under this hydrology as there is no reduction in demand unless Lake Mead is below 1,000 feet msl.

2026. In 2026, the last year of the interim period, the majority of the shortages still fall below 1.0 maf. However, with all inflow scenarios, a larger portion of the shortages are distributed at deeper levels. Under DP and NPC there are more shortages above 750 kaf than below in the Reservoir Storage Alternative.

2060. In 2060 the majority of the shortages are 500 kaf or below. All alternatives have reverted to the No Action Alternative and are all under the same shortage strategy. The distribution of shortage above 500 kaf is similar across all alternatives and inflow scenarios. This indicates that by 2060 the effects of the alternatives have washed out. Lake Mead is receiving a steady release from Lake Powell and therefore does not fluctuate as much as during the interim period.

Appendix O

Analysis of Power and Energy Impacts to Glen Canyon Dam, Shortage Criteria EIS

This appendix contains a copy of a report prepared by the Western Area Power Administration entitled *Analysis of Power and Energy Impacts to Glen Canyon Dam, Shortage Criteria EIS*. The report describes the methodology and analysis conducted for energy resources at the Glen Canyon Powerplant. The analysis in Section 4.11 of this Final EIS uses information derived from this analysis of generation capacity and its associated economic value.

Analysis of Power and Energy Impacts to Glen Canyon Dam, Shortage Criteria EIS

July 30, 2007, Update for FEIS

S. Clayton Palmer, Sam Loftin, and Thomas Veselka
Western Area Power Administration
Colorado River Storage Project Management Center
and Argonne National Laboratory

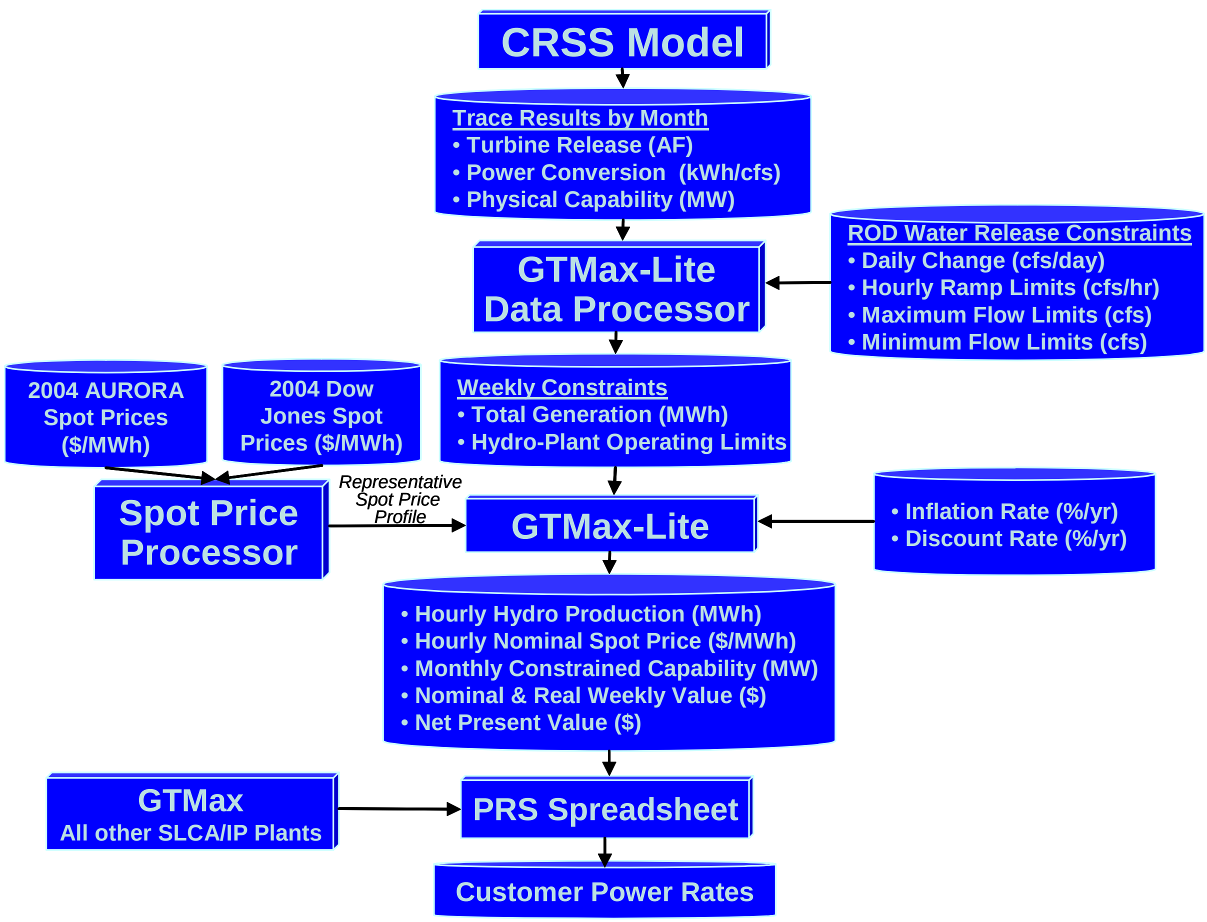
Prepared for the Bureau of Reclamation

This page intentionally left blank.

Methodology Overview

The methodology used by the Western Area Power Administration (Western) to estimate the economics of Shortage Criteria Environmental Impact Statement (EIS) alternatives is a multi-step procedure of data processing and computer simulations. A flow diagram depicting the major components of this procedure and component interactions is displayed in Figure 1. The procedure uses monthly results produced by the Colorado River Simulation System (CRSS) for each of the six EIS alternatives. This includes monthly values of turbine-water releases, power conversion factors, and the physical production capability of the Glen Canyon Dam (GCD) hydropower plant. The CRSS model also simulates operations for other Colorado River System Project (CRSP) reservoirs. However, EIS alternatives only impact the Glen Canyon Dam and are therefore the focus of this analysis.

Figure 1
Diagram Depicting Major Modeling Components and Processes



CRSS results along with operating constraints mandated by the Glen Canyon Dam EIS Record of Decision (ROD) are input into an Excel spreadsheet that prepares input data for a customized variation of the Generation and Transmission Maximization (GTMax) model. To distinguish this customized version from the original model, it is referred to as GTMax-Lite in this document. The Data Processor spreadsheet uses power conversion factors to translate CRSS releases and ROD constraints from water units into a power equivalent. For example, monthly turbine water releases specified in terms of acre-feet (AF) in CRSS output tables are converted into an equivalent electricity production in units of Mega-Watt-hours (MWh). The spreadsheet also selects a subset of CRSS results and calculates statistics that are analyzed in more detail by other processes.

Physical monthly operating limits for capacity and energy along with ROD operational constraints are used by the GTMax-Lite model to simulate hourly Glen Canyon Dam power plant generation levels. The model determines the hourly operation schedule over a 1-week period (i.e., 168 hours) that maximizes the economic value of the hydropower resource. The operation schedule produced by the model is within the physical limitations of the power plant and it complies with all environmental and institutional regulations.

The GTMax-Lite model uses a projection of market prices as a measure of the future economic value of hydropower generation. These prices heavily influence the generation schedule produced by the model when it optimizes the hydropower plant resource. Future hourly price signals are estimated over the study period by a second Excel spreadsheet referred to as the Spot Price Processor. It uses 2004 hourly spot market price patterns produced by the AURORA model (Electric Power Information Solutions, Inc. 2005), an estimate of historical 2004 market prices for the Palo-Verde market hub as reported in the Dow-Jones index, and a nominal inflation rate.

GTMax results include an estimate of the economic value of Glen Canyon power plant capacity and energy production over the simulation period. It also includes an estimate of the hydropower plant maximum production capability taking into account ROD operational constraints. This measure of capacity is mostly, but not always, substantially less than the physical capability of the plant based only on hydrological head; that is, the physical capability estimated by CRSS.

Western customer power rates are calculated using a power repayment study (PRS) spreadsheet-based computer program that contains both general and specific repayment rules associated with a particular hydropower project. This spreadsheet uses GTMax-Lite results for Glen Canyon and from the full-scale GTMax model for all other Salt Lake City Area Integrated Project (SLCA/IP) plants.

A more detailed explanation of the methodology used for the Shortage Criteria EIS is provided in the following sections. This includes both data processing algorithms and the GTMax-Lite simulation model. Detailed explanations of other models, such as CRSS that feed into the process, but are not run by Western, are provided elsewhere.

CRSS Model

The CRSS model mimics operational decisions that are made for CRSP reservoirs. Since EIS alternatives have unique criteria, each simulation contains alternative-specific operating rules that affect monthly and annual water releases. Monthly release patterns affect the economic value of the hydropower resource since the value of power is highly sensitive to seasonal and hourly variations in market prices. Typically market prices are the highest in the summer and winter seasons. Therefore, from a power generation-centric viewpoint, water releases would ideally be concentrated during these two seasons. However, from a broader perspective power benefits must be weighted against other operational objectives such as flood control, irrigation, municipal and industrial water supplies, recreation, and the environment.

Shortage Criteria alternatives also affect reservoir forebay elevations and the amount of water that bypass turbines. The forebay elevation determines the hydraulic head and is the primary factor that influences the amount of power that is produced per volume of water released through the turbines. High forebay elevations typically translate into more power production per AF of turbine water releases as compared to lower forebay elevations. However, maintaining full or nearly full reservoirs increases the risk of releasing water through bypass tubes and spillways. Sudden unexpected inflows under a full reservoir condition may require reservoir releases that exceed maximum turbine flow rates. Maintaining lower reservoir levels, on the other hand, will reduce the risk of non-turbine water releases during flood conditions, but it will also increase the risk of lowering the forebay elevation below turbine inlet tubes during droughts. When this occurs, both power production and the plant capacity is zero. Operating rules must therefore balance the risks associated with either having too much or not enough water stored in Lake Powell.

Balancing risks in a basin with large variations of water inflows, such as the Colorado, require a full-spectrum examination of hydrological conditions. Therefore, the CRSS model produces numerous simulation results for each month. These results represent a range of plausible futures from which probability distributions of future hydropower conditions are constructed. Distributions are influenced by initial reservoir conditions such that distributions are relatively narrow for near-term projections. This represents a relatively low level of uncertainty about the future. However, as the projection period extends further into the future, the distribution widens as uncertainty grows.

CRSS results include scenario-specific estimates of monthly energy production and physical capability for 100 possible futures throughout the analysis period which extends from the beginning of January 2008 through the end of December 2060. For the Shortage Criteria EIS, forecasts are made by simulating reservoir operations with 100 different sequences of inflows. Each sequence is based on a chronological inflow pattern that has occurred in the past, and is referred to as a trace. Refer to for the text of the EIS for a detailed explanation of CRSS reservoir operating rules and traces.

Hydrological Conditions Studied

Ideally detailed simulations of hourly operations at the Glen Canyon Dam hydropower plant would be performed for each of the 100 traces over the 53-year analysis period. However, it is computationally impractical. Therefore, a simplified approach was used to measure differences among alternatives. This involves analyzing only selected points from the monthly distributions produced by CRSS. The Data Processor spreadsheet computes statistics and extracts pertinent information from the CRSS output.

Western chose five hydrological conditions to study to ensure a representative look at the differences between the alternatives. The five conditions are: Mean, Median, 90 percent Exceedence, 10 percent Exceedence, and Trace 94, and are explained below.

- **Mean:** An average value of the 100 CRSS traces was computed for each month of the study period, for each alternative.
- **Median:** The 50th percentile value of the 100 CRSS traces was computed for each month of the study period, for each alternative.
- **90 percent Exceedence:** The 10th percentile value of the 100 CRSS traces was computed for each month of the study period. 90 percent exceedence is often referred to as 10th percentile in Western and Reclamation hydrological studies; the two terms are synonymous.
- **10 percent Exceedence:** The 90th percentile value of the 100 CRSS traces was computed for each month of the study period. 10 percent exceedence is often referred to as 90th percentile in Western and Reclamation hydrological studies; the two terms are synonymous.
- **Trace 94:** Individual traces of the CRSS output were examined. Trace 94 was selected by Western as representing especially poor conditions for generation at GCD, with periods of no generation due to low Lake Powell reservoir elevations (below 3490’). Trace 94 was selected to examine the difference in performance of the six alternatives under conditions of complete loss of GCD generation for an extended period of time. Trace 94 also allows for examination of a time-connected series of potential GCD operations, showing drops and recoveries of Lake Powell elevation over time. The other four hydrological conditions studied are not time-connected in the same manner that a single trace is.

Mean, median, 90 percent exceedence, and 10 percent exceedence values for capability and energy are computed separately. Furthermore, capability statistics are based only on hydrologic head as computed by CRSS. However, under current operating constraints imposed on Glen Canyon, sustainable capability is a function of both the physical powerplant capability and the monthly water release volume (refer to the next section for more details). Although it may be more accurate to compute capacity statistics using both the hydrologic head and monthly water releases, this process would have been very computationally intensive with only a marginal increase in precision. As a simplification, statistical values for physical capability and energy are first calculated and then sustainable capacity is estimated by the GTMax-Lite model using these statistical values.

Glen Canyon Dam Record of Decision

The economics of Shortage Criteria Alternatives is not only a function of monthly water release volumes, but also of physical and institutional limitations on daily and hourly operations. Of particular importance is the Glen Canyon Dam Record of Decision (ROD) that affirmed the selection of the Modified Low Fluctuating Flow Alternative as the preferred operating alternative. The Bureau of Reclamation (Reclamation) issued the operating criteria for Glen Canyon Dam early in 1997. The 1997 Operating Criteria expanded on the operational rules contained in the Glen Canyon Dam Operation EIS and ROD. It also provided Western and Reclamation staff with guidance on the operation of the dam and the Salt Lake City Area Integrated Projects (SLCA/IP) power system.

The ROD imposed a limit on the maximum allowable release from Glen Canyon Dam to 25,000 cubic feet of water per second (cfs) and included exceptions to the maximum release for Beach/Habitat Building Flows and Habitat Maintenance Flows such as occurred in March 1996. Exceptions were also made to avoid spills or flood flow releases during high runoff years. During high hydropower conditions when the total monthly water release volume is greater than a constant 25,000 cfs release rate throughout the month, the maximum release rate is relaxed. However, releases are restricted to a flat-flow operating regime.

Releases must also be at least 8,000 cfs between the daytime hours of 7:00 a.m. to 7:00 p.m., and 5,000 cfs or more at night. The ROD also set limits on the allowable release fluctuations in any continuous 24-hour period. The amounts vary depending on the volume of water scheduled to be released in a given month. For example, the allowable daily change is 5,000 cfs/24 hours for months in which scheduled water releases through the dam are less than 600 thousand acre feet (TAF). Fluctuations will be held at 6,000 cfs/24 hours for months of scheduled releases between 600 and 800 TAF, and at 8,000 cfs/24 hours for months of scheduled releases greater than 800 TAF/month. Finally, the ROD limits the rate at which the generators may ramp up or down during a 1-hour time period. The maximum power plant ramp rates are set at 4,000 cfs per hour increasing and 1,500 cfs per hour decreasing.

GTMax-Lite Data Processor

The Data Processor spreadsheet prepares input data for the GTMax-Lite model by translating CRSS and ROD information from water units into equivalent power and energy units. Equations that are used by the spreadsheet are summarized in Table 1. For example, the processor multiplies a power conversion factor by the ROD allowable maximum flow rate to compute the maximum power plant output. Power factors are approximated by CRSS for each trace in all study months. The maximum output level computed by the data processor is not always achieved since the maximum daily change restriction and hourly up and down ramp rate limits further constrain operations.

Table 1
Equations for Converting ROD Operating Criteria and CRSS Output

CRSS/ROD Criteria	Power Equivalent for GTMax-Lite Input
Monthly Water Release	$E_w^{pow} = \frac{TR_m^{wat} \times CF_m^{w-p}}{1000} \times \frac{7}{ND_m} \;\; \forall \; m \mid m = 1, \ldots, NM$
Maximum Release	$C_w^{pow} = \mathrm{Max}\left(C_m^{CRSS}, \frac{MR_m^{wat} \times CF_m^{w-p}}{1000} \times 0.082644 \right) \;\; \forall \; m \mid m = 1, \ldots, NM$
Maximum Daily Change	$DC_w^{pow} = \frac{DC_m^{wat} \times CF_m^{w-p}}{1000} \times 0.082644 \;\; \forall \; m \mid m = 1, \ldots, NM$
Hourly Up-Ramp Rate Limit	$HU_w^{pow} = \frac{HU_m^{wat} \times CF_m^{w-p}}{1000} \times 0.082644 \;\; \forall \; m \mid m = 1, \ldots, NM$
Hourly Down-Ramp Rate Limit	$HD_w^{pow} = \frac{HD_m^{wat} \times CF_m^{w-p}}{1000} \times 0.082644 \;\; \forall \; m \mid m = 1, \ldots, NM$
Minimum Daytime Release	$DM_w^{pow} = \frac{DM_m^{wat} \times CF_m^{w-p}}{1000} \times 0.082644 \;\; \forall \; m \mid m = 1, \ldots, NM$
Minimum Nighttime Release	$MN_w^{pow} = \frac{MN_m^{wat} \times CF_m^{w-p}}{1000} \times 0.082644 \;\; \forall \; m \mid m = 1, \ldots, NM$

where,

m = Simulation month index

w = Simulation week index with one representative week per month

ND_m = Number of simulation days in month m

NM = Number of simulation months; $636 = 12 \times 53$

E_w^{pow} = Weekly generation (MWh) during week w

TR_m^{wat} = Total water volume (AF) released during month m

C_w^{pow} = Weekly capability (MW) during week w

C_m^{CRSS} = CRSS physical capability (MW) during month m

MR_m^{wat} = Maximum release rate (cfs) during month m; dependent on TR_w^{wat}

DC_w^{pow} = Maximum daily change (MW/day) during week w

DC_m^{wat} = Maximum daily change (cfs/day) during month m; dependent on TR_w^{wat}

HU_w^{pow} = Maximum hourly power increase (MW/h) during week w

HU_m^{wat} = Maximum hourly up-ramp rate (cfs/hr) during month m

HD_w^{pow} = Maximum hourly power decrease (MW/h) during week w

HD_m^{wat} = Maximum hourly down-ramp rate (cfs/hr) during month m

MD_w^{pow} = Minimum daytime hourly generation (MWh) during week w

MD_m^{wat} = Minimum daytime release rate (cfs) during month *m*

MN_w^{pow} = Minimum nighttime hourly generation (MWh) during week *w*

MN_m^{wat} = Minimum nighttime release rate (cfs) during month *m*

It should be noted that the monthly water releases in table are scaled to represent the amount of water that is released in a typical week. GTMax-Lite model is executed for only 1 week per study period month. Total generation during this "typical" week is based on CRSS monthly water release volumes times a scaling factor. This factor is equal to the number of days in the week divided by the number of days in a simulated month. For example, the scaling factor for January equals 7 divided by 31. The inverse of this factor is used to obtain monthly values by scaling-up weekly results.

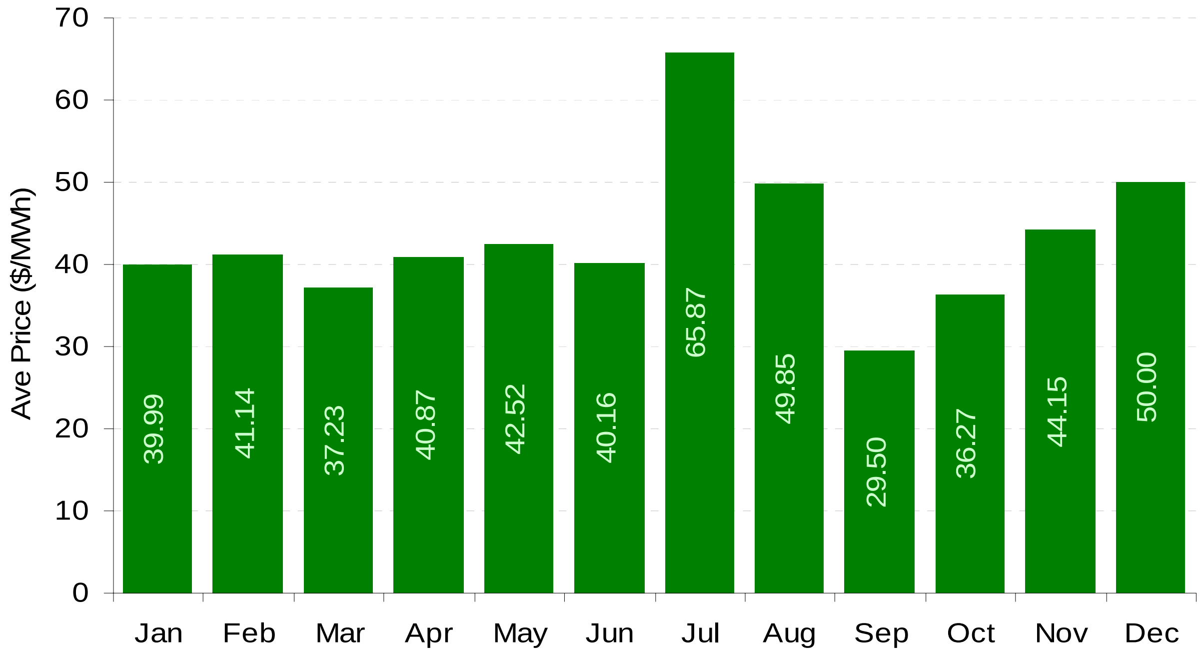
Market Prices

Representative energy and capacity prices are essential for an economic evaluation of Shortage Criteria alternatives. Pricing assumptions tend to be controversial because there are many sources of information, and because the price assumed can make a large difference in the resulting valuation of energy and capacity. Some analysts prefer using historical energy and capacity prices because they can be tied to a specific set of purchase transactions. Others prefer to use estimates of future costs under the assumption that historical costs do not necessarily predict future prices. Prices for historical or future energy can be obtained fairly easily from a variety of sources. However, prices for capacity are more difficult to obtain since they are more closely identified to a particular utility or power generation facility and usually are considered proprietary information by the facility owner.

Western coordinated analysis of energy prices with Reclamation to ensure that both agencies were using the same data. The two agencies agree upon a method that combined two types of energy prices. These data include a historical price index for the Palo-Verde market hub contained in a Dow Jones, Inc. database and hourly market price patterns produced by the AURORA model. Both the historical and modeled data are for the year 2004. Prices for 2005 were rejected from consideration due to the anomalies caused by fuel supply disruptions resulting from hurricane damage that occurred in the summer and autumn.

A review of hourly 2004 Dow Jones price data identified numerous anomalies such as atypically high prices on several Sundays over the course of the year. There were also long and frequent periods of missing data. Although the Dow Jones month average prices, shown in Figure 2, are representative and would suffice for Reclamation's monthly energy modeling, the quality of the hourly price data was inadequate for Western's hourly modeling. To eliminate the hourly energy price problems, Reclamation provided Western with AURORA model simulated market prices for 2004. The Aurora model results had hourly and weekly prices that represented typical weekly price profiles, but average price levels were significantly less than historical levels. To match the Dow Jones index prices, the AURORA hourly model output was scaled such that the average monthly values matched the Dow Jones monthly average values. A more detailed description of the scaling process is provided in the next section.

Figure 2
Average Market Prices for 2004 Based on the Dow Jones Index



Some of the anomalies associated the Dow Jones, Inc. price index may be a reflection of the energy market that is currently functioning in the WECC and small number of reported transactions that is used to calculate the index. For any given hour the Dow index is the weighted average price for all reported bilateral exchanges. A bilateral exchange is a private transaction between two parties at a negotiated price. It should also be noted that only a small percentage of bilateral contracts are reported to the Dow Jones. Although monthly average prices follow a typical pattern, the extent to which the Dow Jones prices reflect the broader WECC electricity market is not known. This method of price discovery differs from a market price that is determined through a central clearinghouse whereby individual buyers and sellers do not directly communicate with each other. Instead a price is determined by the intersection of supply and demand bid curves.

AURORA model simulations used in this analysis were developed for and used in the Northwest Power and Conservation Council's Fifth Northwest Electric Power and Conservation Plan (NWPCC 2005). The Northwest Power and Conservation Council is primarily interested in Northwestern electricity markets. Relatively less attention is devoted to characterizing market conditions in other parts of the WECC region. Consequently, the Palo Verde forecast described in this analysis primarily reflects the default data supplied with the AURORA model.

Market Price Processor

The GTMax-Lite model uses a projection of market prices as a measure of the future economic value of hydropower generation. This assumption implies that market prices reflect the marginal economic cost of serving the last megawatts-hour (MWh) of load in the system (i.e., system lambda). Furthermore, Glen Canyon power injections into the grid are minuscule relative to the entire power system in which it operates. Therefore, its operations do not influence the marginal value of energy. Given the size and complexity of the Western Electricity Coordinating Council (WECC) power grid and the markets that it functions in, these assumptions are reasonable. It should also be noted that the relative economic differences among alternatives are of importance, rather than the absolute economic value of a specific alternative.

The Spot Price Processor prepares typical energy price profiles for GTMax based on the AURORA model results. Instead of using each hourly price, typical spot price patterns were computed for three different day types in each month. These include Sunday, weekday, and Saturday. A daily price pattern is obtained by computing an average hourly price for each similar hour. For example, the weekday price at 1 a.m. is the average of AURORA prices at 1 a.m. for all days in a month that are between Monday and Friday, inclusive. Each day of the month is then assigned hourly prices depending on the month and type of day. For example, every weekday in January is assigned the average price pattern for January weekdays.

The final step of the process scales monthly prices to match the simple (i.e., unweighted) mean of hourly Palo-Verde prices contained in the Dow Jones database. These monthly average prices follow a typical seasonal pattern for the Southwestern United States. Prices are the highest during the summer months reflecting an elevated demand for air conditioning. On the other hand, prices during the spring and autumn seasons are relatively low. Winter prices are somewhat higher than these shoulder seasons as loads are elevated by more lighting and heating demands. Prices are inflated to approximate hourly prices for future years. For this analysis, the annual inflation rate is assumed to be 2.2 percent.

The use of typical (i.e., average) hourly price profiles to estimate Glen Canyon power plant generation patterns is more realistic than estimating generation patterns based on individual hourly prices. This is in part due to the recognition that power marketers have excellent foresight regarding overall daily price patterns over the upcoming week, but the magnitude and individual hourly variations from the typical pattern cannot be accurately predicted. In contrast, the GTMax model has perfect foresight and if provided with the detailed price profile it will react to each individual "perfectly predicted" price. When GTMax is provided with the typical or average pattern, it produces a generation pattern that more closely emulates actual energy scheduling practices.

Market prices have a profound influence on generation schedules prepared by power marketers as well as those produced by optimization models. Figures 3 and 4 show hourly used by GTMax for a winter month, December, and for a summer month, July. The hourly price pattern for weekdays in December follows a typical winter profile with two separate daily peaks. The first peak occurs in the morning followed by a midday price slump. Prices rise again in the evening reaching a high between 6 p.m. to 8 p.m. The lowest prices hours are in the middle of the night, bottoming out at 2 a.m. to 4 a.m. Prices are somewhat lower during the weekends, especially on Sunday. Also weekend hourly price patterns deviate somewhat from weekday price profiles.

While winter prices exhibit a two-hump price pattern, prices during the summer months peak only once during the day – typically in the late afternoon between 4 p.m. to 6 p.m. during the hottest part of the day. Similar to the wintertime, prices are at a minimum in the middle of the night.

GTMax-Lite Model

Western and Argonne National Laboratory simulated Glen Canyon hydropower plant operations on an hourly time step the with the GTMax-Lite modeling software. GTMax-Lite is similar to the full version of the GTMax model except it only contains those features that are required to perform an economic evaluation of Shortage Criteria alternatives. Model run time and data transfers are significantly shorter, while a level of simulation accuracy equivalent to the full version is retained.

The GTMax-Lite objective function is to produce an hourly generation schedule over a one (1) week time period that maximizes the economic value of the hydropower resource. Market prices input into the model convey the economic value of hydropower generation. These prices heavily influence the generation schedule produced by the model when optimizing the hydropower plant resource. To the extent possible the GTMax-Lite model uses its limited energy resource to first generate electricity during on-peak hours when it has the highest economic value. Any remaining energy is scheduled during lower-priced hours.

Glen Canyon power plant operations are subject to a set of constraints. These include a physical operating capability and a limit on the total weekly electricity production. As described in previous sections, these constraints are consistent with CRSS model results. In addition to physical operating constraints, the GTMax-Lite model also complies with the ROD Criteria. Table 2 contains the GTMax-Lite mathematical formulations consisting of an objections function and a set of operating constraints.

Table 2
GTMax-Lite Equations

Description	GTMax-Lite Equation
Objective Function	$Maximize: \quad SP_h \times Gen_h \quad \forall\ h \mid h = 1,...,168$
Maximum Hourly Generation	$Gen_h \le C_w^{pow} \quad \forall\ h \mid h = 1,...168$
Weekly Generation	$WGen_w = \sum_{h=1}^{168} Gen_h$
Maximum Daily Change	$DC_w^{pow} \ge Gen_{j+k-wrap} - Gen_j \quad \forall\ j \mid j = 1,...,168$ and for each $j,\ k = 1,...,23$ $when\ j + k > 168,\ wrap = j + k - 168\ else\ wrap = 0$
Hourly Up-Ramp Rate Limit	$HU_w^{pow} \ge Gen_h - Gen_{h-1+Wrap} \quad \forall\ h \mid h = 1,...168$ when $h > 1$ $wrap = 0$ else $wrap = 168$
Hourly Down-Ramp Rate Limit	$HD_w^{pow} \ge Gen_{h-1+wrap} - Gen_h \quad \forall\ h \mid h = 1,...168$ when $h > 1$ $wrap = 0$ else $wrap = 168$
Minimum Daytime Release	$MD_w^{pow} \le Gen_h \quad \forall\ h \mid h = 1,...,7,20,...,31,44,...,55,68,...,79,92,...,103,116,...,127,140,...,151,164,...168$
Minimum Nighttime Release	$MN_w^{pow} \le Gen_h \quad \forall\ h \mid h = 8,...,19,32,...,43,56,...,67,80,...,91,104,...,115,128,...,139,152,...,163$
Daily Generation	$DGen_d = \sum_{i=1}^{24} Gen_{(d-1)\times 24+i} \quad \forall d \mid d = 1,...,7$
Minimum Daily Generation for Weekend Days	$DGen_d \ge DGen_2 \times DMin_d \quad \forall d \mid d = 1,7$
Identical Weekday Total Generation Levels	$DGen_2 = DGen_d \quad \forall d \mid d = 3,4,5$

where,

$h =$ Simulation hour index

$d =$ Simulation day index where 1=Sun, 2= Mon, etc.

$wrap =$ index parameter to address temporal boundary conditions

$Gen_h =$ Average generation level (MWh) during hour h

$SP_h =$ Spot market price index ($/MWh) for hour h

$WGen_w =$ Total generation (MWh) during week w

$DGen_d =$ Total generation (MWh) during day d

$DMin_d =$ Minimum daily generation fraction for day d (see Table X)

In practice, hydropower plant operations do not always strictly follow an economic optimization regime as suggested by mathematical models. This occurs because models are a simplification of reality and typically only include those elements that can be described in the form of in mathematical equations. In GTMax-Lite, equations are used to model the power plant based on an economic maximization function subject to physical and legal operating limits. However, marketers must often include other important factors which result in operations that often deviate from the simplified mathematical optimal. Some of these factors include individual risk tolerance levels and intricacies associated with bilateral contracts, block spot purchase patterns, grid limitations, and power exchanges and interchanges. Other factors not included in GTMax-Lite are general agreements that have been made with affected parties, but that are not contained in a legally binding decree.

Despite its limitations, the GTMax-Lite model usually simulates daily and hourly generation patterns that are similar to actual operations. However, compared typical operations, the GTMax-Lite model will at times schedule less power during the weekend when market prices are low, shifting more power to higher-priced weekdays. Although operations comply with ROD constraints, the GTMax-Lite schedule may have some detrimental implications for the environment. Therefore, additional constraints that specify a minimum allocation of daily generation among the days of the weeks are incorporated into the GTMax-Lite mathematical formulation.

Daily minimums are specified as the ratio of daily generation during a weekend day relative to the average daily generation during a weekday. For example, a value of 0.9 assigned to Saturday requires that the total generation during that day must be at least 90 percent of a weekday's generation. Values assigned to the daily generation restrictions are based on historical operations and vary by month as shown in Table 3. Minimum daily generation levels are often not binding in the model and water releases scheduled by GTMax-Lite on Saturday and Sunday frequently are more than the minimum.

Table 3
Daily Generation Fractions for Weekend Days

Month	Sunday	Saturday
January	0.86349	0.88511
February	0.86861	0.94269
March	0.90666	0.94367
April	0.91358	0.98481
May	0.93182	0.95657
June	0.86247	0.89126
July	0.94368	0.96479
August	0.92117	0.94085
September	0.95205	0.96890
October	0.97621	0.97621
November	0.94810	0.98237
December	0.90623	0.96419

Glen Canyon power plant operations simulated by GTMax-Lite under median hydrological conditions for a typical week in the wintertime, 2nd week in December, 2010, are depicted in Figure 5. To maximize the economic value of the hydropower resource, the model generates as much power as possible during hours when market prices are the highest. Generation tends to drop as the spot price decreases; for example, during the midday price valley. Generation during on-peak hours are constrained by the ROD daily change, reaching a peak of about 610 megawatts (MW). That is substantially less than (approximately half) the median capability of 1,205 megawatts (MW) estimated by CRSS based on the Powell Reservoir forebay elevation.

Simulated operations during the summertime also tend to follow prices. As shown in Figure 6, Glen Canyon generation exhibits a one-hump pattern that has a shape similar to the market price profile. Simulated operations are for July 2010 under median conditions. Comparable to the wintertime, peak generation levels are constrained to slightly more than 600 megawatts (MW) despite a hydrological head that is capable of supporting generation levels of approximately 1,232 MW.

Figure 5
Glen Canyon Power Plant Operations under Median Winter Conditions

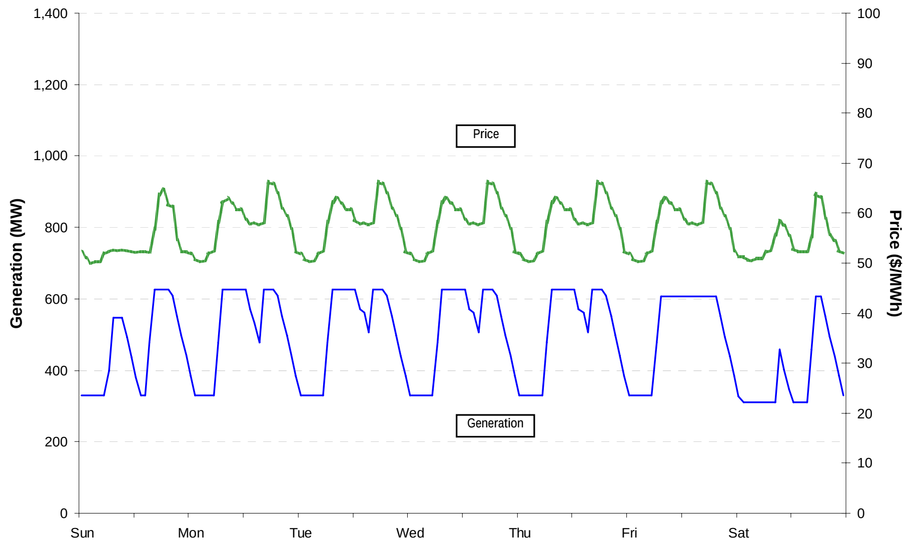

Figure 6
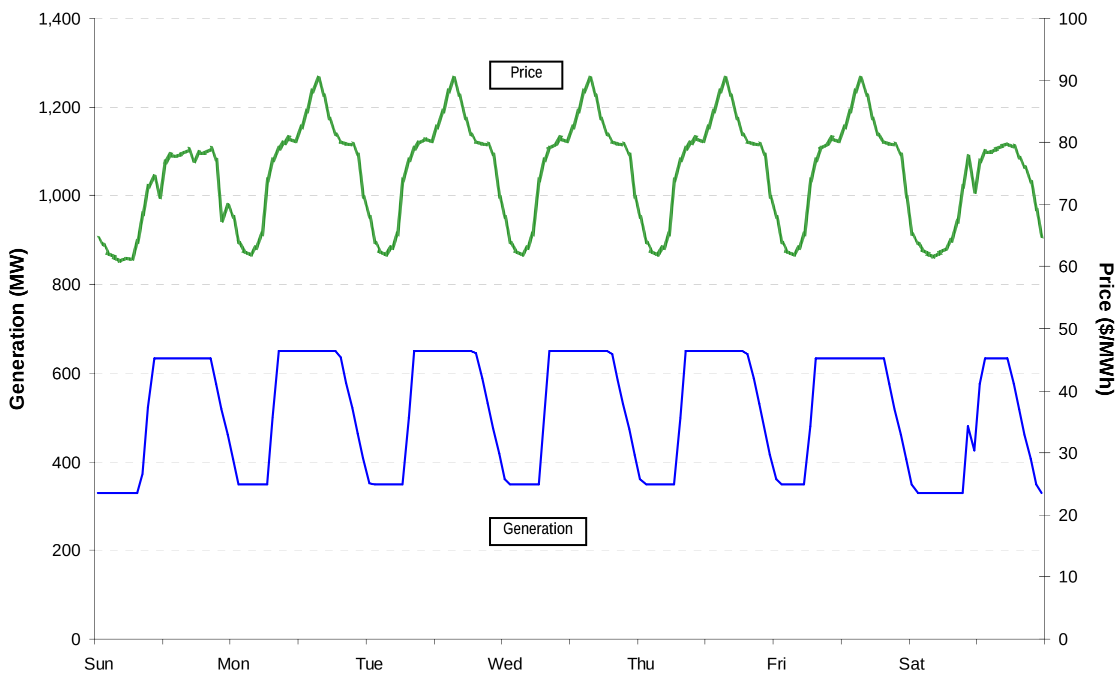
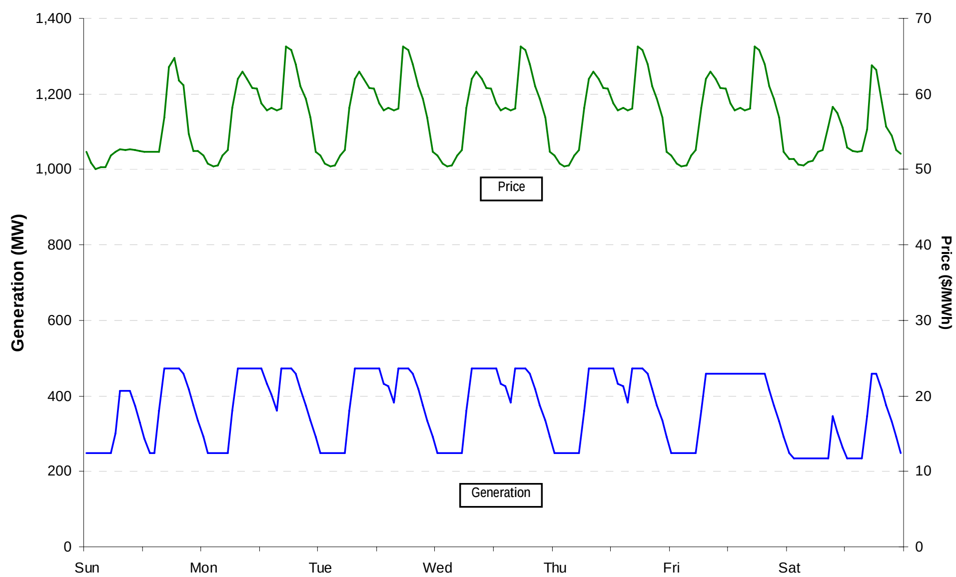
Glen Canyon Power Plant Operations under Median Summer Conditions



Under dry hydrological conditions, the maximum generation levels simulated by GTMax-Lite drop even further. Figure 7 shows that on-peak production levels are less than 475 MW. Under the driest conditions, forebay elevations dip below turbine water inlet tubes resulting in zero monthly electricity generation and zero power plant capacity.

Figure 7
Glen Canyon Power Plant Operations under Dry Winter Conditions



Economic Calculations

The economic value of the Glen Canyon Dam energy is computed by multiplying power plant generation estimated by GTMax-Lite by the market price. Since the model only simulates operations for one representative week in each month, economic values are scaled. This scaling factor equals the number of days in a projection month divided by 7. A net present value (NPV) of the monthly economic values over the study period was calculated by discounting monthly values at an annual rate of 4.875 percent. When discounting, it was assumed that the stream of hourly economic benefits in a month occurred mid-month as a single lump-sum value.

Differences in annual energy and capacity generation were calculated between the No Action Alternative and each Action Alternative. The annual capacity difference in terms of megawatts was assigned a value using a capacity price of $6.32/kilowatt-month. That price represents the market value of generation in 2007 dollars. For valuing capacity, Western obtained a cost of constructing a new combined cycle natural gas power plant. Capacity was valued at the replacement cost identified by some SLCA/IP customer utilities who have recently constructed facilities which provide load following capacity. These customer data were collected in order to get information regarding the construction cost per megawatt of a recently built facility that provides electrical services similar to the GCD power plant.

This value is higher than the average cost of capacity from existing facilities on the system, but was selected for two reasons. (1) Over the 53-year study period, available capacity from existing sources will not be adequate to serve growing loads. New capacity will have to be built. (2) Renewable resource requirements in states such as California could cause new capacity costs to escalate at a rate faster than the 2.2 percent assumed in this analysis.

The two Western offices performing analyses coordinated capacity values, so the same capacity values were used for GCD and for the Lower Basin power plants.

Capacity values were converted to a present value using the same method as for energy, and were then added to the energy present value to obtain a total value of the difference in generation between the No Action alternative and each Action alternative. Reclamation did not value capacity differences in their analysis.

Results of Western's Analysis

Western Area Power Administration's financial analysis of the alternatives concentrated on the effect each alternative has on energy generation and capacity generation at Glen Canyon Dam (GCD). The effects are measured by the difference in generation in gigawatthours (GWh) of energy and megawatts (MW) of capacity between the No Action alternative and each of the Action alternatives, for the five representative hydrological conditions outlined above. The analysis includes the economic effect of changes to capacity and energy calculated by applying energy and capacity costs to the changes in generation. Finally, a net present value calculation was performed to develop a single value to compare each Action alternative to No Action. The sections below break down the results of the analysis into each of the aspects studied.

Glen Canyon Dam Energy Generation

The energy generation at GCD for each alternative was summed over the 53-year study (2008-2060) period and is displayed in Table 4 below in GWh. (One GWh is equal to 1 million kilowatt hours.) The difference in generation of the Action alternatives as compared to No Action is shown in Table 5. Table 6 has those same differences as percentages.

Table 4
Energy Generation

Alternatives	Mean (GWh)	Median (GWh)	90% Exceed. (GWh)	Trace 94 (GWh)	10% Exceed. (GWh)

Glen Canyon Dam Capacity Generation

Generation of capacity at GCD was calculated and averaged over the same study period as shown in Table 7. The numbers in the table represent the average peak capacity output of GCD in megawatts, and is much lower than the power plant capability based on lake elevation. Table 8 displays the difference between each alternative and the No Action alternative. Table 9 has those same differences as percentages.

Present Value of Energy

The NPV of energy generation at GCD was calculated for each Alternative at each hydrological condition. Each of the Action alternatives was compared to the No Action alternative to determine the difference in NPV of energy generation in GWh over the study period. Table 10 shows the NPV of each alternative studied. Table 11 displays the difference between each of the Action alternatives and the No Action alternative. Table 12 has those same differences as percentages.

Impact to Western Area Power Administration's SLCA/IP Firm Power Rate

Western performed a rate analysis of the present value results summarized in Table 13 above. Table 18 shows the results of the analysis on the SLCA/IP firm power rate, while Table 19 shows the difference of each alternative as compared to the No Action alternative, both in mills/kWh and in percent change. Because of time constraints, the rate analysis was confined to the Median and 90 percent exceedence hydrological conditions. (The 90 percent exceedence No Action SLCA/IP rate is a cursory study meant to illustrate the higher rate at low hydrologic levels. It shouldn't be mis-interpreted as the result of a thorough rate PRS.) An explanation of the methodology Western used to perform the rate analysis is presented below in Tables 18 and 19.

Table 18
SLIP Firm Power Rate

Alternatives	Median (Mill/kWh)	90% Exceed. (Mill/kWh)
No Action	25.28	27.34
Basin States	23.39	31.17
Conservation Before Shortage	23.41	31.17
Water Supply	23.17	30.83
Reservoir Storage	24.89	29.01
Preferred Alternative	23.65	31.17

Table 19

Preferred Alternative	(1.63)	-6.45%	3.83	14.01%

Customer Rates

Western sets rates for firm electric service from Federal hydropower projects in its marketing territory based on Department of Energy regulations and applicable Federal statutes. Power rates are calculated using what is referred to as a power repayment study. The PRS is a special spreadsheet-based computer program that contains the general and any specific repayment rules associated with a particular hydro project such as the SLCA/IP. (The SLCA/IP comprises the Colorado River Storage Project [CRSP], Rio Grande, Collbran, Dolores, and Seedskadee Projects, consolidated for marketing and ratemaking purposes.) When coupled with pertinent project historical data and future projections, the PRS calculates the power rate that is charged to customers who receive SLCA/IP power. The PRS ensures that all identified project costs are repaid within the time frames established by law and regulation.

For the rate analysis work done for this report, two base case PRS's were developed. The two base cases correspond to the power rates for the No Action alternatives at Median and 90 percent Exceedence hydrological conditions. The first is basically the same as the PRS Western used for its current firm power rate. This case is based on Median hydrological conditions, meaning that it includes firming purchase cost estimates for future years based on Median generation estimates. The second base case is the same as the first, except that future firming purchase estimates are based on 90 percent exceedence (10th percentile) estimates of future generation, and firming purchases.

These two base case PRS's produce a rate of 25.28 mills per KWh (Median) and 27.34 mills per KWh (90 percent exceedence). Once the base case PRS's are done, the difference in NPV dollars of each Action alternative as compared to the No Action alternative is inserted into the PRS's and a change in the power rate is computed. These PRS results are what are displayed in Tables 5 and 5a above.

Discussion of Results

Overall, at all hydrological conditions, the Reservoir Storage alternative provides the most favorable conditions for power at GCD, while the Water Supply alternative provides the worst results for power generation, based on the above financial analysis. The Basin States, and Conservation Before Shortage alternatives and the Preferred Alternative show similar results and are ranked between the Reservoir Storage alternative and the Water Supply alternative in their effect on power resources at GCD.

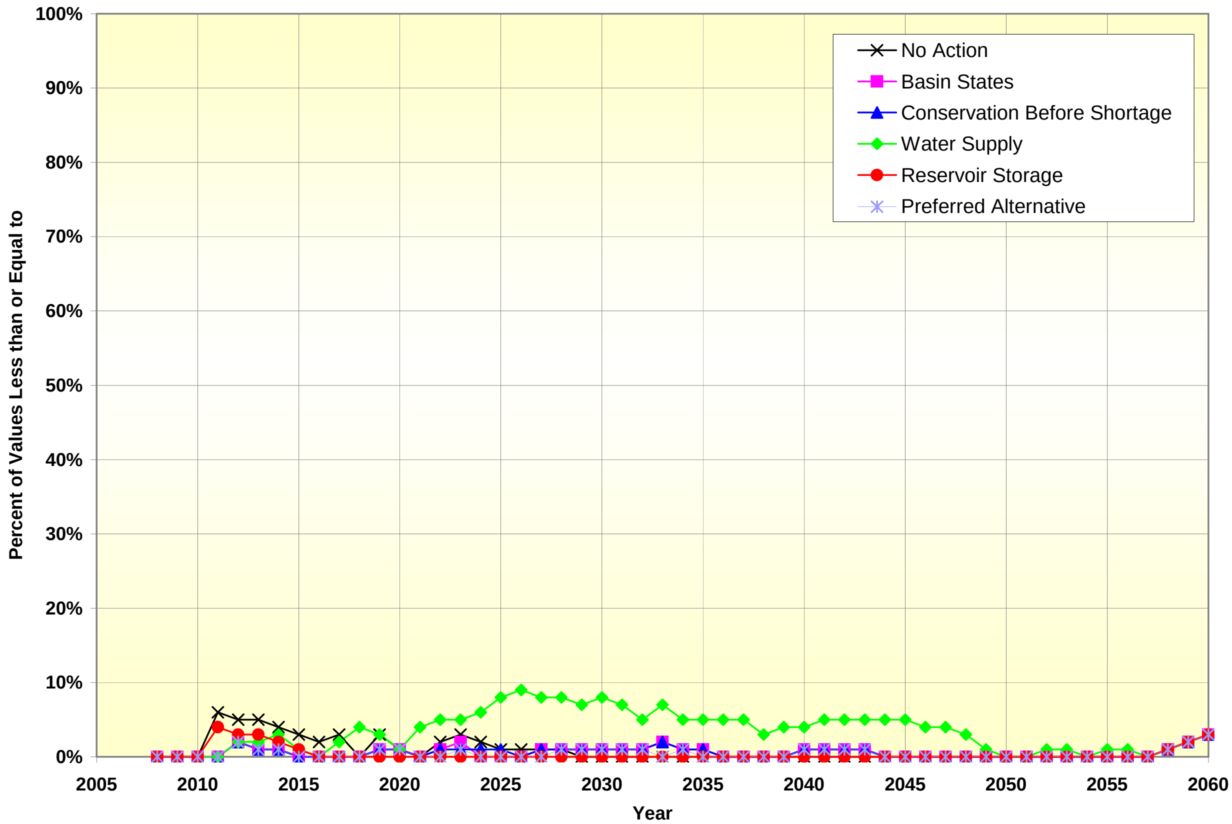
One result is common to Table 19 as well in the preceding tables. At 90 percent exeedence level, the Action Alternatives show consistently worse results (lower energy and capacity generation, lower NPV, higher SLCA/IP rate) than the No Action alternative. Likewise, at Median conditions, the Action alternatives show better results than the No Action alternative. Results at the Mean conditions are more mixed, with some results being better under No Action, and others at one or more of Action alternatives. Trace 94 shows consistent improvement in results of the Action alternatives as compared to No Action. The 10 percent exceedence cases show a lower present value in four of the five alternatives as compared to the No Action alternative, with only the Reservoir Storage alternative showing improvement. At the high levels of generation and revenues represented in the 10 percent exceedence case, the loss of generation in the action alternatives as compared to the No Action alternative is inconsequential to SLCA/IP financial health.

The practical effect of Action alternatives is to produce a widening effect on power generation, revenues, and rates as hydrological conditions range from wet to dry and back to wet. As conditions get drier, generation drops more under the Action alternatives as compared to No Action. Conversely, as conditions go from drier to wetter, generation improves more under the Action alternatives as compared to No Action. This could result in more variation in the CRSP Basin Fund cash reserves, and could lead to additional actions, such as power rate adjustments, rate surcharges, or reductions to customer allocations to respond to shortfalls in revenue under dry conditions. Under the Action alternatives, Western and its power customers would need to quickly respond to changing hydrological conditions to forestall financial problems.

Notwithstanding the financial analysis discussed above, the most important aspect of any of the Action alternatives to Western and the firm power customers is whether and how much the alternative reduces the probability of a total loss of generation from GCD. Loss of GCD generation would result in a huge loss of revenue to Western, Reclamation, and various environmental programs in the Upper Basin; loss of generation and replacement costs for power customers; and degradation to power system reliability.

Figure 8 on the following page is a graph showing the percentage of trace monthly elevations from Reclamation's CRSS modeling output that are less than or equal to elevation 3490'. This graph is an indicator of how well each alternative is able to forestall a shutdown of GCD generation as compared to the No Action alternative.

Figure 8
Lake Powell End-of-March Elevations
Comparison of Action Alternatives to No Action Alternative
Percent of Values Less than or Equal to Elevation 3,490 feet msl



Using this measure, the Water Supply alternative is worse than the No Action alternative, while the Reservoir Storage, Basin States, and Conservation before Shortage alternatives and the Preferred Alternative are equal to or better than No Action.

Hydrologic Resources Information

This section contains additional information that was used in the hydrologic analysis (Section 4.3 of this Final EIS). The specific information provided in this section consists of a series of figures that provide comparisons of Lake Powell and Lake Mead under the modeled action alternatives to those under the modeled No Action Alternative. Also, this section contains the results of analysis that compares the probability of Beach/Habitat Building Flow release from Glen Canyon Dam under the No Action Alternative to the action alternatives.

P-HR.1 Beach/Habitat-Building Flows

P-HR.1.1 Introduction

The construction and operation of Glen Canyon Dam has caused two major changes related to sediment resources downstream in Glen Canyon and Grand Canyon. The first change is reduced sediment supply. Because Glen Canyon Dam and Lake Powell trap virtually all of the incoming sediment from the Upper Basin, releases from Glen Canyon Dam are mostly as clear water. The second major change is the reduction in the high water zone from pre-dam annual flood elevations to powerplant release elevations. Thus, the height of annual sediment deposition and erosion in the Colorado River reaches downstream of Glen Canyon Dam has been reduced.

During the investigations leading to the preparation of the *Operation of Glen Canyon Dam Final EIS* (Reclamation 1995), the relationships between releases from Glen Canyon Dam and downstream sedimentation processes were brought sharply into focus, and flow patterns designed to conserve sediment for building beaches and habitat (i.e., beach/habitat-building flow, or BHBF releases) were identified. The BHBF releases are scheduled high releases of short duration that exceed the hydraulic capacity of the powerplant. Such releases were presented as a commitment in the 1996 ROD for the *Operation of the Glen Canyon Dam FEIS* (Reclamation 1996e), at a then-assumed frequency of one in five years.

In addition to these BHBF releases that exceed the hydraulic capacity of Glen Canyon Powerplant, the *Operation of Glen Canyon Dam FEIS* identified the need for Beach/Habitat Maintenance Flow (BHMF) releases which do not exceed the hydraulic capacity of the powerplant. These flows were designed to prevent backwater habitat from filling with sediment and to reduce vegetation on camping beaches in years between BHBFs. BHBF and BHMF releases serve as a tool for maintaining a mass balance of sediment in Glen Canyon and Grand Canyon.

P-HR.1.2 Methodology

The frequencies at which BHBF releases from Glen Canyon Dam would occur under the No Action Alternative and the action alternatives were estimated through the use of the Colorado River Simulation System (CRSS) and modeling as described in Section 4.2.3 of this Final EIS.

The model was configured to simulate BHBF releases by incorporating the BHBF hydrologic triggering criteria (contained in Section P-HR.1.3) into the Glen Canyon Dam operating rules. The model was also configured to make no more than one BHBF release in any given year.

P-HR.1.3 Existing Conditions

Sediment along the Colorado River downstream of Glen Canyon Dam is an important and dynamic resource which affects fish and wildlife habitat along the river, creates camping beaches for recreation, and serves to protect cultural resources. Except for remnants of high river terraces deposited prior to the closure of Glen Canyon Dam, the now-limited sediment supply that exists along the river channel is affected by Glen Canyon Dam operations.

Since construction of Glen Canyon Dam, the measured suspended sediment load (sand, silt, and clay) at Phantom Ranch (in the Grand Canyon) averages 11 million tons per year. Most of this load comes from the Paria River and the Little Colorado River. Flash floods from other side canyons also contribute to the sediment supply (Reclamation 1995). The suspended sediment load is sporadic in occurrence, depending on Glen Canyon Dam releases and tributary inputs.

Beneficial sediment mobilization and deposition downstream of Glen Canyon Dam depends on the interaction of two occurrences for full effectiveness: the addition of sediment to the river corridor and BHBF releases. The higher energy of BHBF releases mobilizes suspended and riverbed-stored sediment and deposits it as beaches in beach and shoreline areas. Once a BHBF release has been made, additional sediment supply from tributary inflows is needed before subsequent BHBF releases are fully effective in promoting further beach and sandbar deposition along the river.

Subsequent to the 1996 ROD, specific operating criteria were developed which further refined conditions under which BHBFs would be made. The criteria provide that under either of the following two triggering conditions, BHBF releases may be made from Glen Canyon Dam:

1) if the January forecast for the January-July unregulated spring runoff into Lake Powell exceeds 13 maf (about 140 percent of normal) when January 1 content is greater than 21.5 maf; or

2) any time a Lake Powell inflow forecast would require a monthly powerplant release greater than 1.5 maf.

Research concerning the relationships among dam operations, downstream sediment inflow, river channel and sandbar characteristics, and particle-size distribution along the river is ongoing.

P-HR.1.4 Modeling Results

The effects of the No Action Alternative and the action alternatives on BHBF releases from Glen Canyon Dam were analyzed in terms of the yearly frequency at which BHBF releases could be made. Specifically, the frequency was indicated by the occurrence of one or both of the triggering criteria cited above, during a calendar year. The following discussion presents probability of occurrence under the No Action Alternative, and then compares the probability of BHBF releases under each action alternative to the No Action Alternative.

Figure P-HR-5 shows the probabilities that BHBF releases could be made under the No Action Alternative and the action alternatives. This figure shows that in the initial two years of the modeling period (2008 and 2009), under the assumed hydrologic sequences and reservoir starting conditions, there is a zero probability of BHBF releases. From 2010 through about 2016, the probability of BHBF releases under the No Action Alternative increases each year to about ten percent. Between 2017 and 2039, the probability under the No Action Alternative varies between nine percent to 12 percent. Between 2040 and 2060, the probability under the No Action Alternative increases slightly and varies between nine percent to 15 percent.

The probability of BHBF releases under the Basin States, Conservation Before Shortage, and Water Supply Alternatives, and the Preferred Alternative, are similar to those observed under the No Action Alternative and differ no more than one percentage point in any one year. The exception to this occurs in 2042 when the probability under all of these alternatives is three percent lower than that of the No Action Alternative. This occurrence is the result of the relatively lower reservoir conditions in 2026 that occur under these alternatives.

The Reservoir Storage Alternative generally provides a higher probability of BHBF releases than the No Action Alternative and the other action alternatives between 2011 through 2045. This occurs due to the generally higher reservoir elevations that are provided under the Reservoir Storage Alternative. Because these elevations are higher than the first part of the BHBF release triggering criteria, The Reservoir Storage Alternative provides slightly higher probability for BHBF releases.

The probability of BHBF releases under the No Action Alternative and the action alternatives all converge in about 2046 and remain the same through 2060.

Table P-HR-1 summarizes the BHBF release probabilities during the interim period (2008 through 2026) and the subsequent period to 2060, based on the data plotted in Figure P-HR-5. The table reflects the higher average probability during the post-interim period than during the interim period due to the low reservoir starting conditions in 2008.

Table P-HR-1
Average Probability of BHBF Releases from Glen Canyon Dam

Period	Percent of Time That Conditions Needed for BHBF Releases Would Occur at Lake Powell					
	No Action	Basin States	Conservation Before Shortage	Water Supply	Reservoir Storage	Preferred Alternative
2008 - 2026	6.9	6.9	7.1	6.8	8.0	7.4
2027 - 2060	11.5	11.4	11.4	11.4	12.1	11.4

Water Deliveries Information

This section contains additional information used in the analysis of water deliveries (Section 4.4). Specifically, this information is used in the analysis of multi-year shortages. In this EIS, occurrences of shortages in consecutive years are termed multi-year shortages. The information consists of a series of figures that provide comparisons of the probability of multi-year shortages with volumes equal to or greater than 400 kafy, 500 kafy, 600 kafy, and 1,000 kafy. Consecutive year shortages with durations of two or more years, five or more years, ten or more years, and 15 or more years were considered for these shortage analyses.

Water Quality and Air Quality Information

This section contains additional information used in the water quality and air quality analyses (Section 4.5 and Section 4.6 of the EIS, respectively). This information consists of a series of figures that provide comparisons of flow-weighted annual average salinity concentrations under the modeled action alternatives to those under the modeled No Action Alternative. Additional figures that compare Lake Powell and Lake Mead elevations during different months (End-of-October and End-of-March elevations) are also included in this section.

Figure P-WAQ-1
Colorado River Salinity Downstream of Hoover Dam
Comparison of Action Alternatives to No Action Alternative
Flow-weighted Annual Average Salinity Concentrations

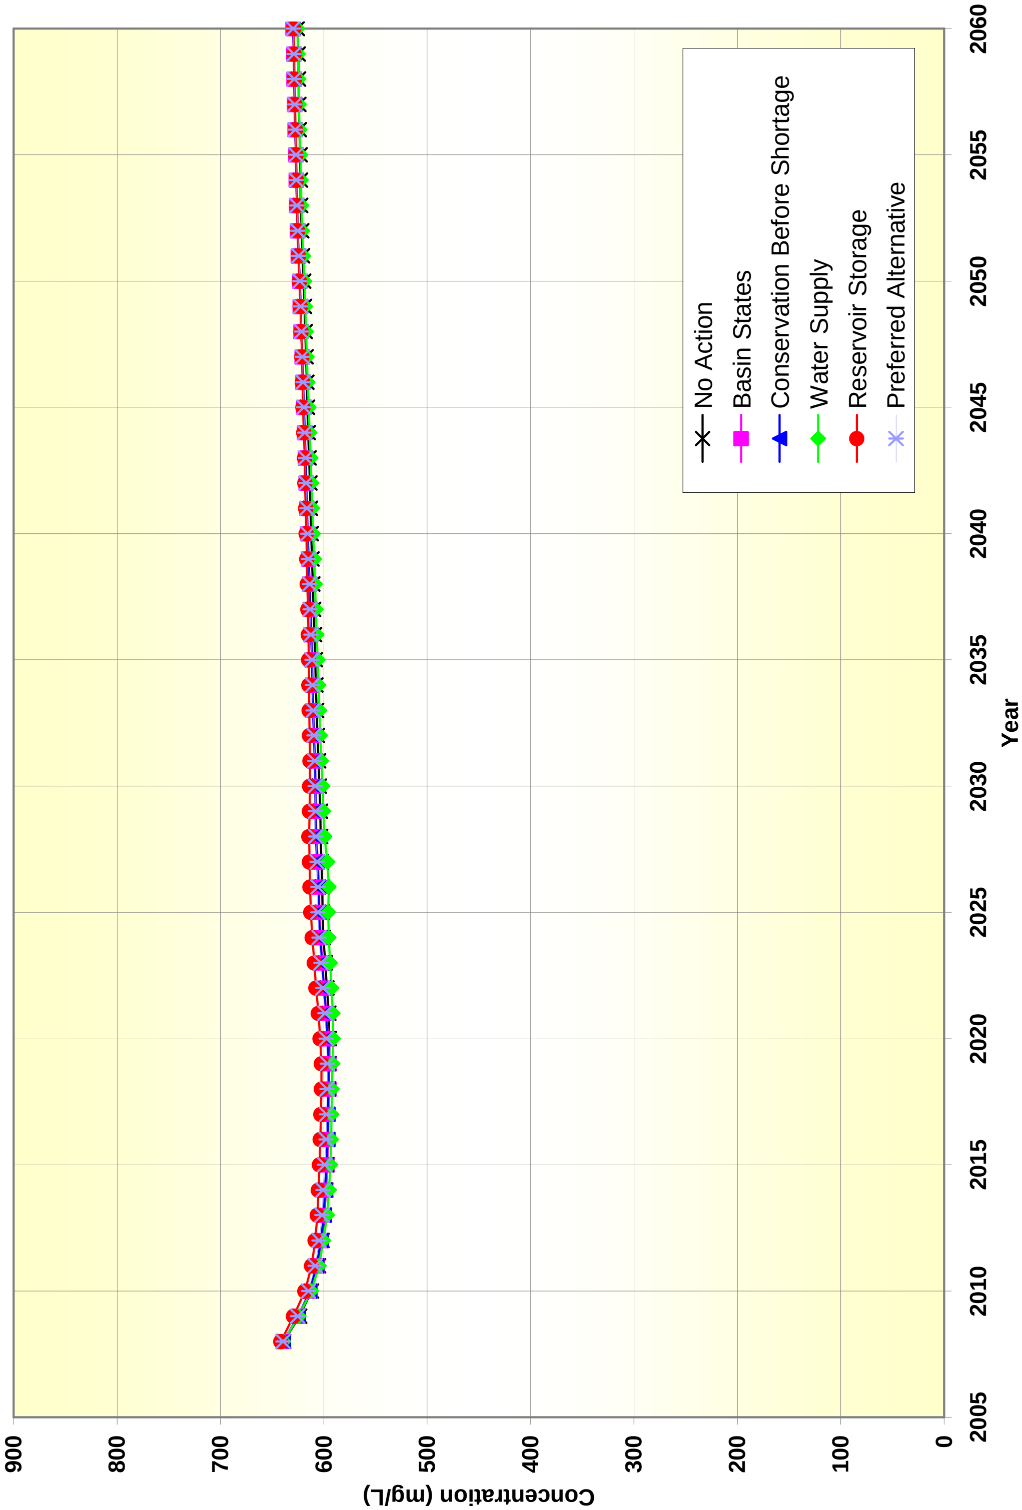

Figure P-WAQ-2
Colorado River Salinity Downstream of Parker Dam
Comparison of Action Alternatives to No Action Alternative
Flow-weighted Annual Average Salinity Concentrations

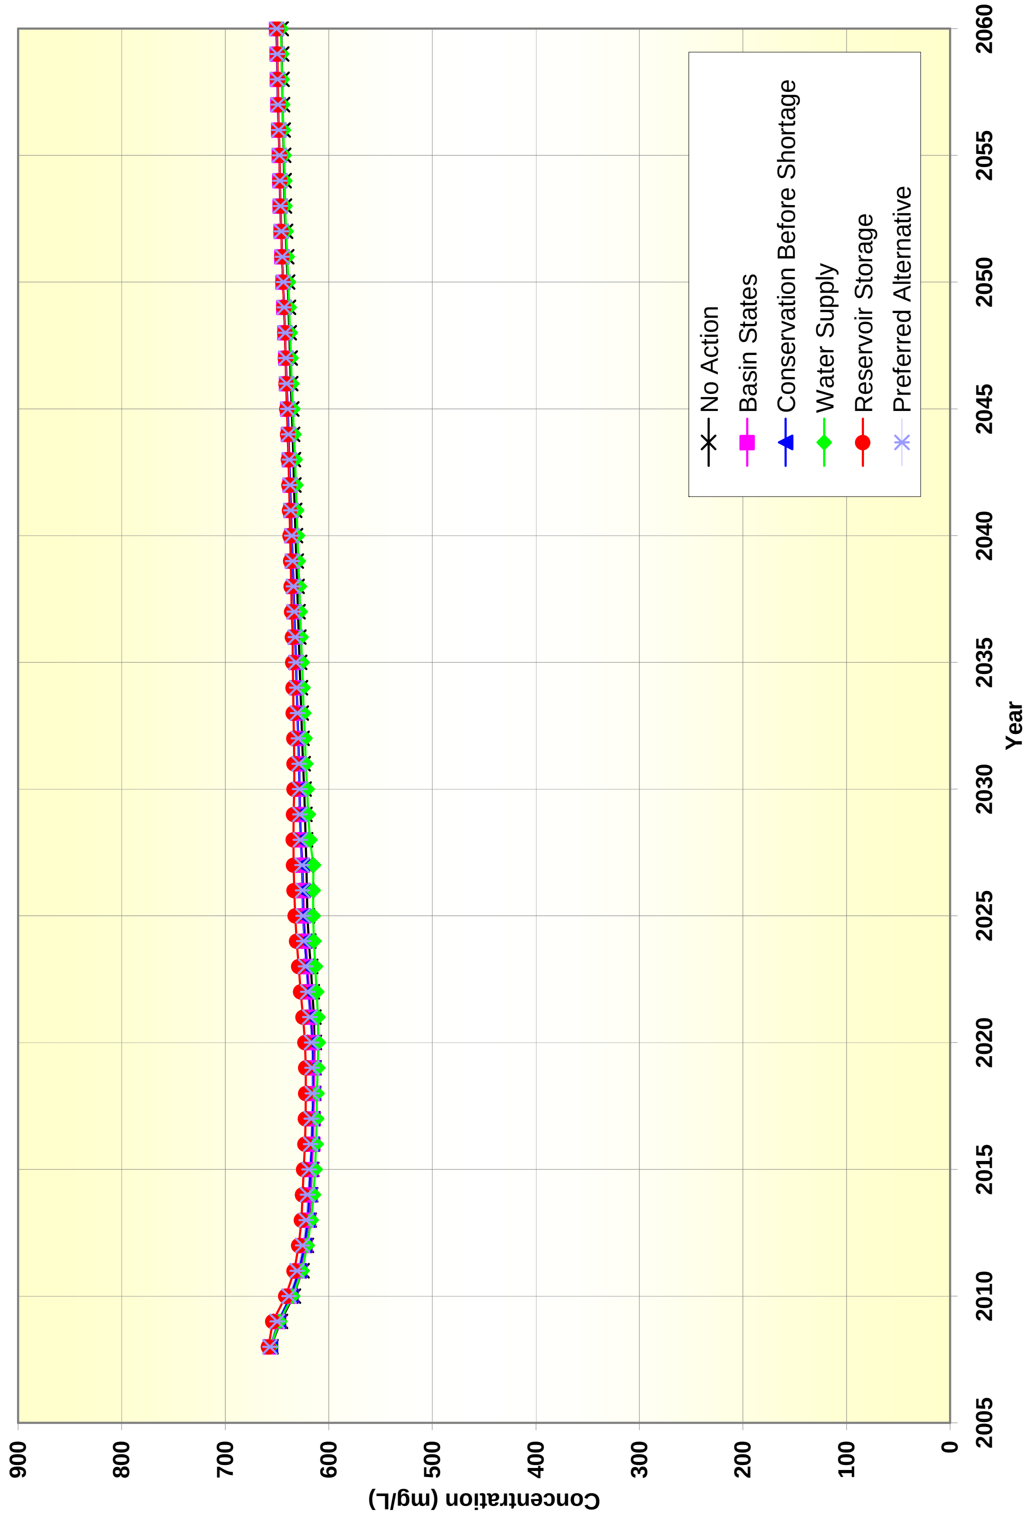

Figure P-WAQ-3
Colorado River Salinity Upstream of Imperial Dam
Comparison of Action Alternatives to No Action Alternative
Flow-weighted Annual Average Salinity Concentrations

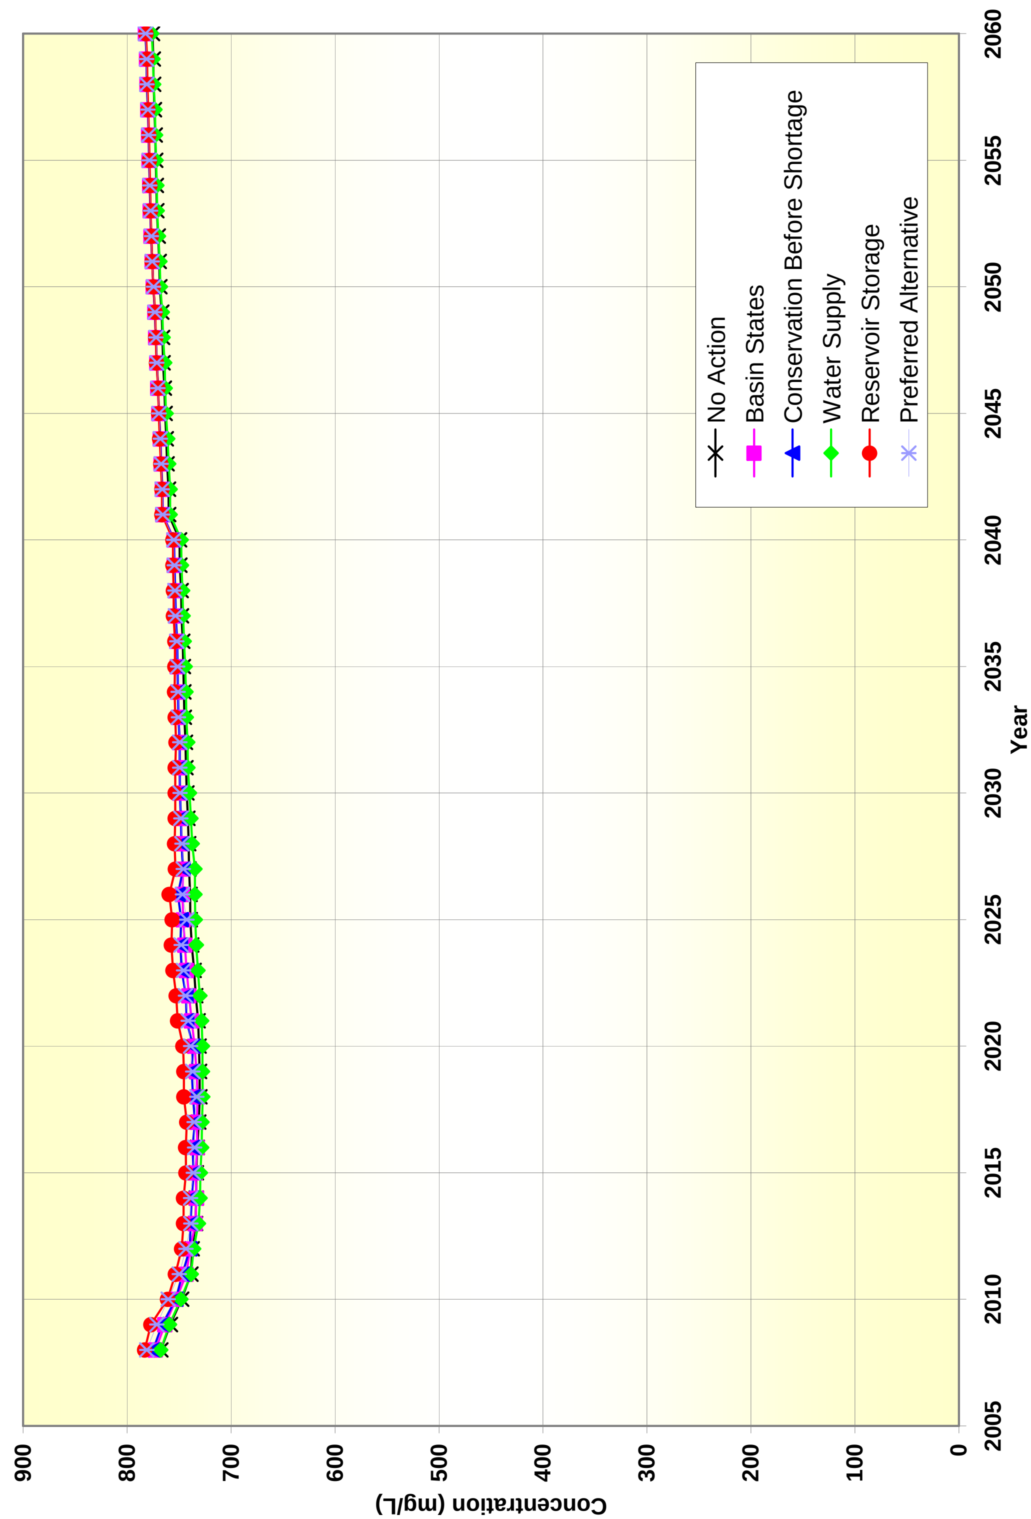

Figure P-WAQ-4
Lake Powell End-of-October Elevations
Comparison of Action Alternatives to No Action Alternative
90th, 50th, and 10th Percentile Values

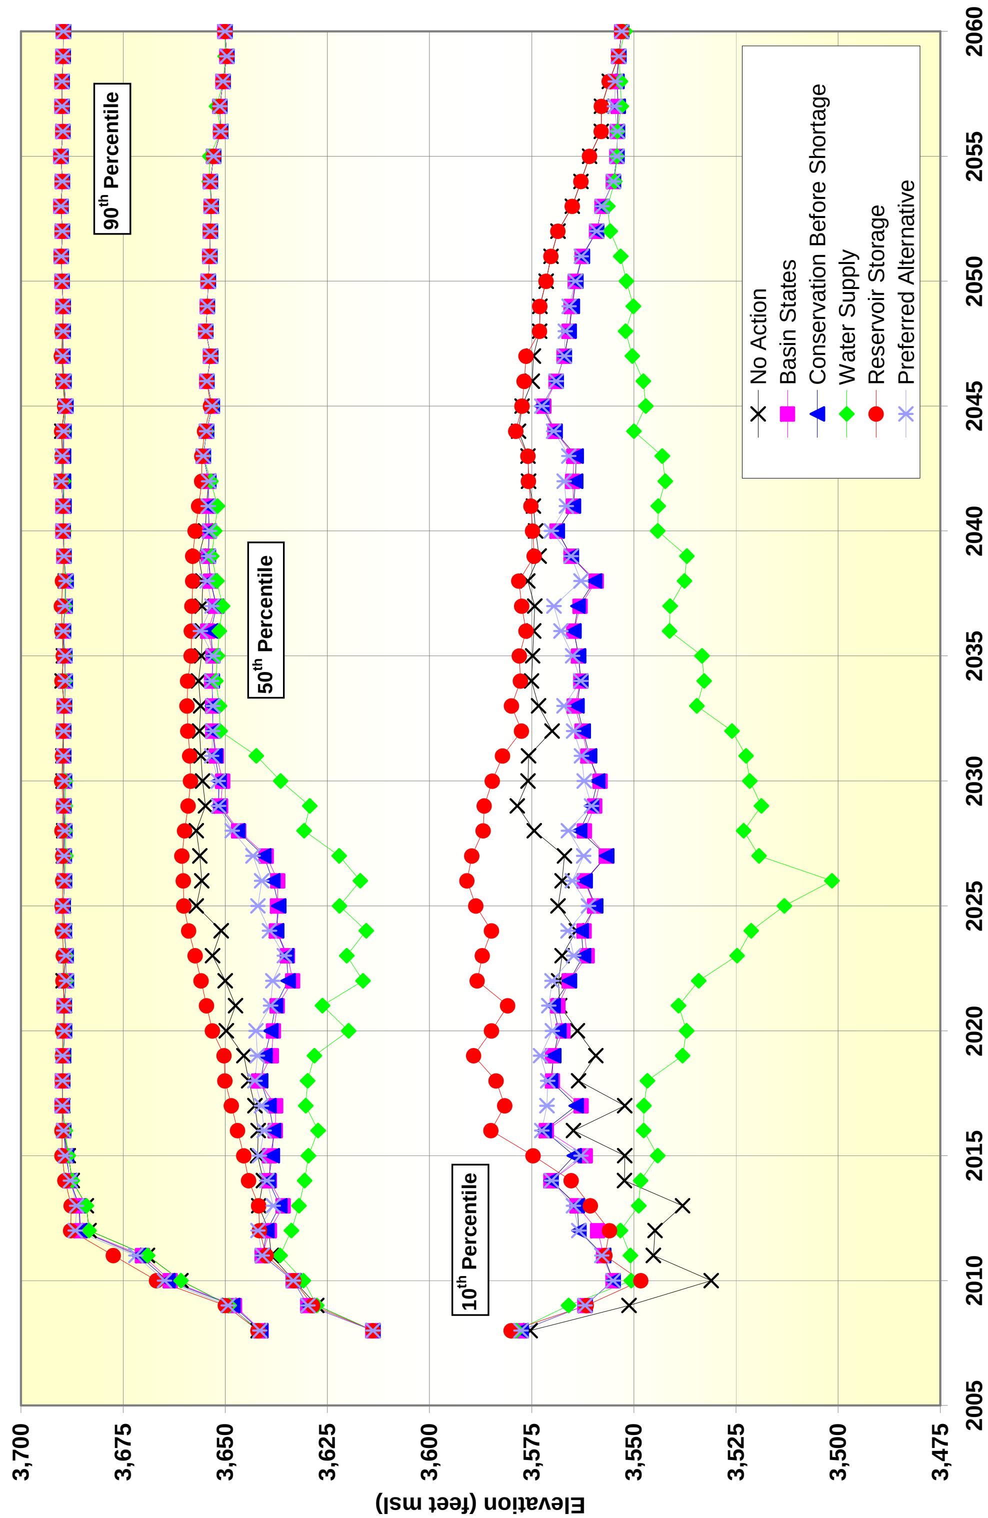

Figure P-WAQ-5
Lake Mead End-of-October Elevations
Comparison of Action Alternatives to No Action Alternative
90th, 50th, and 10th Percentile Values

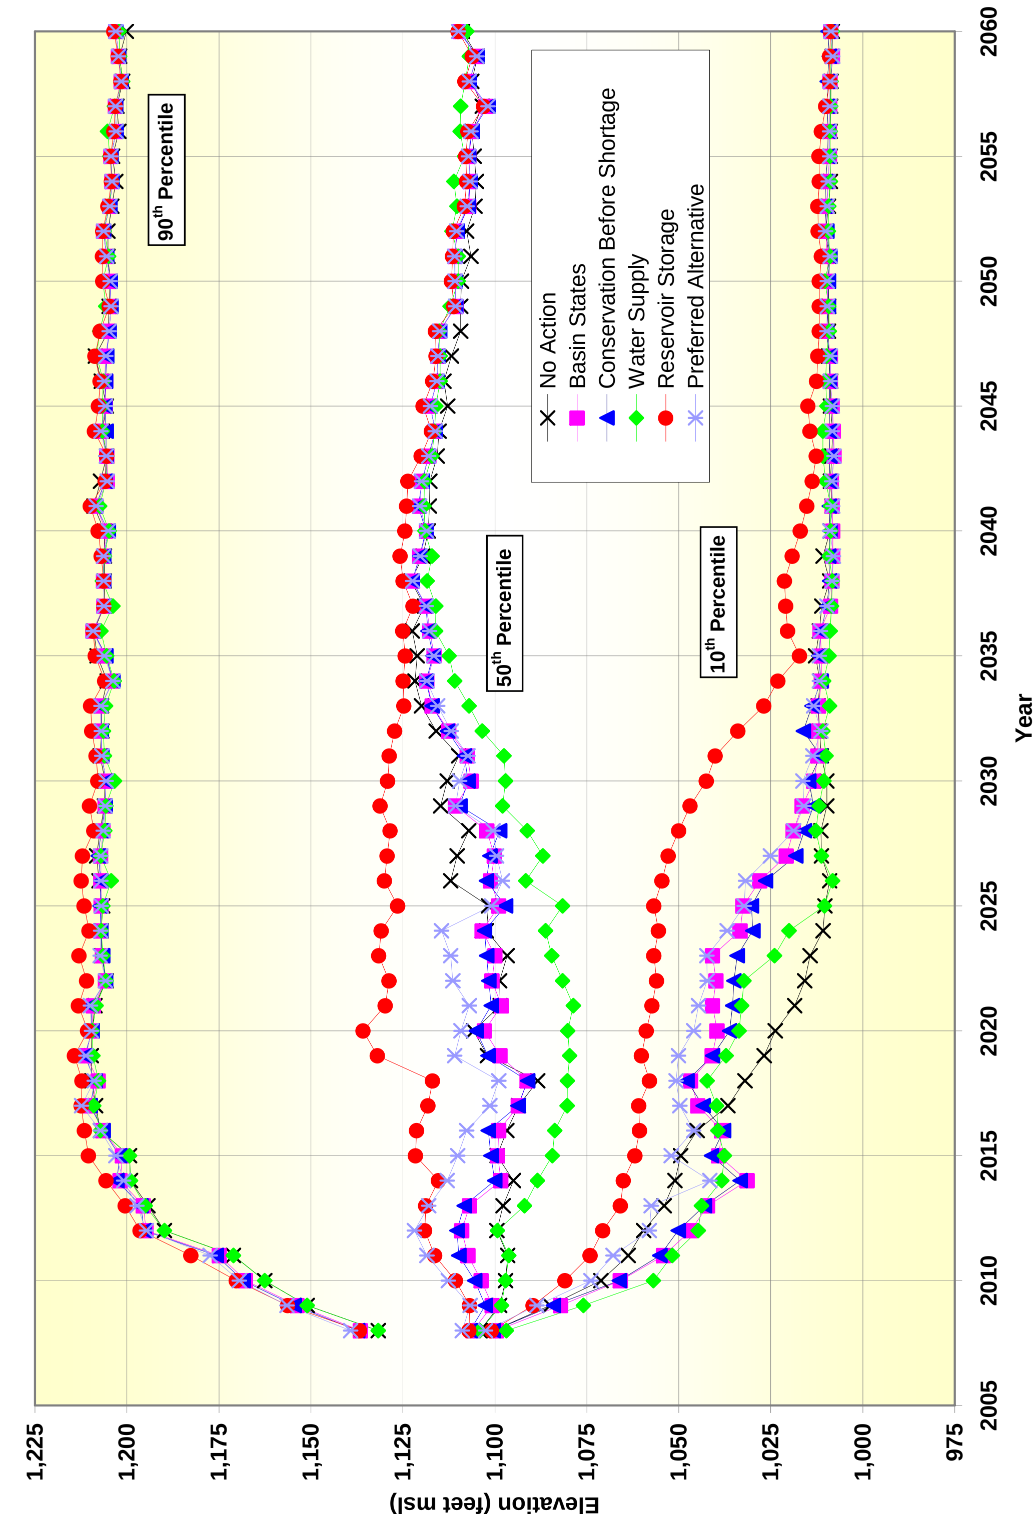

Figure P-WAQ-6
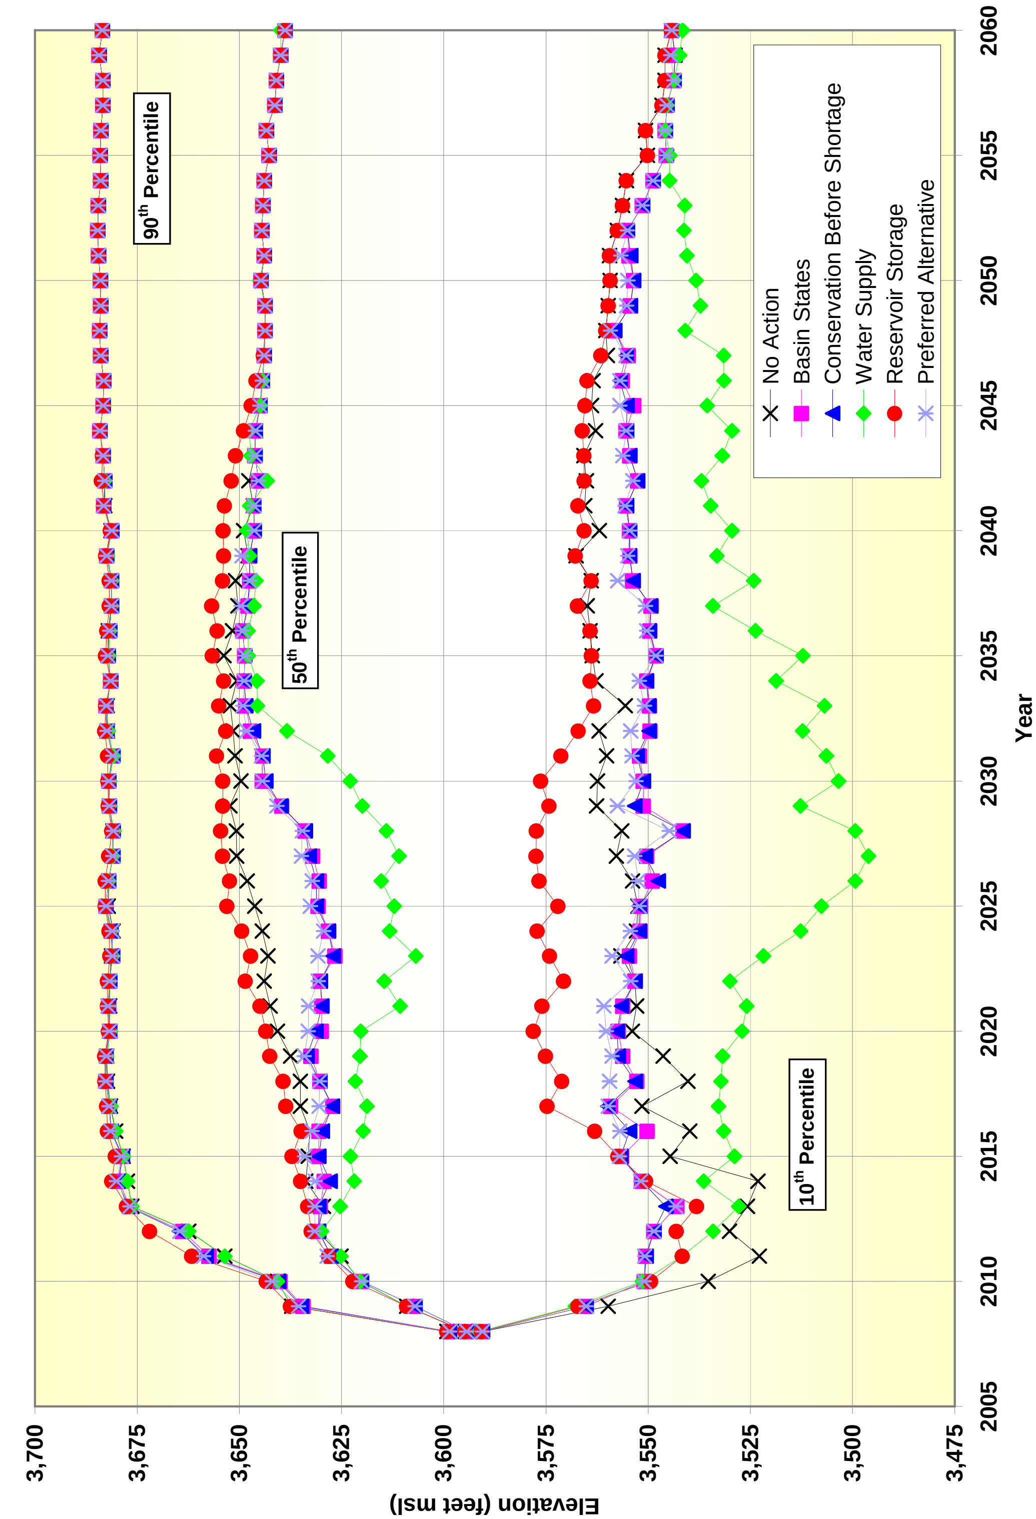
Lake Powell End-of-March Elevations
Comparison of Action Alternatives to No Action Alternative
90th, 50th, and 10th Percentile Values



Biological Resources and Cultural Resources Information

This section contains additional information used in the biological and cultural resources impact analyses (Section 4.8 and Section 4.9 of the EIS, respectively). The information consists of a series of graphs and tables. The initial group of graphs provides comparisons of Lake Powell and Lake Mead elevations under the modeled action alternatives to those under the modeled No Action Alternative. These graphs compare Lake Powell end-of-month elevations for the months of July and September, and Lake Mead end-of-month elevations for the months of March, July, and September under each alternative. The second group of graphs provide a comparison of monthly release volumes (January through December) from Glen Canyon Dam, Hoover Dam, Davis Dam, and Parker Dam. The next graph provides a comparison of the probability of occurrence for excess flows downstream of Morelos Diversion Dam under each alternative. The last group of graphs provide comparisons of the modeled water temperature for various locations along the mainstream Colorado River, including downstream Glen Canyon Dam (Glen Canyon Dam releases), at Lees Ferry, downstream of the Little Colorado River, and near Diamond Creek. The remainder of the information provided in this section consists of tables that provide comparisons of the average modeled water temperature along the mainstream of the Colorado River at Lees Ferry, downstream of the Little Colorado River, and near Diamond Creek.

Electrical Power Resources Information

This section contains additional information used in the electrical power resources impact analyses (Section 4.11 of this Final EIS). This information consists of three groups of graphs. The initial group of graphs provide a comparison of the energy production at Glen Canyon, Hoover, Davis, and Parker Powerplants. The second group of graphs provide a comparison of the Lake Powell and Lake Mead elevations under the modeled action alternatives to those under the modeled No Action Alternative. These graphs compare Lake Powell end-of-July and Lake Mead end-of-December elevations. The last group of graphs provide a comparison of the Headgate Rock Dam annual releases and energy production values under the modeled action alternatives to those under the modeled No Action Alternative.

Appendix Q

Modeling Assumptions with Regard to Future Water Deliveries to Mexico Sensitivity Analysis

This appendix provides a comparative analysis of the sensitivity of the hydrologic resources to different modeling assumptions with regard to how Mexico may incur future water delivery reductions. Two methodologies for determining future water delivery reductions to Mexico are described. The modeling assumptions used to implement the methodologies are also presented.

Q.1 Introduction

The proposed federal action includes the adoption of specific interim guidelines for Lower Basin shortages. The interim guidelines would be used by the Secretary to determine those circumstances under which the Secretary would reduce the annual amount of water available for consumptive use from Lake Mead to the Colorado River Lower Division states (Arizona, California, and Nevada) (Section 1.7) below 7.5 million acre-feet (maf) (a ‘‘Shortage’’) pursuant to Article II(B)(3) of the Consolidated Decree. The determination of deliveries to Mexico is not a part of the proposed federal action. Any such determination would be made in accordance with the 1944 Treaty. Nevertheless, modeling assumptions with respect to the distribution of shortages for the Lower Division states include water delivery reductions to Mexico in order to analyze potential impacts to hydrologic and other environmental resources (Section Q.2.2.1 and Appendix A)[1]. These modeling assumptions were applied to the No Action Alternative as well as the action alternatives, i.e., the modeling assumptions with regard to the distribution of shortages to the Lower Division states include water delivery reductions to Mexico and are identical in all alternatives.

This appendix provides a comparative analysis of the sensitivity of the hydrologic resources to different modeling assumptions with regard to how Mexico would be impacted by future water delivery reductions. Two methodologies for determining future water delivery reductions to Mexico are described. The modeling assumptions used to implement the methodologies are also presented.

Q.2 Description of Methodologies

Although many possible methodologies exist that would result in different volumes of potential future water delivery reductions to Mexico, two methodologies were considered in this analysis in order to assess the sensitivity of the hydrologic resources to a wide range of possible water delivery reductions. Both methodologies are similar and both assume that the water deliveries to Mexico would be reduced in the same proportion as reductions in consumptive uses in the United States (shortages). The difference between the methodologies is whether shortages in both the Upper Basin and Lower Basin in the United States are considered when applying water delivery reductions to Mexico. Methodology A applies water delivery reductions to Mexico only when shortages to United States users in the Lower Basin occur, and water deliveries to Mexico are reduced in the same proportion as the reduction to United States users in the Lower Basin. This is the methodology that was used for the resource analyses in Volume I of this Final EIS. Methodology B applies water delivery reductions to Mexico when shortages to United States

[1] Reclamation’s modeling assumptions are not intended to constitute an interpretation or application of the 1944 Treaty or to represent current United States policy or a determination of future United States policy regarding deliveries to Mexico. The United States will conduct all necessary and appropriate discussions regarding the proposed federal action and implementation of the 1944 Treaty with Mexico through the IBWC in consultation with the Department of State.

users in either the Upper Basin or Lower Basin or both occur, and water deliveries to Mexico are reduced in the same proportion as the reduction to United States users in both the Upper and Lower Basins. These methodologies are described below along with comparisons of the results of the methodologies.

Q.2.1 Methodology A

Under Methodology A, water delivery reductions to Mexico are triggered only when deliveries to United States users in the Lower Basin are reduced. When triggered, the water deliveries to Mexico are reduced in the same proportion as the reduction to the United States users in the Lower Basin. The methodology is as follows:

1) Determine the shortage to be applied to United States users in the Lower Basin. Under the Preferred Alternative, shortages of specific magnitudes are triggered by specific Lake Mead elevations.

   - Example: for the Preferred Alternative, if Lake Mead elevation is below 1,025 feet msl, the shortage to United States users in the Lower Basin is 500 kaf

2) Compute the proportional reduction to United States users in the Lower Basin by dividing the shortage to be applied to United States users in the Lower Basin by the total United States Lower Division states apportionments (7.5 maf).

   - Example: assuming a shortage to United States users in the Lower Basin of 500 kaf, the proportional reduction would be computed as:

     500 kaf / 7.5 maf = 6.7 percent

3) Compute the water delivery reduction to Mexico by applying the same proportional reduction to United States users in the Lower Basin to Mexico. This is computed by multiplying Mexico's annual Colorado River allotment (1.5 maf) by the proportional reduction to United States users in the Lower Basin. [2]

   - Example: assuming the proportional reduction to United States users in the Lower Basin is 6.7 percent, the water delivery reduction to Mexico would be computed as:

     *1.5 maf * 6.7 percent = 100 kaf*

A summary of shortages to United States users in the Lower Basin and water delivery reductions to Mexico for the three levels of shortages under the Preferred Alternative is provided in Table Q-1 and Table Q-2 respectively.

---

[2] Alternatively, under Methodology A, the same volume of the reduction to Mexico may be computed by taking 16.7 percent of the total water reduction applied to the United States and Mexico. This percentage is computed by taking the ratio of Mexico's allotment to the sum of the Lower Basin United States apportionments and Mexico's allotment (1.5 maf/(7.5 maf + 1.5 maf) = 0.167 or 16.7 percent). This approach results in the same proportional reduction to Mexico as occurs to the United States users in the Lower Basin (see Attachment A).

Table Q-1
Examples of Shortages to United States Users in the Lower Basin for Methodology A

Lake Mead Elevation (feet msl)	Reduction to United States Lower Basin users (kaf)	Delivery to United States Lower Basin Users (kaf)	Percent Reduction to United States Lower Basin Users
1,075 to 1,050	333	7,167	4.4
1,050 to 1,025	417	7,083	5.6
Less than 1,025	500	7,000	6.7

Table Q-2
Examples of Water Delivery Reductions to Mexico for Methodology A

Mead Elevation (feet msl)	Reduction to Mexico (kaf)	Delivery to Mexico (kaf)	Percent Reduction to Mexico
1,075 to 1,050	67	1,433	4.4
1,050 to 1,025	83	1,417	5.6
Less than 1,025	100	1,400	6.7

Q.2.2 Methodology B

Under Methodology B, water delivery reductions to Mexico are triggered by shortages to United States users in the Upper Basin, by shortages to United States users in the Lower Basin, or both. When triggered, the water deliveries to Mexico are reduced in the same proportion as the reduction to United States users in both the Upper and Lower Basins. The methodology is as follows:

1) Determine the shortage to be applied to United States users in the Lower Basin.

    - Example: for the Preferred Alternative, if Lake Mead elevation is below 1,050 feet msl, the shortage to United States users in the Lower Basin is 417 kaf

2) Determine the shortage to be applied to United States users in the Upper Basin. Shortages to United States users in the Upper Basin are assumed to occur when the delivery to those users is less than their scheduled use. Shortage is calculated as Upper Basin scheduled use minus Upper Basin actual use.

    - Example: in the year 2016, the Upper Basin scheduled use is 4.779 maf and under one hydrologic sequence, the model computed a delivery of 4.355 maf, resulting in a shortage to United States users in the Upper Basin of 424 kaf, in addition to the shortage to United States users in the Lower Basin of 417 kaf

3) Compute the proportional reduction to United States users in both the Upper and Lower Basins as the sum of shortages to United States users in the Upper and Lower Basins

divided by the sum of the Upper Basin scheduled use and the total United States Lower Basin apportionments (7.5 maf).

- Example: the proportional reduction to the United States users would be computed as:

  (417 kaf + 424 kaf) / (7.5 maf + 4.779 maf) = 6.8 percent

4) Compute water delivery reduction to Mexico by applying the same proportional reduction to United States users in both the Upper and Lower Basins to Mexico. This is computed by multiplying Mexico's annual Colorado River allotment (1.5 maf) by the proportional reduction to United States users in both the Upper and Lower Basins.

   - Example: given the proportional reduction to United States users in both the Upper and Lower Basins is 6.8 percent, the water delivery reduction to Mexico would be computed as:

     *1.5 maf * 6.8 percent = 102 kaf*

Since Upper Basin scheduled use varies each year (Section 3.4.1 and Appendix C) and the computed shortages in the Upper Basin vary for each hydrologic sequence, a wide range of possible proportional reductions are simulated by Methodology B (from zero to approximately 11.7 percent resulting in water reductions to Mexico of zero to approximately 175 kafy as shown in Figure Q-9 and Q-7 respectively).

Table Q-3 shows some examples taken from the modeling results for year 2016. The scheduled Upper Basin uses in 2016 are 4.779 maf, resulting in the proportional reduction to the United States equal to the sum of Upper and Lower Basin United States shortages divided by 12.279 maf (7.5 maf plus 4.779 maf).

Table Q-3
Examples of Shortages to the United States Users for Methodology B

Example	Shortage to Upper Basin (kaf)	Shortage to Lower Basin (kaf)	Total Shortage to United States (kaf)	Total Use in the United States (kaf)	% Reduction to United States*
a) Upper and Lower Basin Shortage	424	417	841	11,438	6.8
b) Upper and Lower Basin Shortage	100	417	517	11,762	4.2
c) Upper Basin Shortage only	21	0	21	12.258	0.2
d) Lower Basin Shortage only	0	333	333	11.946	2.7

** Percent reduction on total delivery to United States of 7.5 maf + 4.779 maf = 12.279 maf*

Given the shortages examples in the United States in Table Q-3, the resulting equal proportional water delivery reductions to Mexico under Methodology B are provided In Table Q-4.

Table Q-4
Examples of Water Delivery Reductions to Mexico for Methodology B

Example	Reduction to Mexico Delivery (kaf)	Total Delivery to Mexico (kaf)	% Reduction to Mexico
a) Upper and Lower Basin Shortage	102	1,398	6.8
b) Upper and Lower Basin Shortage	63	1,437	4.2
c) Upper Basin Shortage only	3	1,497	0.2
d) Lower Basin Shortage only	41	1,459	2.7

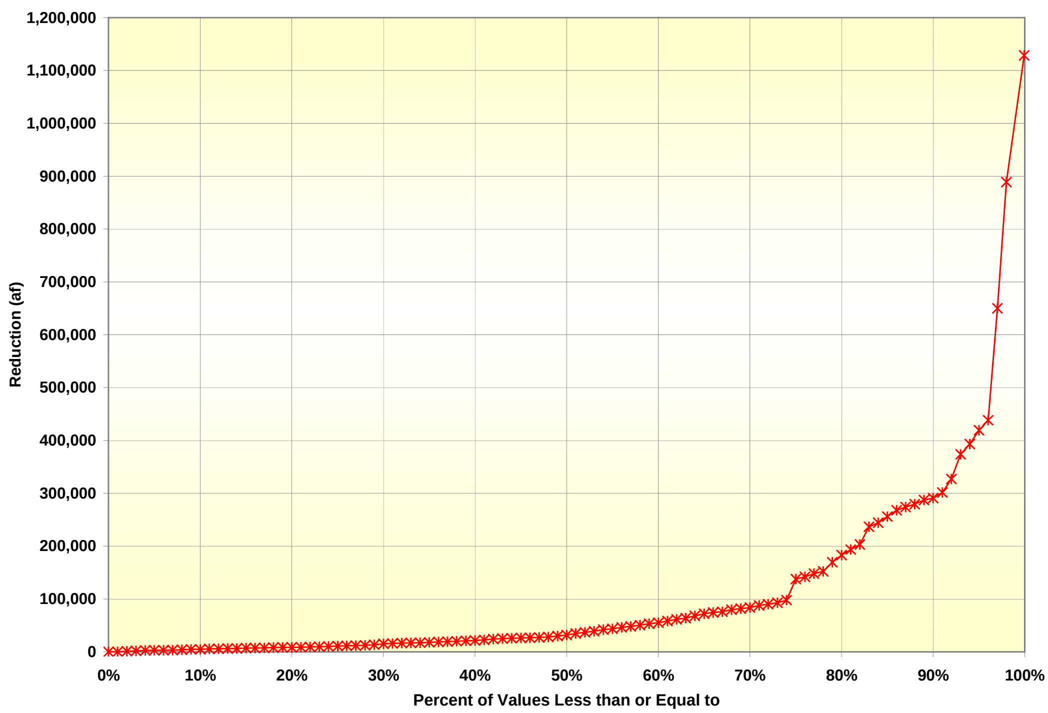
Q.3 Modeling Results

An analysis was performed to test the sensitivity of the hydrologic resources to these two sets of modeling assumptions (Methodology A and B). The Colorado River Simulation System (CRSS) model was used to simulate water deliveries to Mexico under these two methodologies with all other modeling assumptions held constant. The modeling assumptions under the Preferred Alternative were used for this assessment with one major exception. It was assumed that there was no storage and delivery mechanism in place in order to isolate the effects of each methodology. Also, the sensitivity analysis also only considers the interim period (years 2008 through 2026).

Q.3.1 Upper Basin Shortages

CRSS assumes that shortages in the Upper Basin occur only when there is not sufficient water within a given reach to meet a user’s demand. As described previously, the total Upper Basin shortage for any year is computed as the total Upper Basin delivery subtracted from the Upper Basin scheduled use for that year. Figure Q-1 provides a cumulative distribution of Upper Basin shortage amounts generated by CRSS over the period 2008 through 2026. The computed shortages to the Upper Basin users are dependent solely upon the hydrologic sequences and are therefore identical under Methodology A and Methodology B.

Figure Q-1
Upper Basin Shortages
Years 2008 to 2026



From this figure, it can be seen that modeled Upper Basin shortages range from approximately 1.05 kaf to 1,130 kaf and are frequent, occurring approximately 98 percent of the time. Approximately 75 percent of the shortages are of magnitudes less than 100 kaf. Shortages of magnitudes between 100 kaf and 400 kaf occur about 20 percent of the time and shortages of magnitudes above 400 kaf occur about five percent of the time. As a point of reference, Upper Basin shortages of 100 kaf and 400 kaf represent about two percent and eight percent of the average scheduled Upper Basin depletion over the interim period, respectively.

Q.3.2 Lake Powell and Lake Mead Water Surface Elevations

Figure Q-2 compares the 10th, 50th and 90th percentile elevations at Lake Powell under Methodology A and B.

The effect of the Methodology B water delivery reduction assumption on elevations at Lake Powell is negligible. The elevations of Lake Powell under Methodology B are higher than for Methodology A by approximately 0.001 feet at the 10th percentile and lower than under Methodology A by approximately 0.1 feet at the 50th percentile.

Figure Q-2
Lake Powell End-of-December Elevations
Comparison of Methodologies A and B
90th, 50th and 10th Percentile Values

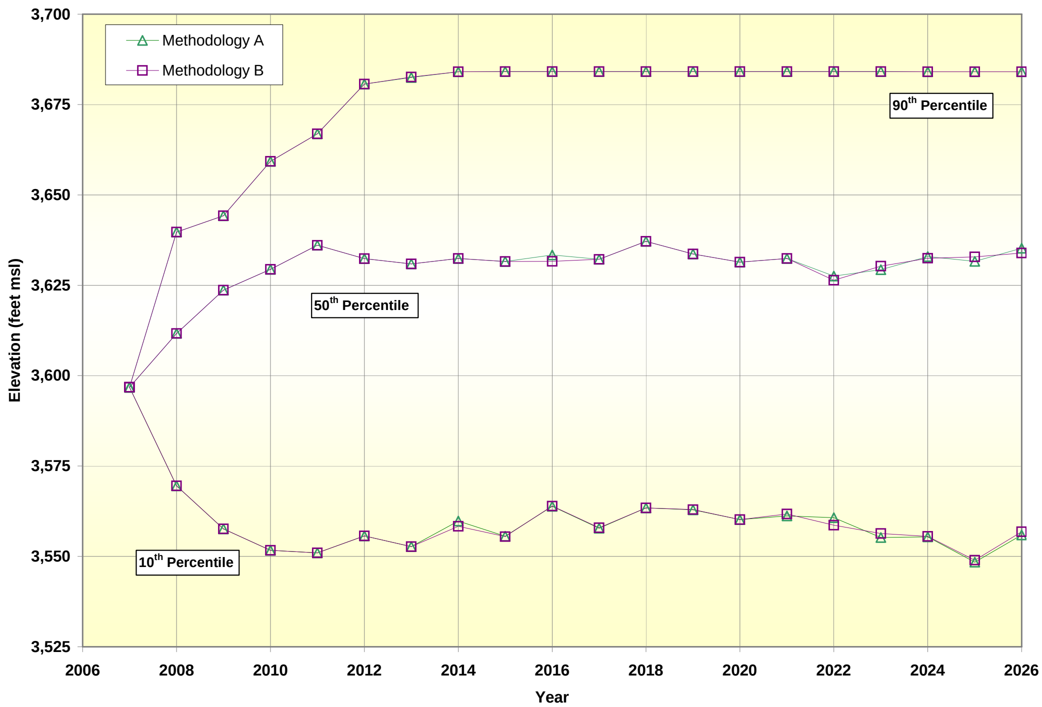


Figure Q-3 compares the 10th, 50th and 90th percentile elevations at Lake Mead under Methodology A and B. Methodology B results in somewhat lower elevations at the 10th percentile (a maximum of 3.6 feet in 2024) and slightly higher elevations at the 50th percentile (a maximum of 2.4 feet in 2020). Because the majority of the Upper Basin shortages are relatively small, Mexico may incur smaller water delivery reductions under Methodology B as compared to those observed under Methodology A when Lake Mead is relatively low (i.e., when United States users in the Lower Basin incur shortages), resulting in lower elevations at the 10th percentile. However, due to the higher frequency of Upper Basin shortages, Mexico experiences more frequent water delivery reductions under Methodology B, resulting in slightly higher Lake Mead elevations at the 50th percentile.

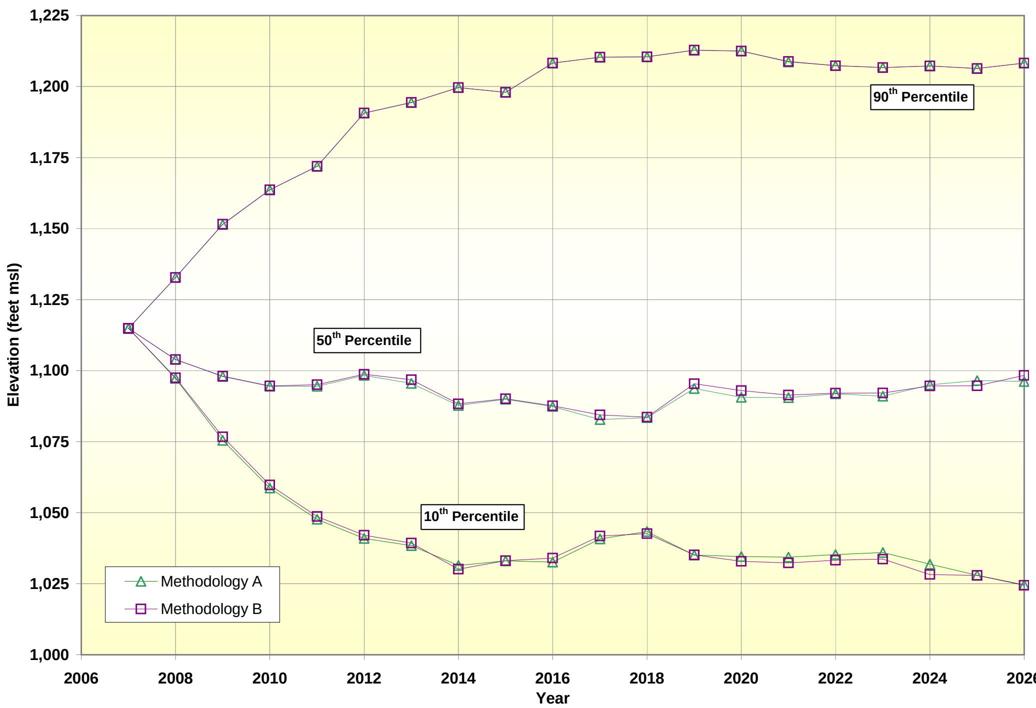
Figure Q-3
Lake Mead End-of-December Elevations
Comparison of Methodologies A and B
90th, 50th and 10th Percentile Values



Q.3.3 Comparison of Water Deliveries to Mexico

As described in Section 4.2, water deliveries to Mexico are assumed to be 1.5 mafy, except when the model assumes that additional deliveries of up to 200 kaf have been scheduled or a water delivery reduction has been incurred. Additional deliveries to Mexico of up to 200 kaf are assumed to occur when Lake Mead is in flood control operations. Reductions in the water deliveries to Mexico are simulated consistent with the modeling assumptions described previously under each methodology. Consequently, simulated water deliveries to Mexico are expected to fluctuate throughout the interim period (2008 through 2026) reflecting variations in hydrologic conditions under these assumptions.

Figure Q-4 displays the 10th, 50th and 90th percentile values for Mexico's water deliveries under Methodology A and Methodology B. At the 90th percentile, the results are essentially the same.

Water deliveries are 1.5 mafy at the 50th percentile under Methodology A. Water deliveries are less than 1.5 mafy at the 50th percentile under Methodology B, with an average reduction of approximately 25 kafy over the interim period. The more frequent reductions under Methodology B are due to the fact that Upper Basin shortages occur frequently and are included in the calculation of the proportional reduction under Methodology B.

At the 10th percentile, water deliveries to Mexico are higher under Methodology B after 2010, averaging approximately 16 kafy higher compared to Methodology A over the interim period. This result can be explained as follows. For a specific shortage to Lower Basin United States users, Upper Basin shortages are often small enough in magnitude to result in a proportional reduction to United States users (and to Mexico) under Methodology B that is less than the proportional reduction computed under Methodology A for the same shortage to Lower Basin United States users. These occurrences result in higher water deliveries to Mexico under Methodology B at the 10th percentile.

This occurrence is illustrated in Table Q-1 through Table Q-4. As shown in Table Q-1, a shortage of 417 kaf to Lower Basin United States users results in a proportional reduction of 5.6 percent under Methodology A. As shown in Table Q-2, applying the same proportional reduction to Mexico would result in a reduction of 83 kaf. The same shortage to Lower Basin United States users (417 kaf), coupled with shortages to Upper Basin United States users of 100 kaf (Example (b) in Table Q-3), results in a smaller proportional reduction of 4.2 percent under Methodology B. As shown in Table Q-4, applying the same proportional reduction to Mexico would result in a reduction of 63 kaf.

Figure Q-4
Mexico Modeled Annual Depletions
Comparison of Methodologies A and B
90th, 50th and 10th Percentile Values

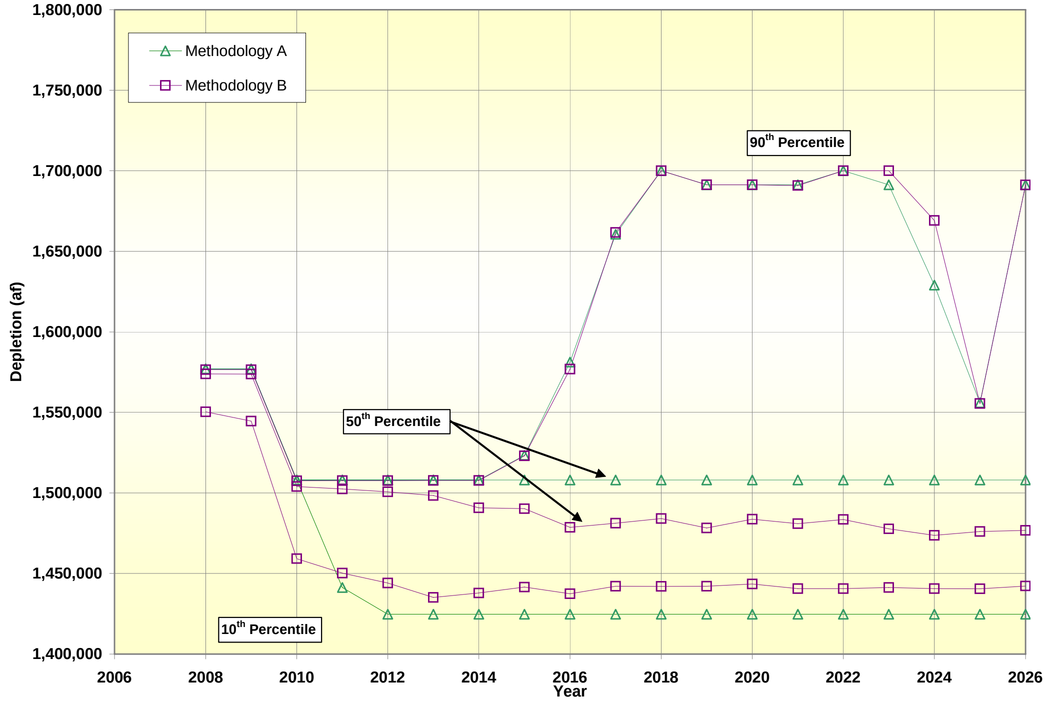


Table Q-5 provides a comparison of the information presented in Figure Q-4 for specific years in the interim period.

Table Q-5
Mexico Modeled Annual Depletions
Comparison of Methodologies A and B

Year	Methodology A			Methodology B		
	90th Percentile	50th Percentile	10th Percentile	90th Percentile	50th Percentile	10th Percentile
2008	1,577,000	1,577,000	1,577,000	1,576,571	1,573,935	1,550,313
2016	1,581,288	1,508,000	1,424,668	1,576,830	1,478,643	1,437,371
2026	1,691,360	1,508,000	1,424,668	1,691,215	1,476,758	1,442,230

Figure Q-5 provides a comparison of the cumulative distribution of Mexico's water deliveries under Methodology A and Methodology B. The results presented in Figure Q-5 can be used to compare how often Mexico might expect deliveries in excess of, or less than,1.5 maf under these different modeling assumptions. The occurrence of water deliveries to Mexico greater than 1.5 maf reflect years when additional water up to 200 kaf is made available when Lake Mead is in flood control operations. Deliveries less than 1.5 maf reflect the modeling assumptions regarding water delivery reductions to Mexico. Again, because Upper Basin shortages occur more frequently than Lower Basin shortages, there are also more frequent water delivery reductions to Mexico under Methodology B relative to Methodology A.

Figure Q-5
Mexico Modeled Annual Depletions
Comparison of Methodologies A and B
Years 2008 to 2026

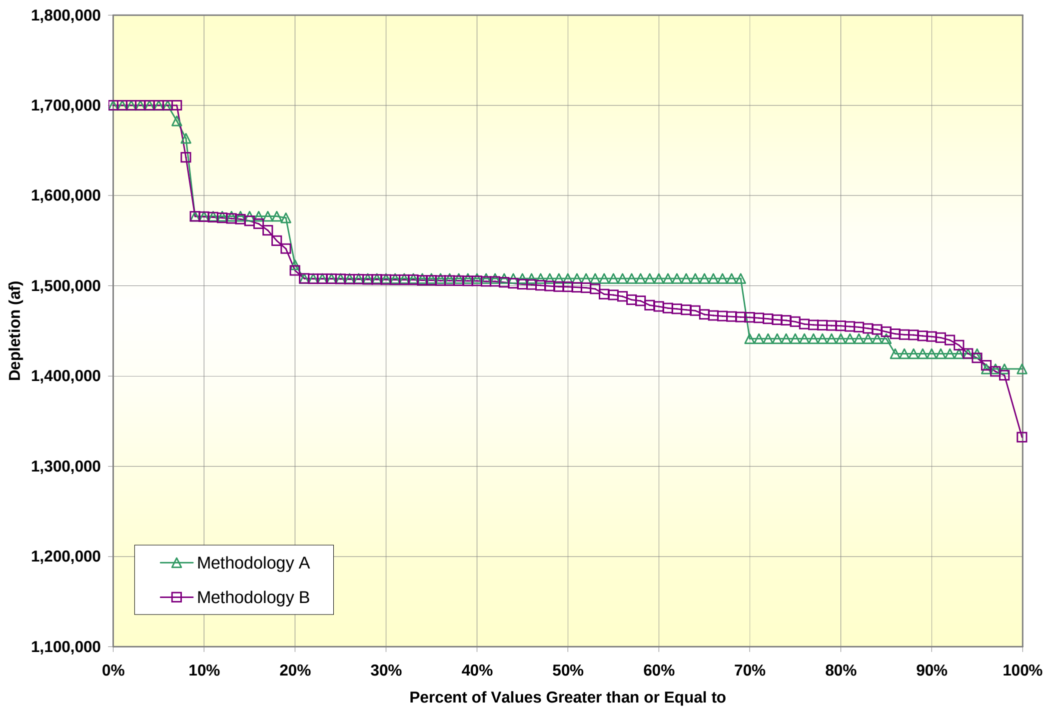

Table Q-6 provides a comparison of the information presented in Figure Q-5 in tabular format. Again, the data presented in this table shows that the modeling of the Preferred Alternative using Methodology B will generally result in lower water deliveries to Mexico during the interim period as compared to the modeled conditions using Methodology A.

Table Q-6
Mexico Modeled Annual Depletions
Comparison of Methodologies A and B
Years 2008 to 2026

Percent Exceedence	Mexico Annual Depletions (afy)	
	Methodology A	Methodology B
Maximum	1,700,000	1,700,000
10	1,577,000	1,576,354
25	1,508,000	1,507,411
50	1,508,000	1,498,902
75	1,441,332	1,460,289
90	1,424,668	1,443,716
Minimum	1,408,000	1,332,081

Figure Q-6 shows a comparison of the probability of annual deliveries to Mexico less than 1.5 maf under Methodologies A and B. The modeling assumptions under Methodology B provide higher probabilities that Mexico will receive less than 1.5 maf. The average probability of deliveries less than 1.5 maf to Mexico under Methodology A is 31 percent and the average probability under Methodology B is 89 percent. The more frequent occurrence of reduced deliveries under Methodology B reflects the more frequent occurrence of shortages due to drought conditions in the Upper Basin.

Figure Q-6
Mexico Modeled Annual Depletions
Comparison of Methodologies A and B
Probability of Depletions Less than 1.5 kaf

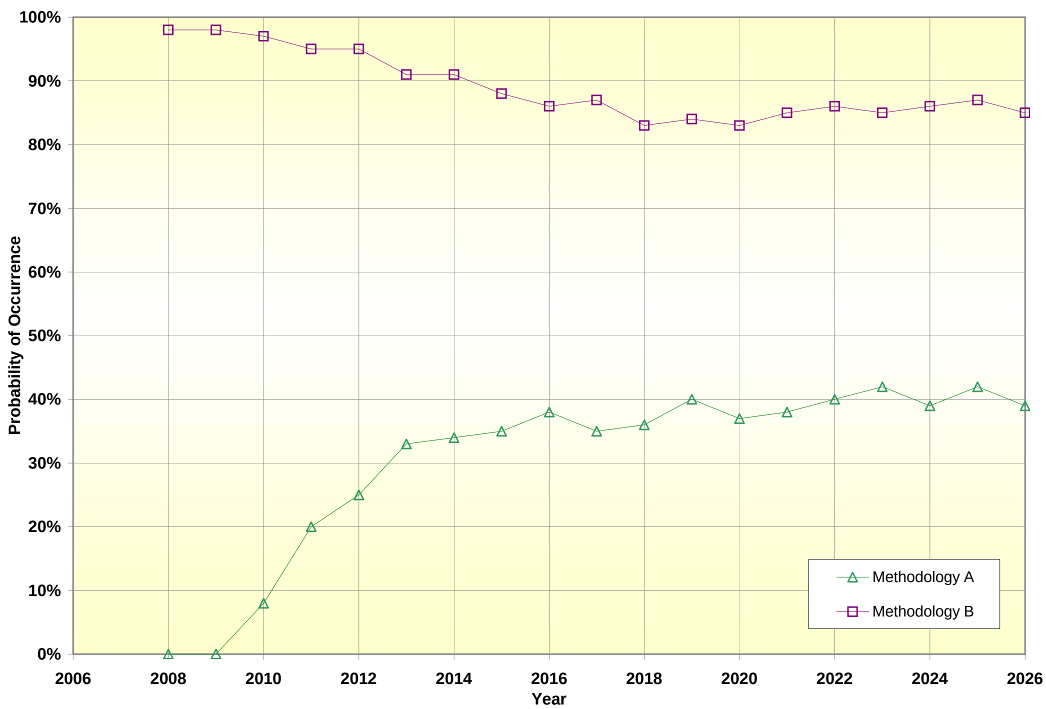

Figure Q-7 shows the cumulative annual water delivery reductions to Mexico under Methodologies A and B. Under Methodology A, there are only three water delivery reduction volumes that can occur: 67 kaf, 83 kaf or 100 kaf. Approximately 30 percent of the time there is a water delivery reduction to Mexico of at least 67 kaf. Approximately four percent of the time there is a water delivery reduction to Mexico of 100 kaf.

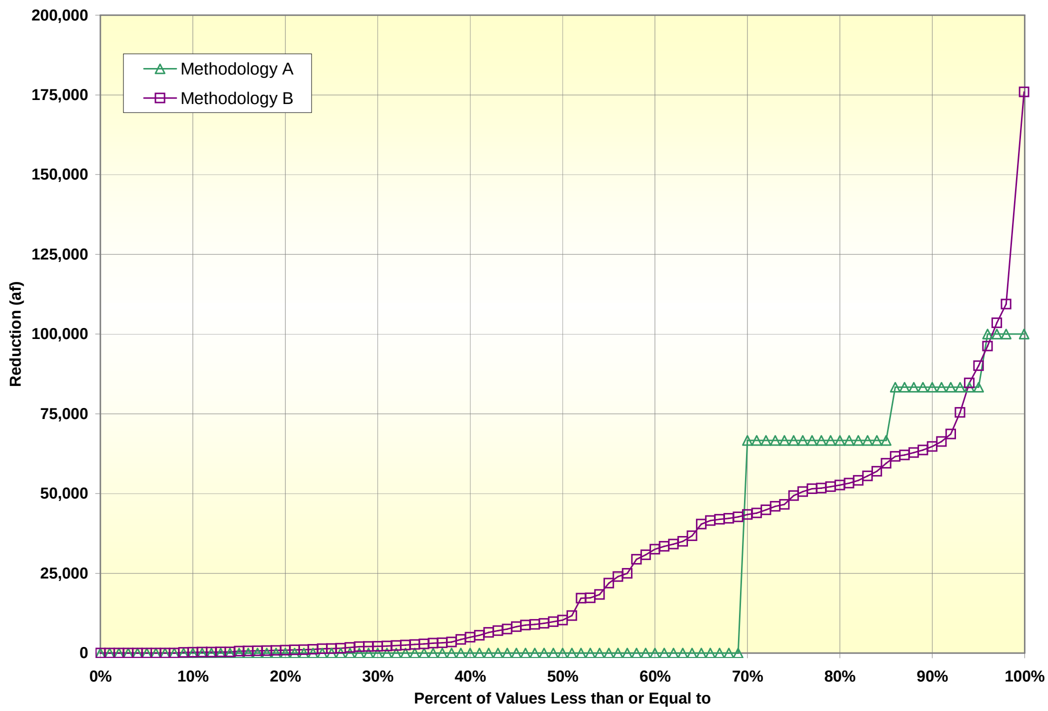
Figure Q-7
Mexico Water Delivery Reductions
Comparison of Methodologies A and B
Years 2008 to 2026



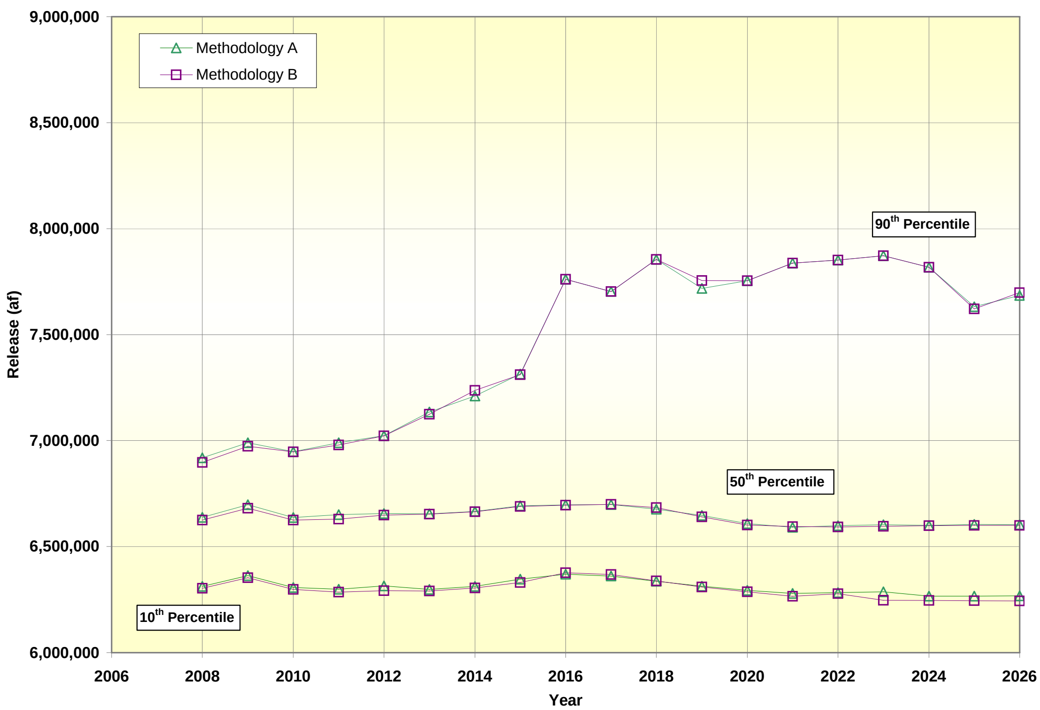
Under Methodology B, there is a water delivery reduction to Mexico approximately 92 percent of the time. This high frequency of water delivery reductions is due to the high frequency of shortages in the Upper Basin. However, 57 percent of these water delivery reductions are less than 25 kaf. Water delivery reductions of the magnitude 67 kaf or greater occur approximately nine percent of the time under Methodology B compared to approximately 30 percent under Methodology A. Methodology B results in a maximum water delivery reduction of 176 kaf compared to 100 kaf under Methodology A. A higher maximum reduction amount exists under Methodology B because shortages can occur simultaneously in both the Upper and Lower Basins, resulting in a larger volume reduction when compared to Methodology A.

Methodology B generates a larger range of water delivery reductions to Mexico when compared to Methodology A. Under Methodology B these reductions also occur more frequently due to the high frequency of Upper Basin shortages compared to the frequency of shortages in the Lower Basin.

Q.3.4 Parker Dam Releases

The flows in the river from Parker Dam to Imperial Dam result primarily from the controlled releases from Parker Dam. Figure Q-8 compares the 90th, 50th and 10th percentile releases from Parker Dam.

Figure Q-8
Parker Dam Annual Releases
Comparison of Methodologies A and B
90th, 50th and 10th Percentile Values



The effect of the Methodology B water delivery reduction assumptions on releases from Parker Dam is minor. The releases under Methodology B are slightly lower due to the increased frequency of water delivery reductions to Mexico. This results in less water being delivered to Mexico when compared to Methodology A. The maximum difference at the 10th and 50th percentiles is about 40 kaf (in 2023) and 22 kaf (in 2011), respectively. The average difference at the 10th and 50th percentiles is approximately 11 kaf and 5 kaf, respectively.

Attachment A

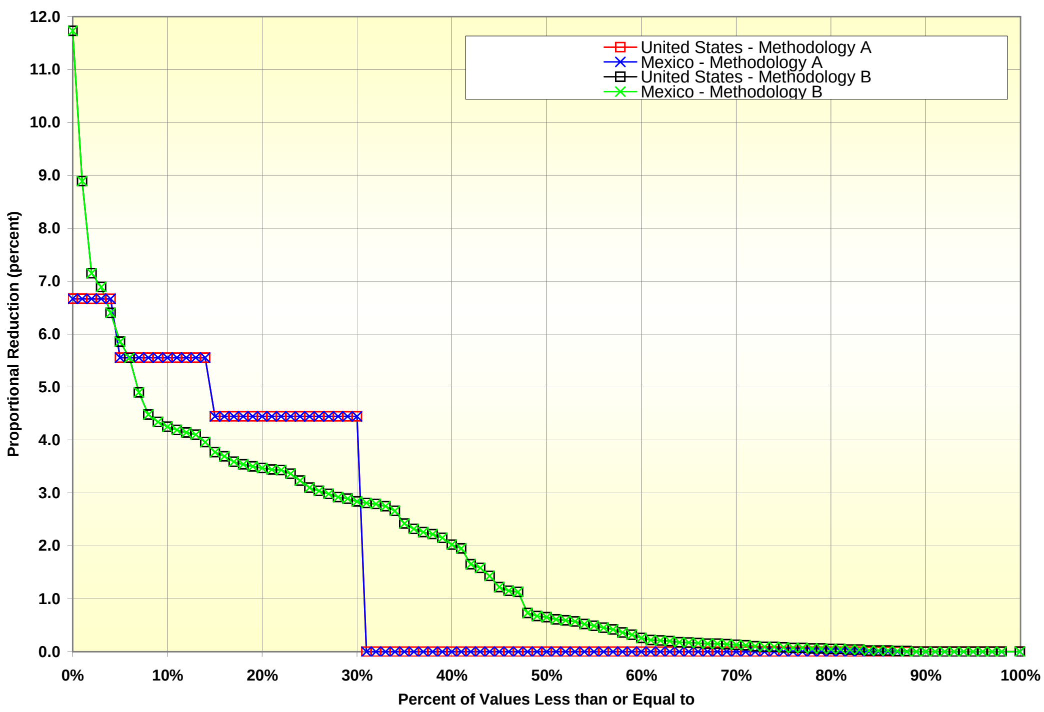
Verification of Equal Proportional Reductions to United States and Mexico for Methodology A and Methodology B

Both Methodology A and Methodology B assume that the water deliveries to Mexico would be reduced in the same proportion as reductions in consumptive uses in the United States (shortages). This attachment provides additional information with regard to equal proportional reductions.

Model Verification

In order to verify that the model was accurately computing equal proportional water delivery reductions to Mexico, output from the model included the computed proportional reduction for both the United States and Mexico each time a shortage occurred in the United States. Figure Att. A-1 provides a comparison of the cumulative distribution of these computed values using Methodology A and Methodology B for the United States and Mexico. Figure Att. A-1 verifies that under both methodologies, deliveries to Mexico are reduced in the same proportion as deliveries to the United States.

Figure Att. A-1
Proportional Reductions to United States and Mexico
Comparison of Methodologies A and B
Years 2008 to 2026



Alternative Representation of Methodology A

Under Methodology A, water delivery reductions to Mexico are triggered only by shortages to United States users in the Lower Basin. When triggered, the water deliveries to Mexico are reduced in the same proportion as the reduction in the United States users in the Lower Basin. Alternatively, the volume of the reduction to Mexico may be computed by taking 16.7 percent of the total water reduction applied to both the United States and Mexico. This percentage is computed by taking the ratio of Mexico's allotment to the sum of the Lower Basin United States apportionments and Mexico's allotment (1.5 maf/(7.5 maf + 1.5 maf) = 0.167 or 16.7 percent).

It can be shown algebraically that this approach results in the same proportional reduction to Mexico as occurs to the United States users in the Lower Basin.

<u>Define</u>:

TS = total water delivery reduction to Lower Division states and Mexico
% reduction to United States or Mexico = amount of reduction / apportionment or allotment * 100

<u>Assume</u>:

The percentage of the total water delivery reduction applied to the Lower Division states = 7.5/9.0 * 100 = 83.3%
The percentage of the total water delivery reduction applied to Mexico = 1.5/9.0 * 100 = 16.7%

Then:

% reduction to United States = TS * (7.5/9.0)/7.5 = TS/9.0
% reduction to Mexico = TS * (1.5/9.0)/1.5 = TS/9.0
Clearly yielding the same proportional reduction

<u>Example</u>: (with rounding)

Total shortage = 0.400 maf
Shortage to Lower Division states = 0.400 * 0.833 = 0.333 maf
Water delivery reduction to Mexico = 0.400 * 0.167 = 0.067 maf
% reduction to United States = % reduction to Mexico = 0.400/9.0 = 4.4%

<u>Check</u>:

% reduction to United States = 0.333 / 7.5 * 100 = 4.4%
% reduction to Mexico = 0.067 / 1.5 * 100 = 4.4%

Appendix R

Biological Assessment

This appendix contains the biological assessment (BA) for Reclamation's proposed Colorado River interim guidelines for Lower Basin shortages and coordinated operations for Lake Powell and Lake Mead prepared by Reclamation as part of its compliance with the Endangered Species Act of 1973, 87 Stat. 884, as amended, 16 U.S.C. §1531 et seq.

R.1 Introduction and Background

This document serves as the biological assessment (BA) for Reclamation's proposed Colorado River interim guidelines for Lower Basin shortages and coordinated operations for Lake Powell and Lake Mead prepared by Reclamation as part of its compliance with the Endangered Species Act of 1973 (ESA), 87 Stat. 884, as amended, 16 U.S.C. §1531 et seq. This document is designed to facilitate compliance with Sections 7 and 9 of the ESA with respect to potential effects to listed species within the United States.

R.1.1 Proposed Federal Action

The Secretary of the United States Department of the Interior (Secretary), acting through the Bureau of Reclamation (Reclamation), proposes to adopt specific interim guidelines for Colorado River Lower Basin (Lower Basin) shortages and coordinated operations for Lake Powell and Lake Mead. Reclamation, as the agency that is designated to act on the Secretary's behalf with respect to operation of Glen Canyon Dam and Hoover Dam and managing the mainstream waters of the Colorado River pursuant to applicable federal law, has prepared this Biological Assessment (BA) to determine if its proposed discretionary actions, as described in a forthcoming final environmental impact statement (Final EIS) that will be entitled *Colorado River Interim Guidelines for Lower Basin Shortages and Coordinated Operations for Lake Powell and Lake Mead*, may affect endangered or threatened species or destroy or adversely modify critical habitat of those species, as defined under the ESA.

Reclamation desires that this consultation, as defined under ESA §7(a)(2) and its implementing regulations, and resulting biological opinion (BO), if applicable, cover the period from the Secretary of the Interior's decision (proposed to be from December 2008 through September 2026)[1]. The proposed federal action includes the adoption and implementation of interim Colorado River guidelines for Lower Basin shortages and coordinated operations for Lake Powell and Lake Mead. These interim guidelines would remain in effect for determinations to be made through water year 2025 regarding water supply and reservoir operating decisions through 2026 and would provide guidance each year in development of the Annual Operating Plan for Colorado River Reservoirs (AOP). This proposed federal action considers four operational elements that collectively are designed to address shortages and coordinated operations for Lake Powell and Lake Mead.

[1] It should be noted that although the interim guidelines are for the period 2008 through 2026, the creation and delivery of conserved water from the Muddy and Virgin Rivers by Southern Nevada Water Authority, which is addressed as an interdependent/interrelated action in this BA, is proposed to be approved for a 50-year period.

The interim guidelines would be used by the Secretary to:

1. Determine those circumstances under which the Secretary would reduce the annual amount of water available for consumptive use from Lake Mead to the Colorado River Lower Division states (Arizona, California, and Nevada) below 7.5 million acre-feet (maf) (a ‘‘Shortage’’) pursuant to Article II(B)(3) of the United States Supreme Court in the case of *Arizona v. California*, 547 U.S. _____ (2006) (Consolidated Decree);

2. Define the coordinated operation of Lake Powell and Lake Mead to provide improved operation of these two reservoirs, particularly under low reservoir conditions;

3. Allow for the storage and delivery, pursuant to applicable federal law, of conserved Colorado River system and non-system water in Lake Mead to increase the flexibility of meeting water use needs from Lake Mead, particularly under drought and low reservoir conditions; and

4. Determine those conditions under which the Secretary may declare the availability of surplus water for use within the Lower Division states. The proposed federal action would modify the substance of the existing Interim Surplus Guidelines (ISG), published in the Federal Register on January 25, 2001 (66 Fed. Reg. 7772), and the term of the ISG from 2016 to 2026.

The ESA compliance for the proposed action is comprised of three distinct segments. This approach is being used because three geographical areas of impact are involved, with varying degrees and types of impacts. These geographical areas include:

- Lake Powell and the Colorado River from Glen Canyon Dam to the upper end of Lake Mead (primarily related to operational element no. 2, coordinated reservoir operations).

- The full length of the Muddy River in Nevada, and the Virgin River from the Mesquite Diversion near Mesquite, Nevada, to Lake Mead (primarily related to operational element no. 3, storage and delivery mechanism).

- The Colorado River from Lake Mead to the Southerly International Boundary with Mexico (related to operational element no.1, shortage guidelines; operational element no.2, coordinated reservoir operations; operational element no. 3, storage and delivery mechanism; and operational element no. 4, ISG). These operational elements constitute “covered actions” covered by the 2005 Biological and Conference Opinion on the Lower Colorado River Multi-Species Conservation Program (MSCP) and are encompassed within the boundaries of the MSCP planning area and are not addressed in this transmittal.

Each of the three segments of the consultation is prepared as a stand-alone analysis for ease of understanding. The specific elements of the proposed action that are considered discretionary and subject to compliance are described in detail below, after reviewing Reclamation's legal authorities.

R.1.2 Relevant Statutory Authority

In complying with ESA §7(a)(2) and its implementing regulations at 50 CFR §402.03, Reclamation is responsible for defining the extent of its discretionary authority with respect to this action. Reclamation's authority (discretionary and non-discretionary) stems from the following laws.

R.1.2.1 Law of the River

The Secretary is vested with the responsibility to manage the mainstream waters of the Lower Basin pursuant to applicable federal law. The responsibility is carried out consistent with a body of documents commonly referred to as the Law of the River. While there is no universally accepted definition of this term, the Law of the River comprises numerous operating criteria, regulations, and administrative decisions included in federal and state statutes, interstate compacts, court decisions and decrees, an international treaty, and contracts with the Secretary.

Particularly notable among these documents are:

1) The Colorado River Compact of 1922 (Compact), which apportioned beneficial consumptive use of water between the Upper Basin and Lower Basin;

2) The Boulder Canyon Project Act of 1928 (BCPA), which authorized construction of Hoover Dam and the All-American Canal (AAC), required that water users in the Lower Basin have a contract with the Secretary, and established the responsibilities of the Secretary to direct, manage and coordinate the operation of Colorado River dams and related works in the Lower Basin;

3) The California Seven Party Water Agreement of 1931, which, through regulations adopted by the Secretary, established the relative priorities of rights among major users of Colorado River water in California;

4) The 1944 Treaty (and subsequent minutes of the IBWC) related to the quantity and quality of Colorado River water delivered to Mexico;

5) The Upper Colorado River Basin Compact of 1948, which apportioned the Upper Basin water supply among the Upper Basin states;

6) The Colorado River Storage Project Act of 1956 (CRSPA), which authorized a comprehensive water development plan for the Upper Basin that included the construction of Glen Canyon Dam and other facilities;

7) The 1963 United States Supreme Court Decision in *Arizona v. California* which confirmed that the apportionment of the Lower Basin tributaries was reserved for the exclusive use of the states in which the tributaries are located; confirmed the Lower Basin mainstream apportionments of 4.4 maf for use in California, 2.8 maf for use in Arizona and 0.3 maf for use in Nevada; provided water for Indian reservations and other federal reservations in California, Arizona and Nevada; and confirmed the

significant role of the Secretary in managing the mainstream Colorado River within the Lower Basin;

8) The 1964 United States Supreme Court Decree in *Arizona v. California* which implemented the Court's 1963 decision; the Decree was supplemented over time after its adoption and the Supreme Court entered a Consolidated Decree in 2006 which incorporates all applicable provisions of the earlier-issued Decrees;

9) The Colorado River Basin Project Act of 1968 (CRBPA), which authorized construction of a number of water development projects including the Central Arizona Project (CAP) and required the Secretary to develop the LROC and issue an AOP for mainstream reservoirs;

10) The Colorado River Basin Salinity Control Act of 1974, which authorized a number of salinity control projects and provided a framework to improve and meet salinity standards for the Colorado River in the United States and Mexico; and

11) The Grand Canyon Protection Act of 1992, which addressed the protection of resources in Grand Canyon National Park and in Glen Canyon National Recreation Area, consistent with applicable federal law.

R.1.3 Detailed Description of Discretionary Elements of the Proposed Action

The proposed action includes a coordinated operation of Lake Powell and Lake Mead that is designed to minimize shortages in the Lower Basin and avoid risk of curtailments of use in the Upper Basin; and also provides a mechanism, called Intentionally Created Surplus (ICS), for promoting water conservation in the Lower Basin. Upon adoption of the proposed action, the maximum cumulative amount of ICS credits that can be available at any one time will be 2.1 million acre-feet (maf). This amount could be increased up to 4.2 maf in future years during the interim period. The analysis of potential effects in this assessment includes this maximum ICS volume of 4.2 maf. The expansion of the ICS mechanism in the future would be based on operational experience gained during implementation of the proposed action. The formulation of the four operational elements for the proposed action follows.

R.1.3.1 Shortage Guidelines

The proposed action provides discrete levels of shortage associated with specific Lake Mead elevations as presented below. The shortages modeled under the proposed action are as follows:

- ♦ When Lake Mead is projected to be below elevation 1,075 feet msl and at or above 1,050 feet msl on January 1, a shortage of 333 kaf shall be declared for that year;

- When Lake Mead is projected to be below elevation 1,050 feet msl and at or above 1,025 feet msl on January 1, a shortage of 417 kaf shall be declared for that year;

- When Lake Mead is projected to be below elevation 1,025 feet msl on January 1, a shortage of 500 kaf shall be declared for that year; and

- When Lake Mead is below elevation 1,025 feet msl, the Secretary shall undertake appropriate consultation, including with the Basin States, to discuss further measures that may be undertaken consistent with the Law of the River. [2]

The volumes of shortages are expressed as reductions to water users in the United States. However, modeling of the proposed action includes the assumption that Mexico would also incur water reductions proportional to the reductions to United States users in the Lower Basin at the same Lake Mead elevations (equivalently expressed as a water reduction to Mexico of 16.7 percent of the total shortage volume). As such, the maximum shortage volume modeled under this alternative is 600 kaf and water reductions of water deliveries are assumed to be applied to deliveries to the Lower Division states and Mexico.[3]

R.1.3.2 Coordinated Reservoir Operations

Under the proposed action, the annual Lake Powell release is based on a volume of water in storage or corresponding elevation in Lake Powell and Lake Mead as described below.

R.1.3.2.1 Equalization

The proposed action provides an elevation schedule (Table R-1) that would be used in determining when equalization releases would be made.

When Lake Powell is at or above these specified elevations and when the volume of Lake Powell is projected to be greater than the volume of Lake Mead at the end of the water year, Lake Powell would release greater than 8.23 mafy to equalize its volume with Lake Mead. Otherwise, 8.23 maf is released from Lake Powell.

---

[2] The specific outcome of a consultation process to define additional shortages cannot be predicted; therefore, for modeling purposes it was assumed that shortages of 500 kaf would continue to be imposed at Lake Mead elevations below 1,025 feet msl.

[3] Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1994 Treaty between the United States and Mexico Relating to the Utilization of the Waters of the Colorado and Tijuana Rivers and of the Rio Grande (1944 Treaty) or to represent current United States policy or a determination of future United States policy regarding deliveries to Mexico. The United States will conduct all necessary and appropriate discussions regarding the proposed federal action and implementation of the 1944 Treaty with Mexico through the International Boundary and Water Commission in consultation with the Department of State.

Table R-1
Proposed Action
Lake Powell Equalization Elevations

Year	Reservoir Elevation (feet msl)
2008	3,636
2009	3,639
2010	3,642
2011	3,643
2012	3,645
2013	3,646
2014	3,648
2015	3,649
2016	3,651
2017	3,652
2018	3,654
2019	3,655
2020	3,657
2021	3,659
2022	3,660
2023	3,662
2024	3,663
2025	3,664
2026	3,666

R.1.3.2.2 Upper Elevation Balancing

When Lake Powell is below the elevations stated in Table R-1 and is projected to be at or above 3,575 feet msl at the end of the water year, a release in the amount of 8.23 maf from Lake Powell would be made if the projected elevation of Lake Mead is at or above 1,075 feet msl at the end of the water year. If the projected end of water year elevation of Lake Mead is below 1,075 feet msl, the volumes of Lake Mead and Lake Powell would be balanced if possible, within the constraint that the release from Lake Powell would not be more than 9.0 maf and no less than 7.0 maf.

R.1.3.2.3 Mid-Elevation Releases

When Lake Powell elevation is projected to be below 3,575 feet msl and at or above 3,525 feet msl at the end of the water year, a release in the amount of 7.48 maf would be made if the projected end of water year elevation of Lake Mead is at or above 1,025 feet msl. If the projected end of water year elevation of Lake Mead is below 1,025 feet msl, a release of 8.23 maf from Lake Powell would be made.

R.1.3.2.4 Lower Elevation Balancing

When the projected end of water year elevation of Lake Powell is below 3,525 feet msl, Lake Mead and Lake Powell would be balanced if possible, within the constraint that the release from Lake Powell would not be more than 9.5 maf and no less than 7.0 maf.

R.1.3.3 Storage and Delivery of Conserved Water

The proposed action includes the adoption of a mechanism (ICS) to encourage and account for augmentation and conservation of water supplies, e.g., fallowing of land, canal lining, system efficiency improvements, and tributary conservation (retirement of pre-Boulder Canyon Project Act of 1929 water rights on the Virgin and Muddy rivers). The ICS mechanism provides for creating credits for the conserved or imported water and delivering the water at a later date.

The analysis of potential effects in this assessment includes a maximum cumulative amount of ICS credits that would be available at any one time of up to 4.2 maf. However, it is anticipated that the ICS mechanism will be initially implemented to allow a maximum cumulative amount of ICS credits of up to 2.1 maf.

The volumes of ICS activity that are assumed for each state and other entities (shown as "Additional Amounts") are presented in Table R-2. At this time, it is unknown exactly which entities might participate in the ICS mechanism. Furthermore, the timing and magnitude of the conservation and subsequent delivery of conserved water is unknown. In order to analyze the maximum effects of the mechanism to reservoir storage and river flows below Lake Mead, it was assumed that conservation would originate from a point on the river within each state located furthest downstream with respect to ICS activities within that state. Similarly, conservation within the Additional Amounts category was assumed to originate in Mexico in order to disclose the maximum effects of the mechanism to reservoir storage and river flows below Lake Mead.[4]

In addition to increasing the flexibility of meeting water use needs from Lake Mead, the ICS mechanism would benefit the system through Lake Mead storage credits. At the time the ICS credits are created, five percent of the ICS credits would be dedicated to the system on a one-time basis. Additionally, ICS credits would be subject to annual evaporation losses of three percent per year. If flood control releases occur, ICS credits would be reduced on a pro-rata basis among all holders of ICS credits until no credits remain.

[4] Notwithstanding the lack of an existing mechanism to implement such modeling assumptions, Reclamation utilized these assumptions for a number of reasons, including the following: (1) a larger volume of potential storage in Lake Mead is identified, (2) the maximum potential impacts on river flows below Hoover Dam are identified, (3) the arbitrary assignment of water conservation amounts to entities in the Lower Basin states is avoided, and (4) the modeling impacts of a program of potential future cooperation between the United States and Mexico are identified.

Table R-2
Proposed Action Alternative Volume Limitations of Storage and Delivery Mechanism

Entity	Maximum Annual Storage of Conserved System or Non-system Water (kaf)	Maximum Total Storage of Conserved System or Non-system Water (kaf)	Maximum Annual Delivery of Conserved System or Non-system Water (kaf)
Arizona	100	300	300
California	400	1,500	400
Nevada	125	300	300
Total[1]	625	2,100	1,000
Additional Amounts	625	2,100	1,000
Total[2]	1,250	4,200	2,000

1 *It is anticipated that the ICS mechanism will be implemented to allow a maximum cumulative amount of ICS credits that would be available at any one time of up to 2.1 maf.*

2 *The analysis of potential effects in this BA includes a maximum cumulative amount of ICS credits that would be available at any one time of up to 4.2 maf.*

Under the assumptions made for the analysis contained herein, the maximum amount of ICS credits that can be created during any year, the maximum cumulative amount of ICS credits that can be available at any one time, and the maximum amount of ICS credits that may be recovered in any one year under the proposed action are presented in Table R-2.

R.1.3.4 Interim Surplus Guidelines

The proposed action includes both a modification and an extension of the existing ISG currently in place through 2016. The ISG would be extended through 2026 and be modified by eliminating the Partial Domestic Surplus Condition, beginning in 2008, and limiting the amount of water available under the Full Domestic Surplus Condition during the period 2017 through 2026.[5] These modifications reduce the amount of surplus water that could be made available and leaves more water in storage to reduce the frequency and severity of future shortages.

R.1.3.5 Interdependent and Interrelated Actions

Interdependent and interrelated actions are defined as those actions having no independent utility from the proposed action (50 CFR §402.02) and actions that are part of a larger action and depend on the larger action for their justification (50 CFR § 402.02) respectively. The following describes the interdependent actions associated with the proposed action.

[5] During 2017 through 2026, the distribution of Domestic Surplus water would be limited as follows: 1) for use by MWD, 250 kafy in addition to the amount of California’s basic apportionment available to MWD; 2) for use by SNWA, 100 kafy in addition to the amount of Nevada’s basic apportionment available to SNWA; and 3) for use in Arizona, 100 kafy in addition to the amount of Arizona’s basic apportionment available to Arizona contractors.

R.1.3.5.1 Storage and Delivery of Conserved Water by Southern Nevada Water Authority

The Southern Nevada Water Authority (SNWA) intends to allow water in the Muddy and Virgin Rivers that was historically diverted from those rivers for beneficial use to remain in the rivers. Such water will flow downstream to be captured in and diverted from Lake Mead as part of the ICS feature of the proposed action. The mechanism to allow for the creating, storage and delivery of conserved water in Lake Mead does not currently exist. Therefore, SNWA would not be able to perform this activity absent adoption of the proposed action. Therefore, the effects of routing the additional Virgin and Muddy River flows downstream to Lake Mead will be analyzed in this BA (Attachment B) as an interdependent action.

R.1.4 Geographic Scope and Extent of Action Area

The geographic region that could be affected by the proposed action and interdependent actions (i.e., the action area) is shown in Figure 1 and includes the following areas:

- The Colorado River and its floodplain from the high pool elevation of Lake Powell (elevation 3,700) to the high pool elevation of Lake Mead (elevation 1,229). Elevation 1,229 was used to define the full pool of Lake Mead in the MSCP BA.

- The channel of the Lower Virgin River and its floodplains and the channel of the Muddy River and its floodplains. The action area in the Lower Virgin River extends from the Nevada/Arizona border, to the confluence of Lake Mead. The action area in the Muddy River begins south of the headwaters at Warm Springs and extends to the confluence of Lake.

- The Colorado River and its floodplain from the high pool elevation of Lake Mead to the Southerly International Boundary (SIB) with Mexico.

This BA addresses the potential affects of the proposed action for all portions of the action area except from the high pool elevation of Lake Mead (elevation 1,229) to the SIB. The Lower Colorado River MSCP provides ESA compliance for a range of river operations from the high pool elevation of Lake Mead to the SIB and included development of shortage criteria as a covered action. Based on Reclamations review of the proposed action described in Attachment A (transmitted in a separate letter), Reclamation has concluded that the range of operations under the proposed action was fully covered under the MSCP BCO, and that no significant new information exists that would require additional consultation for the four operational elements of the proposed action within the MSCP planning area boundary. This conclusion is documented in Attachment A. Consequently, the potential effects of the proposed action on the segment of the action area from the high pool elevation of Lake Mead to the SIB is not addressed further in this BA.

Reclamation has concluded that the service areas of the CAP (and other 4th priority Arizona contractors), SNWA, and Metropolitan Water District should not be included within the action area for this BA. Section 7 analyses require the definition of an "action area" for use in describing the environmental baseline and the effects of the action (including indirect, interrelated, and interdependent effects). The action area is defined as the area likely to be affected by the direct and indirect effects of the proposed agency action (50 CFR §402.02). Regulations for implementing section 7 of ESA define indirect effects as those effects that are caused by or result from a proposed action, occur later in time than the direct effects, and are reasonably certain to occur. All of these conditions must be met to qualify as an indirect effect.

As described in the EIS for Colorado River Interim Guidelines for Lower Basin Shortages and Coordinated Operations for Lake Powell and Lake Mead, the proposed action is expected to have socio-economic effects in the service areas in terms of fallowing of agricultural lands and reductions in Colorado River water available to municipal users during shortages.[6] However, Reclamation does not have the authority to decide how farmers or municipal water providers will operate under Shortage conditions. For example, Reclamation does not control, and cannot anticipate which specific agricultural acreages may be planted or fallowed as a result of changes in water deliveries under the proposed action, nor are individual water district's and farm operator's responses to various water delivery conditions predictable over the long-term given access to alternative sources of water, economic conditions, and other factors. Additionally, many of the potentially affected Colorado River water users have alternative water supplies. Reclamation has no relationship or role with respect to how these entities may use these alternative water supplies.

In order to identify indirect effects on listed species, the effect must be identifiable (site-specific), caused by the proposed action, and reasonably certain to occur. Available information does not support a substantive causal connection between shortage conditions and fallowing of specific lands in the Arizona. While fallowing is likely to occur under the proposed action (and under No Action), the extent and location of such fallowing is subject to a number of factors beyond Reclamation's control as described above. Therefore, the effect on any specific parcel of land is not reasonably certain to occur as a result of the adoption of the proposed action. Accordingly, Reclamation has determined to exclude the water-use areas from the action area described in this BA.

The proposed action will not affect environmental conditions along the Muddy and Virgin Rivers, however, as described under Section 1.3.5, *Interdependent and Interrelated Actions*, SNWA's interdependent action could affect ESA-listed, proposed, and candidate species present along the Muddy and Virgin Rivers. A separate assessment of the potential effects of SNWA's action on ESA-listed, proposed, and candidate species within this portion of the action area is included in Attachment B and is summarized in this BA.

---

[6] It should be noted that shortage conditions also occur under the No Action Alternative. The timing, probability, and magnitude of shortages may be different under the proposed action.

Figure R-1 shows the geographic scope for the BA. The portion of the Geographic Scope from the full pool of Lake Mead to the SIB is addressed via correspondence with the FWS found in Attachment A and is not specifically addressed further in this BA. Attachment B describes the geographic scope associated with the interdependent and interrelated actions of SNWA on the Muddy and Virgin Rivers. The portion of the Geographic Scope shown on Figure 1 that is specifically analyzed further in this BA includes the full pool of Lake Powell and the Colorado River and its floodplain from Glen Canyon Dam to the full pool elevation of Lake Mead defined by elevation 1,229 feet msl.

R.1.5 Species Identified for Analysis

ESA-listed, proposed, and candidate species that are or could be present in the action area and the species that are evaluated in this BA are listed in Table R-3. Reclamation has determined that, based on information presented in the MSCP BA and BCO regarding the potential effects of similar actions, the proposed action will have no effects on the California brown pelican, California condor, and desert tortoise. The portion of the Colorado River within the action area is outside of the range of the California brown pelican, though a few individuals may infrequently stray into the study area during migration. Additionally, anticipated effects of the proposed action on aquatic habitats used by the species (i.e., reservoir and river stage elevations) are not expected to affect individuals that stray into the affected area. The California condor and desert tortoise are both associated with upland habitats that will not be affected by the proposed changes in reservoir and river operations. The bald eagle has recently been delisted and only occurs as a wintering species from Lake Powell to Lake Mead. The proposed action is not expected to affect the bald eagle because it will not affect the availability of fish or other bald eagle prey. The relict leopard frog only occur from Lake Mead to the SIB and, therefore, are covered under the MSCP BCO and are not addressed further in this BA.

Figure R-1
Geographic Scope

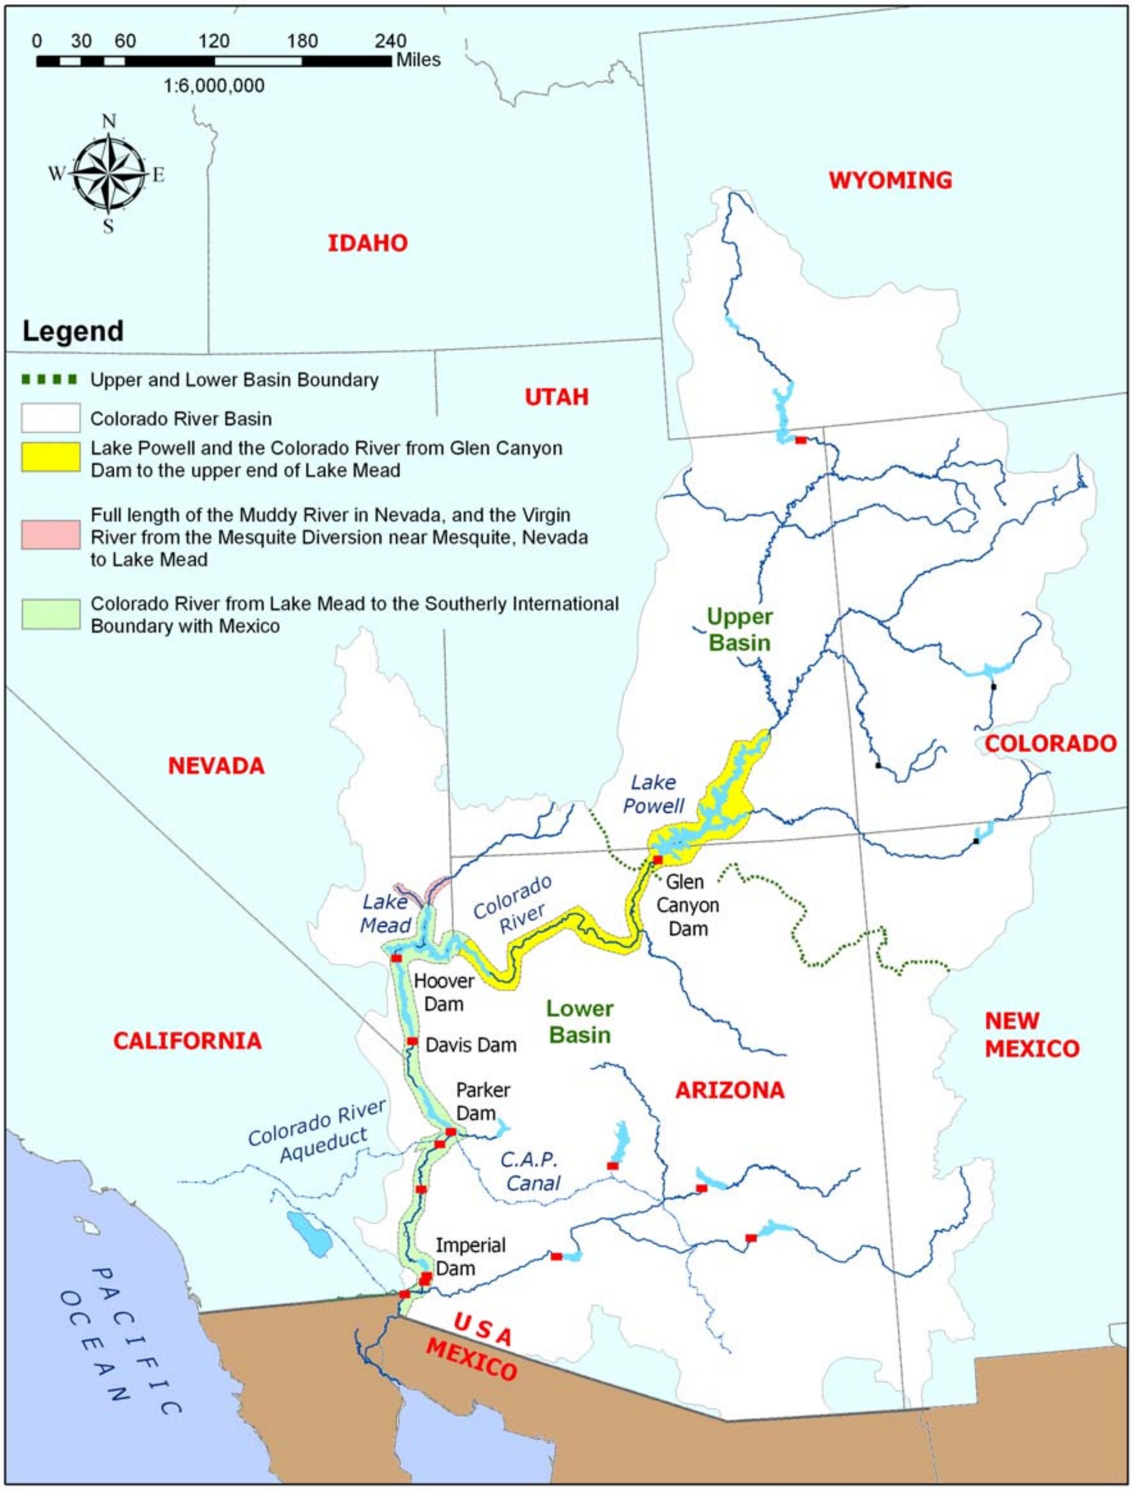

Table R-3
Species Analyzed in this Biological Assessment from Lake Powell
to the Upper End of Lake Mead, and Along the Muddy and Virgin Rivers in Nevada

Common and Scientific Name	ESA Status[1]	Designated Critical Habitat Present in the Action Area	Evaluated in this BA
California brown pelican[2] *Pelecanus occidentalis*	E	No	No
Bald eagle[3] *Haliaeetus leucocephalus*	D	No	No
Yellow-billed cuckoo[5] *Coccyzus americanus*	C	Not applicable	Yes
Southwestern willow flycatcher[4] *Empidonax trailii extimus*	E	Yes	Yes
California Condor[3] *Gymnogyps californianus*	E	No	No
Yuma clapper rail[5] *Rallus longirostris yumanensis*	E	No	Yes
Desert tortoise (Mohave population)[2] *Gopherus agassizii*	T	Yes	No
Relict leopard frog[2] *Rana onca*	C	Not applicable	No
Moapa dace[6] *Moapa coriacea*	E	No	Yes
Woundfin[6] *Plagopterus argentissimus*	E	Yes	Yes
Virgin River Chub[6] *Gila robusta seminude*	E	Yes	Yes
Bonytail [4] *Gila elegans*	E	No	Yes
Humpback chub[7] *Gila cypha*	E	Yes	Yes
Razorback sucker[4] *Xyrauchen texanus*	E	Yes	Yes
Colorado pikeminnow[4] *Ptychocheilus lucius*	E	Yes	Yes
Kanab ambersnail[4] *Oxyloma haydeni kanabensis*	E	No	Yes

1 ESA Status
E = Listed as endangered under the Federal Endangered Species Act (ESA).
T = Listed as threatened under ESA.
C = Candidate for listing under ESA.
D = Delisted.

2 Species only present from Lake Mead to the Southerly International Boundary (SIB).

3 Species present only from Lake Powell to the SIB.

4 Species present in all portions of the action area.

5 Species present from Lake Mead to the SIB, and along Muddy and Virgin Rivers.

6 Species present only along the Muddy and/or Virgin Rivers and only analyzed in Attachment B.

7 Species present from Lake Powell to Lake Mead.

R.2 Environmental Baseline

The environmental baseline for Lake Powell to Separation Canyon includes past and present impacts of all Federal, state, or private actions and other human activities in an action area, the anticipated impacts of all proposed Federal projects in an action area that have already undergone formal or early section 7 consultation, and the impact of state or private actions that are contemporaneous with the consultation in process (50 C.F.R. §402.02). In terms of past federal actions, the most important past actions that are included in the baseline are:

- Reclamation's construction and continued operation of Glen Canyon Dam and Hoover Dam;
- Reclamation's implementation of the 1996 ROD on Glen Canyon Dam and subsequent experimental actions and consultations, including the Interim Surplus Guidelines; and
- Stocking of rainbow trout, brook trout and brown trout in the Colorado River and various tributaries.

In terms of past state or tribal actions, the most important past actions in the baseline are:

- Stocking rainbow trout in the tailwater below the dam;
- Stocking sport fish (largemouth bass, crappie, smallmouth bass, striped bass) in Lakes Powell and Mead; and
- Stocking threadfin shad to provide a forage base (NPS, 1996).

R.2.1 Related Consultation History

Reclamation has consulted with the USFWS under section 7 of the ESA for various projects that could have had effects on ESA listed species and designated critical habitat within the action area from Lake Powell to Lake Mead. These consultations are included in the environmental baseline. Although the projects and their potential effects have varied, the FWS has concluded that the projects would not jeopardize the continued existence of any species or adversely modify designated critical habitat or that jeopardy and adverse modification could be avoided through reasonable and prudent alternatives (RPAs). All elements of the 1995 Biological Opinion on Glen Canyon Dam have not yet been fully implemented.. However, FWS has agreed with Reclamation that significant progress has been made on some elements of the of the 1995 biological opinion. Reclamation continues efforts to implement the 1995 biological opinion through experimentation and adaptive management in consultation with FWS. Reclamation consultations on projects relevant to the proposed action are summarized below.

R.2.1.1 Operation of Glen Canyon Dam

Reclamation received a BO from the FWS on their proposed alternative for the Operation of Glen Canyon Dam EIS in January 1995. The FWS concluded that the preferred alternative, the modified low fluctuating flow (MLFF) alternative, was likely to jeopardize the continued existence of the humpback chub and razorback sucker and was likely to destroy or adversely modify their critical habitat, but was not likely to jeopardize the bald eagle, Kanab ambersnail and peregrine falcon. The 1995 BO on the Operation of Glen Canyon Dam identified reasonable and prudent alternatives (RPAs) that were necessary to avoid jeopardizing the continued existence of the humpback chub and razorback sucker. Elements of the RPA included the following:

- Development of an adaptive management program including: an experimental flow program, including study of seasonally adjusted steady flows; feasibility analysis of a selective withdrawal program for Glen Canyon Dam; and determination of native fish responses to various temperature and flow conditions.

- Protection of the humpback chub spawning population in the Little Colorado River by participating in development of a management plan for this river.

- Sponsor a workshop to develop a razorback sucker management plan for the Grand Canyon.

- Establishment of a second spawning aggregation of humpback chub downstream of Glen Canyon Dam.

The Operation of Glen Canyon Dam Final EIS analyzed alternative operation scenarios that met statutory responsibilities for protecting downstream resources and achieving other authorized purposes. The 1996 Glen Canyon Dam ROD describes detailed criteria and operating plans for dam operations and includes other management actions to accomplish this objective; among these are the Glen Canyon Dam Adaptive Management Program (AMP) of scientific monitoring and experimentation, beach/habitat-building flows (BHBF), and further study of temperature control.

The AMP provides a process for assessing the effects of Glen Canyon Dam operations on downstream resources and project benefits. The results of those assessments are used to develop recommendations for modifying Glen Canyon Dam operations and other resource management actions. This is accomplished through the Adaptive Management Work Group (AMWG), a federal advisory committee. The AMWG consists of stakeholders that include federal and state agencies, representatives of the seven Basin States, Indian tribes, hydroelectric power customers, environmental and conservation organizations, and recreational and other interest groups.

The BHBF releases are scheduled high releases of short duration that are in excess of power plant capacity in accordance with hydrologic triggering criteria. These BHBFs are designed to rebuild high elevation sandbars, deposit nutrients, restore backwater channels, and provide some of the dynamics of a natural system. The first test of a BHBF was conducted in spring of 1996, and a subsequent test of a BHBF was conducted in November 2004.

Evaluating the feasibility of increasing the temperature of water released from Glen Canyon Dam was a common element in the Glen Canyon Dam EIS and one of the elements of the reasonable and prudent alternative in the 1995 Biological Opinion (BO) of that document. In 1999, Reclamation issued an environmental assessment regarding potential modification of Glen Canyon Dam to construct a selective withdrawal structure, and has subsequently continued to investigate various structural designs. The recent drought-induced drawdown of Lake Powell has resulted in warmer release temperatures, providing an opportunity to monitor the effects on habitat, reproduction and recruitment. Reclamation has initiated a NEPA process that, among other elements, will consider construction of a selective withdrawal structure as part of a long-term experimental plan. This process will include additional consultation on the long-term experimental plan, which includes a program of experimentation, building on past scientific efforts within the AMP(71 Fed. Reg. 64982-64983 and 71 Fed. Reg. 74556-74558).

R.2.1.2 Spring 1996 Beach/Habitat-Building Flow from Glen Canyon Dam

The consultation that resulted in the January 1995 BO on the preferred alternative for the Operation of Glen Canyon Dam (Section 2.4.1.2 above) was re-initiated in November of 1995 to allow for a proposed test of beach/habitat-building flow (test flow) from Glen Canyon Dam in the spring of 1996 in the Colorado River. Consultation with the FWS was re-initiated on the preferred alternative from the 1995 FEIS because a new species was listed since the original consultation (the southwestern willow flycatcher with proposed critical habitat), and new information revealed that incidental take for the Kanab ambersnail determined in the January1995 biological opinion on the Operation of Glen Canyon Dam preferred alternative would be exceeded. Reclamation concluded in its BA that the test flow would have no effect on the endangered peregrine falcon, threatened bald eagle and the endangered razorback sucker. The FWS concluded it its BO that the proposed test flow was not likely to jeopardize the continued existence of the humpback chub, Kanab ambersnail and southwestern willow flycatcher, and was not likely to destroy or adversely modify humpback chub critical habitat. The FWS also provided a conference opinion that the test flow was not likely to destroy or adversely modify proposed southwestern willow flycatcher critical habitat.

R.2.1.3 November 1997 Fall Test Flow from Glen Canyon Dam

The Fall Test flow was proposed as a test of a powerplant release of 31,000 cfs for 48 hours. While powerplant capacity releases were described in the FEIS as Habitat Maintenance Flows, such a test in the fall was not addressed in the 1995 FEIS, which necessitated the re-initiation of consultation. Reclamation concluded in its BA that this proposed action would have no effect on the southwestern willow flycatcher or its critical habitat, the razorback sucker or its critical habitat, the bald eagle or the American peregrine falcon. The FWS in its BO concluded that the test flow was not likely to jeopardize the continued existence of the humpback chub or Kanab ambersnail and is not likely to destroy or adversely modify designated critical habitat for the humpback chub.

R.2.1.4 2002-2004 Proposed Experimental Releases From Glen Canyon Dam and Removal of Non-Native Fish

The 2002 biological opinion included the following actions: (1) experimental releases from Glen Canyon Dam (2) mechanical removal of non-native fish from the Colorado River in an approximately 9-mile reach in the vicinity of the mouth of the Little Colorado River to potentially benefit native fish and; (3) release of non-native fish suppression flows having daily fluctuations of 5,000-20,000 cfs from Glen Canyon Dam during the period January 1-March 31.

Reclamation in its September 2002 BA (included within the Environmental Assessment for the proposal) concluded the action was likely to adversely affect the Kanab ambersnail, humpback chub and its critical habitat and bald eagle and was not likely to adversely affect the razorback sucker and its critical habitat, southwestern willow flycatcher and its critical habitat and California condor. The FWS concluded that the proposed action was not likely to jeopardize the continued existence of the humpback chub, Kanab ambersnail and bald eagle and concurred that the proposed action was not likely to adversely affect the razorback sucker or its critical habitat, California condor and southwestern willow flycatcher. The December 2002 BO included the incidental take of up to 20 humpback chub during the non-native fish removal efforts and the loss of up to $117m^2$ of Kanab ambersnail habitat.

Two Conservation Measures included were included in the FWS BO. The first included re-location of 300 humpback chub above Atomizer Falls, an impassable barrier, in the Little Colorado River to increase the likelihood of humpback chub surviving a flood in the Little Colorado River basin, reduce predation and other inclement environmental conditions. The second conservation measure consisted of temporary removal and safeguard of approximately $29m^2$ – $47m^2$ (25 to 40 percent) of Kanab ambersnail habitat that would be flooded by the experimental release. The relocated habitat would be replaced once the high flow was complete to facilitate re-establishment of vegetation.

The sediment input-triggered high experimental flow was analyzed for an indefinite period of time because of the uncertainty of knowing when the sediment trigger would be reached. The other two actions were analyzed for the period of water years 2003 and 2004. Consultation was re-initiated in 2004 to make several changes to the timing and duration of the proposed experiments described in the 2002 consultation. The 2004 high flow experiment was intended to occur in the fall, immediately following significant tributary sediment inputs, while the 2002 high flow experiment was proposed to occur in the spring. In November 2004 Reclamation reinitiated consultation and concluded that the proposed changes were likely to adversely affect the humpback chub and its critical habitat, Kanab ambersnail and bald eagle. Reclamation requested concurrence that the proposed changes to the action were not likely to adversely affect the razorback sucker and critical habitat, the California condor and southwestern willow flycatcher. In a BO dated November 2004, the FWS concurred that the project was not likely to affect razorback sucker or its critical habitat, California condor or southwestern willow flycatcher and concluded that the modified action was not likely to jeopardize the continued existence of the humpback chub, Kanab ambersnail or bald eagle. The FWS also concluded that designated humpback chub critical habitat would not be destroyed or adversely modified. The BO included several conservation measures related to humpback chub including the continuation of translocating humpback chub in the Little Colorado River, and further study and monitoring of the results and study of effects on chub from various flow conditions. Kanab ambersnail conservation measures included removal and safeguard of Kanab ambersnail habitat that would be inundated by the experimental release.

R.2.2 Regulatory Context

Glen Canyon Dam is operated in accordance with the 1996 ROD, its associated BO and subsequent experiments under the AMP. These requirements serve as the regulatory baseline for this BA between Lake Powell and Lake Mead. This reach was not addressed in the MSCP and thus no ESA coverage from the MSCP applies upstream of Lake Mead. The range of releases and operational constraints covered by the 1996 ROD is described below in Table R 4.

Table R-4
Glen Canyon Dam Release Constraints

Parameter	Release Volume (cfs)	Conditions
Maximum Flow[1]	25,000	
Minimum Flow	5,000	Nighttime
	8,000	7:00 a.m. to 7:00 p.m.
Ramp Rates		
Ascending	4,000	Per hour
Descending	1,500	Per hour
Daily Fluctuations[2]	5,000 to 8,000	

1 *May be exceeded for emergency and during extreme hydrological conditions.*

2 *Daily fluctuation limit is 5,000 cubic feet per second (cfs) for months with release volumes less than 0.6 maf; 6,000 cfs for monthly release volumes of 0.6 maf to 0.8 maf; and 8,000 cfs for monthly volumes over 0.8 maf.*

In the past, the annual volume of water released from Glen Canyon Dam has been made according to the provisions of the LROC that include a minimum objective release of 8.23 maf. The proposed action would allow Reclamation to change these operations by allowing for potential annual releases less than the minimum objective release under certain conditions. However, even in years with an annual release less than 8.23 maf, daily and hourly releases would continue to be made according to the parameters of the 1996 Glen Canyon Dam ROD, which would not be affected by the proposed federal action. The No Action alternative as described in the DEIS for the proposed action (Bureau of Reclamation, 2007) depicts how Reclamation would likely operate Glen Canyon Dam under shortage conditions without adoption of the proposed Shortage Criteria and Coordinated Operations for Lake Powell and Lake Mead. Effects to the species may occur when flow or reservoir conditions in this reach would deviate from flow, reservoir or water quality conditions that would occur under baseline conditions (the No Action alternative in the DEIS).

On September 1, 2006, Reclamation and the Center for Biological Diversity, Arizona Wildlife Federation, Living Rivers, Sierra Club – Grand Canyon Chapter and Glen Canyon Institute entered into a settlement agreement whereby Reclamation agreed to assess under NEPA and ESA the impacts of modifying current or prospective operations of Glen Canyon Dam. Reclamation initiated an analysis under NEPA of a long-term experimental plan (LTEP) related to the operation of Glen Canyon Dam (71 Fed. Reg. 64982-64983 and 71 Fed. Reg. 74556-74558) and anticipates that it will initiate consultation under ESA by May 1, 2008. The LTEP process is properly excluded from the Environmental Baseline and Cumulative Effects analysis in this BA as it has not yet undergone consultations. Reclamation is committed to perform this assessment and further study and has included completion of the LTEP as a proposed conservation measure for the above-listed fish species, which will be discussed later in this BA.

R.2.3 Description of Glen Canyon Dam Adaptive Management Program

The Glen Canyon Dam Adaptive Management Program (AMP) was established in 1997 to implement the Grand Canyon Protection Act of 1992 (GCPA), the 1995 Operation of Glen Canyon Dam Final Environmental Impact Statement (final EIS), and the 1996 Record of Decision (ROD). The AMP provides a process for assessing the effects of current operations of Glen Canyon Dam on downstream resources and using the results to develop recommendations for modifying operating criteria and other resource management actions. This is accomplished through the Adaptive Management Work Group (AMWG), a federal advisory committee. The AMWG consists of stakeholders that are federal and state resource management agencies, representatives of the seven Basin States, Indian Tribes, hydroelectric power marketers, environmental and conservation organizations and recreational and other interest groups. The duties of the AMWG are in an advisory capacity only. Coupled with this advisory role are long-term monitoring and research activities that provide a continual record of resource conditions and new information to evaluate the effectiveness of the operational modifications to Glen Canyon Dam and other management actions.

The GCDAMP consists of the following major components:

- The Adaptive Management Work Group (AMWG) which is a Federal Advisory Committee which makes recommendations on how to adjust the operation of Glen Canyon Dam and other management actions to fulfill the obligations of the GCPA.
- The Secretary of the Interior’s Designee which serves as the chair of the AMWG and provides a direct link between the AMWG and the Secretary of the Interior.
- The Technical Work Group (TWG) which translates AMWG policy into information needs, provides questions that serve as the basis for long-term monitoring and research activities, and conveys research results to AMWG members.

The USGS Grand Canyon Monitoring and Research Center (GCMRC) which:

- ♦ Provides scientific information on the effects of the operation of Glen Canyon Dam and related factors on natural, cultural, and recreational resources along the Colorado River between Glen Canyon Dam and Lake Mead.

- ♦ The independent review panels (IRPs) which provide independent assessments of the program to ensure scientific validity. Academic experts in pertinent areas make up a group of Science Advisors (SAs).

R.2.4 Status of Species and Critical Habitat

R.2.4.1 Southwestern Willow Flycatcher

Please refer to Attachment B for additional information related to the southwestern willow flycatcher along the Muddy and Virgin Rivers.

Legal Status. The southwestern willow flycatcher (SWFL) was designated by the U.S. Fish and Wildlife Service as endangered, on February 27, 1995 (USFWS 1995a). A final recovery plan was completed in August 2002 (USFWS 2002a), and the designation of critical habitat was finalized in October 2005 (USFWS 2005). Critical habitat was previously designated on July 22, 1997 (62 FR 39129), but was rescinded by court order on May 11, 2001.

Critical habitat has been designated for the southwestern willow flycatcher in the action area along a contiguous segment of the Virgin River in Utah, Arizona, and Nevada (USFWS 1995b). The segment extends for 73.8 miles from the Washington Field Diversion Impoundment in Washington County, UT, downstream through the Town of Littlefield, AZ, and ends in NV at the upstream boundary of the Overton State Wildlife Area in Clark County, NV.

Historical and Current Range. The historic breeding range of the SWFL included southern California, southern Nevada, southern Utah, Arizona, New Mexico, western Texas, southwestern Colorado, and extreme northwestern Mexico (Unitt 1987, Browning 1993, Paxton 2000, USFWS 2002a). According to the critical habitat designation for SWFL, the current occupied geographic area crosses six southwestern states including southern California, southern Nevada, southern Utah, southern Colorado, Arizona, and New Mexico, from sea level to approximately 8000 feet above sea level. In general, flycatcher distribution occurs mainly in lower elevation riparian habitat, with a few patches distributed in relatively small isolated locations. When SWFL was listed as endangered in 1995, populations were estimated at 350 territories (USFWS 2002a). Through an increase in survey effort that number has increased to over 1000 territories (Durst et al. 2005). Arizona Game and Fish documented 883 resident flycatchers at 483 territories in 47 sites in 2005 (English et al. 2006). Nevada Department of Wildlife reported a total of 18 resident flycatchers at sites not surveyed by SWCA Environmental Consultants, and an average of 9 territories for surveys from 2001-2005. Approximately 73 territories were documented in 2005 by SWCA

Environmental Consultants along the lower Colorado River and at sites in Nevada and the lower Grand Canyon (Koronkiewicz et al. 2006).

Another important aspect to the distribution of SWFL is its migration routes and migration stopover habitats. This neotropical migrant travels between breeding areas in the United States to wintering grounds in Central and South America (USFWS 2005). Migration flyways include major river corridors and their tributaries such as the Gila River, Rio Grande and lower Colorado River basins (Yong and Finch 1997, Moore 2005, Koronkiewicz et al. 2006, English et al. 2006, USFWS 2005).

Wintering grounds for the willow flycatcher include portions of southern Mexico, Central America, and northern South America. Specific surveys have been conducted at sites in El Salvador, Costa Rica, Panama, Mexico, Ecuador, Nicaragua, and Guatemala (Phillips 1948, Koronkiewicz and Whitfield 1999, Koronkiewicz and Sogge 2000, Lynn and Whitfield 2002, Lynn et al. 2003, Nishida and Whitfield 2005). It is suspected that all subspecies may winter in similar locations. Because it is difficult to identify subspecies of willow flycatchers, specific areas where the SWFL winters are not fully known at this time.

Populations within the Action Area. Presence/absence surveys, along with life history studies, have been conducted along the LCR since 1996 (McKernan 1997, McKernan and Braden 1998, 1999, 2001a, 2001b, 2002, 2006, Koronkiewicz et al. 2004, 2006, and McLeod 2005). Approximately 100 sites have been surveyed in an area that includes the Virgin River, Pahranagat NWR, the Grand Canyon south of Separation Canyon, and throughout the LCR from Lake Mead to the Southerly International Boundary with Mexico. These surveys indicate that the main breeding populations occur along the Virgin River from north of Mesquite, NV to the Virgin River Delta with Lake Mead, at Pahranagat National Wildlife Refuge, in the Grand Canyon from Separation Canyon to the delta of Lake Mead, at Topock Marsh near Needles, CA, and on the Bill Williams National Wildlife Refuge. Flycatchers have nested along the river corridor in the Grand Canyon, particularly in salt-cedar. One to five territories of breeding southwestern willow flycatcher were observed between 1992 and 2003 in any one year between the Little Colorado River confluence and the Grand Canyon gauging station (Gloss, et al 2005). These occurrences have been in riparian vegetation between river miles 28 and 71. Between the Grand Canyon gauging station and the western boundary of Grand Canyon National Park, southwestern willow flycatchers have been detected at a several locations. Seven to twelve territories were identified between 1998 and 2001 between river miles 246 and 273. Surveys in 2002 and 2003 found no territories and surveys in 2004 found two territories (Gloss, et al 2005). Southwestern willow flycatcher breeding occurred in 2005 at river mile 274.5 and 15 southwestern willow flycatchers were detected during 2006 surveys at 13 different sample sites in the Lower Grand Canyon and Lake Mead delta (approximately river mile 251 to 286) (SWCA, 2007).

Populations of southwestern willow flycatcher along the LCR over the past 10 years are listed in Table R-5.

Table R-5
Southwestern Willow Flycatcher (*Empidonax traillii extimus*)
Population Along the Lower Colorado River from 1996-2005

Year	Total WIFL Detected*	SWFL Summer Resident/ Breeding
1996	202	34
1997	154	68
1998	302	113
1999	NA	133
2000	NA	135
2001	NA	218
2002	NA	142
2003	356	115
2004	793	193
2005	473	133

* *Total WIFL Detected = Migratory and breeding birds detected during presence/absence surveys. Migratory birds include other subspecies than just E.t. extimus and thus we can only confirm to species E. traillii. NA=not available.*

Breeding. The SWFL breeds across the lower southwestern United States from May through August. SWFL typically arrive on the breeding grounds between early May and early June. Males generally arrive first to set up territories, with females arriving a week or two later. Males are highly territorial and will defend their territory through counter singing and aggressive interaction. Flycatchers often clump together in one area of the habitat patch, which leads to an indication that this species is "semi-colonial". Males are usually monogamous, but polygyny does occur at approximately 10-20 percent (USFWS 2002a, Pearson 2002). Genetic evidence suggests extra pair copulation exists by either mated or unmated males with females in neighboring territories (USFWS 2002a).

Territory size varies greatly, potentially due to population density, habitat quality, and nesting stage. Territory sizes have been estimated from approximately 0.1 ha to 2.3 ha (0.25-5.7 acres) (McCabe 1991), with most territories encompassing 0.2-0.5 ha (.5-1.2 ac) (Sogge 1995, USFWS 2002a). Territories of polygynous males are usually larger than those of monogamous males. Flycatchers' home ranges are greater than their territories and can vary in size from 0.13 to 360 ha, depending on breeding status and surrounding habitat areas (Bakian and Paxton 2004, Cardinal and Paxton 2005).

Multi-year color banding studies have shown high site fidelity among after-second-year birds returning to former breeding patches (McKernan and Braden 2002, Koronkiewicz et al. 2006a). Juvenile dispersal is largely within the regional area, although long distance dispersal has occurred, with movements greater that 200 km reported (McKernan and Braden 2001b, Koronkiewicz et al. 2006). These movements and site fidelity suggest that the Virgin River/LCR population may be a sub-population of a greater meta-population (Koronkiewicz et al. 2006).

Nest building usually begins 3-7 days after pair formulation. Flycatchers nest in various tree species including Goodding's willow, coyote willow, cottonwood, saltcedar, boxelder, and other native and exotic tree species. Egg laying can start as early as late May, but is usually in early to mid June (Sogge et al. 1997a, Sogge et al. 1997b). Upon completion of egg laying, the female usually incubates the eggs for approximately 12 days, and all eggs usually hatch within 24-48 hours of one another. Nestlings fledge usually within 12-15 days (Paxton and Owen 2002). Chicks are usually present from mid-June through early August. SWFL will re-nest, either after the first nest fledges or after failure, and have been documented to have up to four nesting attempts and three clutches (Sferra et al. 1997, McKernan and Braden 2001b, Koronkiewicz et al. 2006). Adults depart from breeding territories as early as mid-August, but may stay until mid-September if nesting was late. Fledglings usually leave the breeding areas a week or two after adults (Sogge et al. 1997a).

Nest success averages from 40-50 percent through all years of study along the lower Colorado River (McKernan 1997, McKernan and Braden 1998, 1999, 2001a, 2001b, 2002, 2006, Koronkiewicz et al. 2004, 2006, and McLeod 2005) and approximately 25-70 percent over complete range of the SWFL (USFWS 2002a). Predation has been the leading cause of nest failure at many study sites throughout the range (USFWS 2002a), including along the LCR (McKernan and Braden 2001b and 2002, Koronkiewicz et al. 2004, 2006, McLeod 2005).

Parasitism by brown-headed cowbirds is another cause of nest failure. Cowbird parasitism may impact some SWFL populations enough to warrant management actions. The cowbird lays it eggs in the nest of the host species, and the host then incubates the cowbird eggs, which typically hatch prior to the hosts own young.

Abandonment and desertion, although typically low, are also causes of nest failure. Typically, causes for these are unknown, but addled or unfertilized eggs, disturbance, and in some cases brood parasitism may all contribute. Abandonment and desertion accounted for 13 percent and 9 percent respectively, for nest failures at life history study sites along the LCR and tributaries in 2005 (Koronkiewicz et al. 2006). For Arizona statewide surveys, abandonment and desertion together accounted for less than 6 percent of the nest failures.

Diet. The SWFL is an insectivore that hawks insects while in flight, gleans insects from foliage, and occasionally captures them from the ground (USFWS 2002a). Flycatchers forage from within the habitat or above the canopy, above water, or glean from trees and herbaceous cover (McCabe 1991, Sogge 2000, USFWS 2002a). The main diet of the flycatcher consists of small to medium size insects such as true bugs (order Hemiptera), wasps and bees (Hymenoptera), flies (Diptera), beetles (Coleoptera), butterflies and caterpillars (Lepidoptera), and spiders (Araneae) (Drost et al. 1998, McCabe 1991, Sogge 2000, Drost et al. 2001, DeLay et al. 2002, Durst 2004). Berries and small fruits have also been reported but are typically rare (McCabe 1991). The flycatcher can exploit a diverse array of insects depending on availability within the habitat (Drost et al. 1998, Drost et al. 2001, Drost et al. 2003, DeLay et al. 2002, Durst 2004). Diet may differ between sites and between years depending on abundance and availability of insects in and near the breeding habitat (DeLay et al. 2002, Drost et al. 2003, Durst 2004). Although there were differences in prey types consumed by the flycatcher among different habitats (e.g. native versus non-native), there is no significant differences in the abundance of insects available between habitats (Durst 2004), and there is no evidence that the physiological condition of flycatchers is lower in saltcedar habitats (Owen et al. 2005).

Habitat. The SWFL breeds in dense riparian vegetation near surface water or saturated soil, across a large elevational and geographic area (USFWS 2002a, Sogge et al. 1997a). Dominant plant species consist of large riparian trees such as Coyote willow (*Salix exigua*), Goodding willow (*Salix goodingii*), Fremont cottonwood (*Populus fremontii*), boxelder (*Acer negundo*), and non-native saltcedar (*Tamarix* spp.) and Russian olive (*Elaeagnus angustifolia*) (USFWS 2002a). SWFL typically nest in saltcedar in the Grand Canyon (Gloss et al. 2005).

Occupied sites vary in size and shape but all are relatively dense, with some open areas, and are usually associated with open or standing water. Occupied patches can be as small as 0.8 ha and as large as several hundred hectares, but are typically greater than 10 m wide. Although most of the sites are associated with open water, marshy seeps, or saturated soil where the nest tree can be in standing water, hydrologic conditions can change drastically during the breeding season and between years (Sogge et al. 1997a, Sogge and Marshall 2000, USFWS 2002a, Koronkiewicz et al. 2006). Because birds are exposed to extreme environmental conditions throughout the desert southwest, dense vegetation and moist soils at the nest may be needed to provide a more suitable microclimate for raising young by increasing humidity within the utilized site (Allison et al. 2003, Sogge and Marshall 2000, Koronkiewicz et al. 2006).

Vegetation analysis has occurred at life history sites along the LCR and its tributaries since 1996 (McKernan and Braden 2002, Koronkiewicz et al. 2006). Data gathered includes average canopy height, total canopy closure, woody ground cover, distance to nearest standing water or saturated soil, and additional foliage density measurements. Measurements have been taken at the nest, within territory, and at non-use plots. Analysis of this data is still being conducted and will be presented in a final report in 2008. Preliminary analysis suggests that, overall, flycatchers breed in a wide variety of habitats throughout the Virgin River and LCR. These areas contain relatively homogenous, contiguous stands of riparian vegetation that differ from each other both structurally and compositionally. Preliminary nest productivity, as related to vegetation type (e.g. non-native versus native), shows no significant difference (McKernan and Braden 2002), but further analysis will be conducted.

The presence of water is an important component of SWFL habitat (Sogge and Marshall 2000, USFWS 2002a). Studies indicate that SWFL nest sites are usually closer to water than non-use sites (Stoleson and Finch 2003, Paradzick 2005, Koronkiewicz et al. 2006). Nest sites are usually located within 200 m of open or standing water and usually contain soils that are higher in water content than non-use sites (McKernan and Braden 2002, Stoleson and Finch 2003, Paradzick 2005, Koronkiewicz et al. 2006). Water and/or moist soils help regulate temperature and relative humidity within the stand, produce the right conditions for insect development and survival, and are associated with creating a greater foliage density (USFWS 2002a, Paradzick 2005, Koronkiewicz et al. 2006).

Threats. Habitat alteration, as well as loss and fragmentation are considered one of the greatest threats to the SWFL (Marshall and Stoleson 2000). Riparian habitats in the Southwest are naturally patchy and subject to periodic disturbance. Factors contributing to habitat loss include water management, such as dams and reservoirs, diversions and groundwater pumping, channelization and bank stabilization, agricultural development, livestock grazing, phreatophyte control, increased recreation, and urbanization. All of these cause loss of habitat, habitat fragmentation, loss of critical water underneath stands, and human disturbance (Marshall and Stoleson 2000).

Although the SWFL now nests in saltcedar, this has some disadvantages. Saltcedar exudes salts and creates soils that are too salty for other native species to propagate, thus reducing diversity in the stand which may affect prey base for flycatchers. Deep root systems and extended production and proliferation of seeding from March through October gives saltcedar selective advantage over natives under stressed conditions such as lack of flooding, and may reduce soil moisture and standing water conditions needed for flycatcher habitat (Marshall and Stoleson 2000).

The SWFL has evolved with predation and cowbird parasitism, but increased populations of predators and cowbirds has become a major threat to some local populations. Predation is the leading cause of nest failure in many populations of SWFL (Marshall and Stoleson 2000, USFWS 2002a), including those along the LCR and its tributaries (McKernan and Braden 2002, Koronkiewicz et al. 2006). Known and suspected nest predators include snakes, predatory birds such as raptors, corvids, grackles and cowbirds, small mammals, and even ants (Marshall and Stoleson 2000).

Other threats that have not been studied as thoroughly include parasites, disease, and environmental toxins. Internal and external parasites have been recorded, but the extent of impacts has not been determined. Diseases such as West Nile Virus and Avian Flu are new threats that so far have not gotten into the SWFL population, but could have a devastating effect if they do, due to the small population size and the semi-colonial aspect of the SWFL. Environmental toxins may also play a factor as populations close to agriculture and human habitats, such as golf courses, increase the possibility of toxins entering into the diet of the flycatcher. Although this has not been studied to any great extent, bill deformities and missing eyes have been reported from birds at sites in Arizona, Colorado, and New Mexico. A study was completed on environmental contaminants in surrogate birds and insects found in SWFL habitat in Arizona. This study showed an accumulation of inorganic elements in eggshells and contents of eggs, although the only contaminant in this study with unusually high levels was strontium (Mora 2002). Increased concentrations of this metal may be associated with decreased egg production, and potentially higher embryonic mortality, but further studies are needed.

R.2.4.2 Yellow-billed cuckoo, Yuma Clapper Rail, Moapa Dace, Woundfin, Virgin River Chub

Please refer to Attachment B for information related to the yellow-billed cuckoo, Yuma clapper rail, Moapa dace, woundfin and Virgin River chub along the Muddy and Virgin Rivers since these species do not occur in the action area from Lake Powell to Lake Mead.

R.2.4.3 Bonytail Chub

Legal Status. The bonytail was federally listed as endangered under the Endangered Species Act in 1980. No critical habitat is designated in the action area.

Historical and Current Range. Bonytail was historically widespread and common throughout tributaries of the Colorado River and other larger rivers, with historical captures documented from Mexico to Wyoming (Behnke and Benson 1980, Minckley and Deacon 1991, Mueller and Marsh 2002). The first recorded capture of bonytail from the Upper Colorado River Basin (UCRB) was by Jordan (1891) with one specimen collected from the Green River. Subsequent historical collections, albeit limited largely to anecdotal and historical fishing creel interviews, in conjunction with limited scientific collection information combine to demonstrate the once-expansive range of bonytail (USFWS 2002b). However, during the 1950s bonytail populations began a rather large, yet poorly documented decline in abundance following numerous biotic and abiotic habitat modifications. Holden (1991) described the effects of a large-scale rotenone treatment in the upper Green River, while simultaneously providing insight to the rather large population of bonytail present until 1962, at which time a large piscicide treatment occurred in the UCRB. Bonytail numbers were drastically reduced following the closure of Flaming Gorge Dam in 1963, with very few and sporadic captures of bonytail occurring in the UCRB since that time (Vanicek and Kramer 1969, Holden and Stalnaker 1975, Tyus et al. 1982, Valdez 1990).

Bonytail captures along the Lower Colorado River (LCR) follow similar trends. The USFWS (2002b) documents an early capture of 16 individuals from the LCR by R.R. Miller (from the Grand Canyon). Jonez and Sumner (1954) documented a large aggregation of an estimated 500 adults spawning over a gravely shelf in Lake Mohave. During the period between 1976-1988, 34 bonytail were captured in Lake Mohave, and some of these fish were incorporated in the establishment of a brood stock, the progeny of which are presently stocked into Lakes Mohave and Havasu (Minckley et al. 1989, Minckley et al. 1991, USFWS 2002b) and a number of UCRB rivers. Very few documentations of wild bonytail capture have been recorded in recent years and, therefore, little is known about the specific habitat requirements of this unique species. Bonytail are considered extirpated from the Colorado River between Glen Canyon Dam and Lake Mead, and they have a low probability of occurring at the inflow areas of Lake Powell (see below).

Populations within the Action Area. Populations of bonytail in the action area are limited primarily to those within Lake Mohave and Lake Havasu, and these populations are being augmented with stocking with hatchery-reared young due to lack of natural recruitment (Moyle 2002, USFWS 2001). A self-sustaining population has been established in the Cibola High Levee Pond that is not connected to the Colorado River. A few individuals may also be present in Lake Powell (USBR 2000). Small populations may still be present in the Upper Colorado River Basin in the Yampa River, Green River, and Colorado River at the Utah/Colorado border (USBR 2000, USFWS 2006). The last bonytail to be captured in Lake Powell during annual gillnet surveys (1972 through 2006) was in 1972 when a single adult was found (Utah DWR, 2007). Due to the small numbers that appear to be present in Lake

Powell and in the Colorado River upstream of the lake, the probability of any being present in the Colorado River inflow to Lake Powell is very low.

Reproduction. Vanicek and Kramer (1969) documented the last substantial spawning of a wild, riverine population of bonytail in Dinosaur National Monument. Ripe fish were collected from mid June through early July in water temperatures around 18ºC. Bonytail estimated between 5-7 years old were found ripe (Vanicek 1967), whereas in controlled hatchery environments, Hamman (1985) found bonytail to begin maturing sexually at age 2. Johnston (1999) classified bonytail as being broadcast spawners and suggested that loss of eddy habitat types due to the construction of impoundments may contribute to the apparent reproductive failure of a closely related species, the humpback chub. Marsh (1985) reported bonytail eggs to be adhesive and apparently remain so throughout the incubational period, which is thought to be an adaptive strategy to swift-moving currents of the mainstem Colorado River.

Ripe bonytail have also been collected from lentic, reservoir situations. As stated previously, Jonez and Sumner (1954) reported active spawning of a large (approximately 500 individuals) aggregate of bonytail in Lake Mohave. Eggs were described as being adhesive, and one individual female contained over 10,000 eggs, suggesting a high level of fecundity, a trait that appears to be typical for native, Colorado River endemics (see razorback sucker species profile). Even higher levels of fecundity were found in hatchery settings, with individual female egg production averaging over 25,000 eggs per female (Hamman 1982). Spawning bonytail in Cibola High Levee Pond were observed utilizing shoreline riprap materials, typically in mid April and frequently during nighttime hours, in water temperatures ranging from 20.4-21.6ºC. They were observed consuming their own gametes, as well as young razorback sucker larvae (Mueller et al. 2003).

Valdez (2006) summarized spawning and incubation temperatures for bonytail as 18-22ºC with an optimum of 20ºC and 18-28ºC with an optimum of 21ºC, respectively.

Bonytail egg survival appears to be highly influenced by incubation temperature. Hamman (1982) found 90 percent survival at water temperatures of 20-21ºC, 55 percent survival at 16-17ºC, and only 4 percent survival when temperatures were held between 12-13ºC. Incubation periods ranged from 99 hours to nearly 500 hours, depending upon water temperatures. Newly hatched fry averaged 6.8 mm (Hamman 1982). This research is corroborated by Marsh (1985), who found bonytail embryos to have the highest survival rates at temperatures near 20ºC and indicated that newly hatched larvae averaged 6.0-6.3 mm in size.

Diet. Bonytail diet is reportedly comprised of a wide variety of aquatic and terrestrial insects, worms, algae, plankton, and plant debris (Mueller and Marsh 2002). This information is corroborated by McDonald and Dotson (1960) and Vanicek (1967) who also found Colorado River chub to feed omnivorously. More detailed and quantitative descriptions of bonytail diet preferences are not available, including shifts in diet composition by life stage, with the exception of information from bonytail stocked into Cibola High Levee Pond. This experimental population also fed omnivorously, with adult bonytail consuming algae, vegetative material, small fish, and crayfish (Procambarus and *Orcopectes* sp.). Young bonytail were documented to feed near the surface of the pond, with gut analysis demonstrating that smaller size classes typically fed on zooplankton and invertebrates (Mueller et al. 2003). Again, more detailed knowledge is unavailable, likely due to the overall rarity of the species.

Habitat. As stated previously, information pertaining to bonytail habitat preferences is very limited due to the extirpation of this species prior to extensive sampling of the Colorado River and its fishery. Limited, early fisheries surveys indicate that the bonytail tended to be found in higher-gradient, gravelly riverine sections, with some degree of habitat use similarities as described for the flannelmouth sucker. For example, bonytail is widely characterized as being adapted to the swifter sections of the Colorado River, with affinity for areas of high flow and rocky habitat. Available information suggests that adult bonytail used fast-water sections, as well as eddies and pool habitats. Vanicek (1967) noted habitat selection of bonytail to coincide with habitats occupied by another native chub, the roundtail chub. Vanicek (1967) found these species in pools and eddies, typically near “fast-flowing” riverine areas but also in slower sections. Holden (1991), citing Flaming Gorge preimpoundment surveys, noted that bonytail were apparently fairly common in the Flaming Gorge area of the upper Green River, a canyon-bound, relatively fast water section of river. Valdez (1990) reported bonytail habitat use as being similar to that of humpback chub, with collections being made in shoreline eddy habitats, boulders and cobble, and near swift-water sections (in Cataract and Desolation Canyons).

Telemetry studies by Mueller et al. (2003) revealed that adult bonytail prefer interstitial spaces associated with shoreline riprap during daylight hours in Cibola High Levee Pond, whereas open-water areas are more commonly utilized during the nighttime hours. Intensive telemetric surveillance suggests a high degree of site-specific habitat fidelity, with individually marked bonytail consistently returning to the same cavities formed within the riprap type shoreline. These areas may simulate the boulder fields of many of the Upper Colorado River Basin canyon areas where bonytail were once common. Interestingly, a study conducted by Pimentel and Bulkley (1983) suggests that bonytail, when given the opportunity, tend to select water with high levels of total dissolved solids (TDS). Bonytail are able to persist in water with TDS of 4,700 mg/L, the highest tolerance reported for any species of Colorado River Gila, suggesting an ability to persist despite anthropogenic water quality and habitat degradation.

Bonytail have been documented to spawn over gravel substrates, near shore, and were found in water up to 30 ft deep in reservoir situations (Jonez and Sumner 1954). They are hypothesized to use gravel-cobble habitats in lotic environments. Most recently in the Lower Colorado River Basin (LCRB), documentation of successful, natural reproduction in Cibola High Levee Pond suggests that bonytail select shoreline-associated, riprap materials (large-diameter gravel, cobble, and boulder substrates) in water 2-3 m deep for spawning activities (Mueller et al. 2003). Spawning individuals in Lake Mohave display similar diet habitat shifts: adults use in deeper habitats during the day and later form congregations along shoreline habitats (Mueller and Marsh 2002).

Relatively little is known about habitat needs for young bonytail. Similar to other native fishes, backwaters and other slackwater habitat types are thought to serve as important nursery areas for young bonytail (USFWS 2002b). Larval roundtail and humpback chub tend to use low-velocity backwaters, embayments, and other small, low-velocity habitats along shorelines, moving to water with more current as they become larger (50-75 mm) (Holden 1977, Valdez 1990, Valdez and Ryel 1997). Whether bonytail exhibit the same habitat shift is not known, but it is very likely that the primary reason for the loss of bonytail throughout the basin is related to loss of important nursery habitat. Relatively narrow nursery habitat requirements separate razorback sucker and Colorado pike minnow from the non-endangered, more common species such as flannelmouth sucker and roundtail chub. Therefore, it seems likely that in a riverine situation bonytail may have a nursery habitat requirement that has not as yet been fully explained.

Young bonytail were most commonly associated with areas of dense overhead cover in depths greater than 1 m. They displayed schooling in warm, shallow areas of Cibola High Levee Pond (Mueller et al. 2003). These findings suggest that refugia-type backwaters designed for bonytail should have similar components in terms of riprapped shoreline materials, one of the few specific habitat preferences that have been documented to date.

Threats. Numerous researchers have identified that the major factor contributing to the decline of bonytail and other large-river fishes has been the construction of mainstem dams and the resultant cool tailwaters and reservoir habitats that replaced a once warm, riverine environment (Holden and Stalnaker 1975, Minckley et al. 1991, Mueller and Marsh 2002, USFWS 2002b). Competition and predation from non-native fishes that are successfully established in the Colorado River and its reservoirs have also contributed to their decline (Minckley and Deacon 1991, USFWS 2002b). For further detailed information including examples, ramifications, and research needs pertaining of the effects of habitat modifications on native Colorado River fishes, please see Tyus (1982), Minckley and Deacon (1991), Mueller and Marsh (2002), and USFWS (2002b).

R.2.4.4 Humpback chub

Legal Status. Humpback chub is listed as endangered under the ESA. Critical habitat has been designated in the Colorado River from Nautiloid Canyon to Granite Park in the Grand Canyon, and in the lower eight miles of the Little Colorado River, including its confluence with the Colorado River.

Historical and Current Range. Historically, humpback chub populations existed in the Little Colorado, Green, Yampa, White, and mainstem Colorado Rivers. The species was first described in 1946, and exact historical distributions within the Colorado River Basin cannot be confirmed.

Populations in the upper basin occur in canyon reaches of the mainstem Colorado, Green, and Yampa Rivers (Tyus et al. 1982). Populations exist in the Black Rocks and Westwater Canyon reaches of the mainstem Colorado River (Badame and Hudson 2003, Wick et al. 1981, Valdez and Clemmer 1982, Archer et al. 1985) and in Desolation and Gray Canyons on the Green River (Jasckon and Hudson, 2005). In Westwater Canyon an estimated 2,201 to 4,744 adults were present in 1998 to 2000 (Badame and Hudson 2003), and at Black Rocks an estimated 478 (confidence interval of 221 to 1,176) were present in 2003 (unpublished data, C. McAda personal communication, 2007). The population of adults in Desolation and Gray canyons on the Green River was estimated at 937 to 2,612 in 2001 to 2003 (Jackson and Hudson 2005). The Yampa Canyon population is thought to be nearly extirpated (Finney et al. 2006).

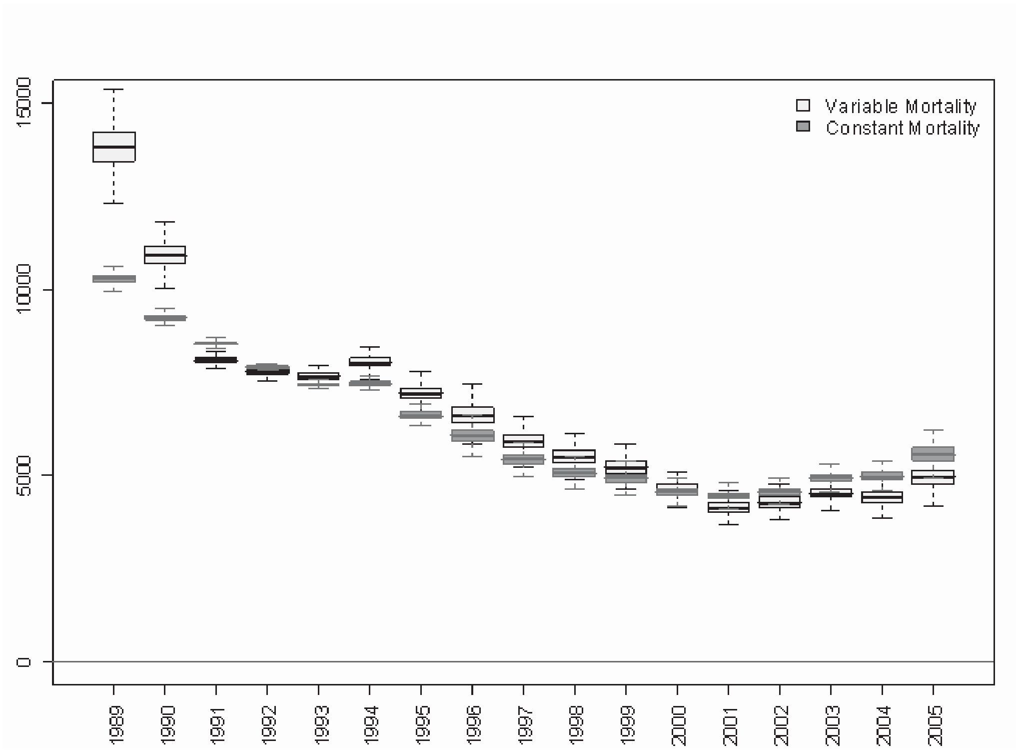
Populations within the Action Area. In the action area, humpback chub is present in the Marble and Grand Canyons of the Colorado River, and in the Little Colorado River for 13 km (8 miles) upstream from the river's mouth (Kaeding and Zimmerman 1983, Maddux et al. 1987). Valdez and Ryel (1995) identified 10 aggregations of humpback chub in the Grand Canyon, mostly near tributary inflows. Young-of-year humpback chub were reported from the warm spring at RM 30 in 1994 as compelling evidence of reproduction at that locale (Valdez and Masslich 1999). Also, young-of-year humpback chub were collected in substantial numbers in both 2005 and 2006 between RM 30 and the LCR, suggesting spawning success in the main channel Colorado River during those years (Ackerman 2007). Observations of this sort since closure of the dam are almost nonexistent and it is hypothesized that water temperatures warmer than the post-dam average may be largely responsible for the successful spawning activity.

In the Little Colorado River, Douglas and Marsh (1996) estimated a population size of 4,508 humpback chub. This population declined from 1989 to 2000 but appears to have stabilized between 2001 and 2005 (Figure R-2) at approximately 5,000 adult fish (USGS 2006a). Stabilization may be due in part to increased water temperatures caused by drought and warmer release temperatures from Glen Canyon Dam, experimental removal of non-native fish, and experimental water releases. The species has also been successfully translocated to above Chute Falls in the Little Colorado River, and the fish have spawned there (USGS 2006b).

Aside from mainstem reaches immediately below the LCR, YOY and juvenile humpback chub occur in the main channel Colorado River most commonly from RM 110-130 (Middlge Granite Gorge) and RM 160-200 (AGFD 1996; Trammell et al. 2000; Lauretta and Johnstone and Lauretta 2004, 2007; Ackerman 2006). The Middle Granite Gorge aggregation (which includes adults) has been stable or increasing in size since 1993 (Trammell et al. 2000) and may be sustained via immigration from the LCR spawning aggregation. Valdez et al. (2000) has identified this aggregation as the most likely candidate for a second spawning population in the main channel given favorable conditions (mainly temperature).

Observations of humpback chub below Diamond Creek are sporadic due to infrequent sampling. In the 1940s, five humpback chub were collected from the Colorado River near Spencer Creek (Miller 1944; Bookstein et al. 1985), and one juvenile humpback chub was reported from Spencer Creek in the 1950s (Wallis 1951; Kubly 1990). One adult humpback chub was captured downstream of Maxson Canyon (RM 244; RKM 407) in 1994 (Valdez 1994). More recently, four humpback chub were collected between Diamond Creek and Lake Mead during 2006 (AGFD, unpublished).

Figure R-2
Adult (age 4+) Humpback Chub Population Estimates (1989-2005) for the Little Colorado River.
Confidence Intervals are 95% Bayesian Credible Intervals. (Source: USGS 2006a)



Habitat. Humpback chubs use swift, deep, canyon stretches of river (Valdez and Clemmer 1982, Archer et al. 1985). Within the lower basin canyon reaches, adults occupy main channel eddies, and subadults are near shore (Valdez and Ryel 1995). Converse et al. (1998) report that the highest densities of subadult humpback chub in the Grand Canyon occur along vegetated shorelines. Kaeding and Zimmerman (1983) found this species in association with large travertine dams in the Little Colorado River. Maddux et al. (1987) captured young-of-the-year humpback chub in sandy runs and backwaters of the Little Colorado River. Valdez and Ryel (1995) found that subadult and adult humpback chub demonstrate diel depth preferences, using deeper water during the day and shallower water at night.

Although humpback chub are generally considered nonmigratory, migrations to spawning areas may occur from the main river to tributary streams, including the Little Colorado River (Kaeding and Zimmerman 1983). The abundance and persistence of the humpback chub in the Grand Canyon reach of the Colorado River may be linked to the use of the Little Colorado River for spawning and nursery habitat (Carothers and Minckley 1981).

In the Grand Canyon, humpback chub larvae are found almost exclusively in the warmer waters of the Little Colorado River (Carothers and Minckley 1981, Maddux et al. 1987) and in mainstem backwaters. Larvae tend to utilize silty bottom habitats. Later, humpback chub utilize a variety of habitats within a boulder strewn canyon environment (i.e., pools, riffles and eddies). They move between habitats dependent on life history needs and natural habitat change (NPS 1998).

Reproduction. Humpback chub reproductive timing is variable; ripe fish have been collected from April to July and at water temperatures of 11.5–23ºC. Under laboratory conditions, however, egg hatching success is greatest at 20ºC (Marsh 1985). Bulkley et al. (1981) estimate a final thermal preferendum of 24ºC for humpback chub during their first year of life (80–120 mm). Valdez (2006) summarized humpback chub temperature requirements as ranging from 16-22ºC with an optimum of 18ºC for spawning and ranging from 16-27ºC with an optimum of 19ºC for egg incubation.

Diet. Humpback chub are omnivorous (Valdez and Carothers 1998). Juvenile humpback chub forage near the substrate, feeding on benthic insect larvae and organic detritus (Carothers and Minckley 1981). Midge larvae, biting midge larvae, fly larvae, and planktonic crustaceans were found in the stomach contents of a juvenile humpback chub collected during the winter (Carothers and Minckley 1981). Adult humpback chub have been observed feeding on *Cladophora* and organic debris (Carothers and Minckley 1981). Valdez and Ryel (1995) found that adult humpback chub from the Little Colorado River and Middle Granite Gorge consumed primarily *Gammarus* sp. (freshwater amphipod), Simuliids (black flies), and terrestrial invertebrates. They concluded that food was not a limiting factor for juvenile and adult humpback chub.

Threats. Numerous researchers have identified that the major factor contributing to the decline of humpback chub and other large-river fishes has been the construction of mainstem dams, which had resulted in altered thermal and hydrologic regimes. Cold, stenothermic dam releases and reservoirs have replaced warm, riverine environments (Holden and Stalnaker 1975, Minckley et al. 1991, Mueller and Marsh 2002, USFWS 2002c). Competition and predation from non-native fishes that have adapted to these conditions have also contributed to decline of native fishes (Minckley and Deacon 1991). For further detailed information including examples, ramifications, and research needs pertaining of the effects of habitat modifications on native Colorado River fishes, see Tyus (1982), Minckley and Deacon (1991), Mueller and Marsh (2002), and USFWS (2002c). Spatial distribution of humpback chub in the Colorado River basin is limited by the species' affinity for and distribution of swift, deep canyon stretches of river within the system (Valdez and Clemmer 1982, Archer et al. 1985). The Colorado River exhibits diurnal and seasonal flow fluctuations in response to variable hydroelectric demands. The diurnal fluctuations in stage approach 2 feet, in contrast to daily flow changes of less than a foot prior to impoundment. The temporal stability of inshore, shallow water, backwater, and low-water environments used by native fish for resting, feeding, spawning, and nursery areas is greatly decreased by existing fluctuating flows (Maddux et al. 1987).

The cooler temperature of the Colorado River due to Glen Canyon Dam releases is strongly implicated as a primary cause of the humpback chub population decline. Egg hatching success of humpback chub is highly temperature dependent, with the highest success occurring at a water temperature of about 20ºC and very low success at temperatures below 15ºC (Hamman 1982, Marsh 1985). Water released by Glen Canyon Dam from Lake Powell is generally cold, with temperatures ranging from 6–12ºC (Maddux et al. 1987). However, recent release temperatures approaching 15°C along with downstream warming may benefit various life stages of humpback chub. When low release temperatures occur, reproductive success of humpback chub in the mainstem Colorado River is drastically reduced below Glen Canyon Dam. . If successful spawning occurred in the mainstem Colorado River, humpback chub would still be adversely affected by the daily fluctuations in discharge below Glen Canyon Dam, which can dry and introduce colder mainstem water to backwaters used by young-of-the-year humpback chub.

Interactions with the many introduced nonnative species continue to threaten the existence of humpback chub. Nonnative species tend to be highly competitive and productive generalists. Habitat and dietary overlap exists between humpback chub and many nonnative species. In the upper basin, common carp (Behnke and Benson 1983, Valdez 1990), green sunfish, largemouth bass, redside shiner (Joseph et al. 1977), red shiner (Joseph et al. 1977, Valdez 1990), and channel catfish (Joseph et al. 1977, Behnke and Benson 1983, Valdez 1990) use habitats with similar environmental conditions as humpback chub. Valdez and Ryel (1995) found habitat and dietary overlap between rainbow trout and humpback chub in the Grand Canyon. Spawning and egg hatching temperatures are similar for humpback chub and common carp, fathead minnows, and channel catfish (Valdez and Carothers 1998). Nonnative fish spawning sympatrically (i.e., in the same area) may displace humpback chub or reduce success. Some species are also predators on humpback chub. Predation by channel catfish, brown trout, rainbow trout, and black bullhead on humpback chub has been documented (Valdez and Ryel 1995).

R.2.4.5 Razorback Sucker

Legal Status. Razorback sucker were listed as endangered under the ESA in 1991. Critical habitat has been designated and it includes the Dirty Devil arm of Lake Powell and the Colorado River and its 100 year floodplain from the confluence of Paria River (located below Glen Canyon Dam) to Hoover Dam, including Lake Mead to its full pool elevation (59 FR 13399).

Historical and Current Range. Razorback sucker was historically widespread and common throughout the larger rivers of the Colorado River Basin, from Sonora and Baja, California, into Arizona, Colorado, Nevada, New Mexico, and Wyoming (Minckley et al. 1991, Marsh 1996). Gilbert and Scofield (1898) noted particularly high razorback sucker abundance in the Lower Colorado River Basin (LCRM) near Yuma, Arizona.

To date, the only substantial natural razorback sucker recruitment (low, yet steady numbers) and documentation of razorback sucker progression through all life stages in the LCRB occurs in Lake Mead, with limited and sporadic captures of naturally occurring fish throughout the remainder of the LCRB (Marsh and Minckley 1989; Holden et al. 1997, 1999, 2000a, 2000b, 2001; Abate et al. 2002; Welker and Holden 2003; Welker and Holden 2004). Razorback sucker do occur above Lake Powell and some may wash down into Lake Powell and persist at the inflow areas. However, there is not a regionally significant population of razorback sucker within Lake Powell. Razorback sucker are rarely caught in the Colorado River between Glen Canyon Dam and Lake Mead and are widely considered extirpated from this reach (Gloss et al. 2005). Annual monitoring at random locations in this reach of the river has not captured any razorbacks in more than 15 years. In 1997, 15 hatchery-reared razorback suckers were released into the lower gorge by the Hualapai Tribe (NPS 2005). Thus, it is possible that a few individuals could still be present.

Several investigators have reported hybrids between razorback suckers and flannelmouth suckers in Grand Canyon (Suttkus et al 1976; Maddux et al. 1987; Valdez and Ryel 1995). Although hybridization between these species has been reported for many years (Hubbs and Miller 1953; McAda and Wydoski 1980), the incidence in Grand Canyon appears high relative to the number of razorback suckers, especially in the LCR where these fish concentrate during spawning (Douglas and Marsh 1998).

Populations within the Action Area. Razorback sucker populations are present in Lake Havasu, Lake Mohave, Lake Mead, as well as in the Cibola High Levee Pond and Senator Wash in the lower Colorado River Basin. This species has been stocked in Lakes Mohave, Havasu, and Mead as well as in the Colorado River below Parker Dam (USFWS 2001). The population estimate for Lake Mohave is 3,000 to 4,000 fish (Stefferud et al. 2003), and less than 300 fish may be present in Lake Mead (USBR 2000). Spawning and recruitment of razorback suckers has been documented for Lake Mead through a monitoring program funded by the Bureau of Reclamation and the Southern Nevada Water Authority (Welker and Holden 2003). Larvae have been collected, and age calculations for juvenile to adult fish are 4 to 35 years indicating that recruitment has taken place. Spawning occurs in Echo Bay and Las Vegas Bay/Wash. Spawning also appears to be occurring in Lake Havasu, Senator Wash, and in the river below Parker Dam with low recruitment (Moyle 2002). Due to spawning and recruitment of razorback suckers in Lake Mead, individuals of this species could move upstream into the Colorado River from the lake.

No population estimates of razorback sucker have been conducted in the upper basin, The species is known to be present in Lake Powell at the mouths of the Dirty Devil, San Juan, and Colorado rivers (USFWS 2006), in the Green River to the confluence with the Colorado River (Modde et al. 2002), and in the San Juan River (Pfeifer et al. 2002). Stocking is being undertaken to augment the populations it the upper basin. Razorback suckers from previous stocking were collected in 2005 (46 individuals) and 2006 (64 individuals) during nonnative control in the lower San Juan River with three adults captured below the waterfall (RM 0.6) in 2005 and one adult taken below the waterfall in 2006 (Jackson 2006, Elverud and Jackson 2007). Approximately one to four individuals are regularly captured in the annual surveys of the San Juan arm of Lake Powell, and all are from hatchery stock (Gustaveson 2007). Gillnet surveys in Lake Powell have recorded one adult razorback in 1975 at the Good Hope station, two at the Wahweap station in 2006, and seven in the San Juan arm in 2004 plus 2006 (Utah DWR, 2007). Larval drift data from the middle Green River in Utah strongly suggests successful reproduction by stocked fish (Bestgen and Haines 2006), and wild juvenile suckers have been collected in the lower San Juan River in recent years.

Habitat. . Bestgen (1990) indicates that razorback sucker may have historically been uncommon in the turbulent canyon reaches of the Colorado River, citing research by Tyus (1987) and Lanigan and Tyus (1989) that suggests that razorback sucker in the Green River (the largest known riverine population) were typically found in calm, flatwater river reaches, not turbulent, fast-water canyon reaches. This trend is evident even within basins, as razorback sucker are typically collected in sand-bottomed, low gradient, flatwater reaches outside of the spawning period. However, razorback sucker inhabit virtually all components of riverine habitat at some point in their lives. In particular, low-velocity habitats such as backwaters, sloughs, oxbow lakes, and other slackwater habitats within the main channel were important for razorback sucker (Holden 1973, Holden and Stalnaker 1975, Behnke and Benson 1980, Minckley 1983). Seasonally submerged off-river habitats, including bottomlands and other marsh-like, lowland habitats, may have also been important habitat for razorback sucker prior to the construction of mainstream dams and the resultant changes in flow regimes, especially during spring-runoff periods (Tyus and Karp 1989, Bestgen 1990, Osmundson 2001).

More recent authors have documented that habitat selection by adult razorback sucker changes seasonally. Tyus and Karp (1990) document habitat use by adult razorback sucker to consist of flooded areas during spring months. Radiotelemetry efforts by Tyus (1987) identified adult fish utilizing near-shore runs during the spring, but they subsequently shifted habitat use during the summer to shallow waters associated with submerged mid-channel sandbars, with little use of backwaters. This suggests that the use of backwaters by razorback sucker may be overstated and an artifact of relatively easy capture with electrofishing rather than actual habitat use and preference. Osmundson and Kaeding (1989) reported adult razorback using pools and slow eddies from November through April, shifting to runs and pools from July through October. They also note increased backwater habitat use by adult fish during the months of May and June, the typical Upper Colorado River Basin (UCRB) spawning period.

Water velocity selection by adult razorback sucker is also typified by seasonal shifts in preferences. Tyus (1987) noted that during the summer, razorback sucker typically were found utilizing velocities averaging 0.5 m/s, while in the winter months adult fish were typically found in currents moving 0.03-0.33 m/s. These findings corroborate hypotheses and findings of Lanigan and Tyus (1989) and Minckley et al. (1991) that few adult razorback sucker utilize swift, whitewater habitats (e.g., Marble and Grand Canyons of the LCRB), although other efforts have documented movement of radio-telemetered fish through these locations (Tyus and Karp 1990). Furthermore, it becomes apparent that razorback sucker in a natural river setting do not appear to utilize solely backwater habitat types, although it appears that these habitats are important to young-of-year and juveniles. Lastly, adult razorback sucker have been reported to select shallower depths during the summer months

(0.9-1.65 m) while typically utilizing deeper depths during the winter months (1.65-2.16 m) (Osmundson and Kaeding 1989).

Razorback sucker are present in lentic environments in the LCRB, where they sometimes exhibit interesting and rather extensive habitat use. The majority of such information suggests that lentic-dwelling razorback sucker use a wide variety of habitats, including vegetated areas, littoral shoreline habitats, and substrates ranging from silt and sand to gravel and cobble. Adult razorback sucker have been documented via sonic surveillance to typically occupy depths less than 30 m (averaging between 3.1-16.8 m) and are generally located within 50 m from the shore during winter months (less than 30 m from shore during peak spawning activity). However, during summer months, adults were located at deeper depths, often surpassing 30 m, in an effort to hold body temperatures between 18-22 degrees C, a behavior thought to maximize bioenergetics (Marsh and Minckley 1989; Holden et al. 1997, 1999, 2000a, 2000b, 2001; Mueller et al. 2000; Abate et al. 2002; Welker et al. 2003; Welker and Holden 2004). Thermal preferendum for adult razorback sucker was estimated to lie within the range of 22-25 degrees C based on laboratory observations (Bulkley and Pimentel 1983).

In lentic (reservoir) settings razorback sucker larvae have been collected over a variety of habitat types, but they typically are collected over or near areas frequented by adult spawning aggregates. As a result, the majority of larval fish are captured over gravel and cobble, at near-shore locations, typically at depths of 0.0-4.9 m (Sigler and Miller 1963; Minckley 1983; Bozek et al. 1984; Marsh and Langhorst 1988; Holden et al. 1997, 1999, 2000a, 2000b, 2001; Abate et al. 2002; Welker et al. 2003; Welker and Holden 2004). In the Green River larval razorback sucker are entrained by spring flows into backwater and flooded bottomland habitats, where they benefit from warmer temperatures and abundant food resources (Tyus 1987, Muth et al. 1998). Historically, high spring flows flooded low-lying areas along the river and redistributed recently emerged and drifting larval razorback sucker into these food-rich backwaters and other seasonally flooded bottomlands, providing unique nursery habitats for razorback sucker (Tyus and Karp 1989, 1990; Modde 1996; Modde et al. 1996; Modde et al. 2005).

Habitat important to the juvenile life stages of razorback sucker remains relatively understudied, as catches of this size class remains minimal, presumably due to the predatory and competitory impacts of non-native species (Tyus 1987, Bestgen 1990, USFWS 1998b). The majority of juvenile, riverine catches come from the UCRB (Taba et al. 1965, Gutermuth et al. 1994, Modde 1996), with almost non-existent data on juvenile habitat use from the LCRB. Brandenburg et al. (2005) recently captured wild-spawned juvenile razorback sucker in the San Juan River. All of the juveniles in the San Juan River were found using seines in shoreline habitats including backwaters, embayments, and other lower-velocity habitats.

Reproduction. Although spawning razorback sucker have been collected over a variety of substrates, the majority of spawning individuals tend to be captured over clean gravel- and cobble-sized substrates (Douglas 1952, Tyus 1987, Bozek et al. 1990, Tyus and Karp 1990, Minckley et al. 1991). In UCRB rivers spawning occurs during the ascending limb of the hydrograph (Modde et al. 2005), which apparently an important adaptive feature for larvae as discussed below. Reservoir-spawning razorback sucker have been documented to successfully spawn in various LCRB impoundments. Spawning populations have been located in Lake Mead (Jonez and Sumner 1954; Holden et al. 1997, 1999, 2000a, 2000b, 2001; Abate et al. 2002; Welker and Holden 2003; Welker and Holden 2004), Lake Mohave (Bozek et al. 1984, Marsh and Langhorst 1988, Mueller 1989, Bozek et al. 1990), Lake Havasu (Douglas 1952, Minckley 1983), Senator Wash Reservoir (Medel-Ulmer 1980), and likely other locations. Spawning fish have been documented to congregate near river inflow areas that tend to be somewhat more turbid than the majority of the available spawning areas (Jonez and Sumner 1954; Holden et al. 1997, 1999).

The spawning season for razorback sucker has been reported to begin as early as November in some LCRB reservoirs and documented to continue through June in some populations of the UCRB. In upper basin riverine habitats, ripe razorback sucker have been collected from mid April to mid June, typically over a very limited time frame (4-5 weeks) (Tyus 1987; Osmundson and Kaeding 1989; Tyus and Karp 1989, 1990; Bestgen 1990). However, in lentic lower basin habitats the majority of spawning generally is carried out between January and April, months when water temperatures are typically within the range of 10-15 degrees C (Bestgen 1990). Male razorback sucker remain ripe for a period of 2-28 days, while females apparently are ripe for less time (2-15 days) in the Green River (Tyus and Karp 1990) but appear to have extended periods of sexual activity in lower basin reservoirs (Holden et al. 2001).

Research efforts by Bozek et al. (1990) show that successful incubation of razorback sucker eggs in Lake Mohave occurs between 9.5-15.0 degrees C, and in the laboratory successful embryo hatching occurs at 10-20 degrees C. Hatching (eggs at a controlled 15 degrees C) was reported to occur in 5.2-5.5 days (Minckley and Gustafson 1982). Egg mortality has been attributed to fluctuating water levels, scouring by currents and/or wave action, suffocation due to silt deposition, and non-native egg predation (Minckley 1983, Bozek et al. 1984). Fertilized gametes are reported by Minckley and Gustafson (1982) as adhesive for a 3-4 hour duration post fertilization, with cleavage being completed within 24 hours, gastrulation occurring at 34 hours, and blood circulation becoming established at 117 hours.

Valdez (2006) summarized temperatures required for spawning and egg incubation for this species as 12-22ºC with an optimum of 18ºC and 14-25ºC with an optimum of 19ºC, respectively.

Diet. Razorback sucker diet composition is highly dependant upon life stage, habitat, and food availability. Upon hatching, razorback sucker larvae have terminal mouths and shortened gut lengths (less than 1 body length) which in combination, appears to facilitate and necessitate selection of a wide variety of food types. Exogenous feeding occurs at approximately 10 mm TL (approximately 8-19 days), after which larvae from lentic systems feed mainly on phytoplankton and small zooplankton, while riverine inhabiting larvae are assumed to feed largely on chironomids and other benthic insects (Minckley and Gustafson 1982, Marsh and Langhorst 1988, Bestgen 1990, Papoulias and Minckley 1990, USFWS 1998b). Papoulias and Minckley (1992) reared larval razorback sucker in three different ponds containing different densities of food resources to demonstrate that increased growth was positively related to invertebrate densities, suggesting the importance of larval food switching from algal and detrital food items to a diet enriched with invertebrates. Papoulias and Minckley (1990) show that larval razorback mortality is minimized when food levels are within the range of 50-1,000 organisms/L.

Later during growth (age and size information unknown, but at some point during the juvenile life stage), razorback sucker undergo an ontogenetic shift in mouth morphology, with the mouth becoming more inferior and allowing for more efficient access to benthic food sources. Thereafter, razorback sucker likely consume a variety of benthic-associated food items (USFWS 1998b).

Threats. Numerous researchers have identified that the major factor contributing to the decline of razorback sucker and other large-river fishes has been the construction of mainstem dams and the resultant cool tailwaters and reservoir habitats that replaced a once warm, dynamic, riverine environment (Holden and Stalnaker 1975, Joseph et al. 1977, Wick et al. 1982, Minckley et al. 1991). This change in the physical environment presumably allowed for an increase in competition and predation from nonnative fishes, which are successfully established in the Colorado River and its reservoirs and have also contributed to native fish population declines (Minckley et al. 1991). In the middle Green River, also, lower peak flows (due to regulation) are thought to limit floodplain nursery habitat availability for larval fish (Muth et al. 2000).

R.2.4.6 Colorado Pikeminnow

Legal Status. Colorado pikeminnow were listed as endangered by U.S. Fish and Wildlife Service in 1967 and given full protection under the Endangered Species Act of 1973. Critical habitat was designated for Colorado pikeminnow in the upper Colorado River basin effective April 20, 1994. Critical habitat includes the Dirty Devil arm and the San Juan arm of Lake Powell in the action area. No critical habitat was designated in Arizona in the lower basin. Outside Arizona, six reaches in the upper Colorado basin [totaling 1848 km (1148 miles)], have been designated as critical habitat (AGFD 2001). Critical habitat is designated within the Colorado, Yampa, White and San Juan Rivers in the upper basin (59 FR 13384, March 21, 1994).

Historical and Current Range. Historically, Colorado pikeminnow were found in the mainstem of the Colorado River and its tributaries, from Wyoming to the Gulf of California. Currently, the species persists only in the upper Colorado River basin. In the upper Colorado River basin, the highest concentration of Colorado pikeminnow occurs in the Green River, from the mouth of the Yampa River to its confluence with the Colorado River. They have been reintroduced in the Salt and Verde Rivers in Arizona. Reintroductions are considered experimental, nonessential populations and reproducing populations of Colorado pikeminnow have not been established (Maddux et al. 1993).

Populations within the Action Area. The Colorado pikeminnow is present in the Colorado River downstream to Lake Powell (USFWS 2006), and the species is present in the San Juan River where it is also stocked (Pfeifer et al 2002). A few individuals are also present in Lake

Powell (USBR 2000). Nonnative fish control efforts in the lower San Juan River in 2005 and 2006 captured 287 and 256 juvenile pikeminnows, respectively, with only two collected below the waterfall in 2005 (Jackson 2006, Elverud and Jackson 2007). Studies of stocked Colorado pikeminnows in the San Juan River from 2002 through 2005 (Golden et al. 2006) collected 22 young pikeminnows between Clay Crossing and Lake Powell from November 2004 to November 2005. These data indicate that few individuals of Colorado Pikeminnow are present in the inflow area below the waterfall when Lake Powell elevations are low.

Habitat. Colorado pikeminnow are fish-eating, long-lived, large-river fish that use a variety of substrates, depths, and velocities. Historically, large adults were found in the turbid, silty waters of the Colorado River and large pools in tributaries to the Colorado River. Currently, they have a home range of approximately 5 km and move around the main stem river in their range. They utilize areas with slower currents, such as backwaters or near shore habitat. During spring and early summer, adult fish use areas inundated by spring flooding. Spring inundation of lowlands is believed to be important to the overall health of this species. Thermal adult preference is 25.3ºC (Black and Bulkley 1985).

Adult Colorado pikeminnow can display long-distance (up to 322 km) migratory behavior in sexually mature fish, and this behavior is important to reproduction (Maddux et al. 1993). Migration in the upper Colorado begins in early summer, possibly in response to falling water levels and increasing water temperatures. Colorado pikeminnow spawning migrations are initiated at water temperatures of 14-20ºC, while spawning occurs at an average temperature of 22ºC in late June to early August (Moyle 2002, 159). Colorado pikeminnow demonstrate a fidelity to spawning locations (Tyus 1985; Tyus 1990; Wick et al. 1983), with reproduction occurring in whitewater canyons. Fertilized eggs adhere to rocks and gravel. After spawning, adult fish return to their home range (Moyle 2002, 159).

In laboratory experiments, embryo hatching success was highest at 20ºC (Marsh 1985). Once larval pikeminnow emerge, they undergo a period of drift to reach nursery habitat. During the larval drift, they may be transported up to 161 km downstream (Tyus and Haines 1991). Nursery areas consist of ephemeral backwaters and shoreline embayments with little or no current (Tyus and Haines 1991). Bestgen (1996) reports that Colorado pikeminnow larval growth rate declines at water temperatures below 22ºC. Temperatures required for spawning and egg incubation summarized by Valdez (2006) are 16-14ºC with an optimum of 22ºC and 19-25ºC with an optimum of 22ºC, respectively.

Juveniles use quiet water habitats but move in and out of the habitats according to water temperatures. Juveniles prefer warmer temperatures in backwater areas rather than the cooler water temperatures in the main stem river. Bulkley et al. (1981) estimate the final thermal preferendums for juvenile Colorado pikeminnow to be 24.6ºC. Young Colorado pikeminnow have very specific streamflow and temperature requirements. Kaeding and Osmundson (1988) correlated lower water temperatures with reduced growth of age-0 Colorado pikeminnow and concluded that Colorado pikeminnow (45-100 mm) would not grow at water temperatures below 13ºC.

Reproduction. Naturally reproducing populations are presently found in the Green, Yampa, upper Colorado, Gunnison and San Juan Rivers. Approximately 8,000 adults spawn in the Green River basin (USFWS 2002d, Appendix A-2); 1,400 adults in the Yampa River (USFWS 2002d, Appendix A-2); and about 600–900 adults (USFWS 2002d, Appendix A-2) are believed to spawn in the upper Colorado River and near Grand Junction, Colorado, and in the lower Gunnison River (USFWS 2002d, Appendix A-2). Adult spawning estimates in the San Juan River range from 19 to 50 fish (USFWS 2002d, Appendix A-2). Average fecundity of 24, 9 year old females was 77,400 (range, 57,766–113,341) or 55,533 eggs/kg, and average fecundity of 9 ten-year old females was 66,185 (range, 11,977–91,040) or 45,451 eggs/kg (USFWS 2002d, Appendix A-2). Hybridization with other species is not known to occur.

Diet. Juveniles up to 50 mm in length consume zooplankton and insect larvae. Colorado pikeminnow from 50-100 mm in length feed on insects, and individuals larger than 200 mm eat mostly fish (Vanicek and Kramer 1969).

Threats. Numerous researchers have identified that the major factor contributing to the decline of Colorado pikeminnow and other large-river fishes has been the construction of mainstem dams and the resultant cool tailwaters and reservoir habitats that replaced a once warm, riverine environment (Holden and Stalnaker 1975, Minckley 1991, Mueller and Marsh 2002, USFWS 2002d). Competition and predation from non-native fishes that are successfully established in the Colorado River and its reservoirs have also contributed to their decline (Minckley and Deacon 1991, USFWS 2002d).

R.2.4.7 Kanab Ambersnail

Legal Status. Kanab ambersnail was listed as an endangered species in 1992 under the ESA (USFWS 1992). No critical habitat has been designated in the action area. The species is undergoing a 5-year review by the FWS, including a genetic evaluation of the species relatedness to other *Oxyloma*.

Historical and Current Range. The genus *Oxyloma* has a broad distribution (North America, Europe and South Africa) with two species recognized in the southwestern U.S.: *O. retusa* in New Mexico and *O. haydeni* in Arizona and Utah. Within O. haydeni there are two subspecies, the Niobrara ambersnail (*O. h. haydeni*) and the Kanab ambersnail (*O. h. kanabensis*), both of which are found in Arizona and Utah. Populations of Kanab ambersnail presently occur from only three springs: one at Three Lakes, near Kanab, Utah, and two in the in Grand Canyon National Park, Arizona, one at a spring and hanging garden at Colorado River mile 31.5 R known as Vaseys Paradise and a translocated population at Upper Elves Chasm, at Colorado river mile 116.6mi L (Gloss et al. 2005). In the Kanab area, two populations were known to exist, but one was extirpated by desiccation of its habitat. The remaining population at Three Lakes is located on private lands at several small spring-fed ponds on cattail (*Typha* sp.) (Clarke 1991).

KAS populations in the American Southwest are believed to be relictual populations from the Late Pleistocene ice age, when springs, seeps, and wetland habitat were more abundant in the region (Spamer and Bogan 1993, Szabo 1990). Historically, the Grand Canyon region may have harbored many populations of ambersnails in close proximity to each that are now lost under Lake Powell. Through analysis of historic photographs of the region, an increase in the vegetative cover along the Canyon to river level has occurred since the completion of the Glen Canyon Dam in 1963 (Turner and Karpiscak 1980). This increase in cover, the reduction in beach-scouring flows, and the introduction of non-native water-cress (*Nasturtium officinale*) has lead to an increase in suitable KAS habitat area at Vaseys Paradise of more than 40 percent from pre-dam conditions (Stevens et al. 1997a). It is believed that a similar increase in abundance of KAS occurred in this region over this same time period.

Intensive search efforts at more than 150 springs and seeps in tributary canyons to the Colorado River between 1991 through 2000 found no additional KAS in the region (Sorensen and Kubly 1997, 1998, Meretsky 2000, Meretsky and North 2000, Webb and Fridell 2000). As part of the KAS recovery effort required under the ESA, three natural springs along the Colorado River corridor were stocked with young snails in September 1998 (AGFD 1998). Release sites were selected in areas above the historic flood elevation (~100,000 cfs stage) and where populations would not be affected by dam operations. One translocation site, Upper Elves Chasm, has established as a new population and continued monitoring efforts have detected numerous KAS persisting and reproducing at the initial release area, including migration into suitable adjacent habitat (Gloss et al. 2005).

Populations within the Action Area. Populations within the action area occur along the Colorado River at Vaseys Paradise and a spring and hanging garden at Colorado River Mile 31.5 R. No other populations are known within the action area.

Habitat. The Kanab Ambersnail is dependent upon wetland vegetation for food and shelter. KAS lives in association with watercress (*Nasturtium*), monkeyflower (*Mimulus*), cattails (*Typha*), sedges (*Carex*), and rushes (*Juncus*). KAS populations in the Grand Canyon region occur in areas where water sources originate from limestone or sandstone geologic strata (Stevens et al. 1997a). Stevens et al. (1997a) found KAS predominantly using crimson monkeyflower and water-cress for food and shelter at Vaseys Paradise and therefore identified these two species as key habitat components for KAS. The other Grand Canyon population, Upper Elves Chasm, is located above the 100,000 cfs stage of the river and is characterized by predominately crimson monkeyflower and maidenhair fern (*Adiantum capillus-veneris*), with lesser amounts of sedges (*Carex aquatilis*), rushes (*Juncus* sp.), cattails (*Typha* sp.), water-cress, helleborine orchids (*Epipactis gigantea*) and grasses (Nelson and Sorensen 2002). From evidence collected in laboratory conditions, microclimatic conditions such as higher humidity and lower air temperatures relative to the surrounding environments and high vegetative cover may be important habitat features related to KAS survival (Sorenson and Nelson 2002).

Reproduction. Kanab ambersnail are believed to live approximately 12-15 months and are hermaphroditic and capable of self-fertilization (Clarke 1991, Pilsbry 1948). Mature KAS mate and reproduce during the summer months (July and August), and deposit clear, gelatinous egg masses on undersides of moist to wet live stems, on the roots of water-cress, and on dead stems of crimson monkey-flower (Stevens et al. 1997a). In some years with relatively warm winters, more than one reproductive period can occur. Adult mortality increases in late summer and autumn leaving the overwintering population dominated by subadults. Young snails enter dormancy in October-November and typically become active again in March-April. Over-winter mortality of KAS can range between 25 and 80 percent (Stevens et al. 1997a & 1997b and IKAMT 1998).

Diet. This species of land snail feeds on plant tissue, bacteria, fungi and algae. It scrapes this food off of plants by means of a radula or rasp tongue. Stevens et al. (1997b) observed KAS feeding largely on crimson monkey-flower and water-cress.

Threats. Current threats to KAS include loss and adverse modification of wetland habitats, which are scarce in this semi-arid region (USFWS 1995c). The habitat for the Utah population is at risk due to commercial development by the private landowner. Historically, the Grand Canyon experienced annual floods of 90,000+ cubic-feet per second (cfs) and KAS were likely swept downstream and drowned (Stevens et al. 1997a). Today, Glen Canyon Dam limits such flood events, although several flows >45,000 cfs have occurred in the last 30 years (IKAMT 1998). For example, during the March 1996 experimental beach/habitat-building flow (BHBF) in the Grand Canyon, up to 16 percent of KAS habitat at Vaseys Paradise was lost or degraded and hundreds of snails were lost. Recovery of this habitat to pre-flood conditions required over two years (IKAMT 1998, Stevens et al. 1997b).

On a lesser scale, trampling by recreationists and flash floods from the talus slope above Vaseys Paradise also contribute to habitat loss and can results in direct KAS mortality. Due to steep slopes and a dense cover of poison ivy at this location, the impacts from recreationists are reduced. Additionally, plateau-origin flash floods are rare in the region (Stevens et al. 1997a).

Evidence exists that a small number of Kanab ambersnails at Vaseys Paradise were parasitized by a trematode, tentatively identified as *Leucochloridium* sp. (Stevens et al. 1997b). Potential vertebrate predators include rainbow trout (*Oncorhynchus mykiss*) in the stream mouth, summer breeding Say's and black phoebe (*Savornis savi* and *S. niaricans*), canyon wren (*Catherpes mexicanus*), winter resident American dipper (*Cinclus mexicanus*), and canyon mice (*Peromyscus crinitus*) (Stevens et al. 1997b, USFWS 1995c). Hard evidence of KAS consumption and predation rates by birds and mice are not available, but analysis of mice feces indicates that snails are not regularly eaten by rodents (Meretsky and Wegner 1999). Another natural threat is bighorn sheep. Water sedge, a plant with patchy distribution in Kanab ambersnail habitat, is a source of forage for bighorn sheep (*Ovis canadensis*), especially during a drought. As a result, the springs at Vasey's Paradise are now habitually visited by bighorn sheep, resulting in vegetation used by the snails being regularly trampled (Gloss et al. 2005).

R.3 Effects Analysis

R.3.1 Analysis Methodology and Assumptions

This section describes the methods and assumptions used to conduct the analysis of potential effects of the proposed action on the evaluated species in the Lake Powell to Lake Mead portion of the action area. Methods and assumptions used to conduct the analysis of SNWA's interdependent actions on the Muddy and Virgin River portions of the action area are described in Attachment B.

The approach for analyzing effects of the proposed action for the Lake Powell to Lake Mead portion of the action area consisted of comparing Lake Powell elevations, river flows, average monthly river temperatures at Lees Ferry, the Little Colorado River confluence and below Diamond Creek, and river sediment transport under the baseline condition to conditions expected under the proposed action and evaluating if differences in hydrologic conditions under the proposed action would affect ESA-listed, proposed, and candidate species and designated critical habitats.

R.3.1.1 Lake Powell Reservoir Elevation and Releases

Future Colorado River system conditions under the baseline and the proposed action conditions were simulated using the Colorado River Simulation System (CRSS). The model framework used for this process is a commercial river modeling software called RiverWare™. RiverWare™ is a generalized river basin modeling software package developed by the University of Colorado through a cooperative process with Reclamation and the Tennessee Valley Authority. CRSS was originally developed by Reclamation in the early 1970s and was implemented in RiverWare™ in 1996. River operation parameters modeled and analyzed in CRSS include the water entering the river system, storage in system reservoirs, releases from storage, river flows, and the water demands of and deliveries to water users in the Basin States and Mexico.

The future water supply used as input to the model consisted of data sampled from the historic record of natural flow in the river system over the 100-year period from 1906 through 2005 from 29 individual inflow points (or nodes) on the system. The future Colorado River water demands were based on demand and depletion projections prepared by the Basin States. Depletions are defined as diversions from the river less return flow credits, where applicable. The operation of the mainstream reservoirs including Lake Powell and Lake Mead is provided as a set of operating rules which describe how water is released and delivered under various hydrologic conditions. Additional information on the hydrologic modeling methodology is available in Section 4.2 of the Final EIS.

CRSS modeling outputs used to conduct the analysis of effects are presented in Attachment C. CRSS model outputs included the relative probability of different sized annual releases and minimum, average and maximum daily releases associated with various levels of annual release. The 10th, 50th and 90th percentile monthly releases from Glen Canyon Dam were also evaluated as a relative indicator of flow conditions between Glen Canyon Dam and Lake Mead. The 10th, 50th, and 90th percentile Lake Powell elevations were used to evaluate potential changes to Lake Powell conditions.

R.3.1.2 Water Temperature

Lake Powell undergoes seasonal transformations that can dramatically affect the temperatures of both the reservoir and the dam releases. During the spring, solar radiation and warmer air temperatures begin to warm the upper surface layers of the reservoirs. This warming is also affected by spring inflow volumes and temperatures. Larger inflows bring greater volumes of warmer water that can cause higher release temperatures. Reservoir draw downs can bring the warmer surface water closer to the power plant intake penstocks, also producing warmer releases. As summer progresses, surface warming of reservoirs increases, as does the warming of releases as the water moves downstream. During the winter months, reservoir temperature stratification is usually eliminated by reservoir mixing, and both reservoir and downstream water cooling occurs. Reclamation's CE-QUAL-W2 model was used to simulate this annual process and to analyze dam release temperatures for various reservoir starting elevations and inflows. The CRSS output of dam release and reservoir elevations was used in the CE-QUAL-W2 model to establish a relationship between reservoir elevations and dam release temperatures and project the impact of reservoir draw down on dam release temperatures. Calibration of the CE-QUAL-W2 model for Lake Powell used historic temperature profiles from 1990 to 2005 at 13 reservoir stations.

This 15-year data set provided a limited range of historic reservoir elevations, inflows, and releases. By using a combination of historic and modeled data for various reservoir elevations, and by analyzing the impact of a repetition of the recent drought years, dam release temperatures for a larger range of reservoir elevations could be analyzed.

The Generalized Environmental Modeling System for Surface Waters (GEMSS) model was used to route Glen Canyon Dam release temperatures through the Grand Canyon downstream to Lake Mead. The GEMSS model was calibrated for water temperature at three locations in this river reach: Lees Ferry, 15.9 miles downstream of Glen Canyon Dam; a point one mile downstream of the Little Colorado River confluence; and the Diamond Creek gaging station 240 miles downstream of Glen Canyon Dam. Below Diamond Creek, water temperatures approached equilibrium with the ambient air temperature, and the rate of temperature change decreased.

For any specific reservoir starting elevation, there is a range of potential dam release temperatures because the reservoir is affected by the magnitude of spring inflow and summer meteorological conditions. Downstream water temperatures produced by a routing of these releases are also affected by meteorological conditions and the magnitude of dam releases. Thus, for a single reservoir elevation the CE-QUAL-W2 and GEMSS modeling resulted in a range of water temperatures. This range is depicted graphically in Attachment C for reference and includes a minimum and maximum monthly temperature at three river locations for the 10^{th}, 50^{th}, and 90^{th} percentile Lake Powell elevation release condition. However, to provide a more meaningful comparison, this analysis used the average of the potential range as the basis of impact analysis. Both the temperature range and average temperatures are provided in Attachment C (Figures BA-18 through BA-27, and Tables BA-5 through BA-7).

Average river temperature by month at Lees Ferry, Little Colorado River confluence and Diamond Creek confluence were evaluated to identify whether the proposed action would affect river temperature compared to baseline conditions. Temperature model results were used to evaluate potential effects to various life stages of the evaluated fish species. Additional information on the water quality modeling methodology is available in Section 4.5 of the Final EIS.

R.3.1.3 Sediment Transport

To estimate the effects of modifying the annual release volumes from Glen Canyon Dam under the proposed action on sediment transport, the USGS prepared an analysis relating normalized sediment transport from the Grand Canyon to annual release volumes. Table R-6 shows this relationship, with 8.23 maf release volumes as the basis for normalization.

The probabilities of different levels of annual release were used to qualitatively evaluate potential differences in sediment transport and instream conditions for ESA-listed fish.

R.3.1.4 Effects of Climate Change

The hydrologic model, CRSS, used as the primary basis of the effects analysis does not project future inflows, but rather relies on the historic record to analyze a range of possible future inflows. Projections of future reservoir elevations are probabilistic, based on the 100-year historic record to protect future inflows. The historic record includes periods of extreme drought and periods with above average flow, allowing analysis of the proposed federal action under a wide range of future flow conditions. However, it is possible that future flows may include periods of wet or dry conditions that are outside the range of sequences observed in the historical record, particularly as a result of climate change and increased climate variability.

Table R-6
Relationship of Glen Canyon Dam Annual Release Volumes to Sediment Transport

Release (maf)	Normalized Sand Export
6.00	0.26
7.00	0.51
8.00	0.89
8.23	1.00
9.00	1.43
10.00	2.15
11.00	3.03
12.00	4.11
13.00	5.43
14.00	7.01
15.00	8.88
16.00	11.02
17.00	13.53
18.00	16.67
19.00	19.72
20.00	23.40

The Fourth Assessment Report (Summary for Policymakers) of the Intergovernmental Panel on Climate Change (IPCC), published in April of 2007, presented a selection of key findings regarding projected changes in precipitation and other climate variables as a result of a range of unmitigated climate changes projected by IPCC over the next century. Although annual average river runoff and water availability are projected to decrease by 10-30 percent over some dry regions at mid-latitudes, information with regard to potential impacts on specific river basins is not included. Recently published projections of potential reductions in natural flow on the Colorado River Basin by the mid 21st century range from approximately 45 percent by Hoerling and Eischeid (2006), to approximately 6 percent by Christensen and Lettenmaier (2006). A recent analysis of future precipitation minus evaporation (a surrogate for runoff) in the basin suggests an "imminent transition to a more arid climate in southwestern North America" (Seager et al (2006). While these projections are of great interest, additional research is both needed and warranted to quantify the uncertainty of these estimates (in terms of the actual uncertainty in the climate response as well as the uncertainty due to differences in methodological approaches and model biases) in order to better understand the risks of current and future water resource management decisions.

Reclamation has been involved in a multi-faceted research and development program over the past three years to improve its risk assessment capabilities regarding projected climate change in the Colorado River Basin. Key components of this program include:

- Sponsorship of NRC’s Committee on the Scientific Bases of Colorado River Basin Water Management in collaboration with the California Department of Water Resources, the Metropolitan Water District of Southern California, the Southern Nevada Water Authority, and the National Research Council’s (NRC) Water Science and Technology Board

  This study culminated in a report published in early 2007, “Colorado River Basin Water Management: Evaluating and Adjusting to Hydroclimatic Variability”. Among several conclusions and recommendations, this report concluded that the trend of increasing mean temperatures across the Colorado River Basin over the 20th century and into the 21st century is likely to continue and although there is less consensus regarding future trends in precipitation and runoff, the preponderance of the scientific evidence suggests warmer future temperatures will reduce future streamflow and water supplies and contribute to increase the severity, frequency, and duration of future droughts. It is anticipated that the Final EIS will include the executive summary of this report as Appendix T.

- Collaboration with several climate researchers to assess the state of knowledge regarding the potential impacts of climate change on the Colorado River Basin, to assess methodologies that would be appropriate to quantify future conditions, and to prioritize future research and development needs

  This work culminated in a report titled “Review of Science and Methods for Incorporating Climate Change Information into Reclamation’s Colorado River Basin Planning Studies”. Among several conclusions and recommendations, this report concluded that for shorter look-ahead horizons (e.g., less than 20 years), interannual and decadal variability is likely to be a more significant source of uncertainty than the uncertainty due to near-term climate change. Although paleoclimatic information may not necessarily represent future climate scenarios, this information may be useful in framing assumed variability in future hydrologic sequences, particularly with respect to drought potential. It is anticipated that the Final EIS will include this report in its entirety as Appendix U.

- Collaboration with several research partners including the USGS, NOAA, and various universities to improve the accuracy and spatial resolution of the output data from the climate change models to enable use in CRSS

- Improvements to the decision-modeling framework (including the CRSS model and associated data handling and analysis tools)

Based on the current inability to precisely project future impacts of climate change to runoff throughout the Colorado River Basin at the spatial scale needed for CRSS, Reclamation based its hydrologic analysis for the Final EIS and this BA primarily on the re-sampled historical record. However, in order to understand the potential effects of future inflow sequences outside the range of the historical flows (i.e., future sequences with increased variability including the severity, frequency, and duration of droughts), particularly during the 19-year period of the application of the proposed action, Reclamation analyzed the sensitivity of the hydrologic resources (including reservoir storage, reservoir releases, and river flows) to hydrologic scenarios derived from alternative methodologies. The methodologies, including stochastic hydrology methods and paleo-reconstruction methods and the results, were analyzed in Appendix N of the Draft EIS. An additional analysis has been added in the Final EIS that incorporates a newly published tree-ring reconstruction (Meko et al., 2007) that extends the estimate of annual flow at Lees Ferry back to the year 762, a record length of 1244 years.

Although precise estimates of the future impacts of climate change to runoff throughout the Colorado River Basin at appropriate spatial scales are not currently available, these impacts may include decreased mean annual flow and increased variability, including more frequent and more severe droughts. Furthermore, even without precise knowledge of the effects on runoff, increasing temperatures alone would likely increase losses (e.g., evapotranspiration and sublimation), resulting in reduced runoff. Acknowledging this potential, the proposed action includes operational elements that would respond if these impacts are realized during the interim period (2008 through 2026). In particular, the proposed action includes a coordinated operation element that allows for the reduction of Lake Powell's release below the current minimum objective release of 8.23 mafy (down to a new proposed minimum of 7.0 maf) if water in storage of Lake Powell decreases to specified levels. In addition, the proposed action includes a storage and delivery mechanism that is designed to enhance conservation opportunities in the Lower Basin and the retention of water in Lake Mead. Finally, the proposed action includes a shortage strategy at Lake Mead that would result in additional shortages being applied, after appropriate consultation, if Lake Mead water surface elevations were to drop below elevation 1,025 feet msl.

R.3.2 Direct and Indirect Effects of the Proposed Action

Potential effects of the proposed action on the evaluated species could result from changes in Lake Powell reservoir storage and release operations from baseline operations. The potential hydrologic effects could result in changes in the range and duration of the water elevations maintained in Lake Powell, river flow, river temperature, and sediment transport that support habitat conditions for the evaluated species. The following section describes the potential effects of the proposed action on the evaluated species from Lake Powell to the upper end of Lake Mead and summarizes the effects of SNWA's interdependent actions that are evaluated in Attachment B.

R.3.3 Species Effects

R.3.3.1 Southwestern Willow Flycatcher

Based on the following analysis, the proposed action in combination with SNWA's interdependent action may affect and is likely to adversely affect the southwestern willow flycatcher through occasional, temporary desiccation of occupied habitat.

Potential southwestern willow flycatcher habitat does not occur below the full pool of Lake Powell due to the steep topography and fluctuating nature of the reservoir. Southwestern willow flycatchers are known to nest in tamarisk along the Colorado River in the Grand Canyon. The southwestern willow flycatcher can be affected by high flows through scouring and destruction of willow/tamarisk shrub nesting habitat or wetland foraging habitat. Conversely, a reduction in flows could have adverse effects on riparian and marsh vegetation, which could adversely affect southwestern willow flycatcher. In April and May, the 90th percentile flows under the proposed action are higher than baseline conditions (Attachment C, Figures BA-9 and BA-10). However, willow flycatcher nests in the Grand Canyon are typically above the 45,000 cfs stage (Gloss et al, 2005), which is not approached at the 90th percentile in these months. Therefore these somewhat higher flows in April and May should not affect southwestern willow flycatcher nests in saltcedar. Monthly low releases (10th percentile) can be lower than under baseline conditions, in part because this action would allow for an annual release lower than 8.23 maf under certain circumstances (Attachment C, Table BA-4). These lower annual releases would result in lower hourly maximum flows as well as lower monthly low flows than baseline (Attachment C, Table BA-3). However, the probability of an annual release of less than 8.23 maf is relatively low (Attachment C, Table BA-4). Southwestern willow flycatcher nest in primarily tamarisk shrub in the lower Grand Canyon which is quite common along the Colorado River in the Grand Canyon. Tamarisk is not an obligate phreatophtye and is capable of surviving lowered water levels. Therefore, the potentially lower flows associated with the proposed action are not expected to kill tamarisk and thus no loss of southwestern willow flycatcher nesting habitat is anticipated.

An important element of flycatcher nesting habitat is the presence of moist surface soil conditions. Moist surface soil conditions are maintained by overbank flow or high groundwater elevations supported by river stage. At the 50th percentile, modeled monthly releases during the breeding season (April-August) from Glen Canyon Dam under the proposed action is almost always either equal to or greater than under baseline conditions (Attachment C, Figures BA-9 through BA-13). Under these conditions, flycatcher habitat conditions would be expected to be the same or improved relative to baseline conditions. During periods of the breeding season that flows could be less than under baseline conditions (10th percentile flows), the potential exists for lowering of groundwater elevations adjacent to the channel to decline, which could desiccate occupied nesting habitat and result in take of southwestern willow flycatcher. The probability for such take is considered to be low and the level of any such take would be low because only a few nest sites are known from this reach of the Colorado River, as indicated in Section 2.4.1 of this BA. Furthermore, the effect of take, should it occur, would be temporary because nesting habitat conditions are expected to be restored during periods when the flows are at or above the 50th percentile (Attachment C, Figures BA-9 through BA-13). The level of this effect, however, is not expected to substantively affect the abundance or distribution of southwestern willow flycatcher in the action area or regionally.

As indicated in Attachment B, interdependent actions on the Muddy and Virgin Rivers are to not expected to result in take of southwestern willow flycatcher nor appreciably diminish the value of critical habitat designated along the Virgin River for flycatcher conservation or the value of critical habitat for survival or recovery of the species.

R.3.3.2 Yellow-billed Cuckoo

The proposed action in combination with SNWA's interdependent action may affect, but is not likely to adversely affect the yellow-billed cuckoo. As described in Attachment B, SNWA's interdependent actions are not expected to result in take of yellow-billed cuckoo and may be beneficial by improving hydrological conditions that support species' habitat.

R.3.3.3 Yuma Clapper Rail

The proposed action in combination with SNWA's interdependent action may affect, but is not likely to adversely affect the Yuma clapper rail. The Yuma clapper rail is only present along the Muddy and Virgin River portion of the action area and, as described in Attachment B, SNWA's interdependent actions are not expected to result in take of the rail and may benefit the rail by improving hydrological conditions that support its habitat.

R.3.3.4 Moapa Dace

The proposed action in combination with SNWA's interdependent action is not expected to have any effects on the Moapa dace. The Moapa dace is only present in the Warm Springs area along the Muddy River portion of the action area and, as described in Attachment B, SNWA's interdependent actions are not expected to affect the dace or its habitat.

R.3.3.5 Woundfin and Virgin River Chub

The proposed action in combination with SNWA's interdependent action may affect, but is not likely to adversely affect the woundfin or Virgin River chub. The woundfin and Virgin River chub are only present along the Virgin River portion of the action area and, as described in Attachment B, SNWA's interdependent actions are not expected to result in take of these species nor appreciably diminish the value of critical habitat designated along the Virgin River for woundfin and Virgin River chub conservation or the value of critical habitat for survival of these species. Furthermore, these independent actions may benefit the woundfin and Virgin River chub by improving hydrological conditions that support their habitat.

R.3.3.6 Humpback Chub

Based on the following analysis, Reclamation has determined there is the possibility of take of individual humpback chub through increased competition, predation, and parasitism, and therefore Reclamation has concluded the proposed action may affect and is likely to adversely affect the humpback chub.

Humpback chub occur in the Colorado River below Glen Canyon Dam and in the Little Colorado River that is tributary to this river segment. None are known to be present in Lake Powell, and the species is not found in the Virgin or Muddy Rivers.

The proposed action could alter sediment transport, water temperature, and daily flows in the Colorado River below Glen Canyon Dam relative to baseline conditions. Sediment transport is directly related to river flow (Table R-6). The proposed action could result in annual releases from Glen Canyon Dam of less than 8.23 mafy approximately 9.7 percent more frequently than under baseline conditions, which would reduce the transport of sand out of the river and into Lake Mead (Attachment C, Table BA-4). During those times, sediment transport out of the river and into Lake Mead would be reduced per the relationship described in Table R-6. Annual release rates above the minimum objective release of 8.23 maf could occur with a frequency about 17 percent higher than under baseline conditions (Attachment C, Table BA-4). These higher releases would transport more sediment out of the river. The probability of releases above 9 mafy (9.01 mafy to above 16 mafy) is very similar under baseline conditions and the proposed action (differ by approximately 0.5 percent) and thus the effect on sediment transport would be very similar.

The quantitative effects of these changes in release rates on instream habitat suitability for humpback chub are difficult to predict. Goeking et al. 2003 noted considerable temporal variability in both backwater number and area with river discharge, and also variability among sights within a given year. They also found that backwater area tends to decline in the absence of floods (releases at or above powerplant capacity) and increase following floods, however the relationship between backwater area, depth and water temperature has not been established, making predictions for the welfare of the fish very difficult. On the other hand, Stevens and Hoffnagle found that both backwater number and area decrease at flows above 10,000 cfs, and similar findings were documented by McGuinn-Robbins (1997). These relationships, together with more frequent releases above 8.23 maf under the proposed action may act reduce backwater availability during certain years, especially during the months of August and September when those habitats are most critical to the fish. High releases along with increased flow fluctuations may exacerbate this problem.

For the baseline and proposed action, modeling results indicate that monthly average water temperatures in the Colorado River at Lees Ferry would be the same and would be below the requirements for humpback chub spawning and egg incubation under the 10th, 50th, and 90th percentile conditions (Attachment C, Table BA-5) during the spawning season of March through July. Near the confluence of the Little Colorado River, the average water temperatures could meet or exceed minimum spawning, egg incubation and growth requirements during July (end of spawning season) only under the 10th percentile conditions for both baseline and the proposed action. The average water temperature near the Little Colorado River would be less than 1ºC warmer for the proposed action than for the baseline in most months (Attachment C, Table BA-6), which may benefit humpback chub during 10^{th} percentile years when life stage minimum temperature thresholds are exceeded; this slight increase may also help minimize thermal shock to young-of-year humpbach chub entering the main channel from the LCR. At the confluence of Diamond Creek, average water temperatures could be suitable for humpback chub spawning, egg incubation and growth in

June and July under baseline 10th percentile conditions and in May through July under proposed action 10th percentile conditions. The average temperatures at the Diamond Creek confluence could be up to 1.4ºC warmer for the proposed action than for the baseline in most months, which may benefit humpback chub during 10^{th} percentile years when optimal spawning, incubation and growth temperatures are attained earlier in the year. However, under the proposed action the maximum temperature for growth (22° C) may be approached more frequently during 10^{th} percentile years, which may result in impeded growth compared to the no action.

For the 50th percentile conditions, average temperatures at Diamond Creek could be less than 1ºC warmer for the proposed action than for the baseline in April through August, and spawning could occur one month earlier (June), compared to the baseline. This would be beneficial to humpback chub as minimum incubation and growth temperatures would also be met earlier in the year. For the 90th percentile conditions, average temperatures at Diamond Creek would be the same for the proposed action and the baseline (Attachment C, Table BA-7). The slightly warmer water temperatures in the river from the confluence of the Little Colorado River to Diamond Creek in some months under the proposed action could also increase growth of humpback chubs and their food base organisms, a benefit to the species.

Under 50^{th} percentile conditions, average monthly temperatures for the proposed action would be less than 1.5ºC lower than under baseline conditions near the Little Colorado River confluence and less than 1.8ºC lower than baseline conditions at Diamond Creek from September through March (Attachment C, Tables BA-6 and BA-7). The temperatures would be the same under baseline and proposed action conditions at Lees Ferry (Attachment C, Table BA-5). Near the Little Colorado River, the average monthly water temperatures during these months would be less than that required for growth (16ºC) of the humpback chub under both baseline and proposed action conditions (Attachment C, Table BA-6). At Diamond Creek, the average monthly water temperature for the proposed action in September would be 0.8 ºC cooler than for baseline but would remain above the minimum growth temperature (Attachment C, Table BA-7). From October through March, average monthly water temperatures would be below the minimum growth temperature under both baseline and proposed action conditions. Thus, the slightly lower water temperatures under the proposed action would adversely affect growth of the humpback chub to about the same extent as the no action alternative.

The slightly warmer water temperatures under the proposed action relative to baseline conditions also could benefit the nonnative fish species present in the river by allowing earlier reproduction and increased growth similar to that for the humpback chub in those years when such temperature increases occur. Nonnative species that are common in the river from the Paria River confluence to Lake Mead include channel catfish, brown trout, rainbow trout, common carp, and fathead minnow. Red shiner, plains killifish and mosquitofish are locally common below the LCR, and striped bass, and channel catfish increase in abundance below RM 160 (Gloss et al. 2005). Also present in low numbers are black bullhead, yellow bullhead, green sunfish (GCMRC, unpublished).

Common carp, fathead minnow, red shiner, and mosquitofish feed primarily on aquatic insects, other small invertebrates, and plant material, although they can eat fish eggs and larvae as well (Moyle 2002). The plains killifish feeds near the surface on invertebrates and algae (Colorado State 2007). The other species, at least larger individuals, are predatory (Moyle 2002). Predatory nonnative fish that are rare to uncommon in the river but common at the inflow to Lake Mead include channel catfish, walleye, striped bass, and largemouth bass. Smallmouth bass are rare in the river, inflow area, and Lake Mead. Temperature requirements for these species are shown in Table R-7. All but rainbow trout, brown trout, red shiner, walleye, striped bass, and smallmouth bass have minimum spawning and incubation temperatures at or above those for humpback chub and thus could benefit from slightly warmer temperatures for the proposed action under 10th percentile conditions (Attachment C, Tables BA-5 through BA-7). Temperatures under the 50th and 90th percentiles would provide no benefits to nonnative fish.

Since many nonnative fish prey on native fish, the potentially increased number and/or feeding activity of nonnative fish at 10th percentile temperatures could adversely affect the humpback chub in this reach. However, many species of non-native fish are already present in this reach and the infrequent, slightly warmer temperatures are unlikely to increase their long-term abundance or species composition. For example, smallmouth bass generally does not establish in habitats where water temperatures do not exceed 19ºC for extended periods in the summer (Moyle 2002). The proposed action would not increase average monthly water temperatures to above 19ºC (based on modeling results) near the Little Colorado River under any conditions (Attachment C, Table BA-6). Near Diamond Creek, average water temperatures are above 19ºC in July through September under baseline conditions, and the proposed action could increase these average temperatures by about 1ºC and extend the duration of warmer temperatures by a few weeks (Attachment C, Table BA-7). Thus, the preferred action would be unlikely to result in a population increase for smallmouth bass in the Colorado River between Glen Canyon Dam and Lake Mead.

Warmer river temperatures could increase the potential for expansion of the Asian tapeworm (*Bothriocephalus acheilognathi*) and anchorworm (*Lernaea cyprinacea*) in the mainstream Colorado River in some years. Currently, these nonnative fish parasites are found primarily in fish in the Little Colorado River and other side tributaries, and they mostly affect native fish. Under baseline conditions, these parasites are less likely to infect fish in the Colorado River because water temperatures are less than optimal for these parasites. The potential for these parasites to infect fish increases when Glen Canyon Dam releases occur at low Lake Powell elevations (10th percentile or lower), and this could adversely affect the humpback chub. The level of effect is unknown but in isolation could be negligible considering the low frequency of such occurrences and the small increase in average temperature that would occur as a result of the proposed action; however, when combined with the aforementioned effects of habitat and nonnative fish, parasitism could be significant. Glen Canyon Dam releases made when Lake Powell water levels are at the higher 50th and 90th percentile elevations result in approximately the same to cooler downstream temperatures that are always below 20°C for the baseline and proposed action (Attachment C, Tables BA-5 through BA-7).

Table R-7
Nonnative Fish Temperature Requirements (Minimum-Maximum)

Common and Scientific Name	Spawning (ºC)	Incubation (ºC)	Growth (ºC)
Black bullhead *Ameiusus melas*	19-22	21-24	20-22
Channel catfish *Ictalurus punctatus*	21-29	20-30	21-30
Brown trout *Salmo trutta*	7-14	8-20	12-20
Rainbow trout *Oncorhynchus mykiss*	8-13	7-15	12-21
Common carp *Cyprinus carpio*	18-30	20-30	15-30
Fathead minnow *Pimephales promelas*	16-30	16-29	18-27
Red shiner *Cyprinella lutrensis*	15-30	15-25	18-28
Mosquitofish *Gambusia affinis*	18-30	20-24	14-28
Plains killifish *Fundulus zebrinus*	20-30	20-30	20-30
Walleye *Stizostedion vitreum*	4-13	4-14	18-23
Striped bass *Morone saxatilis*	14-24	16-26	23-30
Green sunfish *Lepomis cyanellus*	19-31	19-24	26-31
Largemouth bass *Micropterus salmoides*	16-20	16-20	16-30
Smallmouth bass *Micropterus dolomieu*	13-18	14-18	20-26
Endangered Fish Temperature Requirements (Minimum-Maximum)			
Bonytail *Gila elegans*	18-22	18-28	18-24
Colorado pikeminnow *Ptychocheilus lucius*	16-24	19-25	18-23
Razorback sucker *Xyrauchen texanus*	12-22	14-25	18-24
Humpback chub *Gila cypha*	16-22	16-27	16-22

Source: Valdez 2006

Reduced annual releases from Glen Canyon Dam under the proposed action could also result in a reduction in the potential range of hourly maximum and minimum releases from Glen Canyon Dam. At the minimum objective release of 8.23 mafy, the daily range of flows from Glen Canyon Dam under baseline conditions is approximately 6,000 to 8,000 cfs with the wider range in July, August, December, and January (Attachment C, Tables BA-2 and BA-3). The potential hourly range at annual release rates of 7.48 mafy could be reduced by as much as 1,000 to 2,000 cfs/day in April and October through December (Attachment C, Tables BA-1 through BA-3). This lower potential flow range would be unlikely to occur under baseline conditions because there is a low probability 0.05 percent) of an annual release of 7.48 mafy and would have about an approximately 8 percent probability of occurring for the proposed action (Attachment C, Table BA-4). For release rates between 9.0 mafy and over 16 mafy, the probability of such releases under baseline conditions and the proposed action are very similar (differ by approximately 0.5 percent). Therefore, the flow effects of annual releases above 9 mafy on daily flows is very similar under baseline conditions and the proposed action. Because the probability of annual releases above 9 mafy is very similar under baseline and the proposed action, and the frequency of the lower range of potential hourly flows when the annual release is lower than 8.23 mafy is low, effects on habitat that could be used by humpback chubs from changes in the potential range of hourly flows would be negligible (Attachment C, Tables BA-2 through BA-4), unless equalization under volumes > 8.23 maf (17 percent greater chance of that) result in higher fluctuations during the months of August and September, impacts to backwater habitat availability and temperatures could be significant. Humpback chub young-of-year are typically abundant in the mainchannel during those months, so habitat availability may be an issue.

The level of take that could occur from the proposed action relative to that under baseline conditions, particularly due to potential beneficial effects on nonnative fish that result in competition with or predation on humpback chubs, cannot be quantified but is expected to be none in most years. However, a small level of take of individuals could occur in a few years from warmer 10^{th} percentile releases from Glen Canyon Dam, because of these temperatures benefiting non-native fish predators. The small amount of take, if it occurs, is not expected to cause a change in the population of the humpback chub. The benefits of warmer water on populations of the humpback chub could at least partially offset the take due to increased predation by nonnative fish.

The possible effects of the proposed action on the habitat (and its components including water temperature and quality, flows, etc.) as described above would be minor. Consequently, the possibility of impacts on critical habitat resulting from the proposed action is not expected to appreciably diminish the value of critical habitat for humpback chub conservation, affect the survival or recovery of the species, nor appreciably diminish the value of critical habitat for survival of the species

R.3.3.7 Razorback Sucker

Based on the following analysis, Reclamation has determined the proposed action may affect, but is not likely to adversely affect the razorback sucker. Razorback sucker can occur at the riverine inflow areas to Lake Powell but are considered rare here. Razorback sucker have not been found in the Colorado River between Glen Canyon Dam and Lake Mead for over 15 years although a few individuals could still be present. Razorback sucker are not found in the Virgin or Muddy Rivers.

When Lake Powell is below elevation 3,660 feet msl, a waterfall exists at the San Juan River inflow at RM 0.6. This waterfall serves as a fish barrier for the upstream movement of non-native fish into the San Juan River from Lake Powell. The proposed action is expected to result in a greater probability that Lake Powell elevations could be at or below 3,660 feet msl

(Appendix C, Figures BA-1 through BA-5) compared to baseline conditions. Accordingly, the waterfall could be established more often under the proposed action than under baseline conditions in the future, providing a minimal potential benefit to razorback sucker in the San Juan River upstream of Lake Powell. However, this same waterfall would prevent Razorback sucker that wash down into Lake Powell from moving back up into the San Juan River. Adults that are trapped this way could reside at the inflows, though juveniles are more likely to be eaten by striped bass and other piscivorous fish that reside in Lake Powell. However, juveniles that end up in Lake Powell when the waterfall is not present are also likely to be eaten. Therefore, the level of razorback sucker predation due to this waterfall that may be associated with the proposed action is expected to be the same as under baseline conditions. Consequently, compared to baseline conditions the proposed action may affect, but is not likely to adversely affect the razorback sucker.

The lower Lake Powell water levels under shortage conditions would increase the amount of riverine habitat in the Dirty Devil arm of Lake Powell and thus provide more suitable habitat for this species. The proposed action would result in Lake Powell lake levels that are up to 16 feet lower than under baseline conditions at the 50th percentile.

The proposed action could affect sediment transport, water temperature, and the potential range of hourly flows in designated critical habitat present from Glen Canyon Dam to Lake Mead. The proposed action could result in annual releases from Glen Canyon Dam of less than 8.23 mafy approximately 9.7 percent more frequently than under baseline conditions, which would reduce the transport of sand out of the river and into Lake Mead (as described in Section 3.3.6 of the BA for the Humpback Chub). During those times, sediment transport out of the river and into Lake Mead would be reduced (Table R-6). Annual release rates above the minimum objective release could occur with a frequency about 17 percent higher than under baseline conditions. These higher releases would transport more sediment out of the river. The probability of releases above 9 mafy (9.01 mafy to above 16 mafy) is very similar under baseline and the proposed action (differ by approximately 0.5 percent) and thus the effect on sediment transport would be very similar (Attachment C, Table BA-4). The effects of these changes in release rates on habitat suitability for razorback sucker are unknown.

Changes in release volumes also could increase water temperatures in the river when Lake Powell levels are low enough that warmer water would be released. Modeling results show that the increases would occur primarily at the 10th percentile lake levels and that the increase in average temperature would be about 1ºC in spring and summer (Attachment C, Tables BA-5 through BA-7). For the 50th percentile Lake Powell level, average water temperatures would change very little during most of the year with slightly colder temperatures in the fall. At the 90th percentile Lake Powell level, temperatures would be similar to baseline conditions. The slight warming in spring to summer would provide little or no benefit for razorback spawning because the time when suitable spawning temperatures are present would be changed very little (a few weeks at the most), but it could increase growth. The slightly warmer water temperature in the river near Lake Mead at the 10^{th} percentile level could result in some individual razorbacks moving from Lake Mead into the river upstream, at least during the spring to summer of those years when Lake Powell is at the 10th percentile elevation.

As described for the humpback chub above, average monthly water temperatures would be slightly lower for the proposed action than for the baseline from September through March under 50th percentile conditions near the confluence of the Little Colorado River and Diamond Creek (Attachment C, Tables BA-6 and BA-7). Temperatures under both the baseline and proposed action, however, would be below that required for growth of the razorback sucker (18 ºC) during all of these months, and the slightly lower temperatures under the proposed action would not adversely affect growth of this species.

Warmer water temperatures under the proposed action relative to baseline conditions also would have the potential to benefit nonnative fish species that compete with or prey upon razorback suckers by allowing earlier reproduction and increased growth in those years when such temperature increases occur. Furthermore, the small increase in average temperature in some years has a low potential to increase movement of nonnative species into the river from Lake Mead and from tributaries that provide inflow to the river in the years that such temperature increases occur (See discussion on Humpback Chub). Although many nonnative fish prey on native fish, the potentially increased number or feeding activity of nonnative fish would be unlikely to adversely affect the razorback suckers in this reach because the few that may be present are adults that would be too large for most nonnative fish to eat. Many species of non-native fish species are already present in this reach and the infrequent, slightly warmer temperatures are unlikely to increase their long-term abundance or species composition.

Warmer river temperatures could increase the potential for expansion of the Asian tapeworm (*Bothriocephalus acheilognathi*) and anchorworm (*Lernaea cyprinacea*) in the mainstream Colorado River in some years as described for the humpback chub. Under baseline conditions, these parasites are less likely to infect fish in the Colorado River because average water temperatures are less than optimal for these parasites. The potential for these parasites to infect fish increases when Glen Canyon Dam releases occur at low Lake Powell elevations (10th percentile or lower), and potential temperatures exceed 20 ºC. This could adversely affect the razorback sucker. The level of effect is unknown but expected to be negligible considering the low frequency of such occurrences and the small increase in average temperature that would occur as a result of the proposed action. Glen Canyon Dam releases made when Lake Powell water levels are at the higher 50th and 90th percentile elevations result in approximately the same to cooler downstream average river temperatures that are always below 20°C for the baseline and proposed action (Attachment C. Tables BA-5 through BA-7).

Reduced annual releases from Glen Canyon Dam under the proposed action could also result in a reduction in the potential range of the hourly maximum and minimum releases from Glen Canyon Dam. At the minimum objective release of 8.23 mafy, the range of potential hourly flows from Glen Canyon dam under baseline conditions is approximately 6,000 to 8,000 cfs with the wider range in July, August, December, and January (Attachment C, Tables BA-2 and BA-3). The potential hourly range at annual release rates of 7.48 mafy could be reduced by as much as 1,000 to 2,000 cfs in April and October through December. This lower potential flow range would be unlikely to occur under baseline conditions because there is a low probability (0.05 percent) of annual release of 7.48 mafy and would have an approximately 8 percent probability of occurring for the proposed action (Attachment C, Table BA-4). For release rates between 9.0 mafy and 16 mafy, the probability of such releases under baseline conditions, and the proposed action are very similar (Attachment C, Table BA-4). Therefore, the flow effects of annual releases above 9 mafy on daily flows is very similar under baseline conditions and the proposed action. Because the probability of annual releases above 9 mafy is very similar under baseline and the proposed action, and the frequency of the lower range of potential hourly flows when the annual release is lower than 8.23 mafy is low, effects on habitat that could be used b razorback sucker from changes to hourly flows would be negligible (Attachment C, Tables BA-2 through BA-4).

The possibility, therefore, of impacts on critical habitat resulting from the proposed action is not expected to appreciably diminish the value of critical habitat for razorback sucker conservation, affect the survival or recovery of the species, nor appreciably diminish the value of critical habitat for survival of the species.

R.3.3.8 Colorado Pikeminnow

Based on the analysis below, the proposed action may affect, but is not likely to adversely affect the Colorado pikeminnow.

Colorado pikeminnow can occur at the riverine inflow areas to Lake Powell but are considered rare here as indicated in Section 2.4.6 of this BA. Pikeminnow are extirpated from the Colorado River below Glen Canyon Dam and, as a result, the proposed action would not affect the species in this river reach. The species is also not present in the Virgin or Muddy Rivers.

In general, the lacustrine environment of Lake Powell is less than ideal habitat for Colorado pikeminnow. The proposed action may provide a minor benefit to pikeminnow upstream of Lake Powell because it is expected to result in a greater probability that Lake Powell elevations could be at or below 3,660 feet msl in the future than under baseline conditions (Attachment C, Figure BA-1). As indicated above, the waterfall on the San Juan River that can occur at lake levels below 3,660 feet msl, would block the upstream movement of non-native fish from Lake Powell. However, this waterfall also has the potential to block the upstream movement of pikeminnow out of Lake Powell and into the San Juan River. Any adults or juvenile pikeminnows washed into the lake would also be blocked from returning to the river when lake levels are low. Given the rarity of the species in Lake Powell, that the lake serves as less than ideal pikeminnow habitat, and that pikeminnow are similarly affected by Lake Powell conditions and non-native fish interactions when the San Juan waterfall is and is not present, take resulting from the proposed action is expected to be the same as under baseline conditions. Consequently, compared to baseline conditions the proposed action is not expected to result in take of Colorado pikeminnow.

Based on the above assessment, the changes in Lake Powell levels between the proposed action and baseline are also not expected to appreciably diminish the value of critical habitat for Colorado pikeminnow conservation, affect the survival or recovery of the species, nor appreciably diminish the value of critical habitat for survival of the species in the Dirty Devil and San Juan river areas in Lake Powell.

R.3.3.9 Bonytail

Based on the analysis below, the proposed action may affect, but is not likely to adversely affect the bonytail.

Bonytail can occur at the riverine inflow areas to Lake Powell but are considered rare here. Bonytail are presumed extirpated from the Colorado River below Glen Canyon Dam to Lake Mead, and thus, the proposed action would not affect the species in that river reach. Bonytail are not present in the Virgin or Muddy Rivers.

In general, the lacustrine environment of Lake Powell is less than ideal habitat for bonytail chub. Given the rarity of the species in Lake Powell and that the lake serves as less than ideal bonytail habitat, take resulting from the proposed action is expected to be the same as under baseline conditions.

R.3.3.10 Kanab Ambersnail

Based on the following analysis, there is potential for take of individual ambersnails and Reclamation has concluded the proposed action may affect and is likely to adversely affect the Kanab ambersnail.

The proposed action will have no effect on the water flow from the side canyon spring that maintains wetland and aquatic habitat at Vasey's paradise. Kanab ambersnail habitat can be adversely affected by scouring at Colorado River flows exceeding 17,000 cfs. As indicated above, the proposed action will allow Reclamation to release less than 8.23 maf/year under certain circumstances. In years where these lower annual releases occur, the typical hourly maximum flow from Glen Canyon Dam would be lower than would occur under the current minimum annual release of 8.23 (Attachment C, Table BA-3). These lower annual releases have a relatively low probability of occurring under the proposed action (about 0.68 percent for releases between 7.51 to 8.22 maf, 8.11 percent for releases between 7.01 to7.50 maf and 1.26 percent for releases less than or equal to 7.0 maf) (Attachment C, Table BA-4). These lower flows could allow wetland vegetation to establish lower down the canyon wall during some years. This could provide a temporary increase in Kanab ambersnail habitat, though such increase would be inundated and likely scoured in subsequent years with higher annual releases and corresponding higher hourly maximum flows. Consequently, the proposed action could result in take of the snail if the snail occupies new habitat that is created under the proposed action and then is subsequently inundated.

In certain months of the year, the average monthly flow could exceed 17,000 cfs and also be higher than baseline. These higher flows (90th percentile) would inundate a larger area of Kanab ambersnail habitat and are best illustrated in the April and May monthly release graphs (Attachment C, Figures BA-9 and BA-10). Conversely, the average monthly flows above 17,000 cfs in other months (e.g., June) are less frequent under the 90th percentile for the proposed action compared to the baseline condition (Attachment C, Figure BA-11). Consequently, the proposed action could result in some level of take greater than under baseline conditions in some months, but any increased incidence in take would not be expected to substantively affect the abundance or distribution of the snail.

R.3.4 Cumulative Effects

Cumulative effects are defined under ESA regulations as those effects of future state or private activities, not involving Federal activities, that are reasonably certain to occur within the action area of the Federal action subject to consultation (50 C.F.R. §402.02). The action area from Lake Powell to Lake Mead is within the Glen Canyon National Recreation Area, Grand Canyon National Park, and Lake Mead National Recreation Area and is thus is largely under the control of the National Park Service. In addition, the action area includes the westernmost portion of the Navajo Indian Reservation and the northern boundary of the Hualapai Indian Reservation. While portions of these two reservations are within the action area, actions are likely to be subject to consultation through the Bureau of Indian Affairs, as well as the tribal governments. Consequently, it is assumed that activities that would occur in the future would be deemed Federal actions and fall outside the definition of actions causing potential cumulative effects.

R.3.5 Conclusions

Table R-8 on the following page provides the effects conclusions for the species listed in Table R-3. The findings are either "no effect," "may affect, not likely to adversely affect," or "may affect, is likely to adversely affect" and incorporate the conclusions reached in Attachment B where applicable.

Table R-8
Species Effects Conclusions

Common and Scientific Name	ESA Status[1]	No Effect	May Affect: Not Likely to Adversely Affect	May Affect: Likely to Adversely Affect	Will not Modify Designated Critical Habitat	May Modify Designated Critical Habitat[2]
Southwestern willow flycatcher *Empidonax trailii extimus*	E			X		X
Yellow-billed cuckoo *Coccyzus americanus*	C		X			
Yuma clapper rail *Rallus longirostris yumanensis*	E		X			
Moapa dace *Moapa coriacea*	E	X				
Woundfin *Plagopterus argentissimus*	E		X			X
Virgin River Chub *Gila robusta seminuda*	E		X			X
Bonytail *Gila elegans*	E		X			
Humpback chub *Gila cypha*	E			X		X
Razorback sucker *Xyrauchen texanus*	E		X			X
Colorado pikeminnow *Ptychocheilus lucius*	E		X			X
Kanab ambersnail *Oxyloma haydeni kanabensis*	E			X		

1 ESA Status:

E = Listed as endangered under the ESA.

C = Candidate species for listing under the ESA.

2 The effects are not expected to appreciable diminish the value of the critical habitat for species conservation.

Attachment A

Existing ESA Coverage

This attachment to Appendix R is a description of coverage under the Lower Colorado River Multi Species Conservation Program Biological and Conference Opinion for the adoption of Colorado River interim guidelines for Lower Basin shortages and coordinated operations for Lake Powell and Lake Mead.

A. Existing ESA Coverage

A.1 Introduction and Approach

The Bureau of Reclamation (Reclamation) proposes to adopt Colorado River Interim Guidelines for Lower Basin Shortages and Coordinated Operations of Lake Powell and Lake Mead (proposed action). The proposed interim guidelines would remain in effect for determinations to be made through 2026 and would provide guidance each year in development of the Annual Operating Plan for Colorado River Reservoirs (AOP).

A Draft Environmental Impact Statement (EIS) for the proposed action was distributed in February, 2007. After consideration of the comments received on the Draft EIS and further analysis[1], Reclamation has identified the operational elements that it intends to incorporate as the Preferred Alternative, herein after referred to as the proposed action, which will be analyzed in the Final EIS.

The four operational elements of the proposed action are the adoption of guidelines that would be used by the Secretary to:

1) Determine those circumstances under which the Secretary would reduce the annual amount of water available for consumptive use from Lake Mead to the Colorado River Lower Division states (Arizona, California, and Nevada) below 7.5 million acre-feet (maf) (a ‘‘Shortage’’) pursuant to Article II(B)(3) of the United States Supreme Court Decree in the case of *Arizona v. California*, 547 U.S. 150 (2006)(Consolidated Decree);

2) Define the coordinated operation of Lake Powell and Lake Mead to provide improved operation of these two reservoirs, particularly under low reservoir conditions;

3) Allow for the storage and delivery, pursuant to applicable federal law, of conserved Colorado River system and non-system water in Lake Mead to increase the flexibility of meeting water use needs from Lake Mead, particularly under drought and low reservoir conditions; and

4) Determine those conditions under which the Secretary may declare the availability of surplus water for use within the Lower Division states. The proposed federal action would modify the substance of the existing Interim Surplus Guidelines (ISG), published in the *Federal Register* on January 25, 2001 (66 Fed. Reg. 7772), and the term of the ISG from 2016 to 2026.

[1] The Draft EIS and comments are available at http://www.usbr.gov/lc/region/programs/strategies.html.

The ESA compliance for the proposed action is comprised of three distinct segments. This approach is being used because three geographical areas of impact are involved, with varying degrees and types of impacts. These geographical areas include:

1) Lake Powell and the Colorado River from Glen Canyon Dam to the upper end of Lake Mead (primarily related to operational element no. 2, coordinated reservoir operations). This segment is not addressed by this transmittal.

2) The full length of the Muddy River in Nevada, and the Virgin River from the Mesquite Diversion near Mesquite, Nevada, to Lake Mead (primarily related to operational element no. 3, storage and delivery mechanism). This segment is not addressed by this transmittal.

3) The Colorado River from Lake Mead to the Southerly International Boundary with Mexico (primarily related to operational element no. 1, shortage guidelines, operational element no. 2, coordinated reservoir operations, no. 3, storage and delivery mechanism, and operational element no. 4, ISG). These operational elements constitute "covered actions" within the Lower Colorado River Multi-Species Conservation Program (MSCP) and are encompassed within the boundaries of the MSCP planning area.

Each of the three segments of the consultation is prepared as a stand-alone analysis for ease of understanding.

A.2 Detailed Description of Proposed Action

The proposed action is Reclamation's adoption of Colorado River Interim Guidelines for Lower Basin Shortages and Coordinated Operations of Lake Powell and Lake Mead. The action is proposed in order to provide a greater degree of certainty to Colorado River water users and managers of the Colorado River Basin by providing more detailed objective guidelines for the operation of Lake Powell and Lake Mead, thereby allowing water users in the Lower Basin to know when, and by how much, water deliveries will be reduced during drought and other low reservoir conditions.

The proposed interim guidelines are anticipated to be promulgated in 2008 and would remain in effect for determinations to be made through 2026 and would provide guidance each year in development of the AOP. The interim period, 2008 through 2026, is the period of consultation for the potential effects of the proposed action. After the interim period the operations may revert to the AOP process that is described as the No Action Alternative in the EIS.

The proposed action considers four operational elements that collectively are designed to address the purpose and need for the proposed federal action. The interim guidelines would be used by the Secretary to:

- ♦ Determine those circumstances under which the Secretary would reduce the annual amount of water available for consumptive use from Lake Mead to the Colorado River

Lower Division states below 7.5 maf (a ‘‘Shortage’’) pursuant to Article II(B)(3) of the Consolidated Decree;

- ♦ Define the coordinated operation of Lake Powell and Lake Mead to provide improved operation of these two reservoirs, particularly under low reservoir conditions;
- ♦ Allow for the storage and delivery, pursuant to applicable federal law, of conserved Colorado River system and non-system water in Lake Mead to increase the flexibility of meeting water use needs from Lake Mead, particularly under drought and low reservoir conditions; and
- ♦ Determine those conditions under which the Secretary may declare the availability of surplus water for use within the Lower Division states. The proposed federal action would modify the substance of the existing ISG, published in the *Federal Register* on January 25, 2001 (66 Fed. Reg. 7772), and the term of the ISG from 2016 to 2026.

The proposed action includes a coordinated operation of Lake Powell and Lake Mead that would minimize shortages in the Lower Basin and avoid risk of curtailments of use in the Upper Basin; and also provides a mechanism, called Intentionally Created Surplus (ICS), for promoting voluntary water conservation in the Lower Basin.

The formulation of the four operational elements for the proposed action follows:

1) **Shortage Guidelines.** The proposed action provides discrete levels of shortage associated with specific Lake Mead elevations as presented below. The shortages modeled under the proposed action are as follows:

    - When Lake Mead is projected to be below elevation 1,075 feet msl and at or above 1,050 feet msl on January 1, a shortage of 333 thousand acre-feet (kaf) shall be declared for that year;
    - When Lake Mead is projected to be below elevation 1,050 feet msl and at or above 1,025 feet msl on January 1, a shortage of 417 kaf shall be declared for that year;
    - When Lake Mead is projected to be below elevation 1,025 feet msl on January 1, a shortage of 500 kaf shall be declared for that year; and
    - When Lake Mead is below elevation 1,025 feet msl, the Secretary shall undertake appropriate consultation, including with the Basin States, to discuss further measures that may be undertaken consistent with the Law of the River.[2]

[2] The specific outcome of a consultation process to define additional shortages cannot be predicted; therefore, for modeling purposes it was assumed that shortages of 500 kaf would continue to be imposed at Lake Mead elevations below 1,025 feet msl.

The volumes of shortages are expressed as reductions to water users in the United States. However, modeling of the proposed action includes the assumption that Mexico would also incur water delivery reductions proportional to the reductions to United States users in the Lower Basin at the same Lake Mead elevations (equivalently expressed as a water delivery reduction to Mexico of 16.7 percent of the total shortage volume). As such, the total shortage volumes modeled under this alternative are 400, 500, and 600 kaf at elevations 1,075, 1,050, and 1,025 feet msl, respectively, and these reductions of water deliveries are assumed to be applied to the Lower Division states and Mexico.

2) **Coordinated Reservoir Operations.** Under the proposed action, the annual Lake Powell release is based on a volume of water in storage or corresponding elevation in Lake Powell and Lake Mead as described below.

- **Equalization.** The proposed action provides an elevation schedule (Table 1) that would be used in determining when equalization releases would be made.

Table 1
Lake Powell Equalization Elevations

Year	Reservoir Elevation (feet msl)
2008	3,636
2009	3,639
2010	3,642
2011	3,643
2012	3,645
2013	3,646
2014	3,648
2015	3,649
2016	3,651
2017	3,652
2018	3,654
2019	3,655
2020	3,657
2021	3,659
2022	3,660
2023	3,662
2024	3,663
2025	3,664
2026	3,666

When Lake Powell is at or above these specified elevations and when the volume of Lake Powell is projected to be greater than the volume of Lake Mead at the end of the water year, Lake Powell would release greater than 8.23 maf per year to equalize its volume with Lake Mead. Otherwise, 8.23 maf is released from Lake Powell.

- **Upper Elevation Balancing.** When Lake Powell is below the elevations stated in Table 1 and is projected to be at or above 3,575 feet msl at the end of the water year, a release in the amount of 8.23 maf from Lake Powell would be made if the projected elevation of Lake Mead is at or above 1,075 feet msl at the end of the water year. If the projected end of water year elevation of Lake Mead is below 1,075 feet msl, the volumes of Lake Mead and Lake Powell would be balanced if possible, within the constraint that the release from Lake Powell would not be more than 9.0 maf and no less than 7.0 maf.

- **Mid-Elevation Releases.** When Lake Powell elevation is projected to be below 3,575 feet msl and at or above 3,525 feet msl at the end of the water year, a release in the amount of 7.48 maf would be made if the projected end of water year elevation of Lake Mead is at or above 1,025 feet msl. If the projected end of water year elevation of Lake Mead is below 1,025 feet msl, a release of 8.23 maf from Lake Powell would be made.

- **Lower Elevation Balancing.** When the projected end of water year elevation of Lake Powell is below 3,525 feet msl, Lake Mead and Lake Powell would be balanced if possible, within the constraint that the release from Lake Powell would not be more than 9.5 maf and no less than 7.0 maf.

3) **Storage and Delivery of Conserved Water.** The proposed action includes the adoption of a mechanism (ICS) to encourage and account for augmentation and conservation of water supplies, e.g., fallowing of land, canal lining, system efficiency improvements, and tributary conservation (retirement of pre-Boulder Canyon Project Act of 1929 water rights on the Virgin and Muddy rivers). The ICS mechanism provides for creating credits for the conserved or imported water and delivering the water at a later date.

   The analysis of potential effects in this assessment includes a maximum cumulative amount of ICS credits that would be available at any one time of up to 4.2 maf. However, it is anticipated that the ICS mechanism will be initially implemented to allow a maximum cumulative amount of ICS credits of up to 2.1 maf.

   The volumes of ICS activity that are assumed for each state and other entities (shown as “Additional Amounts”) are presented in Table 2. At this time, it is unknown exactly which entities might participate in the ICS mechanism. Furthermore, the timing and magnitude of the conservation and subsequent delivery of conserved water is unknown. In order to analyze the maximum effects of the mechanism to reservoir storage and river flows below Lake Mead, it was assumed that conservation would originate from a point on the river within each state located furthest downstream with respect to ICS activities within that state. Similarly, conservation within the Additional Amounts category was assumed to originate in Mexico in order to disclose the maximum effects of the mechanism to reservoir storage and river flows below Lake Mead.[3]

In addition to increasing the flexibility of meeting water use needs from Lake Mead, the ICS mechanism would benefit the system through Lake Mead storage credits. At the time the ICS credits are created, five percent of the ICS credits would be dedicated to the system on a one-time basis. Additionally, ICS credits would be subject to annual evaporation losses of three percent per year. If flood control releases occur, ICS credits would be reduced on a pro-rata basis among all holders of ICS credits until no credits remain.

Under the assumptions made for the analysis contained herein, the maximum amount of ICS credits that can be created during any year, the maximum cumulative amount of ICS credits that can be available at any one time, and the maximum amount of ICS credits that may be recovered in any one year under the proposed action are presented in Table 2.

Table 2
Proposed Action Alternative Volume Limitations of Storage and Delivery Mechanism

Entity	Maximum Annual Storage of Conserved System or Non-system Water (kaf)	Maximum Total Storage of Conserved System or Non-system Water (kaf)	Maximum Annual Delivery of Conserved System or Non-system Water (kaf)
Arizona	100	300	300
California	400	1,500	400
Nevada	125	300	300
Total[1]	625	2,100	1,000
Additional Amounts	625	2,100	1,000
Total[2]	1,250	4,200	2,000

1 It is anticipated that the ICS mechanism will be implemented to allow a maximum cumulative amount of ICS credits that would be available at any one time of up to 2.1 maf.

2 The analysis of potential effects includes a maximum cumulative amount of ICS credits that would be available at any one time of up to 4.2 maf.

4) **Interim Surplus Guidelines.** The proposed action includes both a modification and an extension of the existing ISG currently in place through 2016. The ISG would be extended through 2026 and be modified by eliminating the Partial Domestic Surplus Condition, beginning in 2008, and limiting the amount of water available under the Full

[3] Notwithstanding the lack of an existing mechanism to implement such modeling assumptions, Reclamation utilized these assumptions for a number of reasons, including the following: (1) a larger volume of potential storage in Lake Mead is identified, (2) the maximum potential impacts on river flows below Hoover Dam are identified, (3) the arbitrary assignment of water conservation amounts to entities in the Lower Basin states is avoided, and (4) the modeling impacts of a program of potential future cooperation between the United States and Mexico are identified.

Domestic Surplus Condition during the period 2017 through 2026.[4] These modifications reduce the amount of surplus water that could be made available and leaves more water in storage to reduce the frequency and severity of future shortages.

A.3 The Lower Colorado River Multi Species Conservation Program

The MSCP is a coordinated, comprehensive, long-term multi-agency effort to conserve and work towards the recovery of endangered species, and protect and maintain wildlife habitat on the lower Colorado River.

As stated above, the MSCP planning area comprises areas up to and including the full pool elevations of lakes Mead, Mohave, and Havasu and the historical floodplain of the Colorado River from Lake Mead to the Southerly International Boundary. This includes a distance of about 400 river miles. The historical flood plain is defined as all lands that are or have been affected by the meandering or regulated flows of the Colorado River, which historically have been defined by the change in elevation that forms the adjoining uplands (see Figure 1).

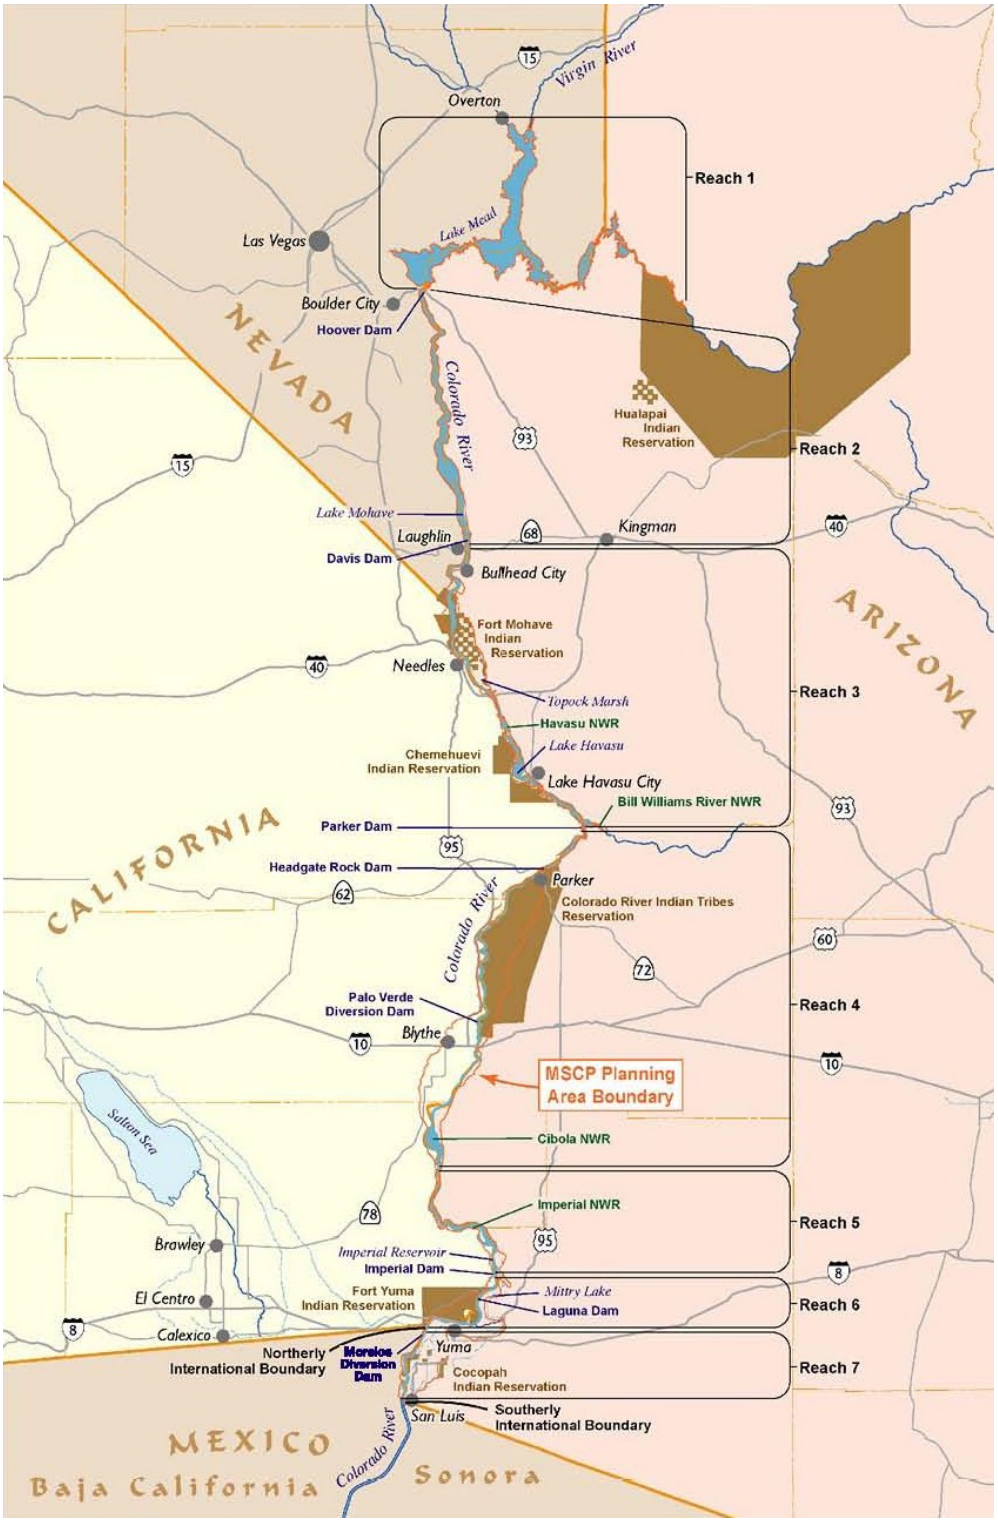
Consultation under Section 7 of the ESA has been completed for the MSCP covered actions and activities. During the planning phase for the MSCP, Reclamation included in the covered actions a set of assumptions for future shortage criteria and the extension of the ISG as part of the effects modeling for the project area. These assumptions provided for future coverage of the proposed action under the MSCP if the specific features of the proposed action fell within the assumptions included in the MSCP analysis. The MSCP Final Biological Assessment (BA) was completed on December 17, 2004. The Biological and Conference Opinion on the Lower Colorado River Multi-Species Conservation Program, Arizona, California, and Nevada (BCO) was completed on March 4, 2005. The BCO determined that, with the ranges analyzed in the BA, proposed future federal actions including the adoption of shortage criteria, the extension of the ISG, and changes to points of diversion (i.e., due to water transfers and other activities) are not likely to jeopardize the continued existence of listed, candidate, or other covered species, and are not likely to destroy or adversely modify designated or proposed critical habitat.

A complete description including program documents cited in this Attachment, and current status of the MSCP are available at http://www.lcrmscp.gov/.

---

[4] During 2017 through 2026, the distribution of Domestic Surplus water would be limited as follows: 1) for use by MWD, 250 kafy in addition to the amount of California's basic apportionment available to MWD; 2) for use by SNWA, 100 kafy in addition to the amount of Nevada's basic apportionment available to SNWA; and 3) for use in Arizona, 100 kafy in addition to the amount of Arizona's basic apportionment available to Arizona contractors.

Figure 1
Lower Colorado River MSCP Planning Area and River Reaches



A.4 Existing MSCP Coverage for the Following Identified Elements of the Proposed Action

The flow-related, future federal actions covered under the MSCP include activities that could result in reductions in flows from Hoover Dam to Imperial Dam, changes in reservoir operations of Lake Mead including shortage and surplus determinations, and changes in flows in excess of Mexico's water order reaching Morelos Diversion Dam. Existing coverage of the potential effects on species within the MSCP planning area boundary of the proposed action is determined by comparison with the range of operations analyzed in the MSCP BA and BCO as well as the other relevant MSCP program documents. All modeling assumptions used in the following comparisons for both the proposed action and the No Action Alternative are fully described in Section 4.2 and Appendix A of the Final EIS.

A.4.1 Reductions in Flow

Flow related impacts covered under the MSCP included the impacts of flow reductions below Hoover Dam to Davis Dam (Reach 2, Figure 1) of up to 845 kaf per year (kafy), below Davis Dam to Parker Dam (Reach 3, Figure 1) of up to 860 kafy, and flow reductions of up to 1.574 maf per year below Parker Dam to Imperial Dam (Reach 4 and 5, Figure 1). For the proposed action, changes in points of diversion due to conservation activities (i.e., the creation of ICS credits) and shortage conditions would contribute to potential flow reductions.

Figures 2, 3, and 4 display the probability of flow reductions for Reaches 2, 3, 4, and 5 for the duration of the proposed action. For comparison purposes, the results for the No Action Alternative used in the Final EIS are also shown. These figures show that the proposed action will not exceed the flow reductions analyzed and are within the range of the reductions anticipated under the MSCP.

Flow reductions result in lower water surface elevations in the main channel of the river and its associated backwaters. The reduced water surface elevations also result in lower groundwater levels. The river stage along the river is correlated directly with discharge.

Therefore, because the discharge below each of the dams is not expected to be reduced below that which the MSCP has coverage, the range of effects resulting from the proposed action is covered by the MSCP BCO.

Percent of Values Greater than or Equal to 860 kaf

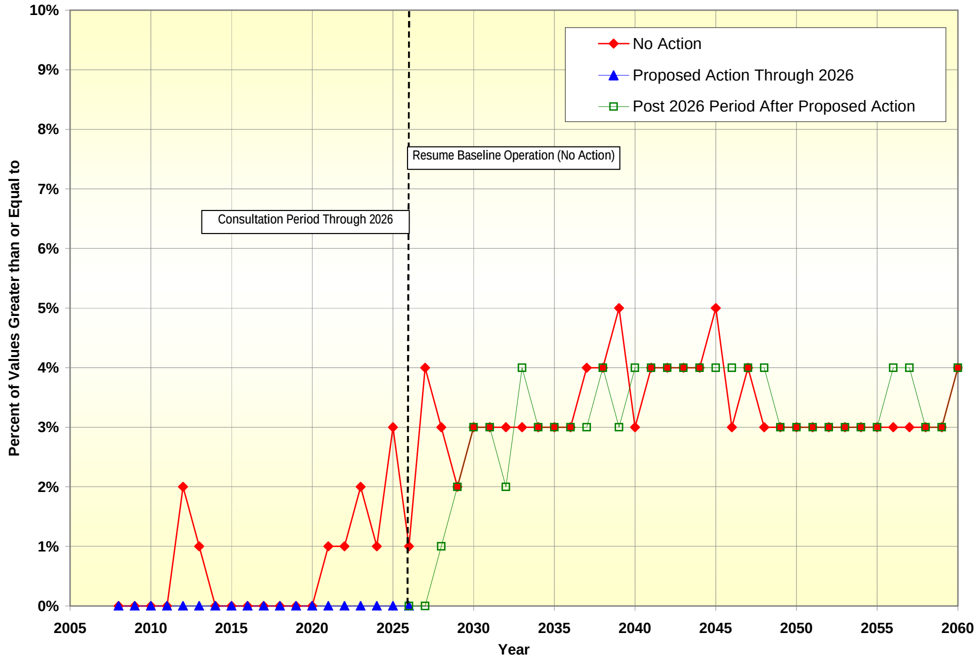

Figure 4
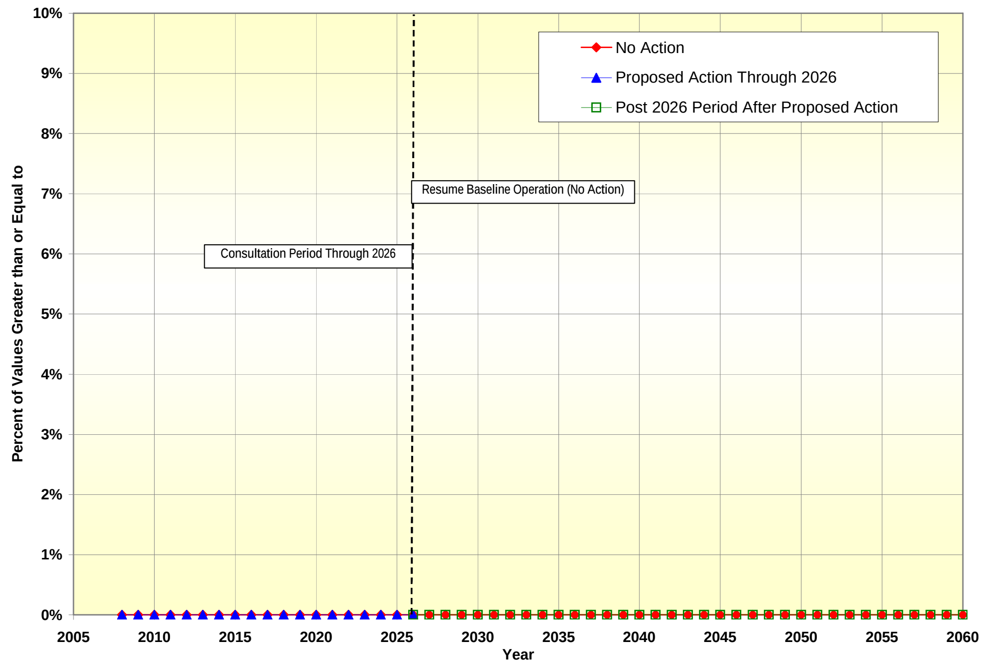
Parker to Imperial Reach Reductions
Comparison of Preferred Alternative to No Action Alternative
Percent of Values Greater than or Equal to 1574 kaf



A.4.2 Reservoir Operations

The proposed action includes the imposition of discrete levels of shortage volumes associated with Lake Mead reservoir elevations and extending and modifying the ISG through 2026, the effects of which were analyzed in and accordingly are covered by the MSCP BCO and described below.

The MSCP analysis assumed that under a first level shortage, elevation 1,050 msl would be protected with an approximate 80 percent probability. In a given year, a shortage that ranges from approximately 350 to 500 kaf would be imposed when the projected January 1 Lake Mead elevation is below a trigger elevation for that year. Under a second level shortage, shortages would be imposed by amounts required to maintain the Lake Mead water elevation at or above 950 feet msl. In comparison, the proposed action includes shortage reductions to United States water users of 333, 417, and 500 kaf imposed at elevations 1,075, 1,050, and 1,025 feet msl, respectively. Additionally, the modeling assumed a 500 kaf shortage to United States users was imposed at or below elevation 1,025 feet msl. As previously mentioned, modeling of the proposed action includes the assumption that Mexico would also incur water delivery reductions proportional to reductions to Untied States users at the same Lake Mead elevations, resulting in total water delivery reductions of 400, 500, and 600 kaf at elevations 1,075, 1,050, and 1,025 feet msl, respectively.

The MSCP analyzed and covered the extension of the ISG through 2051. Since the proposed Lower Basin shortage guidelines are anticipated to be implemented through 2026, extending the ISG establishes an operational strategy for the full range of reservoir operations - high and low - at Lake Mead. It should also be noted that the extended ISG have been modified by eliminating the Partial Domestic Surplus Condition in 2008 and limiting the amount of water available under a Full Domestic Surplus Condition during the period 2017 through 2026. These modifications reduce the amount of surplus water that could be made available and leaves more water in storage to reduce the frequency and severity of future shortages.

Although the proposed action proposes reductions in deliveries based on specific reservoir elevations (as compared to the assumptions in the MSCP analysis that assume absolute protection of elevation 950 feet msl), analysis of the proposed action shows that Lake Mead elevations are within the range of effects analyzed in the MSCP BCO. Figure 5 shows the probability of Lake Mead elevations less than 1,050 feet msl during the interim period. Figure 6 shows the probability that Lake Mead elevation will be less than 950 feet msl during the interim period. For comparison purposes, the No Action Alternative from the Final EIS has been displayed in Figures 5 and 6.

Figure 5
Lake Mead End-of-December Water Elevations
Percent of Values Less than or Equal to Elevation 1,050 feet msl

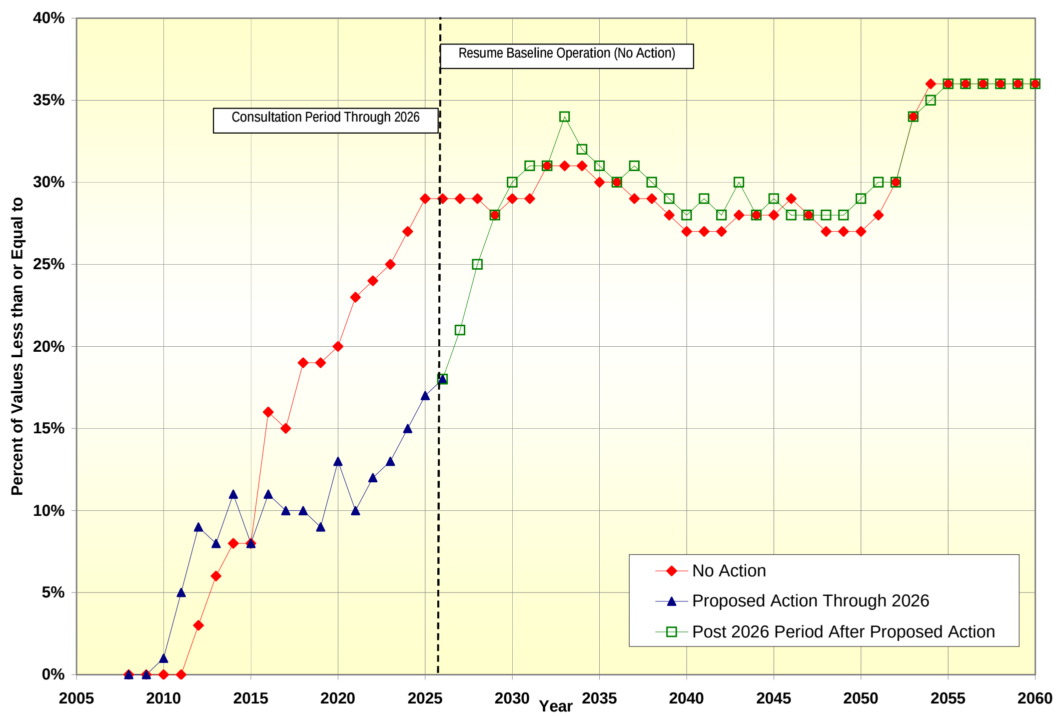


Figure 6
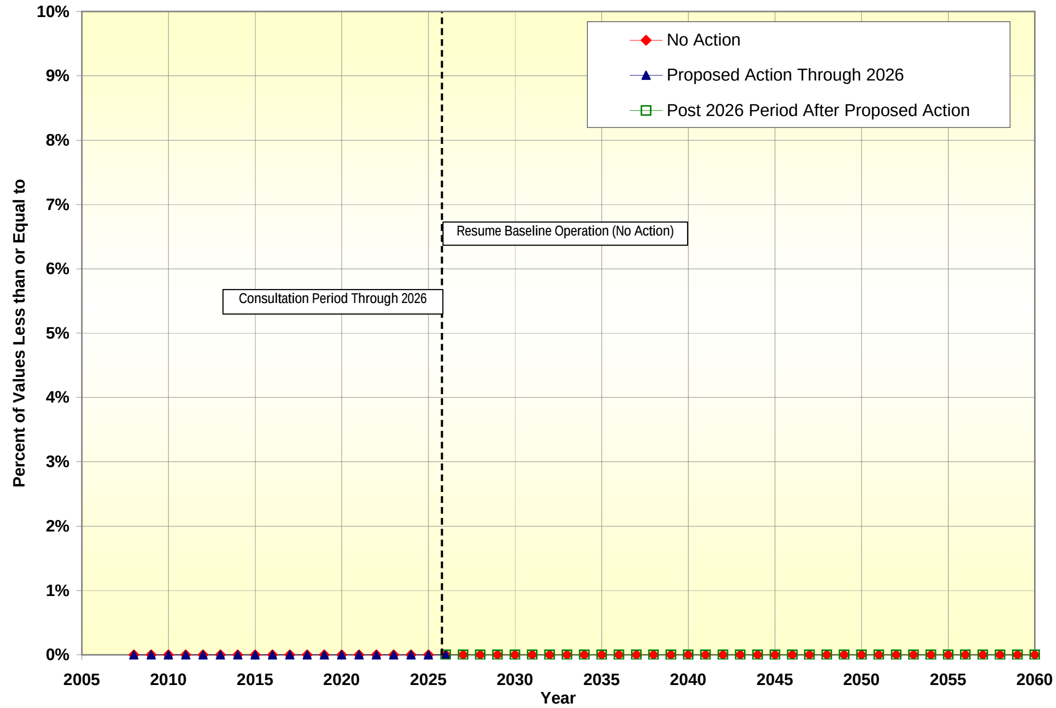
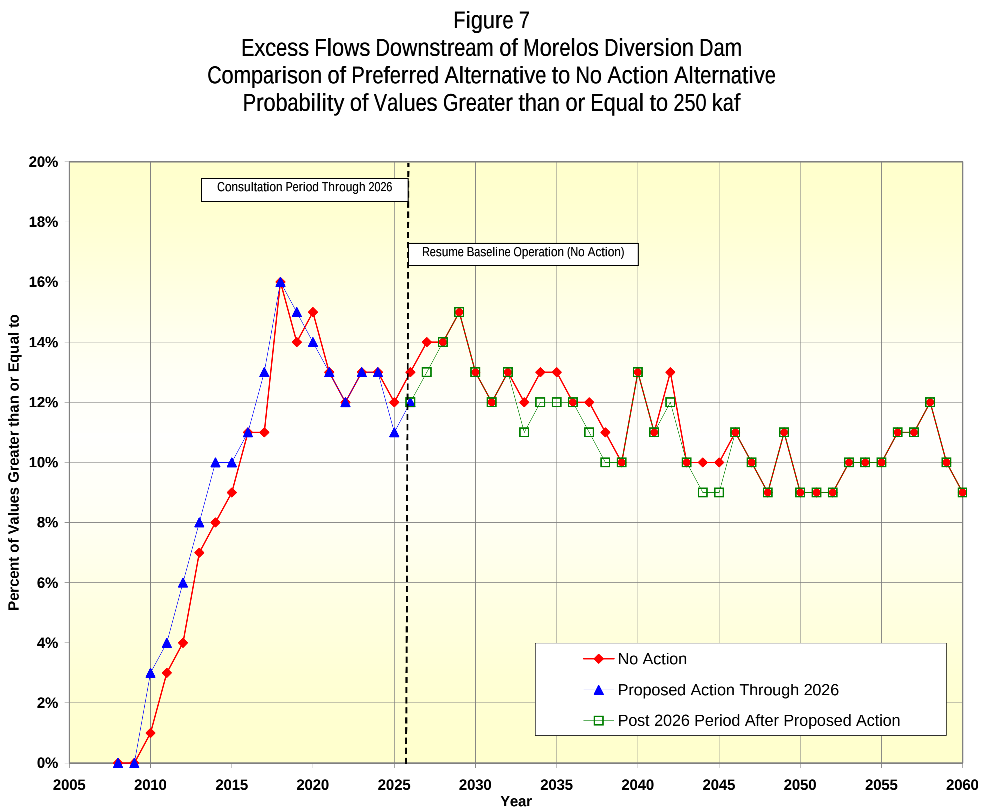
Lake Mead End-of-December Water Elevations
Percent of Values Less than or Equal to Elevation 950 feet msl



A.4.3 Effects of Proposed Action on Beneficial Flows past Morelos Diversion Dam - Limitrophe Reach

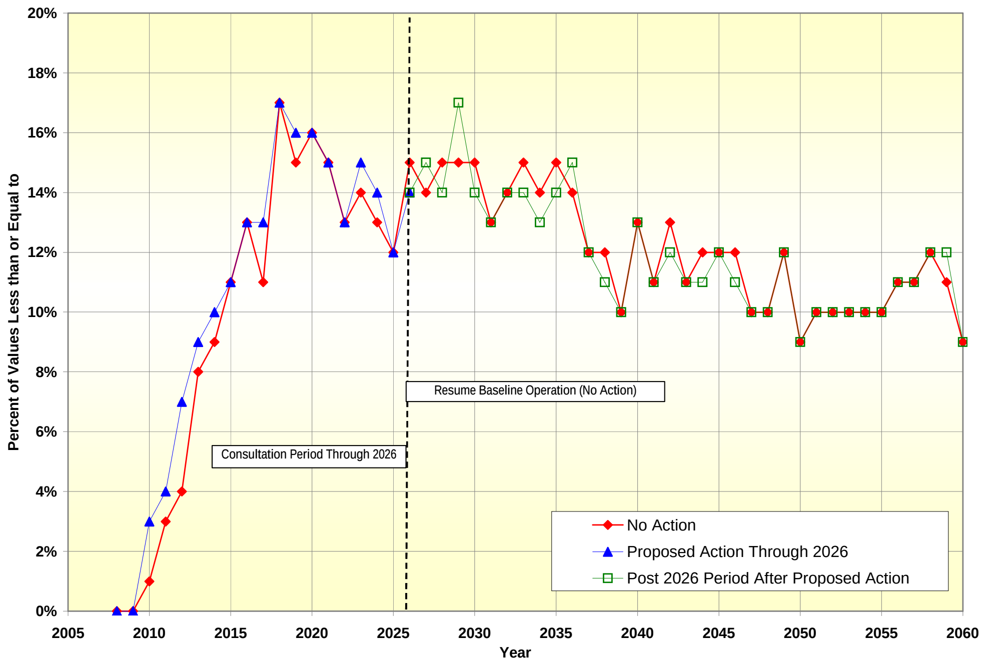
The MSCP BCO included the effects of the covered actions and activities on beneficial flows arriving at Morelos Diversion Dam.

Beneficial flows were defined as flows exceeding 250 kafy in excess of Mexico's water order arriving at Morelos Diversion Dam (MSCP Appendix L). Other ongoing activities including the proposed lower Colorado River Drop 2 Storage Reservoir Project and the Laguna Reservoir Restoration Project would not affect flows arriving at Morelos Diversion Dam exceeding 250 kafy. The MSCP analysis determined that there would be no significant effects on beneficial flows below Morelos Diversion Dam as a result of MSCP covered actions and activities. Figure 7 presents a comparison of the probability of beneficial flows exceeding 250 kafy for the No Action Alternative and the proposed action. Under the proposed action there is a slight increase in probability of beneficial flows over the consultation period (Figure 7) as compared to the No Action Alternative from the Final EIS due primarily to the conservation element of the proposed action. However, this increase is not deemed to be a significant change in the probability of these beneficial flows.



The probabilities of any excess flows of any magnitude arriving at Morelos Diversion Dam were also analyzed. These probabilities showed the same trend in flows of greater than 250 kafy arriving at Morelos Diversion Dam in excess of Mexico's water order (Figure 8).

Figure 8
Excess Flows Downstream of Morelos Diversion Dam
Comparison of Preferred Alternative to No Action Alternative
Probability of Occurrence



It is noted that with the exception of extremely high mainstream Colorado River flows from 1983 to 1985, the beneficial flows arriving at Morelos Diversion Dam since the 1970s have largely been a result of Gila River flows. Gila River flows are unaffected by the proposed action. Tributary inflows from the Gila River to the mainstream are very sporadic, occur very seldom, and when they do, are typically of high magnitude. These flows were not included in the analysis of excess flows arriving at Morelos Diversion Dam prepared for the MSCP or in the analysis presented herein. Therefore, the timing and benefits from those flows reaching Morelos Diversion Dam are not considered in this analysis.

A.5 Conclusion

The MSCP BCO stated, “At the time the shortage guidelines are adopted, Reclamation will complete an analysis to determine if the effects are within the range of effects analyzed in the BA. If they are not, additional consultation may be required.” Based on the analysis herein, Reclamation concludes that the potential effects of the proposed action that fall within the MSCP BCO planning area boundary were covered in the previous consultation for the MSCP, and no significant new information exists that would require additional consultation for the proposed action.

Attachment B

Evaluation of Interrelated/Interdependent Effects of Tributary Conservation Intentionally Created Surplus Projects

This attachment to Appendix R describes the analysis of the effects of the interrelated/interdependent action of Southern Nevada Water Authority's proposed Virgin River and Muddy River tributary conservation Intentionally Created Surplus (ICS) projects.

B. Evaluation of Interrelated/Interdependent Effects of Tributary Conservation Intentionally Created Surplus Projects

B.1 Overview

Between 2000 and 2007, the Colorado River experienced the worst drought in approximately 100 years of recorded history. Currently, the Bureau of Reclamation (Reclamation) does not have specific guidelines to address the operation of Lake Powell and Lake Mead under drought and low reservoir conditions. To address this situation, the Secretary of the Interior (Secretary), acting through Reclamation, proposes to adopt interim Colorado River guidelines for Lower Basin shortages and coordinated operations for Lake Powell and Lake Mead (proposed federal action). The federal action is proposed in order to provide a greater degree of certainty to Colorado River water users and managers of the Colorado River Basin by providing more detailed objective guidelines for the operation of Lake Powell and Lake Mead, thereby allowing water users in the Lower Basin to know when, and by how much, water deliveries will be reduced during drought and other low reservoir conditions.

The Preferred Alternative, the proposed federal action, identified during development of the Environmental Impact Statement (EIS) includes the adoption of a mechanism to encourage and account for augmentation and conservation of water supplies, e.g., fallowing of land, canal lining and other system efficiency improvements, and introduction of tributary and non-system water in the Lower Basin. The mechanism, referred to as Intentionally Created Surplus (ICS), provides for creating credits for the conserved or imported water and delivering the water at a later date. Tributary conservation is a form of ICS where water rights on Colorado River tributaries within the Lower Basin that have been used for a significant period of years and were created prior to Congress' adoption of the Boulder Canyon Project Act of 1929 (BCPA) could be retired and allowed to flow into the Colorado River mainstream. The Lower Division state or contractor that provides such tributary conservation ICS could then recover the amount of water contributed through tributary conservation ICS for municipal or industrial purposes. Additional modeling details of the ICS mechanism are described in the main body of this Biological Assessment (BA) to which this analysis is attached.

B.1.1 Proposed Action

The proposed federal action to be analyzed in the BA is the adoption and implementation of interim Colorado River guidelines for Lower Basin shortages and coordinated operations for Lake Powell and Lake Mead. One of the components of the proposed federal action is the adoption of guidelines for creating and delivering conserved Colorado River system and non-system water in Lake Mead, referred to as ICS. The Southern Nevada Water Authority (SNWA) has proposed a project which would be implemented under this component of the proposed federal action. The SNWA proposal would allow pre-BCPA water rights on the Virgin and Muddy Rivers to be retired from their current use and would cause the water secured by SNWA through this process to flow into Lake Mead for crediting and delivery for municipal and industrial purposes. The SNWA proposal is interrelated/interdependent with the proposed federal adoption of ICS component element of the interim guidelines. Without the proposed federal action, the SNWA proposal for tributary conservation ICS would not go forward as described herein. Specifically, this section of the BA analyzes the interdependent/interrelated effects of the SNWA proposal.

B.1.2 Scope

B.1.2.1 Action Area

The entire action area for the SNWA proposal includes the channel of the Lower Virgin River and its floodplains and the channel of the Muddy River and its floodplains. The action area in the Lower Virgin River extends from the Nevada/Arizona border, to the confluence of Lake Mead (Figure 1). The action area in the Muddy River begins south of the headwaters at Warm Springs and extends to the confluence of Lake Mead (Figure 2).

B.1.2.2 Scope of Biological Assessment

This section of the BA analyzes the potential effects in the action area of allowing water rights perfected before the effective date of the BCPA to flow down through irrigation company systems and/or the channels and floodplains of the Lower Virgin River and Muddy River to Lake Mead. This portion of the BA does not analyze the potential effects of flow from the Virgin and Muddy Rivers after it enters Lake Mead. Those effects have been analyzed and addressed as part of the Lower Colorado River Multi-Species Conservation Program (MSCP) (USBR 2004a:2-18). Further, the effects of the Lower Basin shortage guidelines and coordinated operations of Lakes Powell and Mead (Lake Powell to Lake Mead) are analyzed in a separate BA to which this analysis is attached.

B.2 Project Description

Water rights on the Virgin and Muddy Rivers that were perfected prior to the effective date of the BCPA (1929) are not subject to provisions in the BCPA and have priority over any water rights appropriated on the Virgin and Muddy Rivers after 1929. The SNWA has been purchasing pre-BCPA water rights on the Virgin and Muddy Rivers since 1997, in an effort to reduce SNWA’s dependence on the Colorado River and develop additional water supplies for Southern Nevada. Water rights historically used for agriculture along these rivers are being voluntarily sold or leased to willing buyers, including buyers not associated with SNWA. Sometimes the water rights are leased back for agricultural use with a provision that at the end of the lease term, the water rights will be retired and allowed to return to the river system. SNWA's purchase and retirement of pre-BCPA water rights will allow for assured flows within the entire Muddy River and the portion of the Virgin River below the Mesquite and Bunkerville Irrigation Companies by using flows that were historically consumptively used off channel by agriculture for the creation of tributary conservation ICS.

Pre-BCPA water rights on the Virgin River have a priority date of pre-1905 and were decreed by the Nevada Supreme Court in 1927. The decree allocated 17,785 acre-feet per year (afy) to the

Bunkerville and Mesquite Irrigation Companies. SNWA currently owns shares in the Bunkerville Irrigation Company representing approximately 3,700 afy of surface water rights. On the Muddy River, water rights were decreed in 1920 and that decree allocated the entire flow of the Muddy River. On the Lower Muddy River, the entire flow of the river is diverted by the Muddy Valley Irrigation Company (MVIC) for agricultural use. SNWA currently owns shares in the MVIC representing approximately 7,000 afy of surface water rights and leases approximately 1,000 afy from the LDS Church. The LDS Church lease is for a term of 20 years, with the option to renew the lease for an additional 20 years.

SNWA anticipates acquiring a total of approximately 30,000 afy of pre-BCPA water rights from entities with rights on the Virgin and Muddy Rivers. Approximately one-third of this amount is expected to come from the Virgin River and two-thirds from the Muddy River. This is consistent with the flow volumes that were analyzed in the Final EIS for the shortage and coordinated reservoir operations guidelines and in the analysis for Lake Mead for the MSCP.

As of July 1, 2007, SNWA has acquired water rights from Virgin and Muddy River sources that will yield an average annual water supply of approximately 11,700 afy. The anticipated method of conveying these water supplies through the Virgin and Muddy Rivers to the Overton Arm of Lake Mead is described in Table 1 below. It is anticipated that the additional water supplies to be secured by SNWA (the remainder of the 30,000 afy analyzed here) will be conveyed through the Virgin and Muddy Rivers, via the Overton Arm to Lake Mead through a similar process. SNWA will pursue acquiring water rights on both the Upper Muddy River and on the Lower Muddy River from MVIC; however it is much more likely that the remaining acquisitions on the Muddy River will be from MVIC shareholders. It is unknown at this time from exactly which sources on the Virgin River SNWA will acquire these additional water supplies.

The retired agricultural water rights will be conveyed to Lake Mead via the Overton Arm in one of two fashions. The water will be diverted from the river through its historic point of diversion, flow through irrigation company ditches, and return to the mainstem of the river further downstream if the flow is necessary in the irrigation company ditches to avoid impacts to the irrigation company's operations or wildlife, such as southwestern willow flycatcher and other bird species that may rely on agricultural returns to support their habitat. This is the proposed operation for waters thus far acquired in the Bunkerville Irrigation Company and MVIC. Alternatively, if the water is not associated with an irrigation company or not required for the purposes described above, it will remain in the mainstem of the river. The conveyance of SNWA's water rights can be flexible, based on the irrigation company operating requirements and wildlife needs. To accommodate these needs, the water rights may be diverted at different places or during different times of the year.

Table 1
Example of Conveyance of Tributary Conservation ICS from Virgin and Muddy Rivers to Lake Mead

River	Irrigation Company/Water Right Holder	SNWA's current ownership/leases (approximate values in afy)[a]	SNWA's potential range of acquisitions (approximate values in afy)[b]	SNWA's total future potential ownership/leases (approximate values in afy)[c]	Method of Conveyance
Virgin	Mesquite Irrigation Company	0	0-3,000	Up to 3,000	Remain in river at historic point of diversion
Virgin	Bunkerville Irrigation Company	3,700	4,300 - 6,300	Up to 10,000	Diverted at the historic point of diversion and flow through irrigation company ditches before returning to the river further downstream
Muddy	MVIC	7,000	8,500 - 12,000	Up to 20,000	Diverted at the historic point of diversion and flow through irrigation company ditches before returning to the river further downstream
Muddy	LDS Church Lease	1,000	0 – 1,000	Up to 2,000	Remain in river at the historic point of diversion
Muddy	Other Users	0	0 – 2,500	Up to 2,500	Remain in river at the historic point of diversion

a – Based on conveyance of 11,700 afy water supply secured as of June 1, 2007

b – Based on future potential conveyance of additional 18,300 afy water supply

c - In aggregate supplies will not exceed 30,000 afy however, it is difficult to predict how much water will be purchased from the separate right holder

B.3 Environmental Baseline

B.3.1 Geology and Soils

The project action area is within the Colorado River Regional Flow System (CRRFS) within the southern Great Basin, a sub-province of the Basin and Range Physiographic Province. Land surface elevations in this part of the basin range between approximately 500 feet above mean sea level in the vicinity of Laughlin to approximately 11,900 feet above mean sea level at Charleston Peak in the Spring Mountains. Mountain ranges in this region generally follow northwest southeast trends and the basins are filled with valley-fill sediments, including some volcanic deposits. There are 27 hydrographic areas within the CRRFS. Of these twenty-seven hydrographic areas, five occur within the proposed action area. They are the Lower Meadow Valley Wash, Muddy River Springs Area, California Wash, Lower Moapa Valley (includes the Muddy river), and Virgin River Valley (includes the Virgin River). Other characteristics of the CRRFS include minimal precipitation, intermittent streams, large internal surface drainages, and sparsely distributed springs (BLM 1998).

The CRRFS is located in the southern part of the Great Basin and has an area of about 12,376 square miles (BLM 1998). The region includes part of Clark, Lincoln, Nye and White Pine counties and extends to the south to California, borders the Colorado River to the south and east and extends into the state of Arizona and Utah to the east.

Several periods of regional deposition, uplift, igneous activity and erosion have occurred since the Paleozoic. Thick sequences of marine sedimentary deposits accumulated throughout Paleozoic and Mesozoic times. Approximately 50 million years ago, thick volcanic materials extruded over broad areas of the region, then were uplifted and deformed by faulting.

Soils in the area of the proposed project are classified as "Shallow-Moderately Deep Rocky Gravelly Coarse Textured, Badlands, Shallow-Deep Medium Gravelly Textured, and Shallow-Very Shallow Gravelly Coarse Textured."

B.3.2 Hydrology

B.3.2.1 Lower Virgin River

The Virgin River occupies a 6,000 square mile watershed situated between the Colorado Plateau, the Great Basin, and the Mojave Desert, within the states of Nevada, Arizona, and Utah. The Virgin River is tributary to the Colorado River and discharges to Lake Mead approximately 60 miles upstream of Hoover Dam. The river begins in Washington County, Utah, at an elevation of approximately 10,000 feet above mean sea level (AMSL), some 150 miles from its mouth.

Flows in the Virgin River are principally influenced by snowmelt in the mountains in southwestern Utah and flooding from summer monsoonal storms. The Littlefield gage is located upstream of the Bunkerville and Mesquite Irrigation Companies. Gage flows are highly variable as seen in Table 2. A maximum discharge of 36,500 cubic feet per second (cfs) was recorded in 2005 and a minimum daily flow of 40 cfs was recorded in 1966. Currently, there is no operational gage below the Bunkerville and Mesquite diversions and their respective agricultural return flows. However, the Halfway Wash Gage was operated from 1977 to 1983 and in 1985. The gage record for this site was reconstructed by Bache et al. in 2006 and shows an annual average flow of 144,800 afy. This is approximately 30,000 afy lower than the flow at the Littlefield Gage (see Table 2).

B.3.2.2 Muddy River

The Muddy River watershed is located in Nevada, immediately northeast of the Las Vegas Valley. The Muddy River discharges to Lake Mead approximately 60 miles upstream of Hoover Dam. Before the construction of the dam and the subsequent flooding of the Colorado and Virgin River Valleys, the Muddy River discharged to the Virgin River, upstream of the confluence of the Virgin and Colorado Rivers.

The highest point in the watershed is Hayford Peak at elevation 9,912 ft AMSL in the Desert National Wildlife Refuge, north of the Las Vegas Valley. The headwaters of the Muddy River's longest tributary are in Lincoln County, at an elevation of approximately 7,300 ft AMSL near the Utah border, nearly 100 miles upstream of Lake Mead. The watershed includes the Pahranagat Valley near Alamo. The Pahranagat Wash flows through the Pahranagat Valley and southward into Coyote Spring Valley, where it joins the Muddy River. The Muddy River continues to the southeast, passing through Arrow Canyon, before it heads southeast, emerging into the Moapa Valley. In its lower reach, the Muddy River passes the towns of Moapa, Glendale (at Interstate-15), Logandale, Glassand, and Overton before discharging to Lake Mead. Glendale is located about 4 miles upstream of the existing Bowman Reservoir, a 4,000 acre-feet surface storage reservoir. Several washes contribute flow to the River along its course, the largest of which is Lower Meadow Valley Wash. Lower Meadow Valley wash joins the river near the intersection of the river and Interstate-15 in Glendale.

Irrigated agriculture is practiced along the flood plain of the lower Muddy River near Moapa and further downstream between Logandale and Overton.

Unlike the Virgin River, which gains the majority of its flow from snow melt and rainfall events, a substantial portion of the Muddy River flows are from spring discharges in the Warm Springs area northwest of Moapa. Because of this, the Muddy River has a more stable base flow and has less variance in annual discharge; however, floods from the Pahranagat River or Lower Meadow Valley Wash can cause large spikes in river flow. The USGS maintains a series of gaging stations on the Muddy River shown in Figure 2. Table 3 summarizes data of three USGS gaging station located along the river.

The Muddy River is generally divided into two portions when addressing surface water rights, the area above Wells Siding Diversion (Upper Muddy River) and the area below (Lower Muddy River). The Muddy River decree allocated between 4,000 and 5,000 afy to users upstream of the Wells Siding Diversion (Upper Muddy River) and the entire remaining flow of the river at the Wells Siding Diversion to the MVIC. SNWA's current ownership on the Upper Muddy River is limited to a 1,000 afy lease from the LDS Church. This water was historically used primarily upstream of the Moapa Gage, but some of the leased water currently flows in the river channel. In recent years, the lands along the Upper Muddy River have been used for livestock, not active farming, resulting in a lower water use than what was historically used and decreed.

In the Lower Muddy River, the surface flows are measured at the Overton Gage which averages approximately 9,000 afy. The Overton Gage is very near the top of full pool elevation in Lake Mead (1,229 ft-AMSL). Therefore, this gage is believed to reflect surface water flows reaching Lake Mead. While there have been no studies confirming irrigation system losses to the alluvium, it is believed that there is water bypassing the Overton gage as underflow from irrigation system losses.

B.3.3 Lower Virgin River Vegetation

The riparian corridor of the Lower Virgin River is comprised of several plant vegetation types. The major types of vegetation include screwbean mesquite (*Prosopis pubescens*), salt cedar (*Tamarisk sp*.), cottonwood/willow (*Populus fremontii, Salix sp.*), arrowweed (*Pluchea sericea*), honey mesquite (*Prosopis glandulosa*), iodine bush (*Allenrolfea occidentalis*), atriplex (*Atriplex sp*), and marsh. Along the edges of the floodplain and transitioning into upland habitats creosote (*Larrea tridentata*) and lycium (*Lycium sp.*) vegetation types occur (Bio-West Inc. 2001:13-18). The main channel of the river is void of vegetation because of recent erosional or depositional events within the floodplain during a January 2005 flooding event and consists of open water islands, sandbars, and gravel bars. Substrate consists of coarse sands and gravels. However, the main channel has begun to re-incise itself and site visits have indicated vegetation has begun to sprout from the re-worked sediments. The following is a brief description of the major vegetation types within the Virgin River floodplain:

- **Salt Cedar –** The exotic, non-native salt cedar vegetation type is the most common throughout the floodplain and a co-dominant species with most of the plant communities. The salt cedar vegetation type is dominated by salt cedar and has a dense to moderately dense canopy depending on the maturity of the population and has very little herbaceous cover in the under story. The salt cedar vegetation type is found throughout the floodplain but most often appears to be associated with a fine sand and clay substrate.

- **Screwbean Mesquite –** The screwbean mesquite vegetation type is composed of almost entirely screwbean mesquite with some degree of salt cedar component or arrowweed, and is also found as a co-dominant within other vegetation types. This plant vegetation type occurs on all substrates within the area except bedrock.

- **Cottonwood/Willow –** The cottonwood/willow vegetation type is dominated by cottonwood and varied species of willow including coyote willow (*Salix exigua*), and gooding's or black willow (*Salix goodingii*).

- **Arrowweed –** The arrowweed vegetation type is dominated by arrowweed, a low to medium shrub. The arrowweed habitat is low in plant density and diversity. Arrowweed is found throughout the floodplain on sandy sites near or in old channels adjacent to the present river channel. Single stands of arrowweed are uncommon and the populations usually have co-dominant species of screwbean mesquite or are a co-dominant of other communities.

- **Honey Mesquite –** The honey mesquite vegetation type is similar to the screwbean mesquite vegetation type but is very limited within the area.

- **Iodine Bush –** The iodine bush vegetation type is dominated by iodine bush with occurrences of pickleweed (*Salicornia sp.*) and bush seepweed (*Sueda moquinii*). Iodine bush has a limited occurrence in the area. This vegetation type is found on low areas where water slowly evaporates with saline soil conditions.

- **Atriplex –** The atriplex vegetation type is dominated by various atriplex species and when it does occur it is usually a co-dominant of other communities. This vegetation type is found on low areas where water slowly evaporates with saline soil conditions.

- **Marsh –** The marsh vegetation types vary from areas of prolonged inundation or shallow water with dense cover of cattails (*Typha domingensis*) and bulrush (*Scirpus pungens*) to barely vegetated sand bars with young plants of various species just beyond the seedling stage. The marsh vegetation type is common within the area with smaller size communities in the northern portion of the river and larger areas to the south closer to Lake Mead.

- **Creosote –** The creosote vegetation type is dominated by creosote with occurrences of typical upland species found in Mojave Desert scrub habitats. This vegetation type is found along the edge of the flood plain.

- **Lycium –** The lycium vegetation type is dominated by box thorn (*Lycium sp.*) and is found along the edges of the flood plain. This vegetation type and species are also found within the creosote vegetation type.

B.3.4 Muddy River Vegetation

The major types of vegetation on the Muddy River include screwbean mesquite, salt cedar, cottonwood/willow, arrowweed, honey mesquite, atriplex, Acacia (*Acacia sp.*), mulefat (*Baccharis salicifolia*) and marsh (Provencher 2005:86-92). The Muddy River channel is incised in most areas and has been modified for flood control and agricultural purposes. A majority of the river is adjacent to agricultural lands. The only portion of the river that does not have some adjacent agricultural lands is the portion of the river below the Overton Wildlife Management Area. The banks of the river are dominated by tamarisk with pockets of marsh. The following is a brief description of the major vegetation types within the Muddy River floodplain that are not already described above:

- **Acacia –** The Acacia vegetation type is monotypic being dominated by Acacia and has very limited occurrence within the floodplain. This vegetation type is also a co-dominant within saltcedar and Atriplex vegetation types.

- **Mulefat –** The mulefat vegetation type is monotypic dominated by mulefat and has very limited occurrence in the floodplain. This vegetation type is also a co dominant within the saltcedar vegetation type.

B.3.5 Wildlife

B.3.5.1 Riparian and Aquatic Obligate Wildlife

Lower Virgin River Bird Species. The various riparian habitats along the floodplain of the Lower Virgin River support a variety of wildlife species. The riparian habitats are important sources of water, cover and foraging for many species. Probably the most diverse wildlife that uses this habitat is bird species. Bird species that occur are both year-round residents and migratory. Some of the birds observed along the Virgin River include cedar waxwing (*Bombycilla cedrorum*), lesser nighthawk (*chordeiles acutipennis*), western kingbird (*Tyrannus verticalis*), white-throated swift (*Aeronautes saxatalis*), yellow warbler (*Dendroica petechia*), and yellow-breasted chat (*Icteria virens*) (Braden 2006:21-28).

Lower Virgin River Endangered Bird Species. Two federally listed bird species are known to occur within the Lower Virgin River: southwestern willow flycatcher (*Empidonax trailli extimus*) and Yuma clapper rail (*Rallus longirostris yumanensis*). The southwestern willow flycatcher was listed as endangered in 1995. The species is known to breed in dense, mesic riparian habitats throughout the Southwest, including the Lower Virgin River. Streams of lower gradient and/or more open valleys with a wide/broad floodplain support southwestern willow flycatcher breeding habitat in Southern Nevada. Nesting habitat is largely associated with perennial stream flow that supports thickets of trees and shrubs ranging in height from two to thirty meters. Southwestern willow flycatcher food availability may be largely influenced by the presence of moist soils, which attracts the insects that southwestern willow flycatchers are known to consume (USFWS 2005:60908-60912). Some of the habitat for southwestern willow flycatcher along the Lower Virgin River is associated with agricultural return flows (SWCA 2007:62-63). Approximately 474 acres of southwestern willow flycatcher habitat has been identified along the Virgin River, occurring around Littlefield, Arizona, Mesquite, Nevada, and Mormon Mesa (SWCA 2007:20-26).

Yuma clapper rail was listed as federally endangered in 1967. It is a marsh obligate species that is found in freshwater habitats along the Colorado River and its associated drainages, including the Lower Virgin River. Preferred Yuma clapper rail habitat consists of mature cattail-bulrush stands in shallow water near high ground. Stands of cattails (*Typha spp.*) and bulrush (*Scirpus spp.*) dissected by narrow channels of flowing water have been observed to support the densest populations of birds (USFWS, 1983:7). The marsh habitat found along the Lower Virgin River that supports Yuma clapper rail is typically dominated by cattail and bulrush (Braden 2006:1). It is estimated that about 412 acres of marsh habitat occur along the Lower Virgin River (USBR 2004b:3.4-17)

In contrast to the Upper Virgin River, the Lower Virgin River is largely unaltered by dams or reservoirs. Some portions of the Lower Virgin River have been known to go dry during the summer months due to upstream water uses combined with the effects of drought and the complex geology and braiding of the channel resulting in underflow. However, the river is susceptible to a natural flood cycle that is unimpeded by dams and reservoirs in the Lower Virgin River. These natural floods may temporarily impact the habitat of southwestern willow flycatcher and Yuma clapper rail (SWCA 2007:21, Braden 2006:2). As mentioned above, a natural flood event in January 2005 did impact habitat along the Lower Virgin River. However, recent surveys have shown that the vegetation is returning and this natural cycle of the Virgin River is not anticipated to have long-term impacts on bird species (SWCA 2007:21).

Based on historical surveys and recent surveys by SWCA Environmental Consultants and the San Bernardino County Museum, the Yuma clapper rail occurs within the Virgin River and have been observed at Littlefield, Mesquite, Mormon Mesa, and the Virgin River Landing (Braden 2006:17-18). The southwestern willow flycatcher has been observed along the Virgin River at Littlefield, Mesquite, and Mormon Mesa (SWCA 2007:20-27).

Brown pelican (*Pelecanus occidentalis*) and the recently delisted bald eagle (*Haliaeetus leucocephalus*) have not been observed on the Virgin and Muddy Rivers. Surveys conducted by San Bernardino County Museum on both rivers from 1999 to 2005 have not detected the species (Braden 2005: 3.24-3.28; Braden 2006: 21-28). In addition, brown pelicans are known to feed by visual detection and plunge diving (Ashmole 1971). Turbid waters, such as the Virgin and Muddy Rivers, are typically avoided by brown pelicans (Ainley 1975; Murphy 1936).

Lower Virgin River Candidate Bird Species. One candidate bird species is known to occur within the Lower Virgin River. The western yellow-billed cuckoo (*Coccyzus americanus occidentalis*) was designated as a candidate species for listing under the Endangered Species Act in 2001 (USFWS 2001:38611). The species is found in stream-side willow habitats along the Lower Virgin River consisting of willow, tamarisk, Fremont cottonwood (*Populus fremontii*), and honey mesquite (Braden 2006:1). Based on historical surveys and recent surveys by the San Bernardino County Museum, western yellow-billed cuckoos occur within the Virgin River and have been observed at Littlefield, Mesquite, Mormon Mesa, and the Virgin River Landing (Braden 2006:17-18).

Lower Virgin River Fish Species. Based on data collected after 1984 and more recent sampling conducted by Bio-West Inc. it appears that the dominant fish populations are non-native species (USFWS 1995: 11-12; Bio-West, Inc. 2007: 16, 19, 22, 24). Non-native fish that occur within the Lower Virgin River include black bullhead (*Ameiurus melas*), channel catfish (*Ictalurus punctatus*), common carp (*Cyprinus carpio*), green sunfish (*Lepomis cyanellus*), largemouth bass (*Micropterus salmoides*), western mosquitofish (*Gambusia affinis*), red shiner (*Cyprinella lutrensis*), and blue tilapia (*Oreochromis aureus*) (Bio-West, Inc. 2007:16).

One fish species protected by a conservation agreement is known to occur within the Lower Virgin River. Virgin spinedace (*Lepidomeda mollispinis mollispinis*) was protected by the multi-agency Virgin Spinedace Conservation Agreement and Strategy finalized in 1996. The goal of the agreement is to reestablish and maintain water flows, enhance and maintain spinedace habitats, maintain genetic viability, and monitor populations. The Virgin spinedace is a small silvery minnow no more than two to four inches in length. The species tends to frequent pools with instream vegetation or boulders (Utah Division of Wildlife Resources 2002:4-5). The Virgin spinedace is extremely rare in the Lower Virgin River but one was observed in 2005 (Bio-West Inc. 2007:14).

Lower Virgin River Endangered Fish Species. Two federally endangered fish species are known to occur within the Lower Virgin River: woundfin (*Plagopterus argentissimus*) and Virgin River Chub (*Gila seminuda*). Woundfin was listed as endangered in 1970. The species is a streamlined, silvery minnow that is found within runs and quiet waters adjacent to riffles (USFWS 1995:v). Virgin River chub was listed as endangered in 1989. The species is a silvery, medium-sized minnow that averages 8 inches in total length but can grow as much as 18 inches. Virgin River chubs are most often associated with deep runs or pool habitats of slow to moderate velocities with large boulders or instream cover (USFWS 1995:v).

Bio-West Inc. has observed limited numbers of native fish species. In Fall 2005, 49 flannelmouth suckers (*Catostomus latipinnis*), 46 desert suckers (*Catostomus clarki*), 321 speckled dace (*Rhinichthys osculus*), four woundfin, 57 Virgin River Chub, and one Virgin spinedace were documented (Bio-West Inc. 2007:14, 18, 20, 23). Competition and predation from non-native fish species, drought, increased water temperature, and increased water clarity, are all identified as impacts to native fish species within the Virgin River (Bio-West, Inc. 2007:1). Although non-native fish species are found throughout the Lower Virgin River, they tend to be more prevalent below the Bunkerville Diversion (Bio-West, Inc. 2007: 16, 19, 22, 24). The Bunkerville Diversion is considered to be acting as a partial fish barrier for non-native species moving upstream from Lake Mead.

Muddy River Bird Species. The various riparian habitats along the floodplain of the Muddy River within the proposed action area support a variety of wildlife species. Overall, the same bird species found on the Virgin River are also found on the Muddy River. The riparian habitats are important sources of water, cover and foraging for many species. Probably the most diverse wildlife to use the habitat is bird species. Bird species that occur are both year-round residents and migratory.

Muddy River Candidate Bird Species. The candidate bird species, western yellow-billed cuckoo, is also known to occur on the Muddy River. The species is found in stream-side willow habitats along the Muddy River consisting of willow, tamarisk, Fremont cottonwood (*Populus fremontii*), and honey mesquite (Braden 2006:1). Western yellow-billed cuckoos have been observed in the Muddy River area on Warm Springs Ranch near the headwaters of the river and at Honeybee Pond within the Overton Wildlife Management Area (Braden 2006:17-18).

Muddy River Endangered Bird Species. The Muddy River provides habitat for the same endangered bird species that occur on the Lower Virgin River. Much of the habitat requirements are also the same. However, on the Muddy River, southwestern willow flycatcher habitat is not associated with agricultural return flows.

Based on historical surveys and recent surveys by the San Bernardino Museum, Yuma clapper rails have been observed in the Muddy River area at Honeybee Pond within the Overton Wildlife Management Area and within Maverick ditch behind the Maverick gas station on South Moapa Valley Boulevard just north of Lewis Avenue. Southwestern willow flycatchers have been observed within Overton Wildlife Management Area (SWCA 2007:27). It is estimated about 390 acres of riparian habitat that may support southwestern willow flycatcher is located within the Overton Wildlife Management Area (USFWS 2005: 60922).

Muddy River Fish Species. Based on historical data and more recent sampling conducted by Bio-West Inc., it appears that the dominant fish populations are non-native species (Bio-West Inc. 2005:9). Fish that occur within the Muddy River include black bullhead, channel catfish, common carp, green sunfish, largemouth bass, western mosquitofish, red shiner, and blue tilapia (Bio-West Inc. 2005:7).

Virgin River chub is also found on the Muddy River, however, when the Virgin River chub was listed in 1989, the Muddy River population was excluded from the listing. Therefore, the Virgin River chub found within the Muddy River is not currently protected under the Endangered Species Act (USFWS 1995:v).

Bio-West Inc. collected six Virgin River Chub just below the Wells-siding Diversion in May 2004, four at Cooper Road and one at Lewis Avenue. In addition one speckled dace was collected at the Wells-siding Diversion and one at Gubler Road (Bio-West Inc. 2005:9).

Muddy River Endangered Fish Species. The only endangered fish species in the Muddy River is the Moapa dace (Moapa coricea). Moapa dace was listed as endangered in 1967. It occupies approximately 6 miles of stream habitat in the thermal headwaters of the Muddy River, known as Warm Springs. The species can only successfully reproduce in the thermal spring outflows of the Muddy River headwaters which range from 85- 90 ºF in temperature (USFWS 1996:ii). In February 2007, 1,172 Moapa dace were counted within the upper Muddy River (S. Goodchild, personal communication February 22, 2007).

B.3.5.2 Critical Habitat

Lower Virgin River Endangered Fish Species. On January 26, 2000, the U.S. Fish and Wildlife Service (USFWS) listed critical habitat for woundfin and Virgin River chub within the Virgin River flood plain from the confluence of Ash and La Verkin creeks, Utah to Halfway Wash, Nevada (USFWS 2000:4141). Figure 3 shows the critical habitat designated within the action area. Competition and predation from non-native fish species, drought, increased water temperature, and increased water clarity, are all identified as impacts to native fish species within the Virgin River (Bio-West, Inc. 2007:1).

Muddy River Endangered Fish Species. No critical habitat has been designated for Moapa dace.

Lower Virgin River and Muddy River Endangered Bird Species. On October 19, 2005, the USFWS designated 73.8 miles of the Virgin River as critical habitat for the southwestern willow flycatcher (USFWS 2005:60922). Critical habitat on the river is contiguous from the Washington Field diversion impoundment in Washington County, Utah, downstream through the town of Littlefield, Arizona, and ends at the upstream boundary of the Overton State Wildlife Area in Clark County, Nevada. Figure 3 shows the critical habitat designated within the action area.

No critical habitat has been designated for the Yuma Clapper Rail.

B.4 Species Accounts for Potentially Affected Federally Listed and Candidate Species

This section describes further detail on those plant and animal species that are listed by the USFWS as threatened, endangered or candidate that may occur in the project area.

B.4.1 Virgin River Chub (*Gila seminuda*)

Federal Status: *Endangered* (Virgin River Population)

The Virgin River population of the Virgin River chub has been classified as endangered by the USFWS. Recent genetic studies of the Virgin River Chub on the Muddy River have concluded it is genetically identical to the Virgin River Chub on the Virgin River. The USFWS is currently undergoing status review of the Muddy River Population of the Virgin River Chub to determine whether that population is proposed for listing. This section describes both populations.

Table 4
Summary of Federally Listed and Candidate Species That May Occur in the Project Area

Species	Status	Range and Habitat of Species	Occurrence in Action Area
Fish			
Virgin River Chub (Virgin River Population) (Gila seminude)	E CH	Occurs within the virgin River in deep runs or pools of slow to moderate velocities with large boulders and in stream cover.	The Virgin River Chub is currently distributed within the Virgin River from La Verkin Springs, Utah to the diversion at Mesquite, Nevada USFWS 1970). The species has occurred in Halfway Wash but not downstream to Lake Mead. Critical habitat is from Utah to Halfway Wash.
Virgin River Chub (Muddy River Population) (Gila seminude)	E	Occurs within the Muddy River in deep runs or pools of slow to moderate velocities with sand, large rocks, and cover in the form of overhanging banks and tree roots.	This species has occurred historically from Warm Springs to Logandale. Based on recent surveys this species has been collected just below the Wells-siding diversion to several miles downstream.
Moapa Dace (Moapa coriacea)	E	Occur in spring pools, tributaries and the main portion of the Muddy River, but only reproduces in tributary thermal spring outflows.	This species is restricted to the upper Muddy River because of its affinity for warmer water. It is not expected to occur below the Wells-siding Diversion.
Woundfin (Plagopterus argentissimus)	E CH	Occurs in the Virgin River in run and quiet water regimes adjacent to riffles with sand substrate.	Occurs within the Virgin River from La Verkin Springs to just below Halfway Wash in Nevada. Critical habitat is from La Verkin to Halfway Wash.
Birds			
Western Yellow-billed Cuckoo (Coccyzus americanus occidentalis)	C	Occurs in mature cottonwood willow habitat in the southwestern United States	The western yellow-billed cuckoo occurs along the Muddy River and Virgin River within the project area.
Southwestern Willow Flycatcher (Empidonax traillii extimus)	E	Occurs in many locations in southwestern United States. Preferred habitat within NV is desert riparian habitats along rivers, and streams supporting willows, mulefat, or other riparian vegetation.	The southwestern willow flycatcher occurs within the project area along the Virgin River and Muddy Rivers.
Yuma Clapper Rail (Rallus longirostris yumanensis)	E	Occurs in freshwater marshes and requires regenerating marsh for foraging ad mature stands of cattail and bulrush for nesting.	The Yuma clapper rail occurs within the project area along the Virgin and Muddy Rivers.

E – Federally endangered T – Federally threatened C – Federal candidate for listing CH – Critical Habitat has been designated for species within action area

Species Biology. The Virgin River chub is in the minnow family. Although the typical individual is approximately 8 inches in length, the species can reach up to 18 inches in length (USFWS 2006d). Adults and juveniles inhabit deep runs or pools with slow to moderate velocities (up to 2.5 ft/s) over sand and having instream cover such as boulders. It is not present in water above 30°C (90°F) (USFWS 2006d). The Virgin River chub is omnivorous, eating algae, terrestrial and aquatic insects, organic detritus, and crustaceans; young fish feed primarily on invertebrates while adults eat algae and debris (USFWS 2006d). The species has a high tolerance for turbidity and salinity. Factors that currently limit the Virgin River chub include habitat loss and modification, and non-native fish (USFWS 2006d).Periods of spawning have not been well documented, but appear to coincide with the spawning periods for the woundfin.

Species Habitat and Range. Its distribution was thought to be restricted to the Virgin River, but more recent work has found that the roundtail chub found in the Muddy River is also the Virgin River chub. The current distribution of the Virgin River chub in the Virgin River is from Pah Tempe Springs in Utah to at least the Mesquite diversion near the Arizona-Nevada border (USFWS 2000). It historically was collected in the Virgin River from La Verkin Springs, Utah to the confluence of the Virgin River into the Colorado River. It also was collected in the Muddy River in Nevada. The fish is most often associated with deep runs or pools within the river.

Current Conditions Range Wide. The Virgin River chub is currently restricted to the Virgin and Muddy Rivers. It seems stable in those habitats; although the species is vulnerable to impact due to its limited distribution, increase of non-native species, water diversions and other disturbances.

Occurrence in Project Area. The Virgin River Chub is currently distributed within the Virgin River from La Verkin Springs, Utah to the diversion at Mesquite, Nevada (USFWS 1995). The Virgin River has been sampled most recently by Bio-West Inc. and by the Virgin River Fishes Recovery Team (VRFRT).

Distinct sample sites have been located at Halfway Wash, the Overton Wildlife Management Area (OWMA), and Virgin River Bowl and just above Lake Mead. Data collected from 2001 to 2004 indicates that the Virgin River Chub may no longer be present below Halfway Wash. The reason for the possible loss of this species is the long-term drought conditions and the dominance of non-native fish species. Recent data collected indicates that non-native species of fish are dominant in the lower portion of the river below Halfway Wash (Bio-West, Inc. 2007).

The Muddy River Population of the Virgin River chub was isolated from the Virgin River population by the construction of Hoover Dam and the filling of Lake Mead (USFWS 1996). The Virgin River chub Muddy River population has historically occurred in most abundance between the Warm Springs area and Logandale. The chub was rarely found below the I-15 Freeway and not below the Wells-siding diversion dam (USFWS 1996). Field studies by Bio-West, Inc. (2005) in 2004 found 31 Virgin River chub in there May survey. Surveys were conducted from the Wells-siding Diversion downstream to Lake Mead. Sample sites included

Wells-siding diversion, above Route 169, Route 169, below Route 169, Gubler Road, Yamashita road, Cottonwood road, Cooper road, Lewis Road, OWMA Diversion Dam, and the end of the river channel. With the exception of a year old fish, all were young of the year. Most of the fish caught were immediately below the Wells-siding Diversion, but 4 were found at Cooper Road and another at Lewis Road. In September 2005 Golden and Holden collected twelve adult and one young of the year immediately below the Wells Siding Diversion.

Other Actions by Federal, State or Local Agencies Affecting the Species in the Project Area. Currently, the City of Mesquite is developing the Virgin River Habitat Conservation and Recovery Program (VRHCRP) as a requirement to the Mesquite Lands Act. The VRHCRP is intended to provide coverage for impacts associated with the development of the Mesquite area and proposes to address Virgin River chub on the Virgin River.

Currently, Coyote Springs Investment (CSI), the Moapa Band of Paiutes, the Moapa Valley Water District, USFWS and SNWA are developing the Muddy River Recovery Implementation Program (MRRIP) to provide coverage for future groundwater development in Coyote Spring Valley. The MRRIP proposes to address the Muddy River population of the Virgin River chub.

Designated Critical Habitat. Approximately 140.1 km (87.5 mi) of the Virgin River within the 100-year flood plain from the confluence of Ash and La Verkin creeks, Utah to Halfway Wash, Nevada has been designated as Critical Habitat for the Virgin River population of this species (65 FR 4140-4156). This area is the last remaining occupied habitat for this species.

B.4.2 Moapa Dace (*Moapa coriacea*)

Federal Status: *Endangered*

Species Biology. The Moapa dace is federally-listed as endangered (USFWS 2006e). Moapa dace can grow to 4.7 inches. Adults prefer the main stem of the river as well as tributaries while juveniles prefer tributaries and areas with increasing velocity as they grow. Reproduction occurs all year but peaks in the spring. Threats to the species include non-native fish species and fish parasites brought in with the non-native fish. Moapa dace spawn year round with peak spawning activity in spring and a smaller peak in fall. Sexual maturity occurs in approximately one year. Moapa dace have only been found to successfully breed in warm water ranging between 86 and 89.6 degrees F (USFWS 1996). The dace is omnivorous eating a wide variety of aquatic insects and plants.

Species Habitat and Range. Moapa dace are endemic to the upper Muddy River and tributary thermal spring systems within the Warm Springs Area. Historically, the fish may have occupied as many as 25 springs and 10 miles of river habitat. Cooler water in the middle and lower Muddy River were likely a natural barrier to downstream movement of Moapa dace (USFWS 1996). The species currently occupies approximately 5.9 miles of stream habitat with five springs. This habitat ranges downstream to near the Warm Springs Road Bridge.

Cady Lamb, Baldwin, Muddy, Apcar, and Pederson Springs provide the warm water flows to this habitat.

Current Conditions Range Wide. The species appears relatively stable in its present distribution.

Occurrence in Project Area. The species is restricted to the upper Muddy River due to its affinity for warmer water, which is produced by the stream complex feeding the Muddy River. Therefore, it would not occur at or below the Wells Crossing Diversion Structure. Fish surveys did not find the species below the Warm Springs Road bridge (Bio-West, Inc. 2005).

Other Actions by Federal, State or Local Agencies Affecting the Species in the Project Area. Currently, Coyote Springs Investment (CSI), the Moapa Band of Paiutes, the Moapa Valley Water District, USFWS and SNWA are developing the MRRIP to provide coverage for future groundwater development in Coyote Spring Valley. The MRRIP proposes to address Moapa dace.

Designated Critical Habitat. No critical habitat has been designated for this species.

B.4.3 Woundfin (*Plagopterus argentissimus*)

Federal Status: *Endangered*

Species Biology. The woundfin is a small (less than 3.5 inches) fish in the minnow family with a life span of up to 4 years (NatureServe 2006). Adults are generally found in water less than 1.4 feet deep with velocities between 0.8 and 1.6 ft/s while juveniles occur in slower and deeper waters (USFWS 2000). Both use runs and quiet waters over sand or gravel adjacent to riffles. Larvae are found along the stream margin and in backwaters, often being associated with filamentous algae. Spawning occurs from April to July when water flows are declining (USFWS 2006c) over cobbles to gravel (NatureServe 2006). Woundfin are omnivorous, feeding on filamentous algae, detritus, tamarisk seeds, and insects (USFWS 2006c). Current threats to the species include habitat loss and degradation, competition from non-native fish, and predation. Spawning occurs in the spring months when the water levels are high and water temperatures rather low. Species survival tends to be dependent upon flow conditions and water temperature.

Species Habitat and Range. The woundfin historically ranged within the Colorado River from Yuma to the Virgin River in Nevada, Utah and Arizona. It also extended from the confluence of the Salt and Verde Rivers to the mouth of the Gila River near Yuma. A single individual was collected in the Muddy (Moapa) River (formerly a tributary of the Virgin River but now flows into the Overton Arm of Lake Mead) in the late 1960s, but it has not been found there since then (USFWS 2000). The woundfin has been extirpated from almost all of its historic range except for the Virgin River. Woundfin presently range from Pah Tempe (La Verkin) Springs, Utah on the main stem of the Virgin River and the lower portion of La Verkin Creek, Utah downstream to Lake Mead, Nevada (USFWS 1995).

Woundfin adults and juveniles are normally collected from runs and quiet waters adjacent to riffles. Juveniles generally use areas that are slower and deeper than those areas used by adults. Adults prefer water temperatures near 64 degrees F (USFWS 1995).

Current Conditions Range Wide. As described above, the woundfin is now restricted to the Virgin River.

Occurrence in Project Area. The Virgin River has been sampled most recently by Bio-West Inc. and by the VRFRT. Distinct sample sites have been located at Halfway Wash, OWMA, Virgin River Bowl and just above Lake Mead. They have both found that the woundfin is distributed as far downstream as Halfway Wash. The woundfin has been collected historically, but sporadically at Halfway Wash. The last known record of this species at Halfway Wash or downstream from there is in 1999 when two woundfins were collected by the VRFRT at Halfway Wash (Bio-West, Inc. 2005). No other woundfin have been collected at Halfway Wash or downstream with the most recent sampling event conducted by Bio-West in 2004.

Other Actions by Federal, State or Local Agencies Affecting the Species in the Project Area. Currently, the City of Mesquite is developing the VRHCRP as a requirement to the Mesquite Lands Act. The VRHCRP is intended to provide coverage for impacts associated with the development of the Mesquite area and proposes to address woundfin.

Designated Critical Habitat. Approximately 140.1 km (87.5 mi) of the Virgin River within the 100-year flood plain from the confluence of Ash and La Verkin creeks, Utah to Halfway Wash, Nevada has been designated as Critical Habitat for the species (65 FR 4140-4156). This area is the last remaining occupied habitat for this species.

B.4.4 Western Yellow-Billed Cuckoo (*Coccyzus americanus occidentalis*)

Federal Status: Candidate

Species Biology. The western yellow-billed cuckoo breeding season occurs in late May through early August. Nests are constructed of a variety of plant material and are concealed in a bush or tree at 2 to 20 feet from the ground. A clutch is generally 3 to 4 eggs and is incubated by the female for 9 to 11 days, with occasional help from the male. Nestlings are tended to by both parents and can fly about 21 days after hatching.

Species Habitat and Range. Western yellow-billed cuckoo is generally found in streamside cottonwood/willow and alder groves, open woodlands, parkland, gardens and orchards. Within the United States their breeding range includes areas of Idaho, Utah, California, Arizona and southern Nevada, and throughout most of the continent east of the Rocky Mountains to the Atlantic Coast. In Nevada, the western yellow-billed cuckoo is considered a rare and transient resident.

Current Conditions Range Wide. More information is needed on population size and occurrences of this species. The species is being reduced because of the loss of suitable habitat.

Occurrence in Project Area. Western yellow-billed cuckoo is currently known to occupy areas along the Muddy and Virgin Rivers in Southern Nevada with suitable habitat occupied intermittently among the years.

Surveys for western yellow-billed cuckoo have been conducted on the Muddy and Virgin rivers by the San Bernardino County Museum (Braden 2006). Eleven study sites were surveyed on the Virgin River and 5 sites were surveyed on the Muddy River. Survey sites on the Virgin River included three sites at Littlefield, Arizona, three sites near Mesquite, Nevada, three sites below Mormon Mesa and a site at Fisherman's Cove and at the Virgin River Landing (Braden 2006). Based on historical surveys and recent surveys by the San Bernardino County Museum, western yellow-billed cuckoos occur within the Virgin River and have been observed at Littlefield, Mesquite, Mormon Mesa, and the Virgin River Landing (Braden 2006:17-18).

The five sites surveyed on the Muddy River included Warm Springs Ranch near Glendale, Nevada, three sites near Overton, Nevada, and one site at Logandale, Nevada.

Western yellow-billed cuckoos have been observed in the Muddy River area on Warm Springs Ranch near the headwaters of the river and at Honeybee Pond within the Overton Wildlife Management Area (Braden 2006:17-18).

Other Actions by Federal, State or Local Agencies Affecting the Species in the Project Area. Currently, the City of Mesquite is developing the VRHCRP as a requirement to the Mesquite Lands Act. The VRHCRP is intended to provide coverage for impacts associated with the development of the Mesquite area and proposes to address western yellow-billed cuckoo.

Designated Critical Habitat. No critical habitat for the western yellow-billed cuckoo has been identified.

B.4.5 Southwestern Willow Flycatcher (*Empidonax traillii extimus*)

Federal Status: *Endangered*

Species Biology. The southwestern willow flycatcher is a small bird with an almost exclusive diet of insects. It usually nests in close proximity to water or very saturated soils. Often the habitat will dry up during the nesting season, but there still must be enough water to support riparian vegetation.

The species migrates into the area and normally nests in dense willow and salt cedar. After nesting is completed and young have fledged, individuals may disperse into other riparian areas.

Species Habitat and Range. The southwestern willow flycatcher is a small passerine bird that occupies riparian areas in southern California, New Mexico, southern Nevada, south central Colorado, Utah, west Texas and Arizona. The subspecies species usually nests in riparian habitat along rivers, streams, open water, cienegas, marshy seeps and or saturated soil where sense growth of riparian habitat occurs. The areas are typically dense growth of willows, baccharis, arrow weed, and salt cedar sometimes with an overstory of cottonwood. (Sogge, et al. 1997). The species typically nests in dense riparian areas with canopies 13-23 feet tall. Historically, the species nested primarily in dense willow habitat, but is now found in mixed habitats containing salt cedar.

Current Conditions Range Wide. The willow flycatcher is a riparian obligate species. Riparian habitat within its range has declined for a number of reasons including large-scale loss of wetlands, and degradation of riparian habitat through invasion of introduced plant species such as salt cedar. Brood parasitism by brown-headed cowbirds is also a major threat to nesting success.

Occurrence in Project Area. The southwestern willow flycatcher nests in a number of locations on the Lower Virgin River. Surveys are conducted on a yearly basis by SWCA, Inc. for the U.S. Department of Interior, Bureau of Reclamation (BOR) (SWCA 2007).

The following sites were surveyed along the Virgin River:

1) **Littlefield, Arizona.** The Littlefield site consist of two study areas, Littlefield North and South near the confluence of the Virgin River with Beaver Dam Wash. These sites include a stand of cottonwood with an understory of willow, salt cedar and Russian olive. No willow flycatchers were detected at either location in 2006.

2) **Mesquite, Nevada.** The Mesquite site consists of two study areas, Mesquite West and East. The Mesquite sites consisted of a mosaic of bulrush and cattail marshes separated by strips of willow and salt cedar. This vegetation is supported by runoff from two golf courses immediately adjacent to the site. Twenty-four resident breeding flycatchers were located at Mesquite West in 2006. One pair was detected at Mesquite East in 2006.

3) **Mormon Mesa North, Nevada.** This site is the farthest north of 6 sites located in the 15 km segment upstream from Lake Mead. This area is in a wide (1km) floodplain of the Virgin River. The area consists of a mosaic of habitat including salt cedar and willow forest, cattail forest and mixed native and exotic forests. No flycatchers were detected at Mormon Mesa North in 2006.

4) **Mormon Mesa South, Nevada.** Vegetation in this area consists of salt cedar with patches of willow and cattail. One willow flycatcher was detected at this location in 2006.

5) **Virgin River #1, Nevada.** This site consisted of areas of dense salt cedar with other areas containing a mixture of willows and salt cedar. One pair and two unpaired males were detected at this site in 2006.

6) **Virgin River #2, Nevada.** This site is a monotypic stand of dense salt cedar. In 2006, 11 resident breeding willow flycatchers, seven unpaired males were detected at this site.

One study site has been maintained on the lower Muddy River on the OWMA. The site consisted primarily of salt cedar with some willow. Ten resident breeding willow flycatchers and one unpaired male were detected in 2006.

Other Actions by Federal, State or Local Agencies Affecting the Species in the Project Area. Currently, the City of Mesquite is developing the VRHCRP as a requirement to the Mesquite Lands Act. The VRHCRP is intended to provide coverage for impacts associated with the development of the Mesquite area and proposes to address southwestern willow flycatcher.

Designated Critical Habitat. On October 19, 2005 the USFWS designated 73.8 miles of the Virgin River as critical habitat for the southwestern willow flycatcher (FR70 60886 – 61009). Critical habitat on the river is contiguous from the Washington Field diversion impoundment in Washington County, Utah, downstream through the town of Littlefield, Arizona, and ends at the upstream boundary of the Overton State Wildlife Area in Clark County, Nevada. The Critical habitat within the project area is within the Virgin Management Unit – Virgin River, NV/AZ/UT that is within the Lower Colorado Recovery Unit – Nevada, California/Arizona Border, Arizona, and Utah

The OWMA while having features essential to the southwestern willow flycatcher is being excluded from the critical habitat designation. The reason for the exclusion is the area is already being managed by the state of Nevada for wildlife and riparian habitat for the flycatcher.

B.4.6 Yuma clapper rail (*Rallus longirostris yumanensis*)

Federal Status: *Endangered*

Species Biology. The breeding season for the Yuma Clapper Rail occurs in March through August. Nests are built with plant stems and grasses within the marsh on elevated ground. Live vegetation is often pulled over the nest to form a canopy and conceal the nest. A clutch is generally made up of 8 to 11 eggs. Males and females incubate the eggs for 20 to 24 days. Nestlings are independent of the parents in 35 to 42 days and able to fly 63 to 70 days after hatching.

Species Habitat and Range. The Yuma Clapper Rail is a marsh obligate species found in freshwater habitats along the Colorado, Muddy, and Virgin Rivers as well as isolated portions of the Salton Sea, California (Braden 2006).

Current Conditions Range Wide. More information is needed on population size and occurrences of this species. The species is being reduced because of the loss of suitable habitat.

Occurrence in Project Area. Yuma Clapper Rail is currently known to occupy areas along the Muddy and Virgin Rivers in Southern Nevada with suitable habitat occupied intermittently among the years.

Surveys for Yuma clapper rail have been conducted on the Muddy and Virgin Rivers by the San Bernardino County Museum (Braden 2006). Eleven study sites were surveyed on the Virgin River and 5 sites were surveyed on the Muddy River. Survey sites on the Virgin River included three sites at Littlefield, Arizona, three sites near Mesquite, Nevada, 3 sites below Mormon Mesa and a site at Fisherman's Cove and at the Virgin River Landing (Braden 2006). The five sites surveyed on the Muddy River included Warm Springs Ranch near Glendale, Nevada, three sites near Overton, Nevada, and one site at Logandale, Nevada. The following is brief description of the current survey sites within the project area.

- Virgin River:
  - Mormon Mesa (Big Marsh, East Marsh and Long Marsh)
    1) Big Marsh is located along the northwestern bank of the Virgin River near Mormon Mesa. The marsh is fed by a springs and inflow from the river. Habitat in the marsh consists of dense stands of cattail with limited amounts of water.
    2) East Marsh is a small area east of the Virgin River and northeast of long marsh. East Marsh inflows are from spring runoff from the river.
    3) Long Marsh is a linear marsh habitat that parallels the river channel and is on the west side of the river. The habitat consists of cattail, tamarisk, and various willows.
  - Virgin Delta (Virgin River Landing and Fisherman's Cove)
    1) Virgin River Landing and Fisherman's Cove prior to 2003 were inundated by Lake Mead. In 2004 the sites supported dense stands of cattail with black willow and some tamarisk.
- Muddy River
  - Logandale (Bowman Canal, and Grant Bowler Park)
    1) Bowman Canal an overflow and runoff catchment for Bowman reservoir. The canal supports patches of cattails.
    2) Grant Bowler Park is located in Grant Bowler Park in downtown Logandale. The survey area is a stretch of the Muddy River that is adjacent to the park. The area consists of cattails with patches of tamarisk and willow.

3) Overton (Maverick Ditch)

4) The Maverick Ditch is located in the ton of Overton near the intersection of Cooper and Jones Streets. The site is dominated by cattail, bulrush, tamarisk, and yerba mansa.

5) OWMA (Honeybee Pond)

6) Honeybee Pond is located on the OWMA. The habitat is composed of cattail, and reeds surrounded by water impoundments.

Yuma clapper rail have been recorded sporadically over the last five years along the Virgin River within the Littlefield, Mesquite, Mormon Mesa and Virgin River Delta (Braden 2006). They have never occurred in large numbers and in many instances occur infrequently. Floods in January of 2005 have altered the habitat for these species, especially in the Mesquite area. In 2004 one rail was detected at Big Marsh and 2 rails were detected at the Virgin River Landing. This is the first year individuals were observed since the site emerged in 2002 (Braden 2006).

Yuma clapper rail have been recorded sporadically over the last five years at Honeybee Pond and Maverick Ditch in the Overton area of the Muddy River (Braden 2006). The Muddy River also experienced flooding during January of 2005, altering habitat for the Yuma clapper rail.

Other Actions by Federal, State or Local Agencies Affecting the Species in the Project Area. Currently, the City of Mesquite is developing the VRHCRP as a requirement to the Mesquite Lands Act. The VRHCRP is intended to provide coverage for impacts associated with the development of the Mesquite area and proposes to address Yuma clapper rail.

Designated Critical Habitat. No critical habitat for the Yuma clapper rail has been identified.

B.5 Effects Analysis

B.5.1 Effects to Lower Virgin River Hydrology

Tributary conservation ICS flows of 10,000 afy of water on the Virgin River, if averaged monthly, would equate to approximately 830 acre-feet per month and 30 acre-feet per day. These numbers represent averages and may not correspond to actual diversion schedules for the irrigation company water rights being used for tributary conservation since irrigation company schedules do not allow water users to take a constant stream of water and the schedules change throughout the season and from year to year. This makes it difficult to estimate a precise schedule for delivery of tributary conservation flows. However, assuming water is delivered at least weekly, the average weekly water contribution from tributary conservation would be approximately 210 acre-feet per week. If a gage were installed directly below the lowest return point of the retired water it would probably not reflect an increase of the entire 210 acre-feet per week due to complex geology and underflow that occurs in the floodplains and along the entire Virgin River. Additionally, the gage would have a margin of error of at least 10% and the 10,000 afy of tributary conservation represents less than 7% of the historic annual flow in the Virgin River at Halfway Wash. Therefore, any change measured by the gage would be within the gage's margin of error, so the accuracy of any gage measurement of tributary conservation flows would be questionable. Finally, surface water rights in Nevada are not subject to forfeiture (NRS 533.060(2)), so purchasers of water rights are not required to divert and use this water to guard against forfeiture. Therefore, the water rights that SNWA purchased may have already been regularly fallowed or out of production at the time they were acquired by SNWA. This means that water SNWA would be accounting for as tributary conservation may already be flowing in the river, so a response in a streamflow gage from tributary conservation flows may not be detected. Due to all of the factors mentioned above, 10,000 afy of tributary conservation is not likely to result in a noticeable change to flows on the Virgin River from the current conditions listed in Table 2.

B.5.2 Effects to Muddy River Hydrology

Tributary conservation flows of 20,000 afy of water on the Muddy River, if averaged monthly, would equate to approximately 1,700 acre-feet per month and 55 acre-feet per day. These numbers represent averages and may not correspond to actual diversion schedules for the irrigation company water rights being used for tributary conservation since irrigation company schedules do not allow water users to take a constant stream of water and the schedules change throughout the season and from year to year. This makes it difficult to estimate a schedule for delivery of tributary conservation flows. However, assuming water is delivered at least monthly, the average monthly water contribution from tributary conservation would be approximately 1,700 acre-feet. The Overton gage probably would not reflect an increase of the entire 1,700 acre-feet per month due to complex geology and underflow that occurs before the Overton gage on the Muddy River. Additionally, surface water rights in Nevada are not subject to forfeiture (NRS 533.060(2)), so purchasers of water rights are not required to divert and use this water to guard against forfeiture. Therefore, the water rights that SNWA purchased may have already been regularly fallowed or out of production at the time they were acquired by SNWA. This means that water SNWA would be accounting for as tributary conservation may already be flowing in the river, so a response in the streamflow gage from tributary conservation flows may not be detected.

Upper Muddy River surface water flow is measured at the Moapa and Glendale gages, which average approximately 30,000 afy. The current leased SNWA water rights in the Upper Muddy River (1,000 afy) represent approximately 3% of the gages' flow, well within a typical gage margin of error of 10% and virtually undetectable.

In the Lower Muddy River, the surface flows are measured at the Overton Gage which averages approximately 9,000 afy. The Overton Gage is very near the top of full pool elevation in Lake Mead (1,229 ft-AMSL). Therefore, this gage is believed to reflect surface water flows reaching Lake Mead. While there have been no studies confirming irrigation system losses to the alluvium, it is believed that there is water bypassing the Overton gage as underflow. Because of irrigation system losses and substantial underflow bypassing the gage, simply subtracting the Moapa-Glendale gage readings from the Overton gage readings will not provide an accurate accounting of the volume of tributary conservation flow reaching Lake Mead. Like the Virgin River and Upper Muddy River, the complex geology, gaging accuracies, and historic use of this water will make it difficult to see a marked increase in the Overton Gage from tributary conservation flows. In addition, the limited period of record for the Overton Gage when compared with the Glendale Gage, and uses between the two gages suggests large volumes of water bypass the gage as underflow. Due to all the factors mentioned above, 20,000 afy of tributary conservation is not likely to result in a noticeable change to flows on the Muddy River from the current conditions listed in Table 3.

B.5.3 Effects to Species

As discussed above, flooding has the potential to periodically impact riparian habitat, resulting in naturally occurring impacts to bird species (SWCA, 2007:21). However, the tributary conservation water associated with the proposed action (approximately 1,700 acre-feet per month on the Muddy River and 830 acre-feet per month on the Virgin River) should not cause flood flows or exacerbate natural flood events because the capacity of the two river systems has been determined to be more than adequate to accommodate the proposed tributary conservation flows. Given that the mean monthly gage flow for the Virgin River at Littlefield Arizona ranges from 6,641 acre-feet to 26,380 acre-feet, an additional 830 acre-feet per month is minimal compared to the overall flows in the river. Similarly, on the Muddy River the mean monthly gage flow at the Overton gage ranges from 483 acre-feet to 1,113 acre-feet, and the 1,700 acre-feet per month of tributary conservation water is not anticipated to exacerbate flood flows because of the complex underflow system on the Muddy River. In general, tributary conservation flows are expected to have a beneficial, albeit minor, effect on any marsh or riparian habitat associated with the southwestern willow flycatcher, Yuma clapper rail, or yellow-billed cuckoo located along the Muddy River or within the Mormon Mesa area on the Virgin River. No effect is anticipated for southwestern willow flycatcher, Yuma clapper rail, or yellow-billed cuckoo on the Virgin River above the Bunkerville Irrigation Company service area, as tributary conservation will take place below this area.

Drought has been identified as one type of event that could create conditions that can impact sensitive fish species on the Lower Virgin River and the Muddy River. The assured flows in the Virgin and Muddy Rivers proposed by the SNWA tributary conservation program are expected to have a minor beneficial effect on the endangered and candidate fish and bird species because they may help lessen the effects of drought (Bio-West Inc. 2007:1). While drought tends to decrease river flows, the tributary conservation flows are expected to act as an assured baseflow for sensitive fish and bird species on the Muddy River and below the Bunkerville Irrigation Company service area on the Virgin River. There is a concern that additional flows on the Virgin River may connect the Virgin River to Lake Mead for more days during the year, possibly allowing more non-native species to move up the Virgin River from Lake Mead. However, the small amount of additional flow possible (830 acre-feet per month in tributary conservation versus 6,641 acre-feet to 26,380 acre-feet per month average river flow), coupled with the complex geology of the Virgin River and braiding of the river in that location suggests that a more permanent connection will not be made between the Virgin River and Lake Mead because much of the minor additional flow will reach Lake Mead as underflow. Therefore, this project may affect, but is not likely to adversely affect the endangered and candidate bird and fish species in the Lower Virgin and Muddy Rivers because the potential positive effects are expected to be difficult to meaningfully measure or detect and are therefore insignificant (See hydrology discussion in Sections 5.1 and 5.2) .

B.5.3.1 Southwestern Willow Flycatcher

Riparian habitat that may support southwestern willow flycatcher tends to form at the agricultural returns along the banks of the Lower Virgin River (SWCA 2007:62-63). Potential effects to southwestern willow flycatcher may occur on the Lower Virgin River if the water conserved through tributary conservation is no longer routed through the Bunkerville Irrigation Company ditch systems because this change in operations would result in a loss of agricultural returns that may support the habitat in some areas. However, Bunkerville Irrigation Company will need the tributary conservation water to remain in the ditch systems, even if it is not used for agricultural purposes, because the water is needed to maintain head within the ditch systems so water can be withdrawn for irrigation. If the tributary conservation water is not retained in the ditch systems, Bunkerville Irrigation Company would need to upgrade the ditches to accommodate less flow. On July 21, 2005, the SNWA Board of Directors agreed to keep SNWA water rights used for tributary conservation in the ditches to avoid impacts to southwestern willow flycatcher habitat and to Bunkerville Irrigation Company operations. Therefore, the project will have no effect on the southwestern willow flycatcher within the ditch system of the Bunkerville Irrigation Company because there will be no change in ditch flows from this project.

Flows that were historically consumptively used off channel by agriculture will be used for the creation of tributary conservation. Though this may result in a small positive effect on river flows and underflow along the Muddy and Virgin River, which could benefit the riparian habitats of the southwestern willow flycatcher, these flow effects will be difficult to meaningfully measure or detect as indicated in Sections 5.1 and 5.2. This project is not expected to result in take of southwestern willow flycatcher. Therefore, this project may affect, but is not likely to adversely affect the southwestern willow flycatcher because the effects are expected to be insignificant downstream of the agricultural returns from the Bunkerville Irrigation Company service area in Mormon Mesa and along the Muddy River to Lake Mead.

Southwestern Willow Flycatcher Critical Habitat. As mentioned previously, riparian habitat that may support southwestern willow flycatcher tends to form at the agricultural returns along the banks of the Lower Virgin River (SWCA 2007:62-63). Some of these riparian habitat areas may occur within critical habitat for the southwestern willow flycatcher. There is potential to affect critical habitat for the species if the water conserved through tributary conservation is no longer routed through the Bunkerville Irrigation Company ditch systems because the agricultural returns that support the habitat will cease. However, as noted above, effects to southwestern willow flycatcher critical habitat will be by retaining the tributary conservation water within the ditch systems of the irrigation company. Based on this, it is anticipated that there will be no destruction or adverse modification to southwestern willow flycatcher critical habitat on the Lower Virgin River, and thus no impact to recovery opportunities.

There is no critical habitat for the southwestern willow flycatcher designated on the Muddy River. However, there is Southwestern willow flycatcher habitat on the Muddy River within the Overton Wildlife Management Area (OWMA) that was excluded from the designation of critical habitat since this area is already being managed for wildlife and riparian habitat by the State of Nevada. Assured flows associated with tributary conservation are likely to have a minor beneficial effect on the development and maintenance of southwestern willow flycatcher habitat in the OWMA. For the reasons indicated in Section 5.3.1, this project may affect, but is not likely to adversely affect the southwestern willow flycatcher.

Southwestern Willow Flycatcher Recovery Plan. The Southwestern Willow Flycatcher Recovery Plan has an overall recovery objective to attain a population level and an amount and distribution of habitat sufficient to provide for the long-term persistence of metapopulations (USFWS 2002a: 77). The recovery plan states that there are currently an estimated 40 known territories within the Virgin River. In order to downlist the species from endangered to threatened, a minimum of 100 known territories needs to be present on the Virgin River (USFWS 2002a: 87). No such recovery goal exists for the Muddy River.

Tributary conservation flows in both the Virgin and Muddy Rivers will help maintain and/or develop southwestern willow flycatcher habitat and will assist with meeting the recovery goals for the species. As described above, the assured flows from tributary conservation in the Muddy River and in the Virgin River below the Bunkerville Irrigation Company service area may help support existing southwestern willow flycatcher habitat or develop new habitat because flows that were historically consumptively used by agriculture will be used for tributary conservation. It is anticipated that there will be no destruction or adverse modification to southwestern willow flycatcher habitat on the Lower Virgin River or Muddy River, and thus no adverse impact to recovery opportunities. Because tributary conservation will help to maintain or create additional habitat, it is consistent with the recovery plan goals.

B.5.3.2 Yuma Clapper Rail

Yuma clapper rail occupies marsh habitat along the Virgin and Muddy Rivers which is maintained by river flow and not agricultural returns. Since tributary conservation water will be a part of the river flows that support the habitat, no adverse effects to Yuma clapper rail have been identified on either river for the proposed action. Consequently, the project is not expected to result in take of Yuma clapper rail. Tributary conservation may benefit the Yuma clapper rail by assuring flows, thereby maintaining existing habitat and potentially developing new habitat areas in the Muddy River and in the Virgin River below the Bunkerville Irrigation Company service area. However, the potential changes in flows in the Muddy and Virgin Rivers will be difficult to measure or detect (Sections 5.1 and 5.2). Therefore, this project may affect, but is not likely to adversely affect the Yuma clapper rail because the effects are expected to be insignificant.

No critical habitat has been designated for the Yuma Clapper Rail.

Yuma Clapper Rail Recovery Plan. The primary objective of the Yuma Clapper Rail Recovery Plan is to assure the continued survival of a total breeding population of 700-1,000 Yuma clapper rails in the United States. Consideration for delisting the Yuma clapper rail will be based on an assessment of the population in both the United States and Mexico (USFWS 1983: 12). A five-year status review of the species was conducted in 2006. In that review the USFWS was unable to determine if the primary objective of the recovery plan had been met due to population fluctuations associated with changes in survey effort, survey protocol, observer experience, and habitat changes (USFWS 2006a: 6). However, tributary conservation on the Virgin and Muddy Rivers will assure flows and thereby help maintain existing habitat and potentially develop new habitat areas for the Yuma Clapper Rail in the Muddy River and the Virgin River below the Bunkerville Irrigation Company service area, which is consistent with recovery plan goals.

B.5.3.3 Western Yellow-Billed Cuckoo

Western yellow-billed cuckoo habitat along the Virgin and Muddy Rivers is maintained by river flow and not agricultural returns. As described above, the assured flows from tributary conservation in the Muddy River and the Virgin River below the Bunkerville Irrigation Company service area may help support existing western yellow-billed cuckoo habitat. Consequently, the project is not expected to result in take of yellow-billed cuckoo. However, the potential changes in flows in the Muddy and Virgin Rivers will be difficult to measure or detect (Sections 5.1 and 5.2). Therefore, this project may affect, but is not likely to adversely affect the western yellow-billed cuckoo because the effects are expected to be insignificant.

There is no designated critical habitat for the western yellow-billed cuckoo.

B.5.3.4 Woundfin and Virgin River Chub

In the Virgin River non-native fish species are more prevalent downstream from the Bunkerville Diversion, although they do occur throughout the Lower Virgin River (Bio-West Inc. 2007:16, 19, 22, 24). There is a concern that the higher flows coupled with a possible change in maintenance or operation of the Bunkerville Division will allow additional non-native species to move upstream, which may impact the woundfin and Virgin River chub in the Virgin River. However, SNWA has agreed that its water will continue to be diverted and flow through the ditch systems of the irrigation company, so no change in the operation or maintenance of the Bunkerville Diversion is anticipated as part of the tributary conservation project. It is anticipated that the Bunkerville Diversion will continue to function as a partial barrier to upstream movement of non-native fish during low flows. Although the Bunkerville Diversion is a less effective fish barrier during high flows, the movement of non-native fishes past the Bunkerville Diversion is not expected to increase from current conditions because the possible additional flows are minor and may be manifested as underflow (See Sections 5.1 and 5.2). The small amount of additional flow (830 acre-feet per month in tributary conservation versus 6,641 acre-feet to 26,380 acre-feet per month average river flow), coupled with the complex geology of the Virgin River and braiding of the river at that location suggests that a more permanent connection will not be made between the Virgin River and Lake Mead because much of the minor additional flow will reach Lake Mead as underflow. Consequently, this project is not expected to adversely affect woundfin and Virgin River Chub in the Virgin River by increased opportunity for non-native fish movement upstream of the Bunkerville Diversion. In addition, the Virgin River Fishes Recovery Team and the Lower Virgin River Recovery Implementation Team are developing plans for a fish barrier at Halfway Wash. If installed, the fish barrier will effectively stop most, if not all, upstream movement of non-native fishes from Lake Mead.

Before 2007, woundfin had not been observed below the Bunkerville Irrigation Company service area along the Virgin River since 2001 (Bio-West, Inc. 2007: 23). However, in 2007, Bio-West, Inc. did document one woundfin within the Riverside reach below the Bunkerville Irrigation Company service area (B. Albrecht, personal communication July 12, 2007). It is anticipated that the tributary conservation water in the system may have a minor beneficial effect on the woundfin by providing assured flows below the Bunkerville Irrigation Company service area. However, as indicated in Sections 5.1 and 5.2, these additional flows will be difficult to meaningfully measure or detect. No additional predation by non-native fish species is anticipated because the minor additional flows will not provide enough water to result in a more permanent connection between the Virgin River and Lake Mead. Given the complex geology of the Virgin River at Lake Mead and the fact that the river channel is braided in that area, it is likely that the minor flows associated with tributary conservation will be manifested as underflow where the Virgin River meets Lake Mead. Therefore, this project may affect, but is not likely to adversely affect the woundfin because the potential effects are expected to be insignificant.

In the Virgin River, no effect to the Virgin River chub is anticipated because the tributary conservation flows will only be below the Mesquite and Bunkerville Irrigation Company service areas and Virgin River chub have not been collected below the Mesquite Diversion since the late 1970's (USFWS 1995: 9). As indicated in Section 5.2, flows from SNWA leased water in the Upper Muddy River will be virtually undetectable and therefore are not likely to adversely affect Virgin River Chub here because the flow effects are insignificant.

Woundfin and Virgin River Chub Critical Habitat. The critical habitat for the woundfin and Virgin River chub has historically been impacted by low flows on the Virgin River (USFWS 2000:4142). tributary conservation on the Virgin River is anticipated to have a beneficial, though minor, effect on critical habitat for the woundfin and Virgin River chub. To the extent that tributary conservation flows are not manifested as underflow below the Bunkerville Irrigation Company service area, tributary conservation may provide assured flows that can create additional species habitat and help lessen the effects of drought. Even if no beneficial effect on critical habitat is created from tributary conservation, degradation of critical habitat is not expected. No destruction or adverse modification to designated woundfin or Virgin River chub critical habitat is anticipated and, thus there will be no impact to recovery opportunities.

Virgin River Fishes Recovery Plan. The Virgin River Fishes Recovery Plan contains recovery goals for both the Virgin River chub and woundfin. The objective of the plan is to downlist both of the species from endangered to threatened. In order to meet the requirements for downlisting the following criteria must be met: (1) Virgin River flows essential to survival of all life stages are protected; (2) degraded Virgin River from Pah Tempe Springs to Lake Mead is upgraded and maintained to allow continued existence of all life stages at viable population levels; and (3) barriers to upstream migration of introduced fishes are established, red shiner is eliminated, and other nonnative species which present a major threat to the continued existence of the fish community are reduced (USFWS 1995:v). No additional predation by non-native fish species is anticipated to result from tributary conservation because the minor additional flows will not provide enough water to result in a more permanent connection to Lake Mead. Given the complex geology of the Virgin River at Lake Mead and the fact that the river channel is braided in that area, it is likely that the minor flows associated with tributary conservation will be manifested as underflow where the Virgin River meets Lake Mead. Tributary conservation may help meet the first criteria for downlisting by providing a minor amount of assured flows for woundfin, which have been recently found below the Bunkerville Irrigation Company service area, therefore the project is consistent with recovery plan goals.

B.5.3.5 Moapa Dace

Moapa dace is limited to the Warm Springs area along the Muddy River because of the temperature requirements of the species. The species has only been found within the first 6 miles of the river system (USFWS 1996:4). Assured water flows in that area via tributary conservation will consist of water from the water rights lease between SNWA and the LDS Church and possible purchases from other users. Part of the 1,000 afy of tributary conservation obtained through a lease in the upper portion of the Muddy River is already flowing unused in the Muddy River system. No additional changes are proposed as part of the tributary conservation project in the upper Muddy River and, therefore, no effect on the Moapa dace is anticipated as part of this project.

There is no critical habitat designated for the Moapa dace.

Recovery Plan for Rare Aquatic Species of Muddy River Ecosystem. The Recovery Plan for Rare Aquatic Species of the Muddy River Ecosystem contains recovery goals for the Moapa dace. The objective of the plan is to downlist the Moapa dace from endangered to threatened. In order to meet the requirements for downlisting, the following criteria must be met: (1) existing instream slows and historical habitat in three of the five spring systems in the upper Muddy River have to be protected through conservation agreements, easements, or fee title acquisitions; (2) 4,500 adult Moapa dace must be present among the five spring systems in the upper Muddy River; and (3) the Moapa dace population must be comprised of three or more age-classes, and reproduction and recruitment is documented from three spring systems (USFWS 1996: 33-34). Tributary conservation may help meet the second and third criteria for downlisting by counteracting the effects of low flows on the species. Therefore, this project is consistent with the recovery plan goals.

Appendix S

Draft Interim Guidelines for the Operation of Lake Powell and Lake Mead

---

The information provided in this Appendix S is intended to provide the public with draft information on the structure and content of the type of guidelines that the Department is considering that would implement the proposed federal action. This information is published herein in draft form, and is subject to further modification and refinement. Publication of this information does not represent any final determination by the Department on any of the issues addressed in these draft guidelines. Further, additional and updated information regarding the content and development of the information in these draft guidelines that would be implemented by a Record of Decision is anticipated to be provided to the public through the dedicated project website, (http://www.usbr.gov/lc/region/programs/strategies.html) following publication of this Final Environmental Impact Statement.

III. Conditions of Implementation

A. Forbearance

1. Role of Forbearance Agreements within the Context of the Law of the River and Relationship to Intentionally Created Surplus (ICS).

For the purposes of these Guidelines, the term "forbearance agreements" refers to agreements that a party who has a right to surplus Colorado River water could enter into that would provide that party's agreement to forgo (or not exercise) its right to surplus Colorado River water. In any such agreements, the party agrees to "forbear" or refrain from exercising its right to surplus Colorado River water under the specified terms and conditions of the applicable agreement. Through such agreements, increased flexibility of Colorado River water management can be achieved – resulting in greater conservation of water than would otherwise be accomplished.

In Years in which the Secretary determines that sufficient Mainstream water is available for delivery to satisfy annual consumptive use in the Lower Division states in excess of 7.5 maf, Article II(B)(2) of the Consolidated Decree directs the Secretary to apportion such surplus Mainstream water 50% for use in California, 46% for use in Arizona, and 4% for use in Nevada. The Boulder Canyon Project Act and Articles II(B)(2) and II(B)(6) of the Consolidated Decree, taken together, authorize the Secretary to apportion surplus water and to deliver one Lower Division state's unused apportionment for use in another Lower Division state. Pursuant to such authority and for the purpose of increasing the efficiency, flexibility, and certainty of Colorado River management and thereby helping satisfy the current and projected regional water demands, the Secretary determined that it is prudent and desirable to promulgate guidelines to establish a procedural framework for facilitating the creation and delivery of ICS within the Lower Basin.

In the absence of forbearance, surplus water is apportioned for use in the Lower Division states according to the specific percentages provided in Article II(B)(2) of the Consolidated Decree discussed above. In order to allow for management flexibility, the seven Colorado River Basin States have recommended an operational program for the creation and delivery of ICS. In furtherance of this recommendation, numerous major water users within the Lower Basin have identified their willingness, under specified circumstances, to participate in such an operational program. These parties have submitted a draft "Forbearance Agreement," as preliminarily approved by the parties, as part of a package of documents (Appendix J) submitted for consideration by the Secretary as a necessary element to enable implementation of the operations contemplated by the Basin States Alternative. The Secretary has developed a Preferred Alternative based on this information, as well as other information submitted during the NEPA process.

The parties to the Forbearance Agreement have indicated that they intend that the Agreement provide the appropriate legal mechanism to achieve successful implementation of this element of the Preferred Alternative. The parties have indicated that among the conditions on their forbearance, they will forbear only with respect to a specified ICS volume and only to ICS created by projects described in exhibits attached to the Forbearance Agreement or added thereto by written consent of all parties. Given the voluntary nature of the forbearance concept, it is appropriate for the parties to clearly identify the limited conditions upon which their forbearance is granted.

Through adoption and implementation of these Guidelines, the Secretary will only approve the creation, delivery and use of ICS in a manner that is fully consistent with the provisions of the Consolidated Decree, including Articles II(B)(2) and II(B)(6) therein. The Secretary will require forbearance by the State of Arizona, the Colorado River Board of California, and the Colorado River Commission of Nevada for implementation of this element of these Guidelines (regarding ICS). If, in the opinion of the Secretary, the State of Arizona or the Colorado River Board of California or the Colorado River Commission of Nevada, unreasonably withhold forbearance, the Secretary may, after consultation with the Basin States, modify these Guidelines. Moreover, the Secretary will ensure that implementation of the ICS mechanism does not infringe on the rights of any third party who is a Contractor and who is not a party to the Forbearance Agreement.

2. Monitoring Implementation.

Under these Guidelines, Colorado River water will continue to be allocated for use among the Lower Division states in a manner consistent with the provisions of the Consolidated Decree. It is expected that Lower Division states and individual Contractors for Colorado River water have or will adopt arrangements that will affect utilization of Colorado River water during the Interim Period. It is expected that water orders from Colorado River Contractors will be submitted to reflect forbearance arrangements by Lower Division states and individual Contractors. The Secretary will deliver Colorado River water to Contractors in a manner consistent with these arrangements, provided that any such arrangements are consistent with the BCPA, the Consolidated Decree and do not infringe on the rights of third parties. Surplus water will only be delivered to entities with contracts for surplus water. ICS will be delivered pursuant to Section 3.C. of these Guidelines and a Delivery Agreement.

B. Delivery Agreement

Article II(B)(5) of the Consolidated Decree in *Arizona v. California* states that mainstream Colorado River water shall be released or delivered to water users in Arizona, California, and Nevada “only pursuant to valid contracts therefore made with such users by the Secretary of the Interior, pursuant to Section 5 of the Boulder Canyon Project Act or any other applicable federal statute.” Section 5 of the Boulder Canyon Project Act authorizes the Secretary to enter into such contracts.

Numerous Contractors in Arizona, California, and Nevada now hold contracts which entitle them to the delivery of Colorado River water under the circumstances and in the priorities specified in the individual contracts. Contracts entered into prior to the adoption of these Guidelines do not, however, expressly address circumstances in which ICS or DSS might be created or delivered.

To ensure the requirements of Section 5 of the Boulder Canyon Project Act and Article II(B)(5) of the Consolidated Decree are complied with, and to reduce the possibility of ambiguity, the Secretary anticipates entering into delivery contracts with any person or persons intending to create ICS or DSS. Such contracts are expected to address the requirements set forth in the Guidelines for the approval of ICS or DSS plans, the certification and verification of the ICS or DSS created under the plans, the ordering and delivery of ICS or DSS, the accounting for ICS or DSS in the annual report filed with the United States Supreme Court in accordance with Article V of the Consolidated Decree, and such other matters as may bear on the delivery of the ICS or DSS, as for example the point of delivery and place of use, if not already provided for under existing contracts.

C. Mexico

[text to be inserted]

D. Intentionally Created Surplus

Findings - ICS may be created through projects that create water system efficiency or extraordinary conservation or tributary conservation or the importation of non-Colorado River System water into the Colorado River Mainstream. ICS is consistent with the concept that entities may take actions to augment storage of water in the lower Colorado River Basin. The ICS shall be delivered to the Contractor that created it pursuant to both Article II(B)(2) of the Consolidated Decree and Forbearance Agreements. Implementation of these Guidelines for ICS is conditioned upon execution of Forbearance Agreements and Delivery Agreements as further provided for in these Guidelines.

Purposes - The primary purposes of ICS are to: 1) Encourage the efficient use and management of Colorado River water; and to increase the water supply in Colorado River System reservoirs, through the creation, delivery and use of ICS; 2) Help minimize or avoid shortages to water users in the Lower Basin; 3) Benefit storage of water in both Lake Powell and Lake Mead; 4) Increase the surface elevations of both Lake Powell and Lake Mead to higher levels than would have otherwise occurred; and 5) Assure any Contractor that invests in conservation or augmentation to create ICS that no other Contractor will claim the ICS created by the Contractor pursuant to an approved plan by the Secretary.

Quantities - The maximum quantities of Extraordinary Conservation ICS that may be accumulated in all ICS Accounts, at any time, upon the effective date of these Guidelines is limited to the amounts provided in Section 3.B.5.of these Guidelines. The maximum quantities of Extraordinary Conservation ICS that may be created and/or delivered in any given Year are also limited to the amounts provided in Sections 3.B.4. and 3.C.4., respectively. As described in the Final EIS, Reclamation has analyzed ICS amounts in excess of the amounts approved by this Record of Decision and provided in these Guidelines. Any decision by the Secretary to increase the amounts in excess of the amounts provided in these Guidelines would be based on actual operating experience and would require modification of these Guidelines after consultation with the Basin States.

E. Relationship with Existing Law

These Guidelines are not intended to, and do not:

1. guarantee or assure any water user a firm supply for any specified period;

2. change or expand existing authorities under applicable federal law, except as specifically provided herein with respect to determinations under the Long Range Operating Criteria and administration of water supplies during the effective period of these Guidelines;

3. address intrastate storage or intrastate distribution of water, except as may be specifically provided by Lower Division states and individual contractors for Colorado River water who may adopt arrangements that will affect utilization of Colorado River water during the effective period of these Guidelines;

4. change the apportionments made for use within individual States, or in any way impair or impede the right of the Upper Basin to consumptively use water available to that Basin under the Colorado River Compact;

5. affect any obligation of any Upper Division state under the Colorado River Compact;

6. affect any right of any State or of the United States under Sec. 14 of the Colorado River Storage Project Act of 1956 (70 Stat. 105); Sec. 601(c) of the Colorado River Basin Project Act of 1968 (82 Stat. 885); the California Limitation Act (Act of March 4, 1929; Ch. 16, 48th Sess.); or any other provision of applicable federal law;

7. affect the rights of any holder of present perfected rights or reserved rights, which rights shall be satisfied within the apportionment of the State within which the use is made, and in the Lower Basin, in accordance with the Consolidated Decree; or

8. constitute an interpretation or application of the 1944 Treaty between the United States and Mexico Relating to the Utilization of the Waters of the Colorado and Tijuana Rivers and of the Rio Grande (1944 Treaty) or to represent current United

States policy or a determination future United States policy regarding deliveries to Mexico. The United States will conduct all necessary and appropriate discussions including consultation with the Basin States regarding the proposed federal action and implementation of the 1944 Treaty with Mexico through the International Boundary and Water Commission (IBWC) in consultation with the Department of State.

F. Definitions

For purposes of these Guidelines, the following definitions apply:

1. "24-Month Study" refers to the operational study that reflects the current Annual Operating Plan that is updated each month by Reclamation to project future reservoir contents and releases. The projections are updated each month using the previous month's reservoir contents and the latest inflow and water use forecasts. In these Guidelines, the term "projected on January 1" shall mean the projection of the January 1 reservoir contents provided by the 24-Month Study that is conducted in August of the previous Year.

2. "AOP" shall mean the Annual Operating Plan for the Colorado River System Reservoirs.

3. "BCPA" shall mean the Boulder Canyon Project Act of 1928 (28 Stat. 1057).

4. "Basin States" shall mean the seven Colorado River Basin States of Arizona, California, Colorado, New Mexico, Nevada, Utah, and Wyoming.

5. "Certification Report" shall mean the written documentation provided by a Contractor that provides the Secretary with sufficient information to allow the Secretary to determine whether the quantity of ICS or DSS approved by the Secretary in an approved plan has been created and whether the creation was consistent with the approved plan.

6. "Colorado River System" shall have the same meaning as defined in the 1922 Colorado River Compact.

7. "Consolidated Decree" shall mean the Consolidated Decree entered by the United States Supreme Court in *Arizona v. California*, 547 U.S. 150 (2006).

8. "Contractor" shall mean an entity holding an entitlement to Mainstream water under (a) the Consolidated Decree, (b) a water delivery contract with the United States through the Secretary, or (c) a reservation of water by the Secretary, whether the entitlement is obtained under (a), (b) or (c) before or after the adoption of these Guidelines.

9. "DSS Account" shall mean records established by the Secretary regarding DSS.

10. "Delivery Agreement" shall mean an agreement consistent with these Guidelines entered into between the Secretary of the Interior and one or more Contractors creating ICS.

11. "Developed Shortage Supply ("DSS")" shall mean water available for use by a Contractor under the terms and conditions of a Delivery Agreement and Section 4 of these Guidelines in a Shortage Condition, under Article III(B)(3) of the Consolidated Decree.

12. "Direct Delivery Domestic Use" shall mean direct delivery of water to domestic end users or other municipal and industrial water providers within the contractor's area of normal service, including incidental regulation of Colorado River water supplies within the Year of operation but not including Off-stream Banking. For the Metropolitan Water District of Southern California (MWD), Direct Delivery Domestic Use shall include delivery of water to end users within its area of normal service, incidental regulation of Colorado River water supplies within the Year of operation, and Off-stream Banking only with water delivered through the Colorado River Aqueduct.

13. "Domestic Use" shall have the same meaning as defined in the 1922 Colorado River Compact.

14. "Forbearance Agreement" shall mean an agreement under which one or more Contractors agree to forbear a right to ICS, under a water delivery contract or the Consolidated Decree.

15. "ICS Account" shall mean records established by the Secretary regarding ICS.

16. "ICS Determination" shall mean a determination by the Secretary that ICS is available for delivery.

17. "Intentionally Created Surplus ("ICS")" shall mean surplus Colorado River System water available for use under the terms and conditions of a Delivery Agreement, a Forbearance Agreement, and these Guidelines.

    a. ICS created through extraordinary conservation, as provided for in Section 3.A.1., shall be referred to as "Extraordinary Conservation ICS."

    b. ICS created through tributary conservation, as provided for in Section 3.A.2., shall be referred to as "Tributary Conservation ICS."

    c. ICS created through system efficiency projects, as provided for in Section 3.A.3., shall be referred to as "System Efficiency ICS."

    d. ICS created through the importation of non-Colorado River System Water, as provided for in Section 3.A.4., shall be referred to as "Imported ICS."

18. “Interim Period” shall mean the effective period as described in Section 8.

19. “Long Range Operating Criteria (“LROC”)” shall mean the Criteria for the Coordinated Long Range Operation of Colorado River Reservoirs Pursuant to the Colorado River Basin Project Act of September 30, 1968 (Pub. L. No. 90-537), published at 35 Fed. Reg. 8951 (June 10, 1970), as amended March 21, 2005.

20. “Lower Division states” shall mean the Colorado River Basin States of Arizona, California, and Nevada.

21. “Mainstream” shall have the same meaning as defined in the Consolidated Decree.

22. “Off-stream Banking” shall mean the diversion of Colorado River water to underground storage facilities for use in subsequent Years from the facility used by a Contractor diverting such water.

23. “ROD” shall mean the Record of Decision issued by the Secretary for the Colorado River Interim Guidelines for Lower Basin Shortages and Coordinated Operations for Lake Powell and Lake Mead.

24. “Upper Division states” shall mean the Colorado River Basin States of Colorado, New Mexico, Utah, and Wyoming.

25. “Water Year” shall mean October 1 through September 30.

26. “Year” shall mean calendar year.

G. Interim Guidelines for the Operation of Lake Powell and Lake Mead

These Guidelines shall include Sections III.A., B., E., and F. above and this Section III.G. These Guidelines which shall implement and be used for determinations made pursuant to the Long Range Operating Criteria during the effective period identified in Section 8, are hereby adopted:

Section 1. Allocation of Unused Basic Apportionment Water Under Article II(B)(6)

A. Introduction

Article II(B)(6) of the Consolidated Decree allows the Secretary to allocate water that is apportioned to one Lower Division state, but is for any reason unused in that State, to another Lower Division state. This determination is made for one Year only and no rights to recurrent use of the water accrue to the state that receives the allocated water.

B. Application to Unused Basic Apportionment

Before making a determination of a Surplus Condition under these Guidelines, the Secretary will determine the quantity of apportioned but unused water excluding ICS created in that Year from the basic apportionments under Article II(B)(6), and will allocate such water in the following order of priority:

1. Meet the Direct Delivery Domestic Use requirements of MWD and Southern Nevada Water Authority (SNWA), allocated as agreed by said agencies;

2. Meet the needs for Off-stream Banking activities for use in California by MWD and for use in Nevada by SNWA, allocated as agreed by said agencies; and

3. Meet the other needs for water in California in accordance with the California Seven-Party Agreement as supplemented by the Quantification Settlement Agreement.

Section 2. Determination of Lake Mead Operation During the Interim Period

A. Normal Conditions

1. Lake Mead above elevation 1075 feet and below elevation 1145 feet

In Years when Lake Mead elevation is projected to be above 1075 feet and below elevation 1145 feet on January 1, the Secretary shall determine either a Normal Condition, or, under Section 2.B.5., an ICS Surplus Condition.

B. Surplus Conditions

1. Partial Domestic Surplus

[Adopted January 16, 2001; Deleted [insert Month Day, Year]]

2. Domestic Surplus

(Lake Mead at or above Elevation 1145 feet and below the Elevation that Triggers a Quantified Surplus (70R Strategy))

In years when Lake Mead content is projected to be at or above elevation 1145 feet, but less than the amount which would initiate a Surplus under Section 2.B.3., Quantified Surplus, or Section 2.B.4., Flood Control Surplus, on January 1, the Secretary shall determine a Domestic Surplus Condition. The amount of such Surplus shall equal –

a. From the effective date of these Guidelines through December 31, 2015 (through preparation of the 2016 AOP):

1) For Direct Delivery Domestic Use by MWD, 1.250 maf reduced by the amount of basic apportionment available to MWD.

2) For use by SNWA, the Direct Delivery Domestic Use within the SNWA service area in excess of the State of Nevada's basic apportionment.

3) For use in Arizona, the Direct Delivery Domestic Use in excess of Arizona's basic apportionment.

b. From January 1, 2016 (for preparation of the 2017 AOP) through December 31, 2025 (through preparation of the 2026 AOP):

1) For use by MWD, 250,000 af per Year in addition to the amount of California's basic apportionment available to MWD.

2) For use by SNWA, 100,000 af per Year in addition to the amount of Nevada's basic apportionment available to SNWA.

3) For use in Arizona, 100,000 af per Year in addition to the amount of Arizona's basic apportionment available to Arizona contractors.

3. Quantified Surplus (70R Strategy)[1]

In years when the Secretary determines that water should be delivered for beneficial consumptive use to reduce the risk of potential reservoir spills based on the 70R Strategy the Secretary shall determine a Quantified Surplus Condition and allocate a Quantified Surplus sequentially as follows:

a. Establish the volume of the Quantified Surplus. For the purpose of determining the existence, and establishing the volume, of Quantified Surplus, the Secretary shall not consider any volume of ICS as defined in these Guidelines.

b. Allocate and distribute the Quantified Surplus 50 percent to California, 46 percent to Arizona, and 4 percent to Nevada, subject to c. through e. that follow.

c. Distribute California's share first to meet basic apportionment demands and MWD's demands, and then to California Priorities 6 and 7 and other surplus contracts. Distribute Nevada's share first to meet basic apportionment demands and then to the remaining demands. Distribute Arizona's share to surplus demands in Arizona including Off-stream Banking and interstate banking demands. Nevada shall receive first priority for interstate banking in Arizona.

d. Distribute any unused share of the Quantified Surplus in accordance with Section 1.

e. Determine whether MWD, SNWA and Arizona have received the amount of water they would have received under Section 2.B.2., if a Quantified Surplus Condition had not been determined. If they have not, then determine and meet all demands provided for in Section 2.B.2.

4. Flood Control Surplus

In years in which the Secretary makes space-building or flood control releases[2] pursuant to the 1984 Field Working Agreement between Reclamation and the Army Corps of

[1] 70R is a spill avoidance strategy that determines a surplus if the January 1 projected system storage space is less than the space required by the flood control criteria, assuming a natural inflow of 17.4 maf (the 70th percentile non-exceedence flow). See ISG Final EIS at Section 2.3.1.2.

[2] Under current practice, surplus waters pursuant to the 1944 Treaty are made available to Mexico (when Mexico may schedule up to an additional 0.2 maf) when flood control releases are made. These Guidelines are not intended to identify, or change in any manner that practice. Any issues relating to the implementation of the Treaty, including

Engineers (as may be amended), the Secretary shall determine a Flood Control Surplus for the remainder of that Year or the subsequent Year. In such years, releases will be made to satisfy all beneficial uses within the United States, including unlimited Off-stream Banking.

5. ICS Surplus

   a. In Years in which Lake Mead's elevation is projected to be above elevation 1075 feet on January 1, a Flood Control Surplus has not been determined, and delivery of ICS has been requested, the Secretary may determine an ICS Surplus Condition in lieu of other operating conditions that are based solely on the elevation of Lake Mead.

   b. In Years in which a Quantified Surplus or a Domestic Surplus is available to a Contractor, the Secretary shall first deliver the Quantified Surplus or Domestic Surplus before delivering any requested ICS to that Contractor. If available Quantified Surplus or Domestic Surplus is insufficient to meet a Contractor's demands, the Secretary shall deliver ICS available in that Contractor's ICS Account at the request of the Contractor, subject to the provisions of Section 3.C.

C. Allocation of Colorado River Water and Forbearance and Reparation Arrangements

[Content of 2001 ISG Section 2.C., Allocation of Colorado River Water and Forbearance and Reparation Arrangements, is now found at III.A., as modified]

D. Shortage Conditions

1. Deliveries to the Lower Division States during Shortage Condition Years shall be implemented in the following manner:

   a. In Years when Lake Mead content is projected to be at or below elevation 1075 feet and at or above 1050 feet on January 1, a quantity of 7.167 maf shall be apportioned for consumptive use in the Lower Division States of which 2.48 maf shall be apportioned for use in Arizona and 287,000 af shall be apportioned for use in Nevada in accordance with the Arizona-Nevada Shortage Sharing

---

any potential changes in approach relating to surplus declarations under the 1944 Treaty, must be addressed in a bilateral fashion with the Republic of Mexico.

Agreement dated February 9, 2007, and 4.4 maf shall be apportioned for use in California.

b. In Years when Lake Mead content is projected to be below elevation 1050 feet and at or above 1025 feet on January 1, a quantity of 7.083 maf shall be apportioned for consumptive use in the Lower Division States of which 2.4 maf shall be apportioned for use in Arizona and 283,000 af shall be apportioned for use in Nevada in accordance with the Arizona-Nevada Shortage Sharing Agreement dated February 9, 2007, and 4.4 maf shall be apportioned for use in California.

c. In Years when Lake Mead content is projected to be below elevation 1025 feet on January 1, a quantity of 7.0 maf shall be apportioned for consumptive use in the Lower Division States of which 2.32 maf shall be apportioned for use in Arizona and 280,000 af shall be apportioned for use in Nevada in accordance with the Arizona-Nevada Shortage Sharing Agreement dated February 9, 2007, and 4.4 maf shall be apportioned for use in California.

2. During a Year when the Secretary has determined a Shortage Condition, the Secretary shall deliver Developed Shortage Supply available in a Contractor's DSS Account at the request of the Contractor, subject to the provisions of Section 4.C.

Section 3. Implementation of Intentionally Created Surplus

[Content of 2001 ISG Section 3., Implementation of Guidelines, is now found at Section 7., as modified herein.]

A. Categories of ICS

1. Extraordinary Conservation ICS

A Contractor may create Extraordinary Conservation ICS through the following activities:

a. Fallowing of land that currently is, historically was, and otherwise would have been irrigated in the next Year.

b. Canal lining programs.

c. Desalination programs in which the desalinated water is used in lieu of Mainstream water.

d. Extraordinary conservation programs that existed on January 1, 2006.

e. Extraordinary Conservation ICS demonstration programs pursuant to a letter agreement entered into between the United States Bureau of Reclamation and the Contractor prior to the effective date of these Guidelines.

f. Tributary Conservation ICS created under Section 3.A.2. and not delivered in the Year created.

g. Imported ICS created under Section 3.A.4. and not delivered in the Year created.

h. Other extraordinary conservation measures, including but not limited to, development and acquisition of a non-Colorado River System water supply used in lieu of Colorado River Mainstream water within the same state, in consultation with the Basin States.

2. Tributary Conservation ICS

A Contractor may create Tributary Conservation ICS by purchasing documented water rights on Colorado River System tributaries within the Contractor's state if there is documentation that the water rights have been used for a significant period of Years and that the water rights were perfected prior to June 25, 1929 (the effective date of the Boulder Canyon Project Act). The actual amount of any Tributary Conservation ICS introduced to the Mainstream shall be subject to verification by the Secretary as provided in Section 3.D. Any Tributary Conservation ICS not delivered pursuant to Section 3.C. or deducted pursuant to Section 3.B.2. in the Year it was created will, at the beginning of the following Year, be converted to Extraordinary Conservation ICS and will thereafter be subject to all provisions applicable to Extraordinary Conservation ICS. Tributary Conservation ICS may be delivered for Domestic Use only.

3. System Efficiency ICS

A Contractor may make contributions of capital[3] to the Secretary for use in projects designed to realize system efficiencies that save water that would otherwise be lost from the Colorado River Mainstream in the United States. An amount of water equal to a portion of the water conserved would be made available to contributing Contractor(s) by the Secretary as System Efficiency ICS. System efficiency projects are intended only to provide temporary water supplies. System Efficiency ICS will be delivered to the contributing Contractor(s) on a schedule of annual deliveries as provided in an exhibit to a Forbearance Agreement and Delivery Agreement. The Secretary may identify potential system efficiency projects, terms for capital participation in such projects, and types and amounts of benefits the Secretary could provide in consideration of non-federal capital contributions to system efficiency projects, including identification of a portion of the water saved by such projects.

4. Imported ICS

A Contractor may create Imported ICS by introducing non-Colorado River System water in that Contractor's state into the Colorado River Mainstream. Contractors proposing to create Imported ICS shall make arrangements with the Secretary, contractual or otherwise, to ensure no interference with the Secretary's management of Colorado River System reservoirs and regulatory structures. Any arrangement shall provide that the Contractor must obtain appropriate permits or other authorizations required by state and federal law. The actual amount of any Imported ICS introduced to the Mainstream shall be subject to verification by the Secretary as provided in Section 3.D. Any Imported ICS not delivered pursuant to Section 3.C. or deducted pursuant to Section 3.B.2. in the Year it was created will be converted, at the beginning of the following Year, to Extraordinary Conservation ICS and thereafter will be subject to all provisions applicable to Extraordinary Conservation ICS.

B. Creation of ICS

A Contractor may only create ICS in accordance with the following conditions:

1. A Contractor shall submit a plan for the creation of ICS to the Secretary demonstrating how all requirements of these Guidelines will be met in the Contractor's creation of ICS. Until such plan is reviewed and approved by the

[3] To the extent permitted by federal law, monies to pay construction, operation, maintenance, repair, and/or replacement costs.

Secretary, subject to such environmental compliance as may be required, such plan or any ICS purportedly created through it shall not be a basis for creation of ICS. An ICS plan will consist of at a minimum the following information:

a. Project description, including what extraordinary measures will be taken to conserve or import water;

b. Term of the activity;

c. Estimate of the amount of water that will be conserved or imported;

d. Proposed methodology for verification of the amount of water conserved or imported; and

e. Documentation regarding any state or federal permits or other regulatory approvals that have already been obtained by the Contractor or that need to be obtained prior to creation of ICS.

A Contractor may modify its approved plan for creation of ICS during any Year, subject to approval by the Secretary. A Contractor with an approved multi-Year plan for System Efficiency ICS is not required to seek further approval by the Secretary in subsequent Years unless the Contractor seeks to modify the plan.

2. There shall be a one-time deduction of five percent (5%) from the amount of ICS in the Year of its creation. This system assessment shall result in additional system water in storage in Lake Mead. This one-time system assessment shall not apply to:

   a. System Efficiency ICS created pursuant to Section 3.B. because a large portion of the water conserved by this type of project will increase the quantity of system water in storage over time.

   b. Extraordinary Conservation ICS created by conversion of Tributary Conservation ICS that was not delivered in the Year created, pursuant to Section 3.B. because 5% of the ICS is deducted at the time the Tributary Conservation ICS is created.

   c. Extraordinary Conservation ICS created by conversion of Imported ICS that was not delivered in the Year created, pursuant to Section 3.B. because 5% of the ICS is deducted at the time the Imported ICS is created.

   d. ICS created under demonstration programs in 2006 and 2007 which has already been assessed the 5% system assessment.

3. Except as provided in Sections 3.A.2. and 3.A.4., Extraordinary Conservation ICS can only be created if such water would have otherwise been beneficially used.

4. The maximum total amount of Extraordinary Conservation ICS that can be created during any Year is limited to the following:

   a. 400,000 af for California Contractors;

   b. 125,000 af for Nevada Contractors; and

   c. 100,000 af for Arizona Contractors.

5. The maximum quantity of Extraordinary Conservation ICS that may be accumulated in all ICS Accounts, at any time, is limited to the following:

   a. 1.5 maf for California Contractors;

   b. 300,000 af for Nevada Contractors; and

   c. 300,000 af for Arizona Contractors.

6. Except as provided in Sections 3.A.2. and 3.A.4., no category of surplus water can be used to create Extraordinary Conservation ICS.

7. The quantity of Extraordinary Conservation ICS remaining in an ICS Account at the end of each Year shall be diminished by annual evaporation losses of 3%. Losses shall be applied annually to the end-of-the-Year balance of Extraordinary Conservation ICS beginning in the Year after the ICS is created and continuing until no Extraordinary Conservation ICS remains in Lake Mead. No evaporation losses shall be assessed during a Year in which the Secretary has determined a Shortage Condition.

8. Extraordinary Conservation ICS from a project within a state may only be credited to the ICS Account of a Contractor within that state that has funded or implemented the project creating ICS, or to the ICS Account of a Contractor within the same state as the funding entity and project and with written agreement of the funding entity.

9. A Contractor must notify Reclamation by [insert Month Day] of the amount of ICS it wishes to create for the subsequent Year pursuant to an existing, approved plan. A Contractor may request mid-Year modification(s) to reduce the amount of ICS created during that Year, subject to the requirements of this Section 3.B. A Contractor cannot increase the amount of ICS it had previously scheduled to create during the Year.

C. Delivery of ICS

The Secretary shall deliver ICS in accordance with the following conditions:

1. The delivery shall be consistent with the terms of a Delivery Agreement with a Contractor regarding ICS.

2. The Secretary has determined an ICS Surplus Condition.

3. The existence of Forbearance Agreements necessary to bring the delivery of the ICS into compliance with Articles II(B)(2) and II(B)(6) of the Consolidated Decree.

4. A limitation on the total amount of Extraordinary Conservation ICS that may be delivered in any Year is as follows:

   a. 400,000 af for California Contractors;

   b. 300,000 af for Nevada Contractors; and

   c. 300,000 af for Arizona Contractors.

5. If the May 24-month study for that Year indicates that a Shortage Condition would be determined in the succeeding Year if the requested amounts for the current Year under Section 3.C. were delivered, the Secretary may deliver less than the amounts of ICS requested to be delivered.

6. If the Secretary releases Flood Control Surplus water, Extraordinary Conservation ICS accumulated in ICS Accounts shall be reduced by the amount of the Flood Control Surplus on an acre-foot for acre-foot basis until no Extraordinary Conservation ICS remains. The reductions to the ICS Accounts shall be shared on a pro-rata basis among all Contractors that have accumulated Extraordinary Conservation ICS.

7. If a Contractor has an overrun payback obligation, as described in the October 10, 2003 Inadvertent Overrun and Payback Policy or Exhibit C to the October 10, 2003 Colorado River Water Delivery Agreement, the Contractor must pay the overrun payback obligation in full before requesting or receiving delivery of ICS. The Contractor’s ICS account shall be reduced by the amount of the overrun payback obligation in order to pay the overrun payback obligation.

8. If more ICS is delivered to a Contractor than is actually available for delivery to the Contractor in that Year, then the excess ICS delivered shall be treated as an inadvertent overrun until it is fully repaid.

9. A Contractor may request mid-Year modification(s) to increase or reduce the amount of ICS to be delivered during that Year because of changed conditions, emergency, or hardship, subject to the requirements of this Section 3.C.

10. The Contractor shall agree in the Delivery Agreement that the records of the Contractor relating to the creation of ICS shall be open to inspection by the Secretary and by any Contractor or Basin State.

D. Accounting for ICS

The Secretary shall develop procedures to account for and verify, on an annual basis, ICS creation and delivery. At a minimum such procedures shall include the following:

1. A Contractor shall submit for the Secretary's review and verification, appropriate information, as determined by the Secretary, contained in a Certification Report, to demonstrate the amount of ICS created and that the method of creation was consistent with the Contractor's approved ICS plan, a Forbearance Agreement, and a Delivery Agreement. Such information shall be submitted by [insert Month Date] of the Year following the creation of the ICS.

2. The Secretary, acting through the Lower Colorado Regional Director, shall verify the information submitted pursuant to this section, and provide a final written decision to the Contractor regarding the amount of ICS created. The results of such final written decisions shall be made available to the public through publication pursuant to Section 3.D.3. and other appropriate means. A contractor and any party to an applicable Forbearance Agreement may appeal the Regional Director's verification decision to the Secretary and through judicial processes.

3. Each Year the Decree Accounting Report will be supplemented to include ICS Account balance information for each Contractor and shall address ICS creation, deliveries, amounts no longer available for delivery due to releases for flood control purposes, deductions pursuant to Section 3.B.2., deductions due to annual evaporation losses pursuant to Section 3.B.7., any amounts of ICS converted to Extraordinary Conservation ICS, and ICS remaining available for delivery.

Section 4. Implementation of Developed Shortage Supply

[Content of 2001 ISG Section 4., Effective Period & Termination, is now found at Section 8., as modified herein.]

A. Categories of DSS

1. Tributary Conservation DSS

A Contractor may create Tributary Conservation DSS by purchasing documented water rights on Colorado River System tributaries within the Contractor's state if there is documentation that the water rights have been used for a significant period of Years and that the water rights were perfected prior to June 25, 1929 (the effective date of the Boulder Canyon Project Act). The actual amount of any Tributary Conservation DSS introduced to the Mainstream shall be subject to verification by the Secretary as provided in Section 4.D. Tributary Conservation DSS may be delivered for Domestic Use only.

2. Imported DSS

A Contractor may create Imported DSS by introducing non-Colorado River System water in that Contractor's state into the Colorado River Mainstream, making sufficient arrangements with the Secretary, contractual or otherwise, to ensure no interference with the Secretary's management of Colorado River System reservoirs and regulatory structures. Any arrangement shall provide that the Contractor must obtain appropriate permits or other authorizations required by state and federal law. The actual amount of any Imported DSS introduced to the Mainstream shall be subject to verification by the Secretary as provided in Section 4.D.

B. Creation of DSS

A Contractor may only create DSS in accordance with the following conditions:

1. A Contractor shall submit a plan for the creation of DSS to the Secretary demonstrating how all requirements of these Guidelines will be met in the Contractor's creation of DSS. Until such plan is reviewed and approved by the Secretary, subject to such environmental compliance as may be required, such plan, or any DSS purportedly created through it, shall not be a basis for creation of DSS. A DSS plan will consist of at a minimum the following information:

   a. Project description, including what extraordinary measures will be taken to conserve or import water;

   b. Term of the activity;

   c. Estimate of the amount of water that will be conserved or imported;

d. Proposed methodology for verification of the amount of water conserved or imported; and

e. Documentation regarding any state or federal permits or other regulatory approvals that have already been obtained by the Contractor or that need to be obtained prior to creation of DSS.

A Contractor may modify its approved plan for creation of DSS during any Year, subject to approval by the Secretary.

2. There shall be a one-time deduction of five percent (5%) from the amount of DSS in the Year of its creation. This system assessment shall result in additional system water in storage in Lake Mead.

3. DSS may only be created during a Year when the Secretary has determined a Shortage Condition.

4. DSS may only be created by a project that is approved by the Secretary for creation prior to the Secretary determining a Shortage Condition.

5. A Contractor must notify Reclamation by [insert Month Day] of the amount of DSS it wishes to create for the subsequent Year pursuant to an existing, approved plan. A Contractor may request mid-Year modification(s) to reduce the amount of DSS created during that Year, subject to the requirements of this Section 4.B. A Contractor cannot increase the amount of DSS it had previously scheduled to create during the Year.

C. Delivery of DSS

The Secretary shall deliver DSS in accordance with the following conditions:

1. The delivery shall be consistent with the terms of a Delivery Agreement with a Contractor regarding DSS.

2. The Secretary has determined a Shortage Condition.

3. Delivery of DSS shall not cause the total deliveries within the Lower Division states to reach or exceed 7.5 maf in any Year.

4. Delivery of DSS shall be in accordance with Article II(B)(3) of the Consolidated Decree.

5. If a Contractor has an overrun payback obligation, as described in the October 10, 2003 Inadvertent Overrun and Payback Policy or Exhibit C to the October 10, 2003 Colorado River Water Delivery Agreement, the Contractor must pay the overrun payback obligation in full before requesting or receiving delivery of DSS. The

Contractor's DSS Account shall be reduced by the amount of the overrun payback obligation in order to pay the overrun payback obligation.

6. If more DSS is delivered to a Contractor than is actually available for delivery to the Contractor in that Year, then the excess DSS delivered shall be treated as an inadvertent overrun until it is fully repaid.

7. A Contractor may request mid-Year modification(s) to increase or reduce the amount of DSS to be delivered during that Year because of changed conditions, emergency, or hardship, subject to the requirements of this Section 4.C.

8. The Contractor shall agree in the Delivery Agreement that the records of the Contractor relating to the creation of DSS shall be open to inspection by the Secretary or by any Contractor or Basin State.

9. DSS may only be delivered in the Year of its creation. Any DSS not delivered pursuant to this Section 4.C. in the Year it is created may not be converted to Extraordinary Conservation ICS.

D. Accounting for DSS

The Secretary shall develop procedures to account for and verify, on an annual basis, DSS creation and delivery. At a minimum such procedures shall include the following:

1. A Contractor shall submit for the Secretary's review and verification appropriate information, as determined by the Secretary, contained in a Certification Report, to demonstrate the amount of DSS created and that the method of creation was consistent with the Contractor's approved DSS plan and a Delivery Agreement. Such information shall be submitted by [insert Month Date] of the Year following the creation of the DSS.

2. The Secretary, acting through the Lower Colorado Regional Director, shall verify the information submitted pursuant to this section, and provide a final written decision to the Contractor regarding the amount of DSS created. The results of such final written decisions shall be made available to the public through publication pursuant to Section 4.D.3. and other appropriate means. The Contractor may appeal the Regional Director's verification decision to the Secretary and through judicial processes.

3. Each Year the Decree Accounting Report will be supplemented to include DSS information for each Contractor and shall address DSS creation, deliveries, and deductions pursuant to Section 4.B.2 and 4.B.3.

Section 5. California's Colorado River Water Use Plan Implementation Progress

A. Introduction

[Adopted January 16, 2001; Deleted [insert Month Day, Year]]

B. California's Quantification Settlement Agreement

[Adopted January 16, 2001; Deleted [insert Month Day, Year]]

C. California's Colorado River Water Use Reductions

The California Agricultural (Palo Verde Irrigation District, Yuma Project Reservation Division, Imperial Irrigation District, and Coachella Valley Water District) usage plus 14,500 af of Present Perfected Right (PPR) use would need to be at or below the following amounts at the end of the Year indicated in Years other than Quantified or Flood Control Surplus (for Decree accounting purposes all reductions must be within 25,000 af of the amounts stated):

Benchmark Date (Calendar Year)	Benchmark Quantity (California Agricultural usage & 14,500 AF of PPR Use in MAF)
2003	3.75 [4]
2006	3.64 [3]
2009	3.60 [5]
2012	3.47

In the event that California has not reduced its use in accordance with the limits set forth above in any year in which the Benchmark Quantity applies, the surplus determination under Section 2.B.2. of these Guidelines will be suspended and will instead be based upon the 70R Strategy, for up to the remainder of the term of these Guidelines. If however, California meets the missed Benchmark Quantity before the next Benchmark Date or the 2012 Benchmark Quantity after 2012, the surplus determination under Section 2.B.2. shall be reinstated as the basis for the surplus determination under the AOP for the next following Year(s).

As part of the AOP process during the Interim Period of these Guidelines, California shall report to the Secretary on its progress in implementing its California Colorado River Water Use Plan.

[4] The Benchmark Quantities in 2003 and 2006 were met.

[5] The 2009 Benchmark Quantity is modified from 3.53 maf due to construction delays that have been experienced for the All-American Canal Lining Project.

Section 6. Coordinated Operation of Lakes Powell and Mead During the Interim Period

[Content of 2001 ISG Section 6., Authority, is now found at Section 9., as modified herein.]

During the Interim Period, the Secretary shall coordinate the operations of Lake Powell and Lake Mead according to the strategy set forth in this Section 6.

The objective of the operation of Lakes Powell and Mead as described herein is to avoid curtailment of uses in the Upper Basin, minimize shortages in the Lower Basin and not adversely affect the yield for development available in the Upper Basin.

The August 24-month study projections for the January 1 system storage and reservoir water surface elevations, for the following Water Year, shall be used to determine the applicability of the coordinated operation of Lakes Powell and Mead. Equalization or balancing of storage in Lakes Powell and Mead shall be achieved by the end of each Water Year.

Powell Elevation (feet)	Powell Operation	Powell Live Storage (maf)
3700		24.32
	Equalize, avoid spills or 8.23 maf	
3636 - 3666 (see table below)		15.54 - 19.29 (2008 - 2026)
	8.23 maf; if Mead < 1075 feet, balance contents with a min/max release of 7.0 and 9.0 maf	
3575		9.52
	7.48 maf 8.23 maf if Mead < 1025 feet	
3525		5.93
	Balance contents with a min/max release of 7.0 and 9.5 maf	
3370		0

Lake Powell Equalization Elevation Table

In each of the following Water Years, the Lake Powell Equalization Elevation will be as follows:

Water Year	Elevation (feet)
2008	3636
2009	3639
2010	3642
2011	3643
2012	3645
2013	3646
2014	3648
2015	3649
2016	3651
2017	3652
2018	3654
2019	3655
2020	3657
2021	3659
2022	3660
2023	3662
2024	3663
2025	3664
2026	3666

1. Equalization: In Water Years when Lake Powell content is projected on January 1 to be at or above the elevation stated in the Lake Powell Equalization Elevation Table, an amount of water will be released from Lake Powell to Lake Mead at a rate greater than 8.23 maf per Water Year to the extent necessary to avoid spills, or equalize storage in the two reservoirs, or otherwise to release 8.23 maf from Lake Powell.

2. Upper Elevation Balancing: In Water Years when Lake Powell content is projected on January 1 to be below the elevation stated in the Lake Powell Equalization Elevation Table and at or above 3575 feet, the Secretary shall release 8.23 maf from Lake Powell if the projected elevation of Lake Mead is at or above 1075 feet. If the projected elevation of Lake Mead is below 1075 feet, the Secretary shall balance the contents of Lake Mead and Lake Powell, but shall release no more than 9.0 maf and no less than 7.0 maf from Lake Powell.

3. Mid-Elevation Releases: In Water Years when Lake Powell content is projected on January 1 to be below 3575 feet and at or above 3525 feet, the Secretary shall release

7.48 maf from Lake Powell if the projected elevation of Lake Mead is at or above 1025 feet. If the projected elevation of Lake Mead is below 1025 feet, the Secretary shall release 8.23 maf from Lake Powell.

4. Lower Elevation Balancing: In Water Years when Lake Powell content is projected on January 1 to be below 3525 feet, the Secretary shall balance the contents of Lake Mead and Lake Powell, but shall release no more than 9.5 maf and no less than 7.0 maf from Lake Powell.

5. When determining lake elevations and contents under this Section 6, no adjustment shall be made for ICS.

Coordinated Operation of Lakes Powell and Mead as described herein will be presumed to be consistent with the Section 602(a) storage requirement contained in the Colorado River Basin Project Act.

Releases from Lake Powell for coordinated operations will be consistent with the parameters of the Record of Decision for the Glen Canyon Dam Final Environmental Impact Statement and the Glen Canyon Dam Operating Criteria (62 *Federal Register* 9447, Mar. 3, 1997).

Section 7. Implementation of Guidelines

[Content of 2001 ISG Section 7, Modeling and Data Authority, is now found at Section 7.A., as modified herein.]

A. AOP Process.

[text may be inserted]

B. Consultation

The Secretary shall consult on the implementation of these Guidelines in circumstances including but not limited to the following:

1. The Secretary shall first consult with all the Basin States before making any substantive modification to these Guidelines.

2. Upon a request for modification of these Guidelines, or upon a request to resolve any claim or controversy arising under these Guidelines or under the operations of Lakes Powell and Mead pursuant to these Guidelines or any other applicable provision of federal law, regulation, criteria, policy, rule, or guideline, or the Mexican Water Treaty of 1944, the Secretary shall invite the Governors of all the Basin States, or their designated representatives, to consult with the Secretary in an attempt to resolve such claim or controversy by mutual agreement.

3. In the event projections included in any monthly 24-Month Study indicates Lake Mead elevations may approach an elevation that would trigger shortages in deliveries of water from Lake Mead in the United States, the Secretary shall consult with the Basin States on whether and how the United States may reduce the quantity of water allotted to Mexico.[6]

4. Whenever Lake Mead is below elevation 1025 feet, the Secretary shall consult with the Basin States annually to consider whether Colorado River hydrologic conditions, together with the anticipated delivery of water to the Lower Division states and Mexico, is likely to cause the elevation of Lake Mead to fall below 1000 feet. Upon such a consideration, the Secretary shall consult with the Basin States to discuss further measures that may be undertaken. The Secretary shall implement any additional measures consistent with applicable federal law.

[6] These Guidelines are not intended to constitute an interpretation or application of the 1944 Treaty or to represent current United States policy or a determination of future United States policy regarding deliveries to Mexico. The United States will conduct all necessary and appropriate discussions regarding the proposed federal action and implementation of the 1944 Treaty with Mexico through the IBWC in consultation with the Department of State.

5. During the Interim Period the Secretary shall consult with the Basin States regarding the administration of ICS.

6. During the Interim Period the Secretary shall consult with the Basin States regarding the creation of ICS through other extraordinary conservation measures pursuant to Section 3.A.1.h.

7. During the Interim Period the Secretary shall consult with the Basin States regarding the creation of System Efficiency ICS pursuant to Section 3.A.3.

8. The Secretary shall consult with the Basin States to evaluate actions at critical elevations that may avoid shortage determinations as reservoir elevations approach critical thresholds.

C. Mid-Year Review

[text may be inserted]

D. Operations During Interim Period

[text may be inserted]

Beginning no later than December 31, 2020, the Secretary shall initiate a formal review for purposes of evaluating the effectiveness of these Guidelines. The Secretary shall consult with the Basin States in initiating this review.

Section 8. Interim Period and Termination

[Adopted January 16, 2001; Deleted and Modified [insert Month Day, Year]]

A. Interim Period

These Guidelines will be effective upon the date of execution of the ROD for Colorado River Interim Guidelines for Lower Basin Shortages and Coordinated Operations of Lake Powell and Lake Mead and will, unless subsequently modified, remain in effect through December 31, 2025 (through preparation of the 2026 AOP).

B. Effective Period - Special Provisions

1. The provisions for the delivery and accounting of ICS in Section 3 shall remain in effect through December 31, 2036, unless subsequently modified, for any ICS remaining in an ICS Account on December 31, 2026.
2. The provisions for the creation and delivery of Tributary Conservation ICS and Imported ICS in Section 3 shall continue in full force and effect until fifty years from the date of the execution of the ROD.
3. The provisions for the creation and delivery of DSS in Section 4 shall continue in full force and effect until fifty years from the date of the execution of the ROD.

C. Termination of Guidelines

Except as provided in Section 8.B., these Guidelines shall terminate on December 31, 2025 (through preparation of the 2026 AOP). At the conclusion of the effective period of these Guidelines, the operating criteria for Lake Powell and Lake Mead are assumed to revert to the operating criteria used to model baseline conditions in the Final Environmental Impact Statement for the Interim Surplus Guidelines dated December 2000 (i.e., modeling assumptions are based upon a 70R Strategy for the period commencing January 1, 2026 (for preparation of the 2027 AOP)).

[text may be inserted]

Section 9. Authority and Disclaimer

These Guidelines are issued pursuant to the authority vested in the Secretary by federal law, including the Boulder Canyon Project Act of 1928 (28 Stat. 1057), the Colorado River Storage Project Act (70 Stat. 105), and the Consolidated Decree issued by the U.S. Supreme Court in *Arizona v. California*, 547 U.S. 150 (2006) and shall be used to implement Articles II and III of the Criteria for the Coordinated Long Range Operation of Colorado River Reservoirs Pursuant to the Colorado River Basin Project Act of September 30, 1968 (Pub. L. No. 90-537), as amended.

Appendix T

NRC Executive Summary

This appendix contains the Executive Summary for the National Research Council 2007 report on *Colorado River Basin Water Management: Evaluating and Adjusting to Hydroclimatic Variability*. The information provided in the National Research Council 2007 Report was used by Reclamation to inform the EIS process on the potential impacts on the Colorado River of climate change and hydrologic variability. Copies of the full report are available from the National Academies Press through their website (http://www.nap.edu).

T.1 NRC Executive Summary

Colorado River Basin Water Management: Evaluating and Adjusting to Hydroclimatic Variability
http://books.nap.edu/catalog/11857.html

Summary

Encompassing an area of more than 240,000 square miles, the Colorado River basin covers portions of seven western U.S. states and part of extreme northwestern Mexico. Passing through the heart of what author Wallace Stegner called "the dry core" of the arid western United States, the Colorado's mean annual flow of roughly 15 million acre-feet is not large in comparison to major rivers like the Columbia or the Mississippi. As the largest source of surface water in a large, arid region, however, the Colorado is of great importance to cities, farmers, tribes, anglers, industries, and rafters. In addition to water diversions for municipal, agricultural, and other uses, Colorado River flows generate hydroelectricity, support recreational opportunities and ecological habitats, and sustain cultural and historical values.

Given the Colorado River's importance, variations in its flow record have long been of keen interest to many parties. Direct streamflow measurements date back to the late 1890s when gaging stations were established at a few sites along the river. As the river's flow was measured over the next century, and as a network of stream gaging stations grew, a more complete understanding of Colorado River flows and variability emerged. For example, it is known today that the Colorado River Compact of 1922—the water allocation compact that divides Colorado River flows between the upper and lower Colorado River basin states—was signed during a period of relatively high annual flows. It is also accepted that the long-term mean annual flow of the river is less than the 16.4 million acre-feet assumed when the Compact was signed—a hydrologic fact of no small importance with regard to water rights agreements and subsequent allocations.

Since the 1970s direct measurements of Colorado River flows have been complemented by studies of past hydroclimate conditions that draw from a body of indirect, or proxy, evidence based on tree-

ring data. Because patterns of tree-ring growth of trees at lower elevations can reflect moisture availability, tree-ring data can be used to assemble records, or "reconstructions," of past river flows. Using data from coniferous tree species with long life spans in the Colorado River region, flows dating back several centuries have been reconstructed. The first tree-ring-based flow reconstruction for the Colorado River at Lees Ferry, Arizona—the point at which the Colorado River basin is divided legally into its upper and lower basins—was assembled by Charles Stockton and Gordon Jacoby, Jr., in 1976. Additional reconstructions of Colorado River flows that date back to the 15th century, including several undertaken in the past few years, have enhanced scientific understanding of the region's long-term hydrologic and climate patterns.

Tree-ring-based reconstructions became increasingly prominent topics of discussion in western water circles in the early 2000s. Because this period was exceptionally dry across much of the West, the tree-ring-based reconstructions prompted many questions and concerns about the possible extent and severity of future droughts. The water years 2002 and 2004 (as measured from October 1 through the following September 30), for example, were among the 10 driest years of record in the upper basin states of Colorado, New Mexico, Utah, and Wyoming. Significantly, flows into the basin's reservoirs dropped sharply during this period; for example, 2002 water year flows into Lake Powell above Glen Canyon Dam were roughly 25 percent of mean values. These drought conditions stimulated increased interest in tree-ring-based flow reconstructions and long-term Colorado River flows and water availability.

Out of interest in these issues and their implications, in 2005 the National Research Council's Water Science and Technology Board initiated a study to review hydrologic and climatic sciences of the Colorado River region. The Committee on the Scientific Bases of Colorado River Basin Water Management was appointed to assess the extant body of scientific studies regarding both Colorado River hydrology and hydroclimatic trends that might affect river flows. The committee also was asked to consider related topics, including hydrologic models, data, and methods; organizations for evaluating hydroclimatic data; and systems operations and water management practices (the full statement of task to this committee is listed in Chapter 1).

This committee's statement of task called for a report that produced "an improved hydrologic baseline" for Colorado River water management. In discussing this phrase, the committee noted that it might be interpreted in different ways. An improved hydrologic baseline could, for example, entail a new estimate of long-term mean annual Colorado River flows; establishment of new river gaging stations, computer models, or numerical methods; or a recommendation to reorganize existing (or create new) programs and institutions for evaluating hydrologic and climatic data. After discussing the language in its task statement, the committee concluded that the most appropriate way to help improve a hydrologic baseline for the Colorado River would be to evaluate existing scientific information (including temperature and streamflow records, tree-ring-based reconstructions, and climate model projections) and how it relates to Colorado River water supplies, demands, water management, and drought preparedness.

The following sections of this Summary address the topics of hydroclimatic data and sciences, realities of Colorado River water management, and improving drought preparedness via cooperation, science, and planning. The report's findings and recommendations are presented in bold.

HYDROCLIMATIC DATA AND SCIENCES

Temperature Trends and Model Projections

Temperature records across the Colorado River basin and the western United States document a significant warming over the past century. These temperature records, along with climate model projections that forecast further increases, collectively suggest that temperatures across the region will continue to rise for the foreseeable future. Higher regional temperatures are shifting the timing of peak spring snowmelt to earlier in the year and are contributing to increases in water demands, especially during summer. Higher temperatures will result in higher evapotranspiration rates and contribute to increased evaporative losses from snowpack, surface reservoirs, irrigated land, and vegetated surfaces. Projections of future precipitation are more uncertain than are temperature predictions, leading to uncertainty as to possible changes in future streamflow. Recent studies of the hydrologic implications of warming across the region, based on many global climate models, suggest that on average (across models) runoff and streamflow will decrease. There is, however, uncertainty in these predictions, and some models even suggest increases.

The 20th century saw a trend of increasing mean temperatures across the Colorado River basin that has continued into the early 21st century. There is no evidence that this warming trend will dissipate in the coming decades; many different climate model projections point to a warmer future for the Colorado River region.

Modeling results show less consensus regarding future trends in precipitation. Several hydroclimatic studies project that significant decreases in runoff and streamflow will accompany increasing temperatures. Other studies, however, suggest increasing future flows, highlighting the uncertainty attached to future runoff and streamflow projections. Based on analysis of many recent climate model simulations, the preponderance of scientific evidence suggests that warmer future temperatures will reduce future Colorado River streamflow and water supplies. Reduced streamflow would also contribute to increasing severity, frequency, and duration of future droughts.

Estimating Colorado River Flows: Gaging Stations and Tree-Ring Based Reconstructions

The first gaging stations on the Colorado River were established in the late 19th century. The best-known of the river's many gaging stations is at Lees Ferry, Arizona, established there in 1921. For many years the gaged record of Colorado River flows represented the best science-based knowledge about the river's long-term behavior. Imbedded within this gaged record was an implicit assumption that there was a single, mean value of the river's annual flow, and that interannual variations occurred around this long-term, fixed average. Under this assumption, the basin may have experienced wet and dry periods, but river flows and weather conditions were nonetheless expected to return to an average state, largely defined by climate and hydrology of the early and middle 20th century.

Questions regarding this long-held paradigm of Colorado River mean discharge arose and have been debated in the latter part of the 20th century. Much of this evolving debate reflected concerns over global climate change that came to prominence beginning in the 1970s. Views of the river's long-term variability continued to evolve with more studies of climate change and hydrology that were conducted beginning in the 1980s. Recent tree-ring-based studies demonstrate that Colorado River flows occasionally shift into decade-long periods in which average flows are lower, or higher, than the 15 million acre-feet/year mean based on the current gaged record. The reconstructions also reinforce the point that the gaged record of Colorado River streamflow covers but a small subset of the range of natural hydroclimatic variability present over several centuries and that future Colorado River hydrology may not mimic the hydrologic behavior reflected within the Lees Ferry gaged record.

For many years, scientific understanding of Colorado River flows was based primarily on gaged streamflow records that covered several decades. Recent studies based on tree-ring data, covering hundreds of years, have transformed the paradigm governing understanding of the river's long-term behavior and mean flows. These studies affirm year-to-year variations in the gaged records. They also demonstrate that the river's mean annual flow—over multidecadal and centennial time scales, as shown in multiple and independent reconstructions of Colorado River flows—is itself subject to fluctuations. Given both natural and human-induced climate changes, fluctuations in Colorado River mean flows over long-range time scales are likely to continue into the future. The paleoclimate record reveals several past periods in which Colorado River flows were considerably lower than flows reflected in the Lees Ferry gaged record, and that were assumed in the 1922 Colorado River Compact allocations.

Tree-Ring-Based Reconstructions, Drought, and Future Water Availability

Tree-ring-based streamflow reconstructions allow the gaged record to be placed in the context of longer-term hydroclimatic variability. Although such reconstructions are only estimates of past river flows, they collectively point to a past in which severe, extended drought was recurrent. They also reveal that 1905-1920 was an exceptionally wet period.

Multicentury, tree-ring-based reconstructions of Colorado River flow indicate that extended drought episodes are a recurrent and integral feature of the basin's climate. Moreover, the range of natural variability present in the streamflow reconstructions reveals greater hydrologic variability than that reflected in the gaged record, particularly with regard to drought. These reconstructions, along with temperature trends and projections for the region, suggest that future droughts will recur and that they may exceed the severity of droughts of historical experience, such as the drought of the late 1990s and early 2000s.

Maintaining the Colorado River Streamflow Gaging Network

The Lees Ferry gage record is an important part of the scientific basis for understanding Colorado River discharge and variability and thus for Colorado River water management. Previous federal-level political and financial support for stream gaging stations has been inconsistent. Over the years, some stations have been discontinued. The loss of stations with long periods (greater than 30 years) of record represents a problem of special concern. The value and importance of reliable and continuous hydrologic records will only grow in the future. It would be imprudent and short-sighted to allow the integrity of the Colorado River gaging station network to be compromised or degraded.

Measured values of streamflow of the Colorado River and its tributaries provide essential information for sound water management decisions. Loss of continuity in this gaged record would greatly diminish the overall value of the existing flow data set, and once such data are lost they cannot be regained. The executive and legislative branches of the U.S. federal government should cooperate to ensure that resources are available for the USGS to maintain the Colorado River basin gaging system and, where possible, expand it.

REALITIES OF COLORADO RIVER WATER MANAGEMENT

In considering its full statement of task and in speaking with Colorado River scientific, engineering, and management experts during the course of this study, this committee identified several trends and realities that affect applications of scientific information in water management. Some of them may prove politically contentious, but they nonetheless merit careful consideration by decision makers at all levels in Colorado River water planning.

Increasing Water Demands, Limited Water Supplies

The late 20th and early 21st centuries witnessed high rates of population growth across the western United States. Population in Arizona, for instance, jumped from about 3.7 million in 1990 to over 5.1 million in 2000—a roughly 40 percent increase (this rate would double Arizona's population in less than 20 years). In Colorado, population grew from slightly fewer than 3.3 million in 1990 to about 4.3 million in 2000—a 30 percent increase. These figures do not necessarily equate directly to increases in water demand; conservation measures, pricing policies, and consumer habits and preferences all influence per capita water uses. In fact, some innovative urban water use and conservation programs have led to reductions in per capita use. Nevertheless, expanding populations have prompted significant increases in urban water demands. Water consumption in Clark County, Nevada (which includes Las Vegas), for example, approximately doubled in the 1985-2000 period. Population growth rates and future projections are on a sharply increasing trajectory in the western United States and they point to sizable and growing water demands for the foreseeable future. In addition, other demands on water supplies, such as those emanating from tribal settlements or from reallocations to support instream flows, will likely grow in the years ahead.

From a water resources perspective, the traditional means of coping with (and effectively encouraging) growth in the western United States was to develop new water supplies by creating large storage reservoirs. After a period of vigorous dam construction in the 1950s and 1960s, prospects for constructing additional large dams in the Colorado River basin have diminished. Today, rather than creating new reservoirs, municipalities are focusing on new, often nonstructural, strategies for augmenting water supplies. A significant trend in this quest has been the sale, lease, and transfer of agricultural water rights to municipalities, particularly in southern California and Colorado. (In Arizona, settlements of tribal water right, with subsequent transfers to municipalities, have also been important.)

Agricultural water rights have been crucial to meeting burgeoning urban water demands in many places. There are other ways for urban areas to obtain additional water supplies, such as through greater use of municipal effluent water (the only growing water supply available in the arid West). Nevertheless, agricultural water appears to constitute the most important, and perhaps final, large reservoir of water available for urban use in the arid U.S. West. In aggregate, the amount of water devoted to agricultural uses is quite large; about 80 percent of western U.S. water supplies are devoted to crop production. Modest shifts of agricultural water to municipal and industrial uses can do much to meet increasing urban water demands. The direct effects associated with the loss of agricultural water, however, such as reduced food production capability, can be significant. In addition, agricultural-urban transfers often entail other "third-party" effects that include costs for rural communities, ecosystems, and other groups indirectly dependent on water supplies affected by the transfers. In recent years many creative water transfer arrangements, involving legally defined water banks and underground water storage programs designed to help mitigate third-party effects, have been developed. The availability of agricultural water is finite, however, and such programs thus are limited in their ability to satisfy increasing, long-term demands. The combination of limited Colorado River water supplies, rapidly increasing populations and water demands, warmer regional temperatures, and the specter of recurrent drought point to a future in which the potential for conflict among existing and prospective new users will prove endemic.

Steadily rising population and urban water demands in the Colorado River region will inevitably result in increasingly costly, controversial, and unavoidable trade-off choices to be made by water managers, politicians, and their constituents. These increasing demands are also impeding the region's ability to cope with droughts and water shortages.

Technologies and Strategies for Augmenting Water Supplies

A wide array of technological and conservation measures can be used to help stretch existing water supplies. These measures include underground storage of water, water reuse, desalination, weather modification, conservation, and changes in water pricing structures and rates. These measures may not necessarily be inexpensive or easy to implement, but many of them show promise and will continue to be pursued and developed as water supplies tighten in future years. Areas experiencing population growth will continue to demand additional water supplies, however, and gains realized through technology, conservation, and other measures will be readily absorbed by increasing population and water demands.

Technological and conservation options for augmenting or extending water supplies—although useful and necessary—in the long run will not constitute a panacea for coping with the reality that water supplies in the Colorado River basin are limited and that demand is inexorably rising.

IMPROVING DROUGHT PREPAREDNESS: COOPERATION, SCIENCE, AND PLANNING

Interstate Cooperation

The drought of the late 1990s and early 2000s prompted the Colorado River states to move toward a new level of interstate cooperation in devising water shortage management criteria. A preliminary proposal presented in a February 2006 letter from the seven basin states to the U.S. Secretary of the Interior (see Appendix A) responded to the Secretary's request that the states develop shortage guidelines and management strategies under low reservoir conditions. This letter represents a noteworthy effort to avoid potential disruptions of operational criteria that govern flow allocations among the basin states.

The interstate cooperation and initiative exhibited by the Colorado River basin states in their February 2006 letter to the Secretary of the Interior is a welcome development that will

prove increasingly valuable—and likely essential—in coping with future droughts and growing water demands.

Scientist-Decision Maker Collaboration

The scientific knowledge base of Colorado River hydrology and climate rivals, and may exceed, comparable knowledge bases for any of the world's river systems. Some of this scientific knowledge has been fundamental to legal and operational decisions, such as the Bureau of Reclamation's Operating Criteria, reservoir operations rule curves, and other aspects of Colorado River basin water resources planning and policy. Some of this scientific information, on the other hand, may not be as well integrated in Colorado River basin water policy as it should be.

Drought conditions in the early 2000s stimulated stronger two-way communication between the scientific community and the water management community. This increased collaboration took the form of workshops, conferences, and other discussions among climate and water experts (especially paleoclimate and tree-ring specialists), hydrologists, civil engineers, and water resources planners and decision makers. Communication between scientists and water managers is important because, for example, it is not always clear what types of scientific information the water management community would find most useful. Scientists can help explain scientific concepts and findings to the water management and user community, while water managers can help scientists frame scientific questions and lines of inquiry that they would find most useful for operational and longer term strategic decisions. These interchanges require sustained, two-way collaboration in order to enhance mutual learning between these groups. It will be important for western water managers to sustain this interest in Colorado River climate, drought, and water planning issues when wetter conditions return, as severe drought conditions will undoubtedly occur again. It will also be important for scientists to sustain their interests in water policy issues related to water supply, demand, and drought management.

A commitment to two-way communication between scientists and water managers is important and necessary in improving overall preparedness and planning for drought and other water shortages. Active communication among people in these commu-

nities should become a permanent fixture within the basin, irrespective of water conditions at any given time. Such dialogue should help scientists frame their investigations toward questions and topics of importance to water managers, and should help water managers keep abreast of recent scientific developments and findings.

Comprehensive, Action-Oriented Study of Pressing Colorado River Water Issues

The Colorado River Compact and much of the Law of the River—the federal and state statutes, interstate compacts, court decisions, and other operating criteria and administrative decisions that define the river's overall governance—were framed during an era in which water for irrigation (and municipal uses in Southern California) was of paramount concern. Today, population growth and increasing water demands have moved urban water issues to the fore of the western water landscape. Increasing urban population and water demands have prompted municipal water managers to think creatively about more efficient water management and ways to increase water supplies and/or limit water use. States and municipalities have sponsored many conservation, landscaping, education, and other related programs. There have been few initiatives, however, to systematically document or synthesize these efforts, which may be hindering progress toward more efficient and better coordinated urban water management across the region. Moreover, knowledge of important topics and issues, such as water demand forecasting and the environmental implications of large-scale agriculture-urban water transfers, lags behind advances in hydrologic and climate sciences.

A more systematic and coordinated approach to urban water conservation and drought preparedness could be promoted through a collaborative investigation across the Colorado River basin. The basin states and municipalities generally establish water practices and policies tailored to their unique circumstances. A comprehensive, accessible report of basin-wide urban water practices, comparing the many lessons learned from diverse experiences across the basin in coping with water shortages and limited supplies, could serve as a more systematic and action-oriented basis for water planning. The collaboration involved in preparing such a report could also promote better communication among federal agencies, the basin states, and municipalities on urban water management strategies and alternatives. It could also encourage a sustained commitment toward a more proactive approach to managing urban water during periods of drought and in the face of growing population.

A comprehensive, action-oriented study of Colorado River region urban water practices and changing patterns of demand should be conducted, as such a study could provide a more systematic basis for water resources planning across the region. At a minimum, the study should address and analyze the following issues:

- **historical adjustments to droughts and water shortages,**
- **demographic projections,**
- **local and regional water demand forecasting,**
- **experiences in drought and contingency planning,**
- **impacts of increasing urban demands on riparian ecology,**
- **long-term impacts associated with agriculture-urban transfers, and**
- **contemporary urban water polices and practices (e.g., conservation, landscaping, water use efficiency technologies).**

The study could be conducted by the Colorado River basin states, a U.S. federal agency or agencies, a group of universities from across the region, or some combination thereof. The basin states and the U.S. Congress should collaborate on a strategy for commissioning and funding this study. These groups should be prepared to take action based on this study's findings in order to improve the region's preparedness for future inevitable droughts and water shortages.

THE NATIONAL ACADEMIES

Advisers to the Nation on Science, Engineering, and Medicine

The **National Academy of Sciences** is a private, nonprofit, self-perpetuating society of distinguished scholars engaged in scientific and engineering research, dedicated to the furtherance of science and technology and to their use for the general welfare. Upon the authority of the charter granted to it by the Congress in 1863, the Academy has a mandate that requires it to advise the federal government on scientific and technical matters. Dr. Ralph J. Cicerone is president of the National Academy of Sciences.

The **National Academy of Engineering** was established in 1964, under the charter of the National Academy of Sciences, as a parallel organization of outstanding engineers. It is autonomous in its administration and in the selection of its members, sharing with the National Academy of Sciences the responsibility for advising the federal government. The National Academy of Engineering also sponsors engineering programs aimed at meeting national needs, encourages education and research, and recognizes the superior achievements of engineers. Dr. Wm. A. Wulf is president of the National Academy of Engineering.

The **Institute of Medicine** was established in 1970 by the National Academy of Sciences to secure the services of eminent members of appropriate professions in the examination of policy matters pertaining to the health of the public. The Institute acts under the responsibility given to the National Academy of Sciences by its congressional charter to be an adviser to the federal government and, upon its own initiative, to identify issues of medical care, research, and education. Dr. Harvey V. Fineberg is president of the Institute of Medicine.

The **National Research Council** was organized by the National Academy of Sciences in 1916 to associate the broad community of science and technology with the Academy's purposes of furthering knowledge and advising the federal government. Functioning in accordance with general policies determined by the Academy, the Council has become the principal operating agency of both the National Academy of Sciences and the National Academy of Engineering in providing services to the government, the public, and the scientific and engineering communities. The Council is administered jointly by both Academies and the Institute of Medicine. Dr. Ralph J. Cicerone and Dr. Wm. A. Wulf are chair and vice chair, respectively, of the National Research Council.

Preface

The Colorado River has long been uniquely important in the exploration, development, and culture of the western United States. The Colorado is a desert river, stretching from high in the Rockies, through great canyons and arid regions in Utah and Arizona, and finally ending in the Gulf of California in Mexico. For millions of years it has shaped landforms and in the Grand Canyon has exposed geologic formations that are half as old as the Earth itself. The great American scientist John Wesley Powell explored this region widely. He had extensive knowledge of many Native American tribes and his 1869 boating expedition down the Colorado River through the Grand Canyon is legendary. Powell's 1878 publication *Lands of the Arid Region of the United States, with a More Detailed Account of the Lands of Utah* offered many new ideas regarding the roles of the U.S. federal government in developing western water supplies. Although Powell may have foreseen some aspects of western development, one thing he probably did not foresee was the future extent of population growth in the Colorado River region. Nor was Powell likely to have imagined that changes in regional climate might someday affect hydrologic conditions.

Our committee was asked to review the hydrologic and climatic bases of Colorado River water management. In considering this existing body of scientific information, we were struck by the warming across the region in the past century and by the fact that nearly all global climate models forecast increasing temperatures for the Colorado River region. We also noted the exceptionally hot and dry conditions across much of the nation in the summer of 2006, and that the 2006 average annual temperature for the contiguous United States was the warmest on record and nearly identical to the record set in 1998. These conditions are consistent with warming trends in the region.

As we proceeded it became clear that a broad understanding of Colorado River water management issues is not possible unless both water supply and demand issues are adequately considered. Terms such as "population growth" and "water demand" did not appear in our statement of task. As we spoke with water experts from across the region at our meetings, however, they identified important linkages among hydrology and climate and issues such as population growth and water demands, urban water management and conservation, riparian ecology, and water transfers. Clearly, interest in hydroclimatic issues in the region is being driven in large part by increasing water demands and a limited ability to augment water supplies through traditional means. Furthermore, our statement of task called for us to consider the broad topics of systems operations and water management practices. We thus felt it incumbent upon us to comment on topics of water demand, technologies and practices for augmenting water supplies, and programs for coping with drought.

Our report presents population growth data for much of the western United States that is served by Colorado River water. The cities in the region are collectively the fastest growing in the nation. Of further concern is that this growth seems to be occurring with little regard to long-term availability of future water supplies. Ideally, these issues will be openly discussed and squarely addressed before the water supply-and-demand balance across the region becomes more critical. This is important because, for example, the drought of the early 2000s turned out to be even worse than many assumptions regarding a worst-case-scenario drought. This ongoing drought has contained a sequence of exceptionally dry years. Inflows into the basin's storage reservoirs have been well below normal and it may take 15 years of average future hydrologic conditions to refill the basin's largest water storage reservoirs, Lakes Mead and Powell. These hydroclimatic trends are especially troubling in light of rapidly increasing water demands.

I thank our committee members for the hard work and intellect they devoted to producing this consensus report. Each of them brought unique expertise to our deliberations and report preparation and they all devoted many hours of personal time to our study. Their views were fully considered in our study process and I thank them for their contributions, good will, and spirit of collaboration. I also thank the many water scientists, engineers, administrators, and other experts from across the region that spoke with our committee. They provided a comprehensive and fascinating update of key water and science issues across the region and presented important topics and questions for our committee's consideration, all of which were essential to our deliberations and report (Appendix B lists these speakers).

I also thank the National Research Council (NRC) staff members for their dedication and diligent work in our study process. Jeff Jacobs, senior staff officer with the Water Science and Technology Board (WSTB), ensured that our committee stayed on task and that the varying opinions and written contributions from our committee members were blended to create a single, coherent report. Jeff and the committee were ably assisted by WSTB research associate Dorothy Weir, who handled administrative details of the meetings and ably assisted in all phases of report preparation.

We are grateful to the sponsors who provided support for this study. These sponsors included federal, state, and municipal water organizations across the West, which reflects the broad interest in and importance of in these issues. These sponsors were the California Department of Water Resources, the Metropolitan Water District of Southern California, the Southern Nevada Water Authority, and the U.S. Bureau of Reclamation. We also thank the National Academies for providing a substantial portion of funding and for exercising leadership in initiating this study.

This report was reviewed in draft form by individuals chosen for their breadth of perspectives and technical expertise in accordance with the procedures approved by the National Academies' Report Review Committee. The purpose of this independent review was to provide candid and critical comments to assist the institution in ensuring that its published report is scientifically credible and that it meets institutional standards for objectivity, evidence, and responsiveness to the study charge. The reviewer comments and draft manuscript remain confidential to protect the deliberative process. We thank the following reviewers for their helpful suggestions, all of which were considered and many of which were wholly or partly incorporated in the final report: John A. Dracup, University of California; Jerome B. Gilbert, Orinda, California; W.R. Gomes, University of California; Martin P. Hoerling, National Oceanic and

Atmospheric Administration; Malcolm K. Hughes, University of Arizona; Katharine L. Jacobs, University of Arizona; John W. Keys, III, Moab, Utah; Upmanu Lall, Columbia University; John E. Thorson, California Public Utilities Commission; and James L. Wescoat, Jr., University of Illinois.

Although these reviewers provided constructive comments and suggestions, they were not asked to endorse the report's conclusions and recommendations nor did they see the final draft of the report before its release. The review of this report was overseen by Daniel P. Loucks, Cornell University, who was appointed by the NRC's Report Review Committee, and by A. Dan Tarlock, Chicago Kent College of Law, who was appointed by the NRC's Division on Earth and Life Studies. Drs. Loucks and Tarlock were responsible for ensuring that an independent examination of this report was conducted in accordance with NRC institutional procedures and that all review comments received full consideration. Responsibility for this report's final contents rests entirely with the authoring committee and the NRC.

The seven Colorado River basin states and cooperating agencies, particularly the Bureau of Reclamation, face great challenges in addressing the complex issues of Colorado River water supply management. The pressures of meeting the needs of the burgeoning population in the face of future severe droughts and uncertain impacts of global change are indeed great. Political pressures will abound but there are signs of increasing cooperation on a variety of water use issues. We hope this report represents a contribution to the knowledge base of Colorado River hydroclimate and water management and that it helps promote common understanding and cooperation on these matters.

Appendix U

Climate Technical Work Group Report

This appendix contains a copy of a forthcoming report entitled *Review of Science and Methods for Incorporating Climate Change Information into Bureau of Reclamation's Colorado River Basin Planning Studie*s. The report provides a summary of an assessment of the state of knowledge with regard to climate change and modeling for the Colorado River Basin and provides recommendations on future research and development needs. This report will be a forthcoming Reclamation publication with no change in content; however the formatting will be changed from that used in this appendix. This report was prepared by the Climate Technical Work Group that was empanelled by Reclamation to provide information on climate science and future climate conditions and their potential impact on the Colorado River. The Climate Technical Work Group included climate experts from the University of Colorado (National Oceanic and Atmospheric Administration – Western Water Assessment), the University of Arizona, the University of Nevada – Las Vegas, the University Corporation for Atmospheric Research, Reclamation, and Hydrosphere Consultants, Inc.

U.1 Executive Summary

U.1.1 Background

The potential impacts of climate change and hydrologic variability on the Colorado River have been subjects for discussion for many years. The continuing drought in the Colorado River Basin coupled with recent advances in scientific knowledge regarding the potential impacts of climate change has heightened this interest.

The recent drought has emphasized that the principal influence on water availability is the amount of runoff in the basin. The conventional assumption used in water resources planning is that the past record of runoff can be used to represent future conditions; that the future will look like the recent past. Reclamation, like most water management agencies, has, until recently, relied on this conventional assumption in its planning activities.

Reclamation has recognized the limitations of the conventional assumptions for some time, but the continuing drought conditions accelerated efforts in the agency to investigate alternative assumptions which may be used in its planning and operations. Furthermore, considerable evidence from paleo records concluded that the observed record of the last 100 years did not capture the full range of variability of historical streamflows in the Colorado River.

Reclamation's Lower Colorado Region initiated a multi-faceted research and development program in 2004 to enable the use of other methods for projecting possible future inflow sequences for Colorado River planning studies. The research and development effort has been designed to provide information for the near-term (e.g., some facets have already been completed), as well as the longer-term that involves collaboration with other research organizations (e.g., National Oceanic & Atmospheric Administration and United States Geological Survey). The effort is focused on two key areas:

- collaboration with other federal agencies and universities to conduct research to gain knowledge and understanding of the potential impacts of climate change and climate variability on the Colorado River, and

- improvement of Reclamation's decision support framework, including modeling and data handling capabilities, in order to utilize the new information when it becomes available.

To assist in the direction and prioritization of these efforts, particularly over the next few years, a group of experts in meteorology, climate and hydrology, referred to as the Climate Technical Work Group (Work Group), was empanelled to provide information to Reclamation about the state of knowledge regarding climate science and future climate conditions and their impact on water resources, particularly on the Colorado River Basin.

In addition, the Work Group ran parallel with and informed Reclamation's development of the final environmental impact statement (EIS) for the proposed adoption of interim operational guidelines for Lake Powell and Lake Mead on the feasibility of considering long-term projections of climatic conditions in its assessment of alternative proposed guidelines. Contributions from the Work Group as well as the research and development program were invaluable in advising the analysis and content in the final EIS to address future hydrologic variability and the potential for increased hydrologic variability due to climate change.

Reclamation convened a meeting of the Work Group on November 8, 2006. In addition to the outside expert invitees, a number of Reclamation staff and contractors also attended the meeting. The members of the Work Group and attendees at this meeting are listed in Attachment 1. The November 8 meeting provided the opportunity for a face-to-face discussion between the climate experts and Reclamation staff. Following the meeting, a smaller group of Reclamation staff, contractors and outside experts developed this report. The members of this drafting group are listed in Attachment 1. The drafting group developed an initial outline which was circulated to the entire Work Group in February 2007. Based on feedback on the outline, a draft of this report was developed and circulated to the Work Group for review in April 2007. Comments were received from the Work Group and other interested parties including climate scientists, water resource engineers, and Reclamation personnel. The Work Group revised the document and transmitted it to Reclamation in its final form in August 2007. Reclamation pre-published the final report as an appendix to the final EIS for the proposed adoption of Colorado River interim guidelines for Lower Basin shortages and coordinated operations for Lake Powell and Lake Mead in October 2007.

U.1.2 Findings

U.1.2.1 State of Climate Change Science

There is strong scientific consensus that the earth has been warming, that this warming is driven substantially by human emissions of greenhouse gases, and that warming will continue. Climate models project that temperatures will increase globally by 1 to 2ºC in the next 20-60 years. The projections are fairly consistent for the next 20 years, with a 1ºC increase, but exhibit larger uncertainty in the 40-year projections. Scientists agree on some of the important broad-scale features of the expected hydrologic changes, the most likely of which will be an increase in global average precipitation and evaporation as a direct consequence of warmer temperatures.

U.1.2.2 Potential Impacts to the Colorado River Basin

The impact of climate change on the region of the Colorado River Basin (CRB) is less certain; however, it is expected that regional temperatures will also increase. Regional precipitation response is less certain with comparable evidence suggesting wetter or drier conditions. There is some consistency to indications of a general drying for mid-latitude regions such as the CRB, but this indication must be tempered by the limited precision of existing atmospheric models in resolving the topography of the southwestern U.S.

The potential impacts of climate change on the CRB's water resources have been a subject of research for several decades. Although an aggregate message from these studies may be that a decrease in runoff can be expected, runoff response across these same studies *ranges from increase to decrease*. These studies show that system storage is very sensitive to changes in mean inflows as well as to sequences of dry and wet years.

The degree to which current methods can provide reliable information about future streamflow variability remains a question.

U.1.2.3 Options for Relating Climate Change Projections to Reservoir Operations

There are several options available for translating climate projections into operations response information. The three core steps for long term operations analysis under assumed climate change include: (i) selecting a simulated climate scenario that overlaps with observed historical conditions and extends into a future planning horizon, has been bias-corrected, and has been downscaled to a basin-relevant resolution; (ii) relating the downscaled climate conditions over the basin to natural runoff response; and (iii) relating simulated natural runoff response to water supply and operations response. After these core steps are defined, it is necessary to consider other options about how variability in water resources conditions will be addressed.

In addition to the uncertainties inherent in projections of greenhouse gas concentrations, and in simulation of future climate conditions using General Circulation Models (GCMs), there are various uncertainties associated with relating climate projections to runoff and operations. These include the assumptions on converting simulated climate time series into a meteorological input sequence for runoff analysis, assumptions on how to convert meteorological input to runoff, assumptions on how to represent system operations within the operations model under a changing climate, and assumptions on future land use and land cover.

U.1.2.4 Paleoclimatic Information

Paleoclimatic information for the Colorado River basin is extensive, with the most notable, and reliable, streamflow reconstructions being for Lees Ferry (dividing point between Upper and Lower basin). The streamflow reconstructions there go back as far as AD 762 and have been used to create hydrologic scenarios for planning studies. The main limitation in the use of paleoclimatic information is when reconstructed flow values are beyond the "predictor space" on which the model is based. These values may be less reliable than other reconstructed values. There is an emerging area of research on how paleoclimatic information can be used with climate change projections. The main idea is to combine the variability in the paleohydrologic records with the more certain future warming for assessing possible future scenarios.

U.1.2.5 Interannual and Interdecadal Variability

There is an increasing awareness that in addition to gradual changes (long-term trends) in climate conditions, there is also a large degree of interannual and interdecadal variability in climate, which may dominate the climate experienced in a basin in the short term (10-20 years in the future). The well known El Niño-Southern Oscillation (ENSO) has linkages in the Lower Basin where El Niño events bring generally wetter conditions and La Niña events bring drier conditions. A limitation on research relating interannual and interdecadal variability is the relatively short time periods available for the analysis. The use of paleoclimatic data may enhance the understanding of these multidecadal phenomena. The impacts from interannual and interdecadal climate variability on streamflow may be significant for planning studies with short planning horizons (e.g., 20 years). This could be just as important as evaluating the impacts of climate change that may not really be noticed in the basin for 20-50 years.

U.1.3 Recommendations

U.1.3.1 Planning Studies

Shorter Look-Ahead Studies: For studies and management decisions involving shorter look-ahead horizons (e.g., less than 20 years), an appropriate level of analysis might involve a qualitative discussion of climate change and interannual-to-decadal variability within the study's look-ahead horizon. If the role of shorter-term climate is critical to the study, the proposed qualitative discussion might be accompanied by a quantitative sensitivity analysis based on instrumental record and paleoclimate evidence.

Longer Look-Ahead Studies: For studies and decisions concerned with greater than 20-year look-aheads and being evaluated on the near-term, it is suggested that a quantitative sensitivity analysis be conducted on operations response to projected climate change using approaches previously mentioned in ES 2.3. By comparing system performance using projected climate change hydrology to historical hydrology, useful knowledge about system sensitivity should be ascertained.

U.1.3.2 Research and Development

Improved Availability and Temporal Resolution of Regional Climate Projection Datasets: Currently, there is limited access to bias-corrected and downscaled climate projection datasets over the Colorado River basin. An archive of bias-corrected and spatially downscaled GCM outputs should be made available to researchers and the public. In addition, as dynamically downscaled datasets become available, these datasets should be added to the archive.

Improved Ability to Model Runoff Under Climate Change: Currently there are only a few runoff models available to generate CRB natural flow given climate inputs, and Reclamation does not have easy access to these models. Reclamation needs to build internal staff expertise with available runoff model applications in the basin, and build coalitions with external groups that use such applications. Ideally, such runoff applications would also report other hydrologic processes' response to climate change (e.g., soil moisture, evapotranspiration, groundwater interactions with surface water).

Investigate Paradigm for Colorado River basin Precipitation Response: While there is an evolving paradigm for how the American Southwest and other existing dry subtropical areas of the globe should respond to climate change, it is not clear how nearby relatively wet mountainous areas such as the Rockies should respond. In addition, the ability of GCMs to simulate future precipitation conditions at this spatial scale is questionable. Reclamation should encourage and support work to improve scientific understanding of precipitation response to climate change.

Diagnose and Improve Existing Climate Models Before Adding Additional Features: Given known GCM limitations in simulating regional precipitation, climate research groups should focus a portion of their efforts on diagnosing and correcting biases in the current collection of climate models.

Investigate Changes in Modeled Climate Variability at Multiple Time Scales: It is well appreciated that the Colorado River is sensitive to changes in mean flow. However, variability as represented by drought spells, wet refill periods, and extended decadal and longer periods of above and below-average flow are also critical for determining system yield. Therefore, investigation of such variability in modeled sequences of precipitation, runoff and other climatic variables is critical.

Improve Understanding of Surface water, Groundwater and Land cover Interaction: Because rivers and groundwater are intimately connected, understanding the entire recharge process and its response to climate change is critical. Hence, research is required on groundwater recharge and movement at scales relevant to regional runoff analysis, and this in turn requires understanding the aggregate process of mountain block recharge and the role of riparian and root zone vegetation. The latter leads to additional research questions on how basin land cover and natural evapotranspirative demand will respond to global climate change.

Improve Prediction of Interdecadal Oscillations: The predictability of interdecadal climate oscillation phases and their associated hydrologic impacts on the Colorado River basin are not well understood. Shorter-term planning may be more influenced by these oscillations than by projected changes in climate means. Reclamation should actively support, either materially or otherwise, efforts in the science and applications community to advance knowledge in this area.

Investigate use of Paleo Record to Inform Modeled Streamflow Variability: Reclamation has funded some research on how to use information from the paleoclimate record in modeling studies. While the past will not repeat, the paleo record contains a wealth of information on natural variability that should not be ignored. For example, there may be valuable ways of combining paleo data with modeled and or historical data to modify the variability in these sequences in useful ways.

Interact with Federal Climate Change Science Program and Other Climate Change Research Initiatives: Although Reclamation can pursue and fund some of the Research and Development work described above, many of these problems will require the assistance of the larger scientific and engineering community. The Department of the Interior is one of thirteen agency members of the approximately $2 billion per year federal Climate Change Science Program, the umbrella under which all federal climate change activity is pursued. In order to raise the profile of these issues and obtain resources to help solve them, Reclamation should engage the CCSP. In addition, Reclamation should collaborate with NOAA, the National Center for Atmospheric Research, and the University research community.

U.2 Introduction

U.2.1 Process and Context

As part of its responsibility to manage water resources within the Colorado River basin, The U.S. Department of Interior, Bureau of Reclamation (Reclamation) is continuously evaluating the effect of operating procedures and policies in the basin. The primary effects of changing operating rules are changes in reservoir releases, river flows, reservoir contents, water quality and water deliveries to end users. These primary effects influence economic, social and environmental conditions. Reclamation makes its evaluation of the primary effects of operating policies with modeling studies that simulate the effect of operating rules on system conditions and water availability. Additional models are used to estimate secondary effects.

Conventional water resources planning has been based on two assumptions:

- The observed history of hydrology for a particular system adequately captures the past mean and variability of water supply for that system
- The past mean and variability of water supply is representative of future conditions.

Reclamation has recognized the weakness of the conventional assumptions for some time, but the acute drought conditions that began in 2002 accelerated efforts in the agency to investigate alternative assumptions on which planning and operations could be based. By 2004, the problem with the conventional assumptions had been clearly demonstrated when the reservoirs on the Colorado River reached states that could not have been simulated by conventional approaches in 2002.

The recent drought also brought attention to the need to develop operating rules to allocate the water of the lower Colorado River in times of shortage. Reclamation, the Basin States and the Secretary of the Interior realized that it was necessary to adopt specific operational guidelines to address the operation of Lake Powell and Lake Mead during drought. Accordingly, the Secretary of the Department of the Interior acting through the Bureau of Reclamation, Upper and Lower Colorado Regions (hereinafter, Reclamation), proposed adoption of specific Colorado River Lower Basin (Lower Basin) interim shortage guidelines and coordinated reservoir management strategies to address operations of Lake Powell and Lake Mead, particularly under drought and low reservoir conditions. The guidelines would change the way the reservoir system on the river is operated and define circumstances where deliveries to certain water users would be curtailed. Such operational changes may affect reservoir storage levels and releases at Lake Powell and Lake Mead, which in turn may subsequently affect river flows, available water supplies, and other resources.

The Secretary has designated Reclamation as the lead federal agency for the development and implementation of the proposed interim guidelines, and for the purpose of compliance with the National Environmental Policy Act of 1969 (NEPA). Reclamation and five cooperating federal agencies have prepared a Draft EIS (Draft Environmental Impact Statement, Colorado River Interim Guidelines for Lower Basin Shortages and Coordinated

Operations for Lake Powell and Lake Mead, U.S. Department of the Interior, Bureau of Reclamation, Upper and Lower Colorado Regions; Reclamation 2007) to provide an opportunity to develop the information needed to analyze and consider trade-offs inherent in the proposed action.

Five alternatives have been considered and analyzed in the Draft EIS. The potential hydrologic effects of the alternatives were evaluated through the use of water resources modeling studies. The water resources modeling served as the basis for other analyses of the potential effects of the alternatives on other environmental resources. In addition to making these analyses, Reclamation conducted sensitivity analyses using alternative assumptions regarding the hydrology of the Colorado River basin. Three alternative hydrologic scenarios were used in these sensitivity analyses, two based on reconstructions of pre-historic flows (paleohydrology) and one based on synthesizing new scenarios based on the statistics of the observed record (stochastic hydrology).

Reclamation recognized that the three sensitivity analyses did not directly respond to growing concerns that global climate is changing and with that change would come corresponding changes in the hydrology of the Colorado River basin. Impacts arising from the proposed actions are sensitive to the magnitude and timing of the natural streamflows in the Colorado River, which in turn would be influenced by any changes in climatic conditions.

Reclamation wished to evaluate the potential impact of climate change on water availability and environmental conditions in the Colorado Rive basin, but recognized that there is considerable scientific uncertainty about the precise nature of climate change and its effects in the basin. Reclamation also did not know what tools might be available to evaluate the impact of climate change. The Lower Colorado River Region of Reclamation decided to empanel a group of experts in meteorology, climate and hydrology, referred to as the Climate Technical Work Group (Work Group), to consult with the agency and assist it in addressing these questions. The Upper Colorado River Region and the Technical Services Center of Reclamation also participated in the Work Group process.

Reclamation asked the Climate Technical Work Group to provide information to Reclamation about the state of knowledge regarding climate science and future climate conditions and their impact on water resources. In addition, information regarding the feasibility of considering long-term projections of climatic conditions in its assessment of alternative proposed guidelines and strategies were considered.

U.2.2 Description of Document

This document summarizes the state of climate science and how future climate conditions may impact the water resources of the Colorado River basin. Section W.2.0 describes the Climate Technical Work Group, the charges provided to the Work Group, and the process used in preparing the final report. Section W.3.0 provides background information on how climate assumptions are currently represented in long-term planning. Section W.4.0 summarizes the state of science on observed and projected climate conditions. Section W.5.0 summarizes the various studies that have evaluated the potential impacts of climate change on the water resources of the Colorado River basin. Section W.6.0 describes methods that may be used for relating climate information to long-term water resources planning. Section

W.7.0 summarizes available paleoclimatic information, some of which might serve as proxy information for future climate possibilities. Section W.8.0 summarizes the state of science on shorter- to longer-term climate oscillations and variability that also impact water resources. Lastly, Section W.9.0 provides a summary of key themes from each section, identifies critical issues that warrant further investigation, and offers recommendations for how climate change and variability information could be further incorporated into Lower Colorado (LC) Reclamation's longer term planning efforts.

U.3 Climate Technical Work Group

U.3.1 Formation and Charge

Beginning in September, 2006, Reclamation identified potential members of the Climate Technical Work Group and began extending invitations for participation in the Work Group process to those candidates. Twelve climate scientists and hydrologists were invited to participate on the Work Group. These invitees are listed in Attachment 1.

Reclamation asked the Work Group to provide information in the following areas:

- ♦ The state of knowledge that exists regarding long-term projections of climatic conditions, including the state of knowledge regarding climatic processes, and the state of knowledge regarding numerical simulation of long-term future conditions (Section W.4.0).
- ♦ What methods would be appropriate, timely and cost-effective to quantify future conditions, including quantifying the uncertainty arising from the state of knowledge of climate processes and numerical representations of climate processes?(Sections W.4.0 and W.5.0)
- ♦ The extent to which existing reconstructions of paleo streamflows could be used, alone or in conjunction with long-term climate projections, in the evaluation of alternative guidelines and strategies. (Section W.7.0)

U.3.2 Process

Reclamation convened a meeting of the Work Group on November 8, 2006. In addition to the outside expert invitees, a number of Reclamation staff and contractors also attended the meeting. The attendees at this meeting are listed in Attachment 1.

The November 8 meeting provided the opportunity for a face-to-face discussion between the climate experts and Reclamation staff. It was conducted informally, with considerable give and take. The meeting began with a presentation by Reclamation staff about the purpose of the Work Group and its charge. Reclamation suggested that a report from the Work Group would be a useful work product. Reclamation provided a comprehensive orientation to the Colorado River basin, including the hydrology of the basin, the Law of the River, water use in the basin, the water resources facilities in the basin, and operations. Discussions regarding operations addressed the recent drought and the current process of developing shortage guidelines. Subsequent discussions focused on the science of climate change and the likely impacts of climate change on the hydrology of the Colorado River basin. Considerable attention was given to the uncertainties inherent in projections of temperature and precipitation in the Basin.

Following the meeting, Reclamation convened a group of Reclamation staff, contractors and outside experts to develop an initial draft of a report from the Work Group. The members of this drafting group are listed in Attachment 1. The drafting group initially developed a suggested outline for this report, which was circulated to the entire Work Group in February 2007. The drafting group subsequently prepared a draft of this report, which was circulated to the Work Group in April 2007 for review. Comments were received from the Work Group and other interested parties including climate scientists, water resource engineers, and Reclamation personnel. A revised version of the document was finalized in August 2007.

U.4 Recent Treatment of Hydrology and Climate by LC Reclamation in Long-Term Planning Analyses

U.4.1 Recent LC Reclamation Requirements

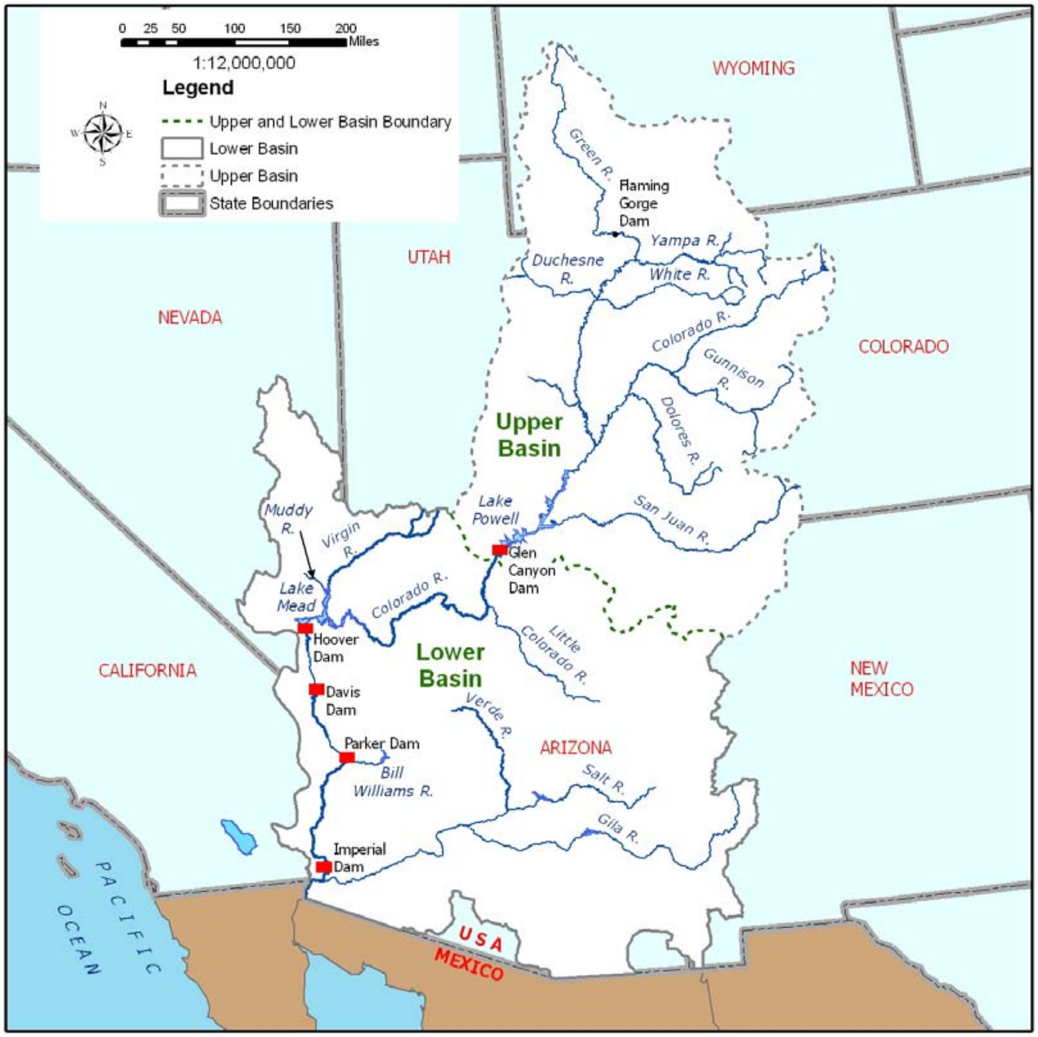
The Colorado River basin is located in the southwestern United States, as shown on Figure U-1, and occupies an area of approximately 250,000 square miles. The Colorado River is approximately 1,400 miles in length and originates along the Continental Divide in Rocky Mountain National Park in Colorado. The basin has been divided into Upper Basin and the Lower Basin, as shown in Figure U-1. Reclamation is the agency that has been designated to act on the Secretary’s behalf with respect to the operation of Glen Canyon Dam and Hoover Dam. More information about the Colorado River and its water resources can be found in Section 1.7 of the Draft EIS (Reclamation, 2007).

As part of its responsibility to manage water resources within the Colorado River basin, Reclamation is continuously evaluating the effect of operating procedures and policies in the basin. The primary effects of changing operating rules are changes in reservoir releases, river flows, reservoir contents and water deliveries to end users. These primary effects influence economic, social and environmental conditions. Reclamation makes its evaluation of the primary effects of operating policies using a water resources system model of the Colorado River that simulates the effect of operating rules on system conditions and water availability. Additional models are used to estimate secondary effects.

U.4.2 Colorado River Simulation System (CRSS)

Future Colorado River system conditions are simulated using the Colorado River Simulation System (CRSS). CRSS is a simulation model consisting of a database and a modeling code. The database describes the physical configuration of the natural and man-made features of the Colorado River system, the operating rules for the man-made features, the natural gains and losses of water that enter and leave the system, and the water used by or requested for use for human activities. The modeling code simulates the physical processes and institutional drivers that determine the system conditions, according to the data contained in the database. The model is run to determine system conditions for a given scenario, as described by the input data. For some resource analyses, results from CRSS are used as input to additional modeling studies that are required to characterize impacts to other resources.

Figure U-1
The Colorado River basin



CRSS simulates 12 reservoirs, 115 water delivery points and 29 inflow points. It simulates water entering the system, storage in system reservoirs, releases from storage, river flows, natural and man-caused losses of water, and the water demands of and deliveries to water users in the basin states and Mexico. The input data for the model include monthly natural inflows, various physical process parameters (such as the evaporation rates for each reservoir), initial reservoir conditions, and the diversion and depletion schedules for entities in the basin states and Mexico. The operating rules are also input for each scenario analyzed. CRSS is fully described in Appendix A of the Draft EIS (Reclamation, 2007).

The principal independent input to the model are data representing the patterns of inflows at the 29 inflow points. These inflows define the water inventory that will be managed in the system for beneficial use and environmental protection. Other inputs, such as water demands and operating rules, are controlled principally by human decisions. Despite differences between operating rules among scenarios, the future conditions of the Colorado River system (especially water levels at Lake Mead and Lake Powell) are most sensitive to future inflows.

U.4.3 Climate-related CRSS Inputs

The hydrology of a watershed is driven by its climate. Liquid water is introduced to a watershed by precipitation of water vapor from the atmosphere and is continuously removed from the watershed in the form of water vapor through the processes of evaporation and evapotranspiration. These processes are said to “deplete” the available water in a watershed. Any remaining liquid water may leave the watershed as stream or groundwater discharge. Some water will be stored temporarily in a watershed as groundwater, as ice or snow, or in man-made impoundments. Evapotranspiration, as used here, is the sum of evaporation of water from soil and transpiration of water from plants as they grow. Natural landscapes and agriculture deplete water through evapotranspiration. Water is evaporated from the surface of natural and man-made water bodies and through the operation of industrial processes. Depletion of available water supplies is the unavoidable cost of putting water to uses that benefit human beings.

As climate changes so will the hydrology of a watershed. Changes in precipitation, radiation and temperature will affect the water balance in a watershed and hence will affect the net runoff leaving that watershed. Changes in precipitation change the water supply input to a watershed. At regional scales, the dominant effect on the rate of evaporation is the availability of radiant energy at the evaporating surface. Air temperature is often used as a surrogate for energy input, and also influences convective heat transport. Changes in radiation and temperature will change the magnitude and pattern of evaporative water losses that deplete outflows from a watershed. In snowmelt-driven basins, changes in radiation and temperature will affect the fraction of precipitation that falls as snow and the rate and timing of snowmelt and will thereby change the pattern of outflows. Changes in radiation, temperature and precipitation will also change the magnitude and patterns of some human water uses. The effect of climate on streamflow is discussed in more detail in Section W.5.0.

Like any other watershed, the hydrology and water resources of the Colorado River basin are driven by climate and therefore are sensitive to climate change. Inputs to CRSS reflect past climate, including past climate variability, but do not reflect projected changes in climate. The input variables for CRSS that are sensitive to climate conditions are inflows and losses, water use by humans, and reservoir evaporation. These are described in the following paragraphs.

U.4.3.1 Inflows

CRSS represents the natural gains and losses to the river system at 29 “inflow points” throughout the basin. Fourteen of these inflows are “rim inflows”, which represent physical flow in a river reach at the outermost perimeter of the watershed. The remaining fifteen inflow points are incremental gains and losses, which represent the amount of water that is introduced to or removed from a particular river reach by “natural” processes. Incremental gains and losses include inflows from smaller tributaries and depletions along the reach. All inflows are expressed as monthly volumes.

These values represent "natural flows" that in turn represent the conditions that would have existed if all man-caused water uses and operational effects (e.g. reservoir storage and release) had not occurred. The natural flows include the effect of natural processes including depletions arising from evapotranspiration and the effect of storage and recharge to and from groundwater.

U.4.3.2 Water Use

Water use can be categorized as natural or social. Natural water use includes, for example, depletion of river flows by riparian vegetation or upland vegetation in a watershed. Social water use includes the demands of agriculture, industry and municipalities. CRSS incorporates natural water uses into the natural flow values representing rim inflows and incremental gains and losses. Social water uses, are driven by management choices and are represented explicitly in the model as variables.

Changes in climate will affect natural water use, but the response of water use to climate change is complex and varies on different time scales. The immediate response to changes in radiation and temperature is change in depletions arising from evaporation and evapotranspiration. Changes in precipitation will not affect depletions directly, but rather change the water supply. The longer term impacts of changes in radiation and temperature, and in the depth and intensity of precipitation will be changes in vegetation and even soil structure, subsequently affecting natural gains or losses in the watershed and riparian systems.

Changes in radiation, temperature and precipitation will change the patterns of diversion and depletion of water applied to social uses. This is primarily driven by changes in the intensity of evapotranspiration from agriculture and outdoor domestic use, but is also influenced by changes in the growing season brought on by changes in temperature. Of indoor domestic and industrial uses, depletions from uses such as cooling and reservoir storage (in the form of evaporation from the reservoir surface) are likely to be affected by changing climate. Because changes in climate will change the pattern of diversion (required to satisfy the irrigation requirements of crops or landscaping plants), the pattern and volume of direct flow diversions, releases from reservoirs and return flows will also change. These responses are driven by economic and institutional factors and are difficult to predict.

The impact of these effects on water use in the Upper Basin will be changes in the pattern and annual volume of inflows to Lake Powell. Section W.5.0 discusses some of the assessments that have been made about the effects of climate change on streamflows in the Colorado River basin. However, quantifying the changes in inflows to Lake Powell is complicated by the economic and institutional responses to the changes in water supply and irrigation requirements.

Because deliveries to Lower Basin water uses are defined by institutional constraints (e.g. contracts and decrees), changes in water use in much of the Lower Basin will not directly change the total amount of water released from system reservoirs. Changes in the seasonal pattern of water deliveries in the Lower Basin could change the timing of operational trigger events in Lake Mead and thus induce subtle but long-lasting effects in upstream reservoir operations. Changes in water use along the Lower Basin tributaries to the Colorado River below Lake Mead will have a more substantial effect on system operation, since changes in the amount and timing of return flows from these uses will change the amount and timing of releases from Lake Mead that are required to meet the water delivery requirements to Mexico.

U.4.3.3 Reservoir Evaporation

CRSS represents the net evaporation (evaporation adjusted for precipitation falling directly on the reservoir) from the water surface of reservoirs. Thus, changes in precipitation, radiation or temperature will affect the net evaporation simulated by CRSS.

U.4.4 Recent LC Reclamation Hydrologic Scenarios

Reclamation has used four different approaches to represent streamflow hydrology in modeling studies of the Colorado River system. These four approaches are summarized below. More detail on each approach can be found in Appendix N of the Draft EIS (Reclamation, 2007).

U.4.4.1 Direct Natural Flow Record (DNF)

Reclamation has developed a database of historical natural flows, gains and losses at the 29 inflow points required by CRSS. This database covers a period from October 1905 through December 2004 (water year 1906 through water year 2004). Analyses using this database are run on a calendar year basis and cover the period January, 1906 through December, 2004.

Reclamation has recognized that due to the natural variability of streamflows, the exact pattern of flows captured in the historical natural flow dataset is unique and will not occur again. In an effort to incorporate variability in system conditions that would reflect the natural variability of streamflow, Reclamation adopted a block bootstrap approach for resampling the historical record, known as the Indexed Sequential Method (ISM) (Reclamation, 1985; Ouarda et. al., 1997). ISM cycles through each year in the natural flow record and extracts a sequence of flows beginning at that year and extending through the desired scenario length. If a flow sequence overlaps the end of the natural flow data set (calendar year 2004) the method wraps around to the start of the natural flow record (calendar year 1906) and continues the sequence from that point. Because there are 99 years in the natural flow record the ISM method can create 99 distinct flow sequences. The ISM method applied to the 1906 to 2004 natural flow record is referred to as the Direct Natural Flow Record (DNF) approach.

The strengths of this method are that it is easy to implement, it is understandable, and it has been widely accepted by stakeholders on the Colorado River. However, each DNF scenario consists only of annual and monthly flow magnitudes and sequences that have occurred in the observed record, with the exception of new sequences being generated as a result of the wrap.

Reclamation has relied for some time on the DNF approach for planning in the Colorado River basin. Because it recognized the limitations in the DNF approach, Reclamation has for several years been conducting or sponsoring research aimed at developing methods that do not suffer from the same limitations as the DNF approach. In evaluating alternative shortage policies Reclamation has conducted sensitivity analyses using three alternative hydrologic scenarios, which are described briefly in the following paragraphs.

U.4.4.2 Non-Parametric Paleo Conditioned (NPC)

This technique also applies a bootstrap re-sampling to the historical natural flow record, but in this case the re-sampling is done on a year-by-year basis and the selection is conditioned on hydrologic state sequences (i.e., wet or dry) that are modeled based on a paleo reconstruction of streamflows at Lees Ferry. In the NPC method the magnitudes of individual flows are taken from the historical natural flow record, but the sequences of flows reflect sequence properties characteristic of the paleo reconstruction. The result is that wet and dry spells represented by the NPC method are different than those represented by the DNF or the direct paleo (DP) (described below) method. In particular, the NPC method will represent longer dry spells than are present in the historical natural flow record because longer dry spells are present in paleo reconstructions of streamflow in the Colorado River basin. Because the magnitudes of individual flows are taken from the historical natural flow record, the NPC method will not generate flow magnitudes beyond those in the observed record. The NPC method was used to generate 125 traces, each of 53 years in length.

This method is described in detail in Appendix N of the Draft EIS (Reclamation, 2007) and in Prairie (2006).

U.4.4.3 Parametric Stochastic Natural Flow Record (PS)

This technique uses parametric stochastic methods to fit the observed natural flows (1906-2003) to an appropriate set of stochastic models for streamflow generation and disaggregation. A parameter fitting procedure is applied to fit the observed natural flow to a contemporaneous autoregressive order 1 (CAR(1)) model. The PS method was used to generate 100 traces, each of 53 years in length. The PS method can generate both flow magnitudes and sequences not seen in the observed record, though the generated scenarios will be statistically similar to the observed record. The PS method can generate flow magnitudes much larger or much smaller than those in the observed record, which may be difficult to justify on a physical basis.

This method is described in more detail in Appendix N of the Draft EIS (Reclamation, 2007) and in Salas (1985) and Lee et al. (2006).

U.4.4.4 Direct Paleo (DP)

This technique uses a reconstruction of streamflow at Lees Ferry by Woodhouse, et al. (2006) which has been disaggregated to the 29 inflow points using a nonparametric disaggregation method (Prairie et al., 2006). The reconstructed trace used in this method is the same trace used in the NPC method, but in the DP approach both the magnitudes and sequences of flows are taken directly from the paleo reconstruction, whereas in the NPC method only the characteristics of the state sequence are taken from the paleo reconstruction, and the values result from resampling the observed streamflow conditioned on the previous resampled streamflow and the current and previous sequence properties. The DP approach will represent the longer droughts indicated by paleo reconstructions, but will also represent individual annual flow magnitudes that are not present in the historical natural flow record. Unlike the other methods, the long-term mean flow produced by the DP method will be different (in this case lower) than that seen in the observed record.

This method is described in more detail in Appendix N of the Draft EIS (Reclamation, 2007).

U.4.5 Climate Assumptions Implied by Hydrologic Scenarios

As noted earlier, the conventional water resources planning has been based on two assumptions: that the observed history of hydrology for a particular river system adequately captures the past mean and variability of water supply for that system, and that the observed history is representative of future conditions. Implicit in these conventional assumptions is the premise that climate, which drives hydrology, is static. Only in recent years have a significant fraction of water resources managers begun to depart from this premise and find ways of incorporating information about the potential hydrologic impacts of climate change in water resources planning.

All four hydrologic scenarios currently in use by Reclamation are based on the implicit assumption that the future mean and variability of streamflow can be adequately characterized by the statistics of past observations. The DNF and PS approaches assume that the last roughly 100 years characterize future conditions while the NPC and DP approaches extend that period to approximately 500 years. These scenarios do not reflect any probability that the future mean and variability of streamflows will differ from past values due to changes in future climate conditions. However, as discussed in Section W.7, the paleohydrology reflected in the NPC and DP approaches could be adapted to reflect alternative assumptions regarding future climate that are consistent with the findings of recent climate research and modeling.

U.5 State of Science: Historic and Future Climate

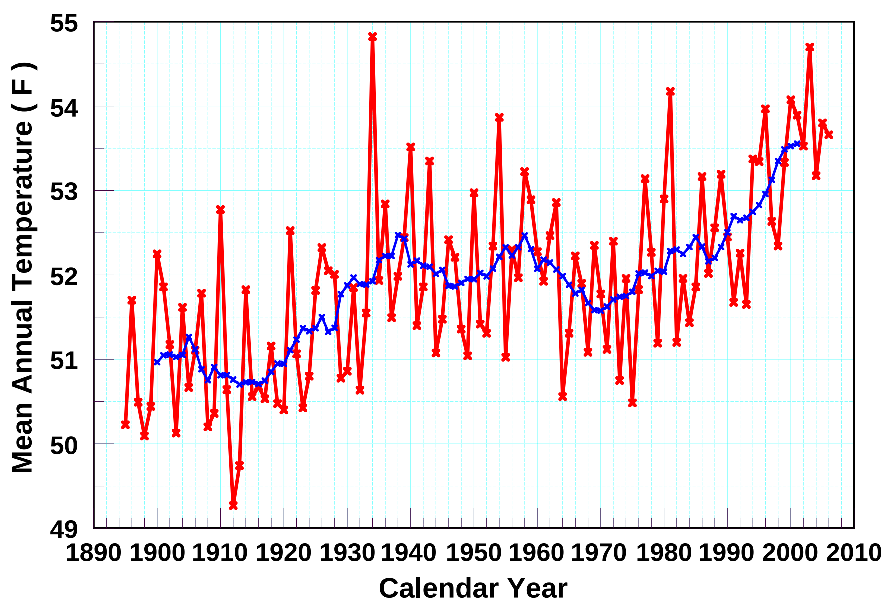
U.5.1 Historical Climate of the Colorado River Basin

One of the motivations for considering climate change implications for Colorado River basin water management is that changes in hydroclimatological conditions have already been expressed in the historical records. Through a variety of statistical methods, modeling efforts, and analytical processes, researchers have begun to identify and quantify trends within environmental time series and, in some cases, begun to forecast future climate trends. Recent climate trend research has focused on time series of streamflow, temperature, precipitation, and snow water equivalent (SWE) time series.

U.5.1.1 Temperature Trends

Trends in temperature for the Colorado River basin were summarized in the recent National Research Council (NRC, 2007) study. Figure U-2 displays the annual average air temperature for the entire Colorado River basin from 1895-2006. Overall there has been an approximately 1.6OC increase in the 11-year running mean. The increases primarily occurred during the periods 1920 to 1940 and 1970 to the present. These trends are also consistent with those seen in regional and global temperature records. However, the trends in the Colorado River basin are the largest in the continental U.S. when expressed as standard deviations. The significance of increase temperatures on the regions snowpack and streamflow are discussed in following sections.

Figure U-2
Annual and 11-year Running Average Temperature for the Colorado River Basin

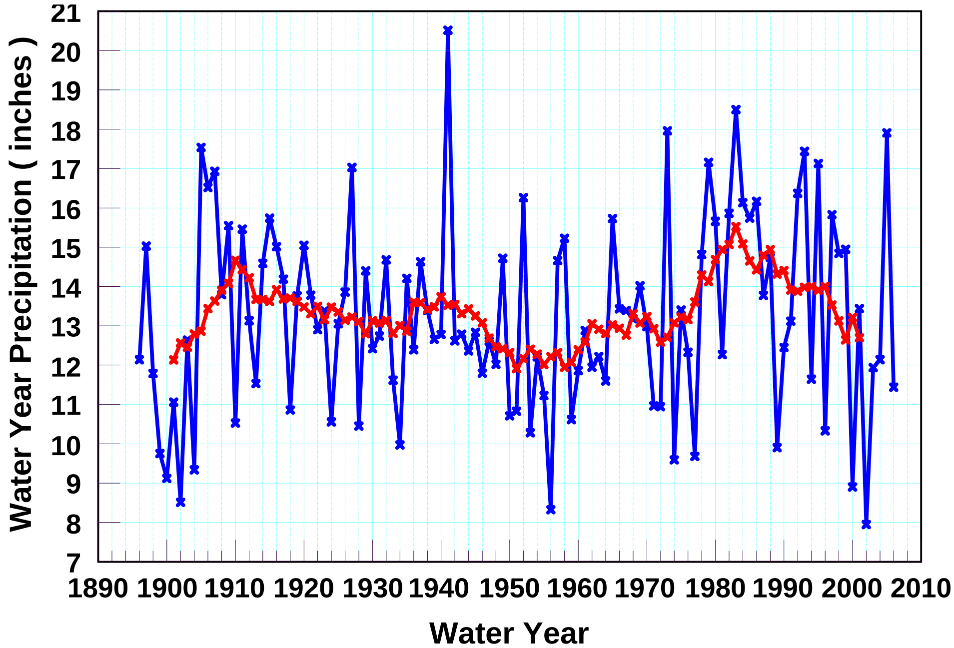


(Source: Western Regional Climate Center and NRC, 2007)

U.5.1.2 Precipitation (Rainfall and Snow) Trends

Trends in precipitation for the Colorado River basin were also summarized in the recent NRC (2007) study. Figure U-3 displays the annual precipitation for the Upper Colorado River basin from water years 1896 to 2006. There is a high degree of variability over the entire record. However, the past 30 years of record seem to have different variability as compared to the early part of the record. For instance, the lowest and highest annual precipitation amounts occurred in the past 30 years. In addition, there is evidence of more regimes of wet and dry episodes, lasting 4-6 years, since the middle 1970's compared with the previous 30-40 years. Even though there is more variability in the recent record, there does not appear to be an overall trend in the annual precipitation over the entire record.

Figure U-3
Annual and 11-year Running Average Precipitation for the Upper Colorado River Basin from Water Year 1896 to 2006



(Source: Western Regional Climate Center and NRC, 2007)

It is also important to evaluate the form of precipitation (i.e., rain or snow). In the mountainous western U.S., approximately 50 – 70% of precipitation is observed as snow (e.g. Clark et. al. 2001). As a result, melting snowpack is an important and significant source of water for much of the west, particularly in the Upper and Lower Colorado River basins (e.g., Hamlet et al., 2005). Recent published research has studied the climate trend of snow data through the investigation of April 1st snow water equivalent (SWE) values, as April 1st is in many locations an accurate estimate of the peak of spring snowpack and total runoff (e.g., McCabe and Dettinger, 2002). Most studies in this review used observed National Resource Conservation Service (NRCS) SNOwpack TELemetry (SNOTEL) or snowcourse data. Table U-1 summarizes the time periods and parameters used in studies focused on snow and streamflow for the western United States.

Table U-1
Summary of Studies Evaluating Trends in Snow and Streamflow for the Colorado River Basin

Study Name	Time Period	Snow	Streamflow
Groisman et. al., 2001	1939-1999		
Hamlet et. al., 2005	1916-2003	Decreasing	earlier peaks
Kalra, et. al., 2007	1941-2004	Decreasing	
Lins and Slack, 1999	1944-1993		
Mote et. al., 2005	1950-1997	Decreasing	
Pagano and Garen, 2005	1901-2002		
Regonda et al., 2005	1950-1999	Decreasing	earlier peaks
Stewart et al., 2005	1948-2002	Decreasing	earlier peaks
Knowles et al., 2006	1949-2004	Decreasing	

Arrows indicate either increasing or decreasing trend. Blank cells indicate that there was no trend or the authors did not investigate that parameter.

All the studies (Mote, 2003; Hamlet et al., 2005; Regonda et al., 2005; Knowles et al., 2006; Mote, 2006; Kalra, 2007) noted a decline in April 1 SWE with a particular emphasis on high elevation stations. Mote (2003) attributes the decline in SWE observations in the Pacific Northwest and western U.S. (including the Colorado River basin) to increased temperature and a greater portion of precipitation falling as rainfall, particularly at elevations below 1800 meters. Mote et al., (2005) expanded upon the study presented in Mote, (2003) by using the Variable Infiltration Capacity (VIC) Model. In the Lower Colorado River basin, the VIC Model showed an increasing trend in SWE, sometimes in excess of 30% from 1950 to 1997. The Upper Colorado River had primarily a decreasing trend.

Regonda et. al. (2005) collected data from snowcourse sites over the period 1950 to 1999 in an attempt to quantify the timing of snowmelt with trends in hydroclimatic variables. April 1 SWE values from snowcourse sites spanning the western U.S. were correlated with streamflow stations in the Western United States. Regonda et. al., (2005) found decreases in SWE correlated to increases in temperature and precipitation. This suggests that the temperature changes (negative) are having a more pronounced change on SWE than increases in precipitation. The decreases in SWE were found to be most pronounced within low elevation basins. As a result of warming trends and lower volumes of snow pack, peak runoff rates from snowmelt have begun to trend earlier in the year.

Knowles et al., (2006) closely evaluated the trend toward earlier runoff by comparing the SWE to winter-total precipitation for the western United States. They found that there is a trend toward smaller SWE compared to winter-total precipitation. This means more precipitation is occurring in the form of rain instead of snow.

Kalra et. al., (2007) evaluated April 1 SWE data from 121 SNOTEL stations from 1941 to 2004 in the western United States. After stations exhibiting significant autocorrelation were excluded, SWE observations at the remaining SNOTEL sites showed decreases from 1941 to 2004.

U.5.1.3 Streamflow Trends

Streamflow patterns in the western U.S. are significantly affected by snowmelt conditions, motivating interest in comparing streamflow and SWE trends. Streamflow is of primary concern in water management, as reduced streamflow can negatively impact reservoir operations. Decreasing streamflow can have an adverse effect on hydroelectric power generation, irrigation demands, recreational activities, and the environment (e.g., Regonda et. al., 2005). The timing of peak streamflow is also of concern, as changes to the timing of peak streamflow may affect flood control, impact the environment, and impose hardship on those dependent on the timing of flow due to seasonal snowmelt, such as farmers. Investigation of streamflow records typically uses observations from the United States Geological Survey (USGS), specifically from gages within the Hydro-Climatic Data Network (HCDN), which are USGS streamgages minimally affected by anthropogenic regulation and with a sufficient period of record.

Kalra et al., (2007) examined long-term trends and abrupt step changes within the USGS HCDN data over various basins and time scales (i.e., water year, seasonal, and decadal). No significant trends in streamflow volumes were found for the Colorado River basin over the entire length of record. These results are also confirmed from prior studies (e.g., Lins and Slack, 1999; Groisman et al., 2001; McCabe and Wolock, 2002; Pagano and Garen, 2005; Stewart et al., 2005). The tendency for no trend in total annual streamflow is reasonable considering that there is no trend in total annual precipitation. However, the tendencies in changes in seasonal streamflow volumes may be more apparent due to the expected changes in temperature (warmer) and the form of precipitation in warmer future climate scenarios.

U.5.2 Future Climate

The future water supply for the Colorado River basin will depend on many climatic factors. Climate change may alter the quantity and timing of local and regional precipitation. Higher temperatures would mean more precipitation falling as rain than snow, reducing snowpack water storage, likely greater evaporative losses, and shift in the timing of runoff to be earlier in the season. While it is difficult to make certain predictions of changes in the overall quantity of precipitation for the region, scientific theory suggests that higher carbon dioxide (CO_2) concentrations warm the lower atmosphere, raising its water holding capacity, which, among other things, intensifies the global hydrological cycle (Meehl, et al. 2005; Trenberth et al. 2003). In some regions, this could lead to more intense but possibly less frequent periods of precipitation. In other words, we may see longer periods of drought, alternating with spells of heavy snowfall and rainfall events, and subsequent changes in the timing and magnitude of runoff. Such changes could create a number of difficulties for water managers throughout the Colorado River basin. For example, greater runoff variability could make it more difficult to maintain optimal reservoir levels, which could reduce the reliability of water storage, although this is less a problem in the Lower Colorado than elsewhere due to the size of overyear storage.

U.5.2.1 Global Climate Change

The scientific evidence for human-caused global climate change has become quite compelling in recent years. The Intergovernmental Panel on Climatic Change (IPCC) recently released the first of four parts of its Fourth Assessment Report (AR4 IPCC 2007), describing the science and physical evidence surrounding climate change. This also includes the anticipated changes in water resources summarized by the Working Group II in "The Summary for Policymakers." The consensus among involved scientists and policy makers is that "… global atmospheric concentrations of carbon dioxide, methane and nitrous oxide have increased markedly as a result of human activities since 1750… and the understanding of anthropogenic warming and cooling influences on climate leads to *very high confidence* that the globally averaged net effect of human activities since 1750 has been one of warming.. ." Certainly, other forcings act on the climate system beyond human influences, most notably solar, volcanic, oceanic, and cryogenic (ice) forcings, but when these processes are included alongside human forcing, an anthropogenic "fingerprint" emerges.

CO_2 is a major green house gas, contributing somewhere between 10 and 25 percent of the natural warming effect, second only to water vapor. As the earth emits long wave radiation toward space, atmospheric constituents like water vapor, CO_2, ozone, and methane absorb this energy flow and radiate energy back to earth. Climate models suggest that without these greenhouse gases the average earth temperature would be about 19ºC cooler, and in the absence of other changes and feedbacks in the climate system, a doubling of CO_2 would warm the lower atmosphere by about 1.2ºC (Kiehl and Trenberth 1997).

Figure U-4 is a plot of annual mean departures from the 1961-90 average for global temperatures (with a mean of 14.0°C) and carbon dioxide concentrations from ice cores and Mauna Loa (1958 on), with a mean of 333.7 ppmv (updated from Karl and Trenberth 2003). The plots show that the rise in CO_2 coincides with a rise in global average surface temperatures.

Increasing CO_2 is not the only human activity affecting our climate system and in fact, CO_2 is only responsible for about two-thirds of the greenhouse effect, the rest being attributable to methane, nitrous oxide, chlorofluorocarbons, and ozone. Changes in land use, aerosol emissions from fossil fuel burning, the storage and use of water for agriculture, etc. are all environmental changes that affect climate (Pielke et al., 2007). Climatologists have tried to quantify the relative role of various human factors on the climate system in terms of each component's "radiative forcing", which are summarized in Figure U-5 and taken from the AR4. Most notably, the radiative forcing of CO_2 is the largest single component, with natural solar irradiance (solar variability) substantially smaller. Also, there are human activities that counteract the positive forcing of CO_2. For examples, aerosols from the burning of fossil fuels tend to reflect heat back into space, reducing the net heat at the surface. When all the components are considered, there is a net positive radiative forcing on the order of 1.5 watts per square meter (W/m^2).

Figure U-4
Global average temperature and CO_2 trends (Karl and Trenberth 2003)

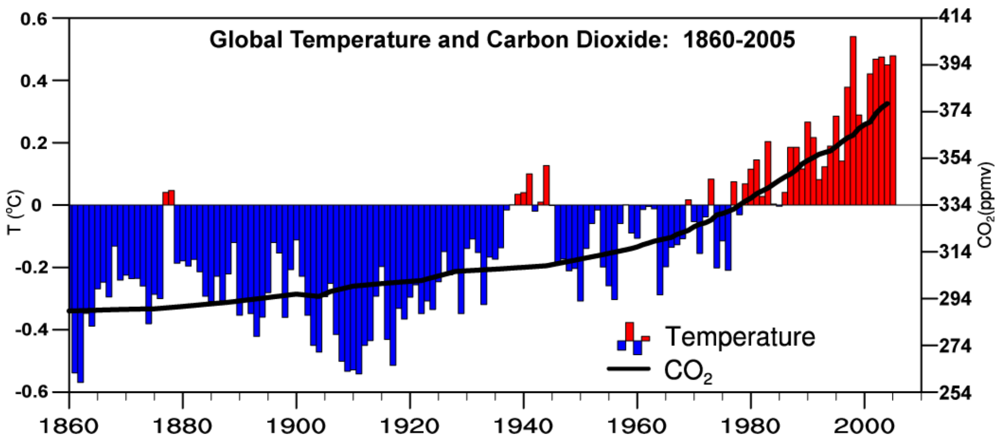


Figure U-5
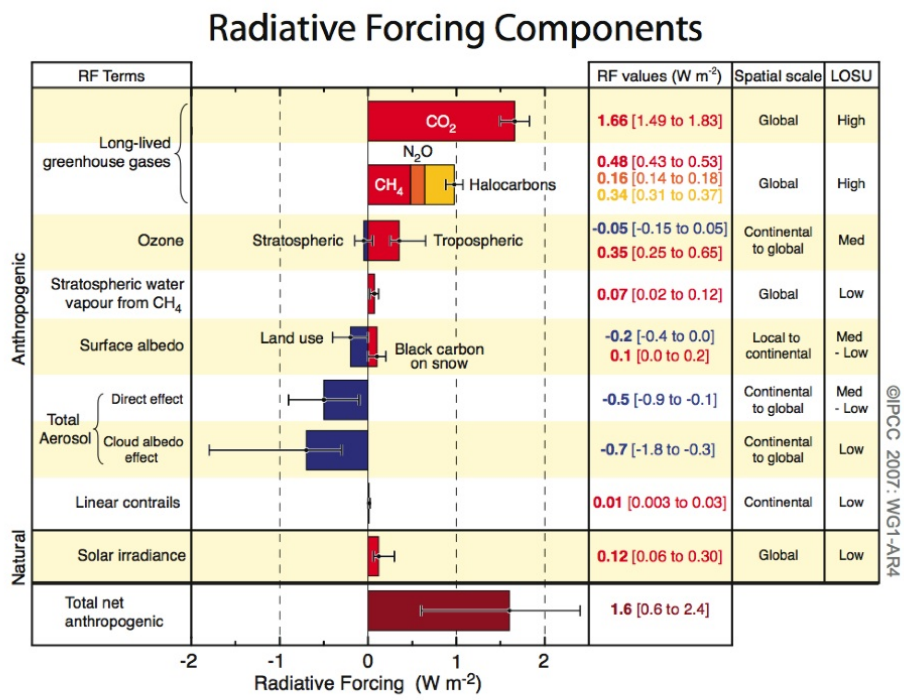
Relative Radiative Forcing Attributable to Human Activities,
Where "Positive" Means that the Earth is Gaining Energy Faster Than It is Losing It
(RF-Radiative Forcing; LOSU- Level of Scientific Understanding)

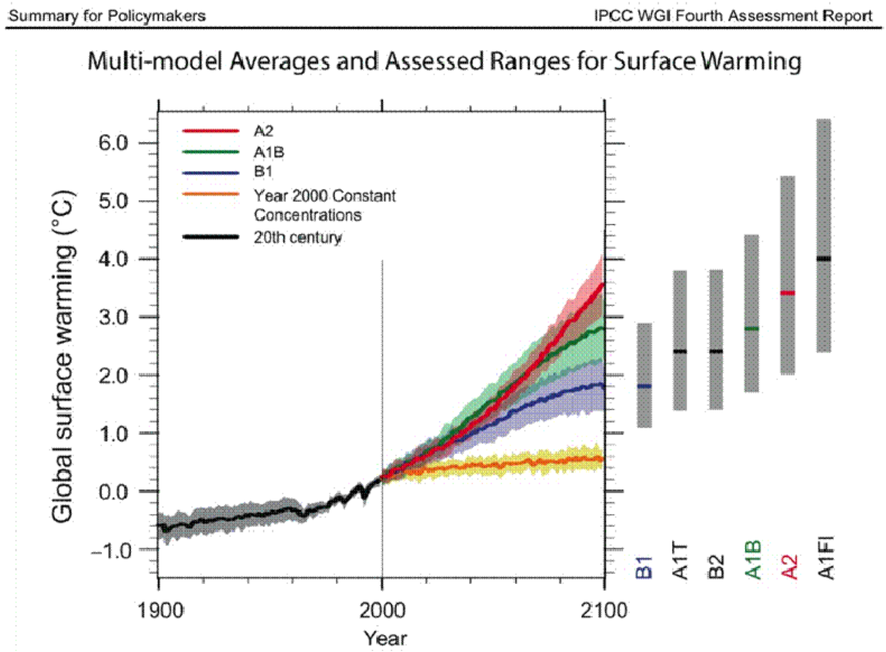


Problematically, CO_2 has a relatively long residence time in the atmosphere and while its sources are local, it is generally globally distributed. Recognizing that it is a strong forcing component, the IPCC has convened panels of experts that have developed “storylines of the future”, which are used to project concentrations of greenhouse gases. These transient concentrations are then used in Generalized Circulation Models (GCMs) to project the relative contribution of CO_2 (and other factors) to future warming. Most GCMs consist of an atmospheric module that is coupled to the other key components of the climate system, including representation of oceans, sea ice, and the land surface. The major GCMs include tens of vertical layers in the atmosphere and the oceans, dynamic sea-ice sub-models and effects of changes in vegetation and other land surface characteristics (Washington, 1996; Gates et al., 1999). The atmospheric part of a climate model is a mathematical representation of the behavior of the atmosphere based upon the fundamental, non-linear equations of classical physics. A three-dimensional horizontal and vertical grid structure is used to track the movement of air parcels and the exchange of energy and moisture between parcels.

The CO_2 storylines include both “green” centered trajectories that moderate fossil fuel use and fossil fuel intensive trajectories, leading to either low or high green house gas concentrations, respectively. These different emission pathways then imply different mean global and regional climate warming rates. The details of these scenarios are beyond the scope of this report, but Figure U-6 summarizes the projected global average surface warming based on a consensus derived from several GCMs across a range of future projections (e.g. referred to ‘A2’, ‘A1B’, and ‘B1’ scenarios; for details about the different scenarios, see http://www.ipcc.ch/pub/sres-e.pdf). Note this figure includes a projected global average temperature if we were to keep CO_2 at 2000 concentration levels, suggesting that we are already *committed* to further warming beyond anything that has taken place already.

The consequences of the projected future warming are likely to be changes in atmospheric and oceanic circulation, and in the hydrologic cycle, leading to altered patterns of precipitation and runoff. Scientists agree on some of the important broad-scale features of the expected hydrologic changes, the most likely of which will be an increase in global average precipitation and evaporation as a direct consequence of warmer temperatures. That, however, does not mean that there will be more precipitation everywhere or that runoff and recharge would increase in proportion to precipitation.

Figure U-6
From the IPCC Working Group I, Fourth Assessment Report, Summary for Policy Makers (IPCC 2007)

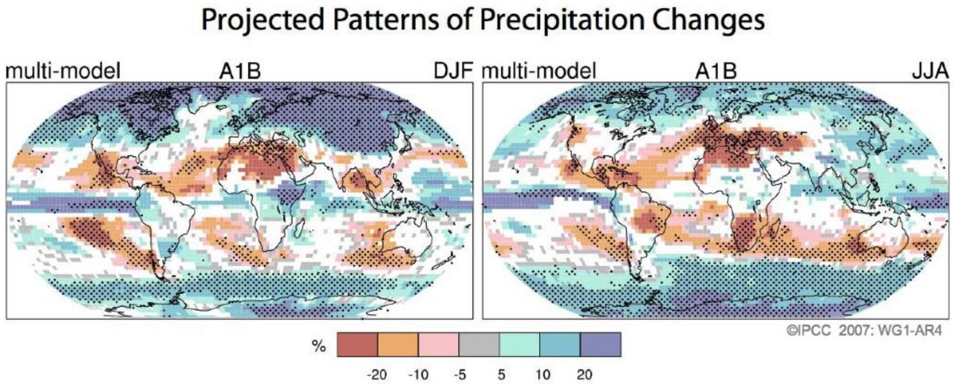


Historic observed global average temperatures, and projected global average temperatures based on various projections of global CO_2 concentrations.

U.5.2.2 Regional Climate Change

At the regional scale, such as the Colorado River basin, there is high confidence in projections of future temperature change, with less confidence in projections of future precipitation change (Dai, 2006). Changes in circulation patterns will be critically important in determining changes in precipitation and water availability, and climate models can provide only a crude picture of how those patterns may change. The currently available evidence suggests that arctic and equatorial regions may become wetter, and that subtropical regions may experience drying. Projections of precipitation changes for mid-latitude regions such as the Colorado River basin are less consistent, but generally indicate a drier climate (e.g., Milly et al., 2005; Seager, 2007). Seager (2007) argues for an imminent transition to a drier climate in southwestern North America. He points out the consistency of climate models in producing a human-induced aridification caused by large scale changes in the atmospheric branch of the hydrological cycle, stating that "the subtropics are already dry because the mean flow of the atmosphere moves moisture out of these regions whereas the deep tropics and the higher latitudes are wet because the atmosphere converges moisture into those regions. As air warms it can hold more moisture and this existing pattern of the divergence and convergence of water vapor by the atmospheric flow intensifies. This makes dry areas drier and wet areas wetter." Figure U-7 shows projected patterns of precipitation change. Note the general pattern of drier conditions in the mid-latitudes and desert regions, and wetting in the tropics and high latitudes (IPCC 2007).

Figure U-7
Statistical Summary of Projected Patterns of Precipitation Change from Multiple
General Circulation Models for December, January and February (left) and June, July, and August (right)



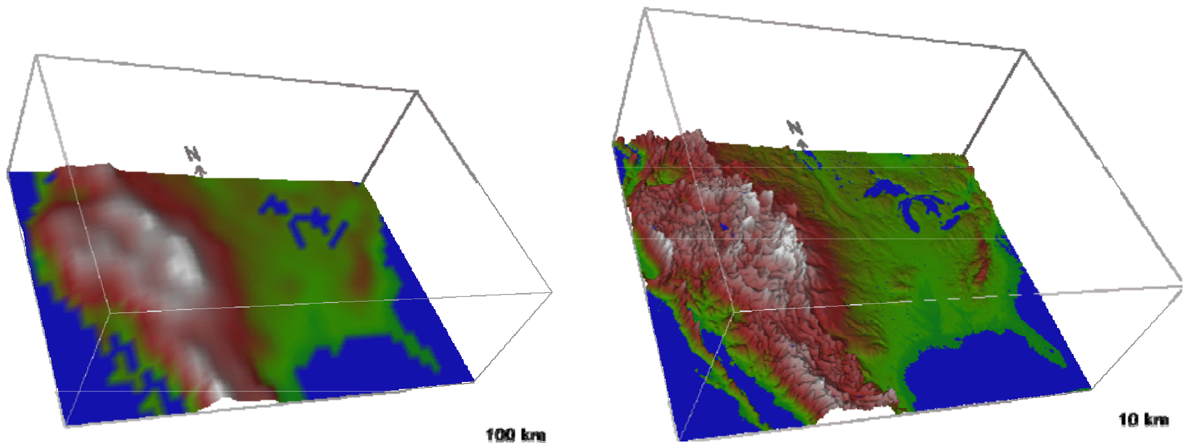
The stippled areas show region where there is greater agreement among models.

However, climate simulations of southwestern North America are problematic because the region is both downstream from the Pacific and also in an area where topography can make a difference, issues that are not well captured in the bulk of GCMs (if correct in any at all). The climate of the Southwestern US depends greatly on the dynamics in the tropical and extra-tropical Pacific Ocean circulations that are not accurately simulated in current GCMs. The subtle dynamics of the jet stream and storm tracks particularly in the winter and the influence of the North American Monsoon in the summer are also important and not well represented. Despite tremendous technological advances in computing capability, it is still very time consuming and costly to use these models to simulate future climates. One of the most important compromises for achieving model results in a reasonable amount of time is to decrease the model's horizontal resolution. This limitation means that it is prohibitively costly to run a GCM at a spatial resolution that would accurately depict the effects of mountains and other complex surface features on regional climates.

The problem with such a coarse horizontal resolution is that important processes occurring at finer scales are not well resolved (Figure U-8). Topography, for example, is very important in determining the location of precipitation. As moist air rises over mountains or hills, the moisture condenses, producing clouds and, if conditions are right, precipitation. Although there has been marked improvement over the last three decades in the simulation of precipitation, it is still not well represented in GCMs, especially in areas of complex topographies, since the coarse horizontal resolution **o**f GCMs tends to smooth out important landscape features that affect atmospheric processes. At the resolution of most GCMs the models represent the mountains of the western United States as a set of gentle ridges and do not resolve finer scale features that influence regional climate. Clearly, that level of spatial resolution is too coarse to reproduce the effects of topography on the region's precipitation and runoff patterns (Grotch and MacCracken, 1991; Giorgi and Mearns, 1991; Pan et al. 2004).

Figure U-8
Horizontal Spatial Resolution Depicted by Typical
Global Climate Models, and Where We Hope to Be in the Next 5 to 10 Years

GCMs in 2006 **GCMs in 5 to 10 years**



The current inadequacies of GCMs and the recognition that each has its own strengths and weaknesses has led researchers to conclude that no single model can be considered ‘best’ and it is important to utilize results from a range of coupled models for regional impact and adaptation studies (Allen et al., 2000). Tebaldi et al., (2006) presented a probabilistic approach that combines the regional output of 21 unique GCMs to produce probabilistic projections of regional, future climate change. Their statistical model combines information from each GCM, including each model’s ability to re-create the regional climate over the period 1960 through 1990 (a measure of a model’s bias), and the agreement among models in future projections. Models that diverge greatly from other models are given less weight in deriving the final statistical distributions of change. Figures U-9 a and b show probabilistic projections of future seasonal temperature and precipitation change in the Upper Colorado River basin for the 2000-2020 and 2040-2060 period for the low CO_2 emission, B1 scenario; the “middle-of-the-road” A1B emissions scenarios; and the high A1 emissions scenario for the Upper Colorado River basin.

Not surprising, the projection differences among the three scenarios from 2000 to 2020 are not substantial since the CO_2 trajectories are very similar in the early period, with regional mean warming just below 1ºC. It isn’t until later in the 21st century, that the projections diverge under the various CO_2 scenarios. The Tebaldi et al., (2006) results suggest a GCM model consensus of temperature increases a bit below 1ºC over the next 20 years, with some seasonal variation. Interestingly, the results show moderate increases in winter precipitation across all scenarios, with little or no change in spring and fall precipitation and slight decreases in summer precipitation, with some scenario dependency (bottom, Figure U-9 b). By the 2040 to 2060 period, the mean regional warming projections exceed 1ºC and the magnitude of the regional temperature increases are much more tied to the specific projection scenario. Remarkably, the temperature projections for the moderate (A1B) and higher emissions scenario (A2) are quite similar, while the precipitation projections show slightly wetter winters under the moderate B1 scenarios and slight *drying* over these decades for the higher A1B and A2 higher CO_2 projection scenarios. All three scenarios show summer drying and little or no change in the spring and fall "shoulder" seasons.

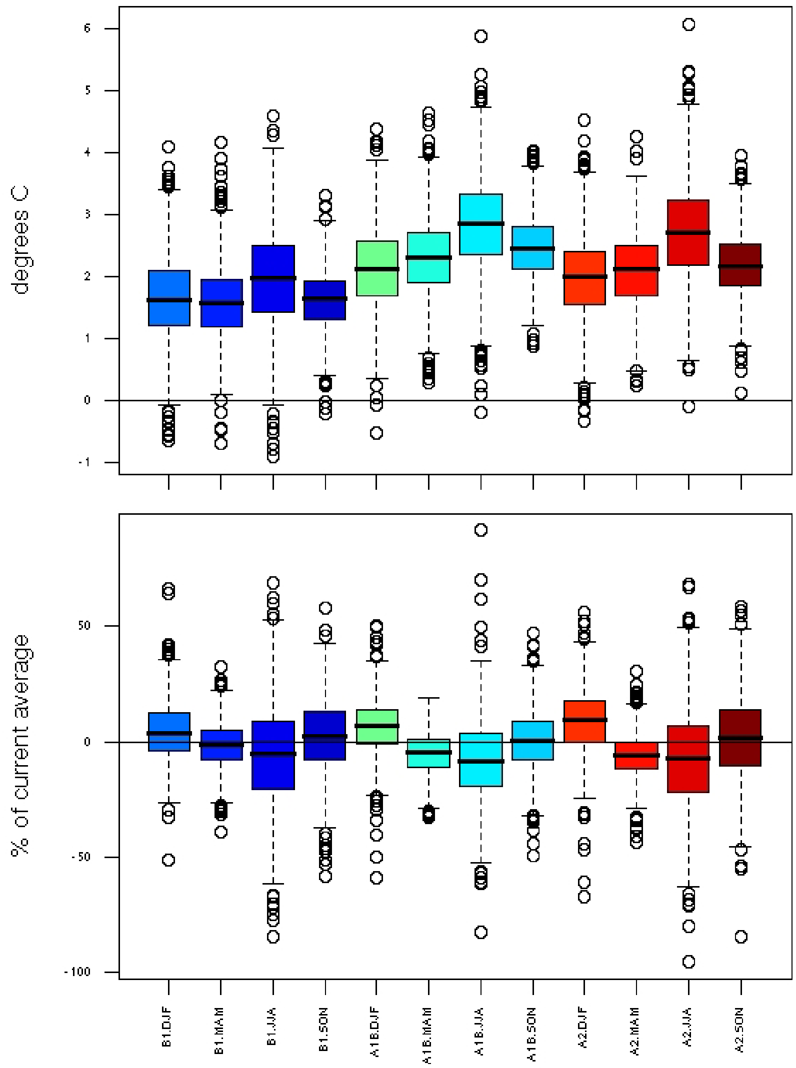
Figure U-9(b)
Scenario-specific Absolute Change in Temperature (top) and
Percent Change in Precipitation (bottom) in the Upper Colorado for the Period 2040-2060
DJF, MAM, JJA, SON for the B1, A1B and A2 Scenarios



GCMs also produce runoff estimates that can be useful in identifying whether regions are going to have more or less water resources. Milly et al., (2005) evaluated the global patterns of water availability under climate change scenarios. Depending on the region of the globe, annual runoff could increase or decrease. The relative changes for the southwest U.S. were decreases in annual runoff. These estimates are for large areas and downscaling is necessary to identify regional impacts. This is discussed further in Section U.4.2.3.

U.5.2.3 Regionalizing Future Climate Projections (Downscaling)

As was summarized in previous sections, GCMs are able to simulate large-scale climate features realistically, but exhibit biases at a regional scale. The regional biases are problematic for analysis of climate implications for hydrology and water resources (Maurer, 2007). Recognizing the regional limitations of GCMs has led to the application of “downscaling” as a means of trying to understand how local scale processes, of greater interest to water resource planners, might respond to larger-scale weather and climate changes (Wilby et al., 2004). Regardless of the technical approach, the primary goal is to process the raw GCM output so that it reflects the large-scale features and temporal trends from the GCM simulation, but also the historical patterns of climate variables at the regional and local scale (Wood et al., 2004).

Downscaling techniques generally fall into classes involving either simulated (dynamical), statistical, or bias-correction/disaggregation methods. Downscaling can produce more sub-regional detail and eliminate system biases between observed local climate and climate generated by GCMs. Downscaling does not necessarily provide more reliable information or increase our confidence in a particular GCM scenario for climate change. Several downscaling approaches are summarized:

Dynamic Methods. This class involves the use of regional climate models run at a relatively high resolution over a limited area with boundary conditions (and sometimes interior domain information as well) prescribed from the lower resolution GCM. This is often referred to as “dynamical” downscaling since the regional climate model explicitly accounts for the dynamic aspects of the climate system that operate on finer spatial scales than the GCM can represent. It is possible for these “nested models” to resolve some limitations of general circulation models for a specific region. They are still limited in their capabilities to give reliable projections for future precipitation change. The intensive computational demands of dynamical models severely limit their usefulness for producing long-range climate change scenarios. Proponents argue, however, that mesoscale models uniquely represent important feedback mechanisms (such as the effects of land surface albedo on boundary layer climate dynamics) that may moderate or enhance climate change.

Statistical and Bias Correction Methods. This class of downscaling methods involves deriving statistical relationships between observed small-scale (often station level) variables and larger (GCM) scale variables, using analogue methods (circulation typing), regression analysis, or neural network methods (Mearns, 1999; Yates et al., 2003, Clark and Hay, 2004). Future values of the large scale variables obtained from GCM projections of future climate are then used to drive the statistical relationships and estimate the smaller-scale details of future climate.

Stochastic weather generators have been used to develop climate datasets for impact analysis. These can address some of the issues just raised with their ability to simulate plausible climate scenarios, and have themselves been used as downscaling techniques in global change studies (Wilks, 1992). Typically, a stochastic weather generator is developed based on the historically observed data at a location, and can then be used to simulate climate scenarios consistent with the global change scenarios. However, Katz

(1996) points out that modifying the parameters of a stochastic model can lead to unanticipated effects. For example, modifying the probability of daily precipitation occurrence using a stochastic weather generator (Richardson 1981) also changes the mean and standard deviation of the daily temperature as well.

The statistical downscaling approach of Maurer (2007) and Wood et al., (2002; 2004) is relevant because it was used in recent studies of the Colorado River basin (Christensen and Lettenmaier, 2006); Christensen et al., 2004). The method involves two steps: (a) identifying and accounting for bias between GCM-simulated climate variables and corresponding observations during a "common historical overlap period", and (b) disaggregating the bias-corrected GCM output to region and local scales so that the information is more spatially consistent with the basin and local scales considered in impacts analyses. The procedure improves upon an earlier downscaling techniques (called the "perturbation" method) that involved identifying and applying adjustment factors based only on climatological monthly mean differences in observed precipitation (P) and temperature (T) and between GCM output and observations (e.g., Lettenmaier et al., 1999; Miller et al., 2003). The limitations of such an approach are that it doesn't consider GCM interannual variability, does not address the GCM's potential bias in temporal variability, and can result in implausible precipitation sequences after rescaling. Recently, techniques address these limitations through the use of distribution-mapping between GCM gridded output and historical gridded observations (Maurer, 2007; Wood et al., 2002).

Implementation of the latter bias-correction technique requires definition of "observed historical" using a reference gridded climate dataset (e.g., usage of National Climate Data Center Cooperative Observer Data aggregated to 2° latitude-longitude spatial resolution). The "common historical overlap period" is then defined, where both "observed historical" data and GCM historical simulation data are considered. Within this historical period, month-specific cumulative distribution functions (CDFs) are calculated, describing the range and distribution of P and T conditions at each grid point in the region of consideration. (Note: GCM historical simulation data may have to be interpolated and mapped to grid point locations consistent with the observed dataset's grid or vice versa) Bias-correction within the "common historical overlap period" then ensues: on a grid-point by grid-point basis, the quantiles for GCM-simulated P and T CDFs are then mapped to the same quantiles for the observationally based CDF at a grid-point by grid-point basis. For example, suppose the 70th percentile GCM P value for December is adjusted to equal the 70th percentile observed P value for December. This basis for adjusting GCM output is then carried forward beyond the "common historical overlap period" to adjust GCM-projected conditions. For example, let's say a projected December P value happens to equal the median unadjusted GCM-historical December P value. Just as the GCM-historical median value was adjusted to equal the observed median value, the projected value would be adjusted in the same fashion. For GCM T values, the full-period linear trend in the simulation is removed prior to bias-correction, and then replaced afterwards (Wood et al. 2004; Maurer 2007).

Following bias-correction, the GCM gridded dataset is spatially disaggregated, or "downscaled", to a finer resolution. While other dynamical or statistical methods could be used at this stage, a relatively simpler interpolation technique has been used in recent applications (Wood et al., 2002; Wood et al., 2004; Maurer et al., 2007; Christensen and Lettenmaier, 2006).

Relative Limitations Among Method. Each technique has strengths and weaknesses. For example, simulated downscaling would seem to offer the best capability in preserving physical relations between local- and larger-scale climate features, even under a changing climate. That said, the simulation approach is computationally intensive and constrains consideration of multiple climate change scenarios and future periods to be considerably less than what might be considered using statistical or bias-correction/disaggregation methods. Likewise, the latter two methods are computationally efficient, but relatively more limited in how they approximate the relation between local- and larger-scale climate features. Statistical methods assume a stationary relationship that may not hold under a changing climate. Disaggregation rests on the assumption that the variance of conditions simulated in a GCM should be constrained by the variance of observed climate conditions, even though such an assumption might not hold true as climate changes.

Substituting Sensitivity Analysis for Downscaling-Analog Methods. Conducting downscaled analyses based on the projections from multiple climate models can be a very laborious and time-consuming task. The daunting prospect of developing detailed climate data sets for impact analysis has led to simpler "scenario" approaches in contrast to the "projection" based approach which rely on GCM results and the downscaling steps just described.

The scenario approach includes simple "back-of-the-envelope" methods that can explore the possible implications of climate change for water resources. Since it is unlikely that we will be able to "predict" the climate of the future, we can be informed by the climate of the past and at least be guided or bound by the projected future changes. For example, what are the consequences throughout the basin of a reoccurring 1930's 'dust-bowl' era drought, with current population and water use, and what if a 1ºC warming were superimposed on top of these conditions? This approach introduces a "worst case" climate scenarios on a regional or local scale based on historical events, such as a region's most severe drought in the past century or climate traces developed from tree ring studies. This approach has the advantage of realism, because events that occurred in the past could occur again. A drawback of this approach is that the hypothetical scenarios may not be internally consistent and it is difficult to estimate their likelihood. Despite those drawbacks, systematic analysis of such scenarios can be useful for delineating the relative importance of changes in temperature and precipitation and can provide an inexpensive way to explore vulnerabilities of water supply systems, water quality, and in-stream resources.

Several analyses have used hypothetical changes in temperature and precipitation amounts by simply scaling a historic record by some predefined amount, essentially amounting to a sensitivity analysis to a climate perturbation. Such a climate scenario would simply take historical climate sequences and add an absolute temperature change and/or a percent change in precipitation to this historical record, with the magnitudes of changes bounded by the regional changes suggested by GCMs. If climate models suggest a 1ºC warming over the next 30 years, then a 30 year, 1ºC trend can simply be added to the historic temperature data. This kind of sensitivity analysis is useful for understanding the response of the hydrologic system to a warmer climate.

U.6 A Review of Assessments of Climate Change Impacts in the Colorado River Basin

Section W.5.1 in this chapter provides an overview of the six major studies since 1979 on how climate change might affect the runoff of the Colorado River. Section W.5.2 discusses more general recent studies on potential hydrological changes in the American Southwest under a warmer climate including the new IPCC regional findings. The final section summarizes and discusses all of the studies including limitations and the range of future projections.

U.6.1 Literature Review of Colorado River Climate Change Studies

Since 1979 there have been six major studies on how climate change might affect runoff in the Colorado River (See Table U-2). These studies approach the problem using two, or in some cases three steps. The first step is to obtain future temperature and precipitation by using either arbitrary scenarios or GCM outputs. Early studies used the former approach while more recent studies have used the latter technique. The second step is to use the temperature and precipitation and possibly other climatic variables in either statistical/empirical relationships or hydrology models to generate streamflow. Finally, some of the studies use an ‘operational’ model to convert projected streamflows into reservoir levels, compact deliveries, energy production, and other information. These steps are depicted in Figure U-14 for one of the studies. In addition to the major studies on the basin, there have been several other smaller studies and these are discussed at the end of this section.

U.6.1.1 Geohydrological Implications of Climate Change on Water Resource Development (Stockton and Boggess, 1979)

Charles Stockton[1], of the University of Arizona Laboratory of Tree-Ring Research, and William Boggess wrote a report prepared for the U.S. Army Corps of Engineers Engineering Research Center in 1979. The authors investigated how four different climate change scenarios would impact the water supplies of the United States.

[1] Stockton was also coauthor of the 1976 Stockton and Jacoby Colorado River tree-ring reconstruction discussed in 7.1

Table U-2
Summary of Model Results for Colorado River Basin

Study	Flow Generation Technique	Selected Results on Typical Changes in Flow (doesn't reflect range of change across studied scenarios)	Notes
Stockton and Boggess, 1979	Langbein's 1949 US Historical Runoff-Temperature-Precipitation Relationships	+2C and -10% Precip = ~ -33% reduction in Lees Ferry Flow	Results are similar for the warmer/drier and warmer/wetter scenarios. Cooler and wetter and cooler and drier are very likely not applicable.
Revelle and Waggoner, 1983	Regression of runoff on Upper Basin Historical Temperature and Precipitation	+2C and -10% Precip= -40% reduction in Lee Ferry Flow	+2C only = -29% runoff, -10% Precip only = -11% runoff. Regression can be used to calculate a variety of projections.
Nash and Gleick, 1991 and 1993	NWSRFS Hydrology model runoff derived from 5 temperature & precipitation Scenarios and 3 GCMs using doubled CO_2 equilibrium runs.	+2C and -10% Precip = ~ -20% reduction in Lee Ferry Flow	Many runoff results from different scenarios and sub-basins ranging from decreases of 33% to increases of 19%. Used USBR CRSS Model for operations impacts
Christensen et al., 2004	UW VIC Hydrology model runoff derived from temperature & precipitation from NCAR GCM using Business as Usual Emissions.	+2C and -3% Precip at 2100 = -17% reduction in total basin runoff by 2100	Used single GCM with low temperature sensitivity to CO_2 increases. Created and used operations model, CRRM.
Hoerling and Eischeid, 2006	Regression of runoff on PDSI developed from 18 AR4 GCMs and 42 runs using Business as Usual Emissions.	+2.8C and ~0% Precip = -45% reduction in Lee Ferry Flow by 2035-2060	Range of results is considerable. Reduction in runoff seen even when using 20th century historical wet period with 21st century projected temperatures.
Christensen and Lettenmaier, 2006	UW VIC Hydrology Model runoff using temperature & precipitation from 11 AR4 GCMs with 2 Emissions scenarios.	+4.4C and -2% Precip at 2070-2099 = -11% reduction in total basin runoff by 2070-2099	Range of results is considerable including some with increased runoff, especially in earlier 21st century periods. Increased winter precipitation apparently buffers reduction in runoff. Also used CRRM operations model.

The scenarios were the four combinations of +/- 2ºC along with +/- 10% change in precipitation, and were generically called *warmer and drier, cooler and wetter, cooler and drier, and warmer and wetter*. At the time of this report there was some discussion about the possibility of a new ice age, (global temperature records indicated a cooling from 1940 to 1970) yet the National Academy of Sciences issued a prescient report about the potential for global warming, Carbon Dioxide and Climate: A Scientific Assessment, (Charney, 1979) that same year. Hence, the study considered all possible future climates.

In all parts of the country except the Upper Colorado basin, they determined that scenarios 1, (*warmer and drier*), and scenario 2 (*cooler and wetter*) set the lower and upper bounds on runoff changes since changes in temperature and precipitation in the *cooler and drier* and *warmer and wetter* scenarios usually offset each other. In the Upper Colorado River the warmer and wetter scenario also showed substantial decreased runoff.

Stockton and Boggess utilized relationships developed by Walter Langbein (Langbein, 1949) of the USGS in the 1940s showing how precipitation and temperature jointly affect runoff across the United States. Langbein's nomograph (Figure U-10) shows that for the *same precipitation* runoff decreases as temperature increases, and for the *same temperature* runoff increases as precipitation increases, with runoff increasing faster when precipitation is high.

For the Upper Colorado River, Stockton and Boggess calculated that runoff would decrease by about one-third to approximately 10 maf under the *warmer and drier*, and, surprisingly, under the *warmer and wetter* scenarios. Under *cooler and wetter*, annual flow doubled to 30 maf, while under the *cooler and drier* scenario runoff was effectively unchanged.

Nomograph of Relationship Between Mean Annual Precipitation (inches), Mean Annual Temperature (ºF) and Mean Annual Runoff (inches) in the United States (from Langbein, 1949)

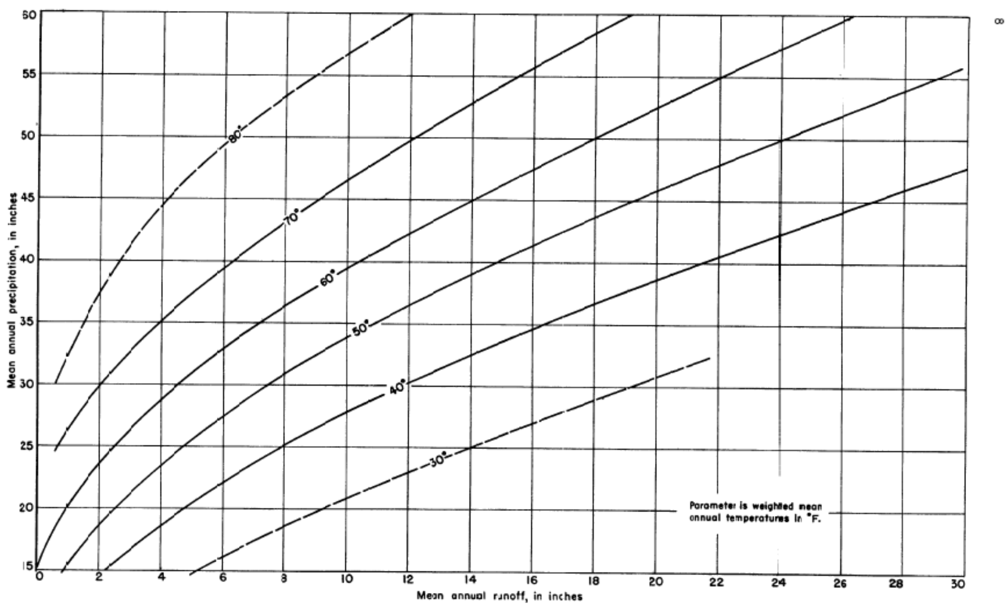

Figure 2.--Relationship of annual runoff to precipitation and temperature.

Data appropriate to Colorado River is in lower left-hand corner.

U.6.1.2 Effects of a Carbon Dioxide-induced Climatic Change on Water Supplies in the Western United States (Revelle and Waggoner, 1983)

In 1983 Roger Revelle, of the Scripps Institution of Oceanography, and Paul Waggoner, of the Connecticut Agricultural Experiment Station, wrote a chapter in *Changing Climate, Report of the Carbon Dioxide Assessment Committee*, published by the National Academy of Sciences. The authors investigated how future warming and drying in the Colorado River might affect runoff. The first part of the article restated in tabular format the empirical relationships established by Langbein in 1949 (Table U-3) among temperature, precipitation and runoff for arid areas.

Table U-3
Revelle and Waggoner's Restatement of Langbein's Relationship
Between Temperature, Precipitation and Runoff

Precip in inches (") →									
Temp (ºC)	Temp (ºF)	8"	%P as runoff	12"	%P as runoff	16"	%P as runoff	20"	%P as runoff
-2	28.4.	2.1	27%	3.6	31%	6.1	39%	9.1	46%
0	32	1.3	20%	2.9	25%	4.9	31%	7.5	38%
2	35.6	1.1	14%	2.2	19%	3.7	24%	6.1	31%
4	39.2	0.7	8%	1.6	13%	3.1	20%	4.9	25%
6	42.8	0.4	4%	1.0	8%	2.4	15%	3.9	20%
8	46.4	0.0	0%	0.7	6%	1.7	11%	3.2	16%
10	50			0.3	3%	1.1	7%	2.5	13%
12	53.6			0.0	0%	0.7	5%	1.9	9%
14	57.2					0.4	3%	1.3	6%
16	60.8					0.0	0%	0.8	4%

Shaded area represents the runoff portion roughly applicable to the Upper Colorado River Basin – Revelle and Wagonner's 1931-1976 data indicated the Upper Basin average temperature was 40F/4C with about 330mm/12" of precipitation.

The second part reviewed the 1979 findings of Stockton and Boggess, discussed above. The third and most frequently cited part of the article generated a multiple linear regression between Upper Basin temperature and precipitation, and unimpaired flow at Lee Ferry. Using the period 1931 to 1976 they established the following relationship:

Lee Ferry Annual Flows (in maf) = 42.1 + 1.07*(Annual Precipitation in inches)
-1.08*(Annual Average Temperature in Fahrenheit)[2]

The equation explains 73% of the variance in flows (r2=.73) and shows that a 2ºC/3.6ºF increase (1931-1976 Upper basin average was 4.18ºC/7.5ºF) would lead to a decline in runoff of by 4800 mcm (3.9 maf) or 29% and a 10% decrease in precipitation (1931-1976 basin average was 333 mm/13.1") would reduce flow by 1730 mcm (1.4 maf) or 11%. With both a 2ºC increase and 10% precipitation decrease, flow would decline by 40%. They note that the regression shows that a 28% increase in precipitation is necessary to balance a 2ºC increase.

[2] The original version was in metric units: Lee Ferry Annual Flows (in cubic meters) = 9274 + 52(Annual Precipitation in mm) -2400(Annual Average Temp in Celsius)

Figure U-11
Scatterplot Showing the 1931-1976 Precipitation and Flow Data
Used by Revelle and Waggoner (1983)

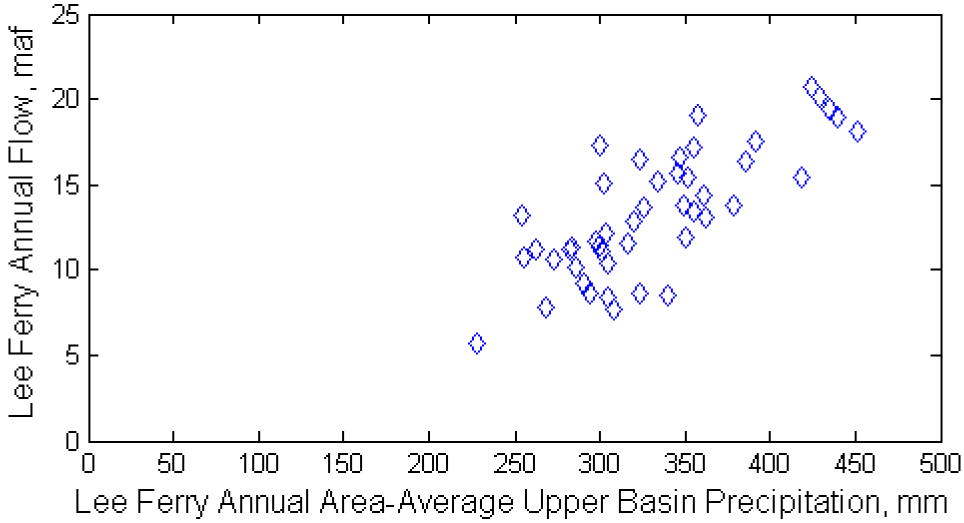

Figure U-12
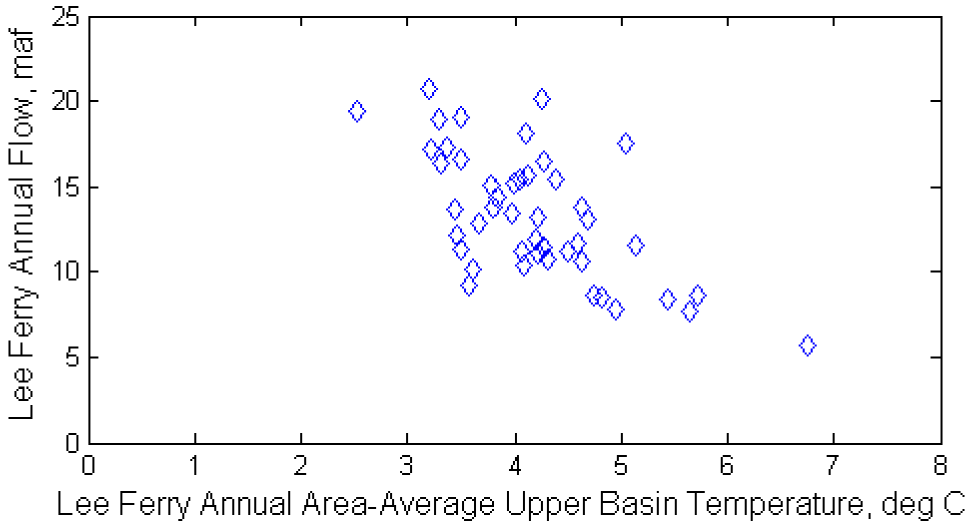
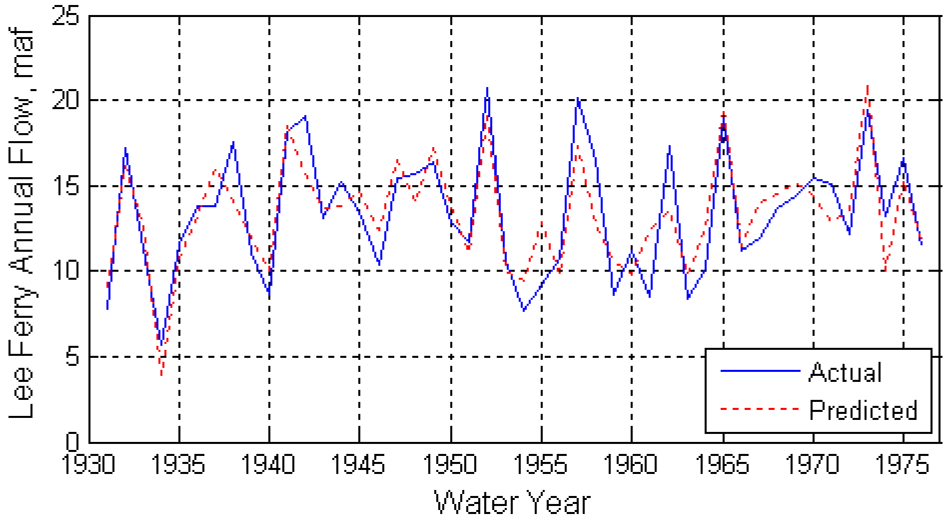
Scatterplot Showing the 1931-1976 Temperature and Flow Data
Used by Revelle and Waggoner (1983)



Revelle and Waggoner also constructed a regression (not provided) using data from 1901 to 1930 but this only explained 57% of the variance. The authors felt the relatively low explained variance was due to a limited number of data stations, a lack of snoU-related precipitation data, and stations unrepresentative of true temperatures.

Figure U-13
Actual and Predicted Flows Using Revelle and Waggoner
(1983) Regression Equation



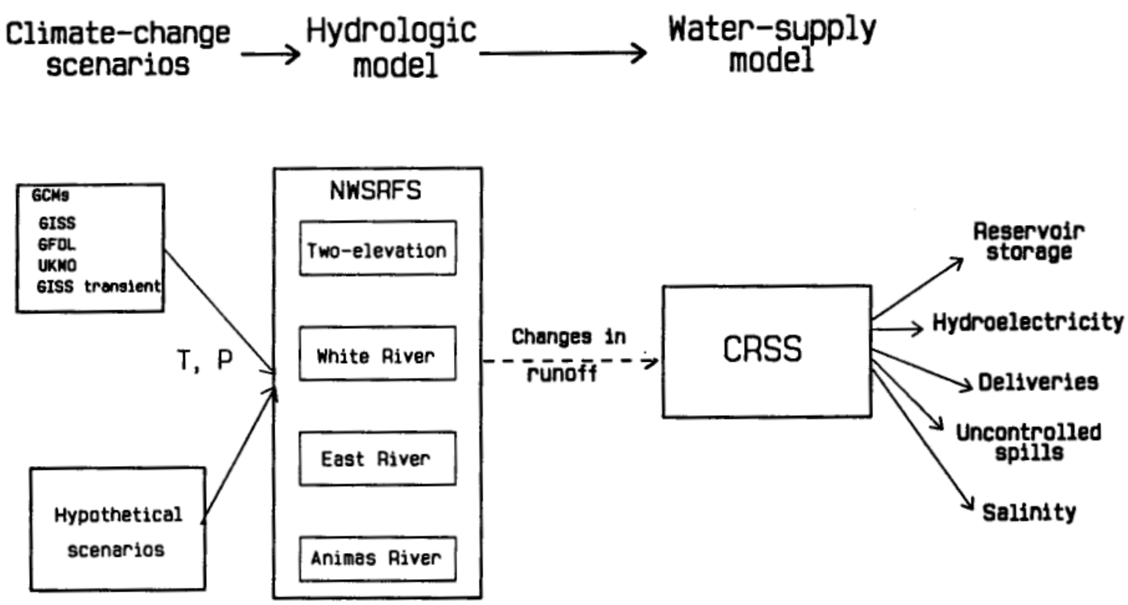
U.6.1.3 Sensitivity of Streamflow in the Colorado River basin to Climatic Changes (Nash and Gleick, 1991) and The Colorado River basin and Climatic Change (Nash and Gleick, 1993)

Linda Nash and Peter Gleick of the Pacific Institute for Studies in Development, Environment and Security wrote two similar articles on future Colorado River flows under varying assumptions of a changing climate, one published in the Journal of Hydrology (Nash and Gleick, 1991) and one as a report to the Environmental Protection Agency as part of a grant (Nash and Gleick, 1993). The 1993 article is an expanded version of the 1991 study and includes the addition of results of modeling simulated future flows with Reclamation's CRSS River operation model (See Figure U-14).

In the Nash and Gleick (1991) study, the authors considered a total of 15 different scenarios for temperature and precipitation conditions, 10 from assumed futures and five based on GCM simulations. These scenarios were then used as meteorological inputs into the National Weather Service River Forecasting System (NWSRFS) hydrologic model in three relatively unimpaired sub-basins of the Colorado River basin above Lake Powell. NWSRFS is the operational model used by the NOAA National Weather Service Colorado River basin River Forecast Center (CBRFC) and all other River Forecast Centers. It is composed of the Sacramento soil moisture model and the Snow17 snowmelt model, among other components.

The NWSRFS applications had been previously calibrated by CBRFC staff and had r2 values between historical and forecasted flows of approximately 0.9 on a monthly basis. Mean streamflow predictions were biased by about +/-1% relative to historical flows. (The authors noted that the NWS used entire historical data set in calibration thereby making it impossible to use some of this data in independent model verification studies.) This study simulated future streamflow in three of the sub-basins in the NWSFRS model with limited human influences, the White River near Meeker, the Animas River near Durango, and the East River near Gunnison. In addition, inflows were simulated for Lake Powell by using a coarser two-elevation aggregated model.

Figure U-14
Drawing from Nash and Gleick, 1993, Showing the Different Models Used in the Study



Sources of different temperature and precipitation inputs used to drive the hydrologic model are on the left. The Christensen studies have a similar hierarchy, but utilize different models at all three points.

The hypothetical scenarios involved all combinations of 2ºC and 4ºC temperature increases, and changes in precipitation of -20%, -10%, 0%, +10% and +20%. The GCM-based efforts used GCM temperature and precipitation outputs from the nearest grid point or grid points in two cases. GCM ouput data were taken from two Goddard Institute for Space Studies model grid points (+4.8ºC /+ 20% precipitation and +4.9ºC/+10% precipitation), a NOAA Geophysical Fluid Dynamics Laboratory model (+4.7ºC / 0% precipitation), and two UK Meteorological Office model (UKMO) grid points (+6.8ºC/+30% precipitation, and 6.9ºC/+10% precipitation)[3]. The GCM outputs were

[3] The versions of the GISS, GFDL, and the UKMO GCMs used in the recent 2007 IPCC AR4 studies are vastly different from those used in Nash and Gleick (1991, 1993).

derived from a doubled-CO_2 experiment where CO_2 concentrations were instantly doubled and then the GCMs were allowed to achieve temperature equilibrium.

Fifty-two (52) different scenarios were evaluated (not every modeled flow point used every scenario.) Thirty-seven (71%) scenarios resulted in flow decreases and fifteen (29%) resulted in flow increases. Runoff varied from a 33% decrease to a 19% increase. A 20% increase in precipitation caused runoff to increase in every case. A 2ºC increase was roughly offset by a 10% increase in precipitation. A 2ºC increase with no change in precipitation caused runoff declines of -4% to -12%. A 4ºC increase with no change in precipitation caused runoff declines from -9% to -21%. A 4ºC increase must be matched with precipitation increases of +15% to +20% for runoff to stay constant. The aggregated two-elevation model for Lake Powell inflow was more sensitive to increases in temperature than the other models, either an artifact of the model or a physical manifestation of increased evaporation in the lower elevation zones of this modeled runoff point compared to the relatively high elevations at the other modeled points. The results follow expectations with higher temperatures and lower precipitation generating less runoff. Temperature increases also cause the peak flow to shift earlier in the year.

In the 1993 study Nash and Gleick added (1) a "transient" climate study showing results for the decade 2030 to 2039, (2) a direct GCM runoff analysis (runoff calculated by the GCM as part of its hydrology code, not the runoff from the NWSRFS), and (3) an operations model, CRSS, to investigate how changes in inflows would affect reservoir operations and system reliability. Transient climate studies use fully specified month by month GHG emissions scenarios that generally increase over time as inputs and keep continuous daily, monthly or annual output data from the GCM for later analysis, rather than just the final equilibrium response. All current studies such as the Christensen et al. (2004), Christensen and Lettenmaier (2006) and Hoerling and Eischeid (2006) are based on models which have archived transient climate output.

This was the first Colorado River study to find that chronic small reductions in streamflow are ultimately manifested as large declines in system storage and hydropower due to total demands that are at or near the mean streamflow. Many other studies such as the Severe and Sustained Drought study (Harding et al., 1995), Christensen et al., (2004), and Christensen and Lettenmaier (2006) have confirmed these findings.

In the 1993 study, runoff reductions of 20% caused mean annual reductions in storage of 60 to 70% and reductions in power generation of 60%. A 15% drop in runoff caused Lee Ferry minimum flows to drop by 86%. A 10% runoff reduction caused Lake Powell releases to fall below the 8.23maf target in several years and storage to decline by 30% relative to historical levels. The specific results from this study are very dependent on assumptions made about how to allocate shortages, reservoir starting conditions, Upper Basin compact deliveries during extended drought, and other factors.

U.6.1.4 The Effects of Climate Change on the Hydrology and Water Resources of the Colorado River basin (Christensen, et al., 2004)

This 2004 study, published in a special edition of the journal Climatic Change, was part of a larger study funded by the Department of Energy known as the Accelerated Climate Prediction Initiative (ACPI). Niklas Christensen, Andrew Wood, Nathalie Voisin, Dennis Lettenmaier and Richard Palmer, all of the Department of Civil and Environmental Engineering at the University of Washington, used the National Center for Atmospheric Research Parallel Climate Model (PCM) to simulate runoff and operations on the Colorado River during three future 21st century periods, 2010-2039, 2040-2069, and 2070-2098 (See Table U-4).

The version of PCM in the study featured coupled atmospheric, ocean, sea ice and land surface components and operated at T42 resolution or approximately 300km grid boxes. At the time, PCM simulations showed less cooling (‘temperature sensitivity’) than many other GCMs for the same greenhouse gas emissions. This version of PCM was part of the multi-model ensemble referenced in IPCC’s Third Assessment Report (2001) and contrasts with the version of PCM and other models that are referenced in IPCC’s Fourth Assessment Report results shown in Section W.4.0.

Table U-4
Changes in Temperature and Precipitation Provided by NCAR GCM, Runoff and Snow Water Equivalent Results from VIC Hydrology Model, and Storage, Hydropower and Spills from CRRM Operations Model
(from Christensen et al., 2004)

Period	Temperature (ºC)	Precipitation	Runoff	Snow Water Equivalent	Storage
Historical Control	0.5	354 mm/yr	45 mm/yr		32.3 MAF/yr
		-1%	-10%		-7%
2010-39	1.0	-3%	-14%	-2%	-36%
2040-39	1.7	-6%	-18%	-7%	-32%
2070-39	2.0	-3%	-17%	-8%	-40%

Monthly temperature and precipitation output from PCM was downscaled to 1/8 degree daily data (see Section W.4.2.3.2) for use by a daily hydrological simulation model, the Variable Infiltration Capacity (VIC) model. VIC simulates snow accumulation and melt, soil moisture, evapotranspiration, and runoff and baseflow. Runoff and baseflow are routed through a flow network so that streamflow can be calculated. VIC was calibrated using climate and natural flow data from 1950 to 1989. Calibration runs indicated a flow match at Imperial Dam within 1% of calculated natural flow at the site. At Cisco near the Colorado-Utah state line, VIC flow was 9% smaller than calculated natural flow, and at Green River, Utah, VIC was 3% larger than calculated natural flow. VIC output was used in a monthly operations model, Colorado River Reservoir Model (CRRM), based roughly on Reclamation’s CRSS model.

Three future PCM runs for the 21st century were used. (These "ensemble members" were created by initializing PCM with slightly different atmospheric conditions.) A 50-year control climate run starting in 1995 with no additional greenhouse gas emissions (i.e., with fixed 1995 GHG levels) was also completed. PCM 21st century results averaged over the three runs were compared to the control run, and to historical observed data or calculated natural flow in the historical period.

Due to lags in the climate system, the control run showed warming of about 0.5ºC which is in rough agreement with what many believe to be 'committed warming' should greenhouse gas emissions stop immediately. The three 21st century runs showed average increases of approximately 3ºC over the observed average temperature of 10ºC. In general the warming was concentrated in spring and summer.

Average annual precipitation in the control run was 1% less than historical, and in the three 21st century runs was 3%, 6%, and 3% lower in Periods 1, 2, and 3 respectively. The seasonal precipitation pattern in the control run was very similar to the historical observed, and the 21st century runs showed a similar pattern but with less precipitation in the spring.

April 1 snow water equivalent (SWE) in the control run was only 86% of the observed historical SWE, while SWE was 76%, 71%, and 70% in Periods 1-3, respectively. The reduction in SWE in the control run was attributed to higher spring temperatures, and the 21st century reductions were due to higher temperatures and/or reduced winter and spring precipitation. Southern Colorado suffered the highest reductions and those occurred in Periods 2 and 3.

Runoff was reduced by 10% in the control run, and by 14%, 18% and 17% in periods 1-3, respectively, in the 21st century runs. A spatial analysis of these reductions indicated that a considerable enhancement of evapotranspiration increases occurred in the high elevation areas where a large portion of runoff occurs. Peak runoff advanced from June in the historical data to May in the latter parts of the control and 21st century runs.

Christensen et al., (2004) also reported extensively on how these flows would affect operations as modeled in CRRM. The authors caution that these results strongly depend on initial conditions in the operations model and should not be interpreted as predictions but used instead to find system sensitivities to changes in future flows. Most of the modeling was predicated on constant year 2000 Upper Basin demands to simplify analysis, but a set of runs were done with Upper Basin demands increasing over time.

As previously reported by Nash and Gleick (1993), the authors found that because the Colorado River is nearly at full allocation, reservoir reliability and storage levels were extremely sensitive to inflow reductions -- average reservoir levels dropped significantly even with small reductions in runoff. For example, storage in the control run dropped by 7%, and periods 1-3 showed reductions of 36%, 32%, and 40%, respectively, relative to simulated historical conditions. Deliveries from Lake Powell were met 92% of the time in the historical data, and 72% in the control run and 59%, 73%, and 77% in periods 1-3, respectively. The control run showed reductions relative to the historic conditions because it used year 2000 demands. Variability in the 21st century runs explains some of the other differences. For example, a wet period at the end of Period 2 left system reservoirs at a relatively high level and hence reliability in Period 3 was slightly higher than Period 2 despite roughly similar SWE and runoff.

U.6.1.5 Past Peak Water in the Southwest (Hoerling and Eischeid, 2006)

Martin Hoerling and Jon Eischeid of the NOAA Earth System Research Laboratory in Boulder published their findings in December of 2006 in Southwest Hydrology, a magazine (not a peer-reviewed journal) that is part of the National Science Foundation funded effort at the University of Arizona known as Sustainability of Semi-arid Hydrology and Riparian Areas (SAHRA). Hoerling and Eischeid (2006) projected future Colorado River flows based on the Palmer Drought Severity Index (PDSI) calculated from modeled climate changes for the Upper Colorado River basin. PDSI is a frequently used drought metric and is calculated by combining temperature, precipitation, evapotranspiration and soil moisture. The index can vary from -4 (extreme drought) to +4 (extreme wetness).

Using historical data from 1895 to 1989, they first created a simple linear regression for the Upper Colorado basin:

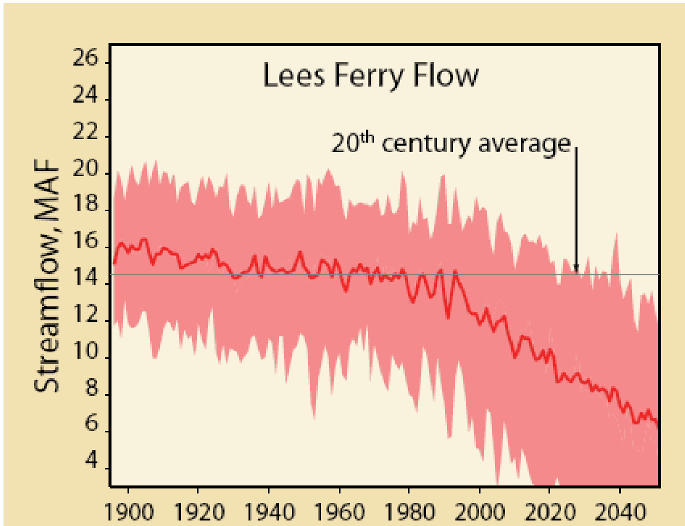
$$\text{Lee Ferry Annual Flows (in MAF)} = 14.5 + 1.69(\text{PDSI})$$

This regression explains 63% of the variance at Lees Ferry over the 105-year calibration period. The equation explained 85% of the variance in the flows over a verification period from 1990 to 2005.

Hoerling and Eischeid then proceeded to calculate the future PDSI using temperature and precipitation data from 42 different climate simulations using ‘business as usual’ greenhouse gas emissions (A1B) from 18 different coupled atmosphere-land-ocean models completed for the recent IPCC 4th Assessment. They then used the regression model above to translate these PDSI values into projected future annual streamflow (See Figure U-15).

The authors found that annual streamflows in the river over the next twenty-five years would average 10 maf, approximately the same as during the recent 1999-2004 drought. From 2035 to 2060 the flows would drop to an average of 7 maf. The individual years vary considerably from these averages with some years being close to the historical mean of 15 maf (see figure). For the next twenty years, individual years may still produce normal flows. In some future years the regression equation did generate some streamflows below zero (not shown). Although negative flows are obviously physically impossible, this is a known limitation when regression equations are used outside of their calibration inputs.

Figure U-15
Projected Lees Ferry Future Flows



Solid line is average of 42 runs, and shaded band shows 10% to 90% range of individual simulations
(from Hoerling and Eischeid, 2006)

The authors noted that the climate models show little net change in precipitation over the next century yet significant drought as represented by the modeled PDSI would be a very common occurrence with average PDSI the same as during the 2000-2003 drought (<-3). They suggested that 20th century droughts were driven by precipitation decreases with enhancement by temperatures but a "near perpetual state of drought will materialize in the coming decades as a consequence of increasing temperature." The models in the study project an average temperature increase of 1.4ºC during 2006-2030, and average warming of 2.8ºC during 2035-2060, compared to 1895-2005.

The authors cautioned that it is unclear if the streamflow PDSI relationship used in the study is strictly applicable to the substantial changes anticipated in future climate. It should also be noted that the PDSI index was developed for use in the Great Plains and does not account for the different phases of precipitation, snow or rain, and their very different characteristics.

U.6.1.6 A Multimodel Ensemble Approach to Assessment of Climate Change Impacts on the Hydrology and Water Resources of the Colorado River basin (Christensen and Lettenmaier, 2006)

Niklas Christensen and Dennis Lettenmaier, both with the Department of Civil and Environmental Engineering at the University of Washington published in an article on future Colorado River flows in *Hydrology and Earth System Sciences* in 2006. The study is based on GCM model results prepared for the 2007 IPCC Fourth Assessment (AR4) (see Table U-5 for rounded temperature, precipitation, runoff and snow water equivalent results; and, Figures U-15 to U-18 for additional information on this study).

The authors used 11 major climate models and two different future emissions scenarios, A2, a relatively high scenario with 2100 CO_2 levels of 850 ppm and B1, a relatively low level scenario with 2100 CO_2 levels of 550 ppm. (Current CO_2 levels are approximately 380 ppm and are increasing at about 1.5 – 2.0 ppm/year.) The authors selected these two scenarios because they likely bracket any future emissions trajectory and because the GCM output for these scenarios was available from a wide variety of models.

This study essentially reapplied the approach from the Christensen et al. 2004 Climatic Change paper but featured an expanded suite of climate models. As in the 2004 study, for discussion the output was broken into 3 periods: 2010-2039, 2040-2069, and 2070-2099.

Table U-5
Average Ensemble Temperature Increase, Percent Changes in Precipitation, Runoff, and April 1 Snow Water Equivalent All Relative to Historic 1950-99 Modeled Base Case for Both the B1 and A2 Emissions Scenarios
(from Christensen and Lettenmaier, 2006)

Period	Temperature (ºC)		Precipitation		Runoff		Snow Water Equivalent	
	B1	A2	B1	A2	B1	A2	B1	A2
2010-39	1.3	1.2	1%	-1%	0%	0%	-15%	-13%
2040-69	2.1	2.6	-1%	-2%	-7%	-6%	-25%	-21%
2070-99	2.7	4.4	-1%	-2%	-8%	-11%	-29%	-38%

For this study VIC was re-calibrated on historic 1950-99 data (an additional 10 years relative to the 2004 study). VIC generated a less than 1% underprediction of streamflow at Imperial Dam, and +3% and -9% errors at Green River and Cisco, respectively, based on reconstructed natural flow at these points.

Temperatures increases (ºC) for the B1 runs during periods 1-3, shown as "average (minimum, maximum)," were 1.28 (0.53, 1.83), 2.05 (1.13, 2.99), and 2.74 (1.13, 2.99), respectively, relative to historical observations (see Table U-5 for rounded temperature, precipitation, runoff and snow water equivalent results. Figures U-15 to U-18 present additional information on this study). For the A2 runs during the same periods, the temperature increases (ºC) by 1.23 (0.63, 1.82), 2.56 (1.61, 3.65), and 4.35 (2.77, 6.06). (Many studies show that temperatures in the next quarter century are tied to existing greenhouse gas concentrations and hence the slightly higher B1 temperature relative to A2 in period 1 is not unusual; generally, changes between emission scenarios show lagged behavior such as reported for Periods 2 and 3.) Temperature increases show more warming from mid-summer to early fall, which is consistent with a reduction in soil moisture during these periods.

Annual precipitation percent change from historical for the B1 runs during periods 1-3, shown as "average (minimum, maximum)," were +1% (-8, 11), -1% (-11, 9), -1% (-11, 19), respectively. For the A2 runs and same periods, percent precipitation changes were -1% (-9, 7), -2% (-21, 13) and -2% (-16, 13), respectively. Of critical importance is that October to March average precipitation increases by +5%, +1%, and +2% for B1 and by

+6%, +5% and +4% for the A2 scenario. In contrast, the 2004 study had winter precipitation decreases in the single digits. The increases occurred generally at the highest elevations in the Rockies.

April 1 snow water equivalent (SWE) change from historical for the B1 runs, shown as "average (minimum, maximum)," was -15% (-41, 0), -25% (-48, -1), -29% (-53, -18) during for periods 1-3, respectively. For the A2 runs, SWE change was -13% (-36, 1), -21% (-52, 6) and -38% (-66, -15) during the same periods, respectively. The authors believe that SWE decreases are due to increasing temperatures, given especially that winter precipitation increases. SWE reductions are greatest in the low to mid elevation areas. The combination of declining SWE and increasing winter precipitation is indicative of more precipitation occurring as rain.

Mean-annual runoff during Periods 1-3 changed from historical by 0% (-23, 17), -7% (-27, 12) and -8% (-30, 29) for the B1 runs, respectively, and by 0% (-16, 14), -6% (-39, 18), and -11% (-37, 11) for the A2 runs during the same periods. These reductions are larger than the precipitation declines and are believed to be driven by increasing temperatures and high evapotranspiration.

Christensen and Lettenmaier (2006) also reported results from their operations model, CRRM. CRRM was modified to reflect the Basin States' current proposal with regard to how Lower Basin shortages should be tied to Lake Mead Levels. Hence, the model calculates shortages when necessary to all major Lower Basin entities. They caution that CRRM results reflect many assumptions and non-linear interactions, such as reservoir initial starting conditions and the sequencing of individual annual inflows. In addition, as previously stated, all Colorado River operations models including CRRM fail to address certain critical issues including, for example, Upper Basin curtailments as may be required by the Colorado River Compact during extended drought. Upper Basin demands were fixed at year 2000 levels to simplify analysis yet over time these demands will surely grow. Thus these results should be used only in a comparative sense.

In general, CRRM reservoir levels are higher than reported in the 2004 study, although the authors claim that the results are within the same range of sensitivity. They state that a decrease of 10% in average streamflow is magnified into a 20% change of the same sign in reservoir storage. Similarly, a 20% inflow change results in a 40% storage impact. The authors state that because of the large ratio of storage to inflow in the basin, neither increases in storage nor changes in operating rules will likely change the storage impacts under declining inflows.

U.6.1.7 Other Colorado River Basin Studies of Note

In addition to the studies reported above, there have been several other studies, either focused on parts of the basin or that summarize past studies. These are discussed briefly below.

In 1990 John Schaake of NOAA's Office of Hydrologic Development investigated the notion of elasticity in flow due to changes in precipitation and temperature in a chapter entitled "From Climate to Flow" in *Climate Change and U.S. Water Resources* (Schaake

1990). Using the NWSRFS hydrologic model on the Animas River basin, Schaake discovered that a 10% increase in precipitation would increase flow by 20% while a 2°C temperature increase would reduce flow by 2%. A 2°C increase and a 10% increase in potential evapotranspiration would change flows by -9%.

Greg McCabe and Lauren Hay of the USGS wrote Hydrological Effects of Hypothetical Climate Change in The East River Basin, Colorado, USA in Hydrological Sciences in 1995 (McCabe and Hay, 1995). McCabe and Hay used 9 hypothetical climate scenarios – all combinations of +4°C, 0C, -4C and -20%, 0%, and +20% precipitation – to drive a USGS hydrologic model, PRMS. Modeled runoff varied from -30% (+4C, -20%) to +40% (-4C,+20%). The authors also investigated how natural variability might mask decreasing runoff and found that it might take 80 to 90 years to detect a runoff reduction at the 95% confidence level due to a gradual +4C and -20% precipitation change.

In 1999 in the Journal of the American Water Resources Association, Peter Gleick and Elizabeth Chalecki wrote The Impacts of Climatic Changes for Water Resources of the Colorado and Sacramento-San Joaquin Basins (Gleick and Chalecki, 1999). This article provides an overview of all studies on the Colorado River prior to the publication date.

U.6.2 Recent Studies Featuring GCM Projections for the American Southwest

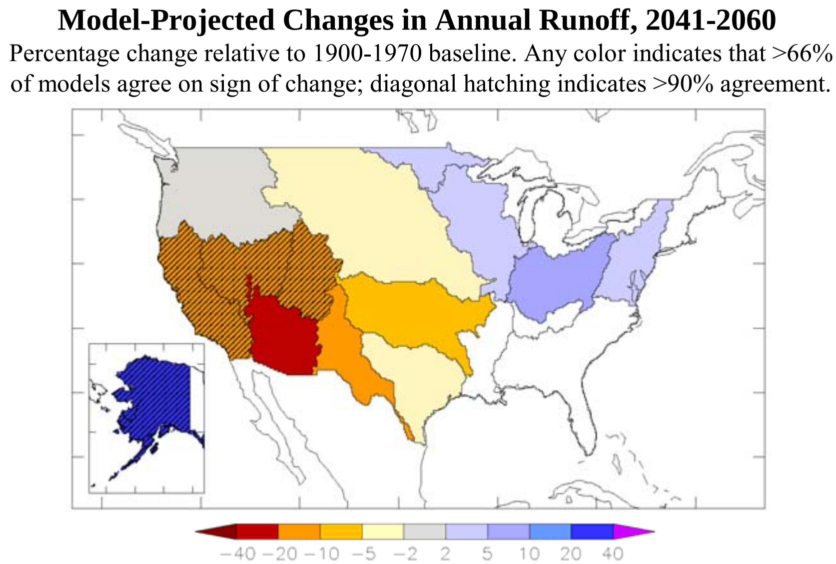
Since 2005 there have been three studies which have analyzed large scale 21st century GCM projections such as runoff, precipitation and evaporation for the American Southwest. These studies have not utilized smaller scale hydrologic or other models like the studies described in Section W.5.1. An important distinction between studies using GCM runoff versus hydrology model runoff is that whereas GCMs calculate runoff as part of their hydrological cycle at the GCM scale (e.g., for 10,000 km^2 grid cells), hydrological models like VIC and NWSRFS run at much higher resolution, contain far more detailed representations of land surface physics, and are calibrated and verified against streamflow records, which is not typically the case for runoff from GCM internal runoff schemes.

U.6.2.1 Global pattern of trends in streamflow and water availability in a changing climate (Milly et al., 2005)

In the journal Nature in 2005, USGS scientist Chris Milly and others surveyed runoff proxy information from 12 AR4 GCMs found to be relatively better skilled at reproducing 20th century streamflow trends over large regions. The study had both a ‘verification’ period which used historical data to select the 12 models from 21 potential candidates, and a projection period using SRES A1B which used future runoff from the selected models. The American Southwest was not one of the areas used to select the models and hence model fidelity to historical conditions in this region is not known. The runoff projections were for the entire globe. In a later not-published addendum to the study, Milly looked specifically at the continental United States and found that based on the same model results greater than 90% of the GCM simulations show future Colorado

River basin runoff reductions from approximately 10 to 30% (see Figure U-16) in the period 2041-2060[4].

Figure U-16
Projected Colorado River Runoff (from Milly et al., 2005)



(After Milly, P.C.D., K.A. Dunne, A.V. Vecchia, Global pattern of trends in streamflow and water availability in a changing climate, *Nature*, **438**, 347-350, 2005.)

The IPCC AR4 Working Group 1 chapter on climate models (Randall et al., 2007) as well as the AR4 Working Group 2 chapter on freshwater resources (Kundzewicz et al., 2007) both relied on this study. Randall et al. noted that this study was an important scientific advance because it showed that despite the limitations in the hydrologic cycle in the climate models, the models can capture observed changes in 20th century streamflow associated with atmospheric conditions. Further, they say that, "This enhances confidence in the use of these models for future projection."

U.6.2.2 Model Projections of an Imminent Transition to a More Arid Climate in Southwestern North America, (Seager et al., 2007)

A 2007 study in Science by Columbia University scientist Richard Seager and others, using many of the same GCMs and runoff proxy information as Milly et al., obtained similar conclusions to Milly et al. Unlike Milly et al.'s world-wide focus, Seager's study was specific to an area he termed the 'American Southwest' but was actually far larger than the general use of this term[5]. This area includes the entire Lower Basin, but excludes

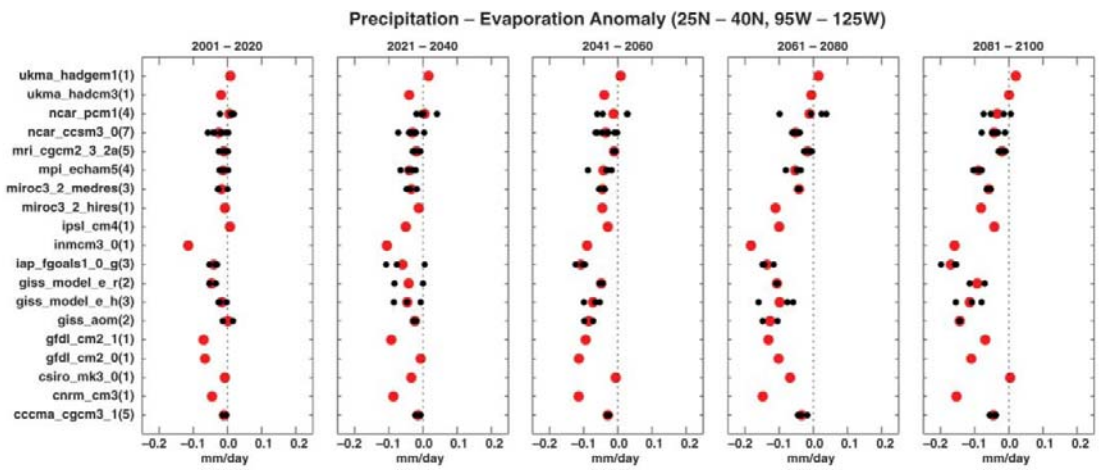
[5] The area was all land from 125U-95W and 24-40N or approximately Brownsville, TX to Lincoln, NE to Eureka, CA in the U.S. It also includes land in Mexico.

almost all of the Green River and hence is not equivalent to the Colorado River basin. Seager et al. used future GCM projections from 19 AR4 climate models using the A1B emissions scenario compared to 1950-2000 model climatologies. Eighteen of the nineteen models show a drying trend (see figure U-17). Seager et al., focus on the change in future precipitation less future evaporation, a proxy for runoff. In support of the modeled runoff declines, Seager et al., (2007) point to theory and studies about Hadley cell expansion and associated poleward storm track movement in a warming climate. They also discuss recent observational and paleoclimate evidence for support of hypothesized Hadley cell changes.

Figure U-17
The Change in Annual Mean Precipitation Minus Evaporation (~ Runoff) for the
American Southwest in Twenty-Year Periods to 2100 Calculated Relative to Model Climatologies 1950-2000



Models are shown at left. Red dots are the ensemble mean and black dots represent individual ensemble members. Only 1 in 19 models has a wet trend and only 3 individual projections out of 49 show a wet trend. (from Seager et al., 2007)

U.6.2.3 Intergovernmental Panel on Climate Change, 2007

The Fourth Assessment of the Intergovernmental Panel on Climate Change released its report in the spring of 2007 (IPCC, 2007). Chapter 11 from The Physical Science Basis Work Group contains regional climate projections, including North America (Christensen et al., 2007). Christensen et al[6]., note that for North America as a whole, the annual mean warming is likely to exceed the global mean warming in most areas. Snow season length and snow depth are very likely to decrease in most of North America, except in the northernmost part of Canada where maximum snow depth is likely to increase. At the coarse horizontal resolution of the climate models, high-altitude terrain is poorly resolved, which likely results in an underestimation of warming associated with snoU-albedo feedback at high elevations in western regions.

[6] This is not the same Christensen as in the Christensen and Lettenmaier studies.

Specific IPCC findings for the Southwestern USA are that warming will likely be greatest in summer, not winter as for other parts of the continent, and that annual mean precipitation is likely to decrease (see Figure U-7). The projection of smaller warming over the Pacific Ocean than over the continent, and amplification and northward displacement of the subtropical anticyclone, is likely to induce a decrease in annual precipitation in the south-western USA and northern Mexico. In the context of the report, 'likely' is used to mean a 66% to 90% chance of occurrence. Regional projections are only made for relatively large areas without definite boundaries such as the "Southwestern USA". The IPCC makes regional projections where there is "near unanimity among models with good supporting physical insights." They note that up-to-date coordinated Regional Climate model projections were not available for North America at the time the report was issued.

U.6.3 Synthesis and Discussion of Results

Almost thirty years have passed since the first attempt by Stockton and Boggess (1979) to quantify how climate change might affect the runoff in the Colorado River basin. Since that early attempt using Langbein's 1949 empirical temperature-precipitation-runoff relationships, scientists have used primarily two types of future climate temperature and precipitation projections– (1) pure hypothetical scenarios and (2) GCM output – to drive two types of flow generation techniques – (1) statistical regression and (2) hydrology process models – in order to project future flows on the river. To put these studies into proper context it is important to understand the limitations relating to GCMs, future applicability of statistical and empirical relationships based on historical data, hydrology model assumptions, and/or operational model assumptions.

These studies utilize three different generations of GCMs, dating from the early 1990s, late 1990s and mid 2000s. GCM-derived climate inputs for the most recent studies (Hoerling and Eischeid, 2006, Christensen and Lettenmaier, 2006) are believed to significantly more robust than older results (Nash and Gleick, 1991, 1993) because of increased understanding and increased model resolution. In general, temperature projections are considered much more reliable than precipitation, even in the latest models. As noted by the IPCC, even with many advances over the years, global climate models still do not adequately resolve precipitation in mountainous areas. It is noteworthy, however, that the most recent GCM results for precipitation in the Colorado River basin show somewhat consistent results across models with very little change in average projected annual precipitation relative to historical conditions. Individual models do, however, show significant variability with the 11 models used in the recent Christensen and Lettenmaier paper showing a range of approximately 80% to 120% of the historical average precipitation.

Studies which used empirical/statistical relationships between temperature, precipitation and runoff (Stockton and Boggess, 1979, Revelle and Waggoner, 1983, Hoerling and Eischeid, 2006) have been criticized for failing to consider how these relationships might change in a future climate due to evapotranspiration and vegetation changes, and changes in seasonality of runoff. Such changes might substantially alter the relationships between temperature, precipitation, and runoff, which could invalidate the findings.

There have been other criticisms of studies using the historical data. Karl and Reibsame (1989) criticized Langbien's 1949 work, and derivatives thereof including Stockton and Boggess, 1979 and Revelle and Waggoner, 1983 for overstating the impact of temperature on runoff. They maintain that changes in precipitation will be far more important than temperature in determining future runoff. Much of their analysis is based on looking at decadal changes in runoff. This study was in turn criticized by Rind et al. (1990) for using average warming only 1/10 that projected for doubled CO_2. Rind et al. suggest that all studies based on the observational record are flawed because the water holding capacity of the atmosphere varies strongly with temperature – potentially up to 30% for 4C warming – and this type of widespread warming and associated increase in water vapor have no analog in the historical record.

Hydrology models can potentially overcome some of the limitations inherent in the statistical/observational approach by modeling many of the physical processes which control runoff such as snow accumulation and melt, groundwater recharge, and evapotranspiration from plants. In theory as the climate changes, these models should correctly handle new physical conditions. Unfortunately, these models require large amounts of data, much of which is imprecisely known. Furthermore, in order to resolve very complex and sometimes poorly known relationships, the models may overly simplify important physical processes. For example, the VIC model uses a two-meter subsurface layer to model all interactions with soil moisture and groundwater, despite the fact that surface water/groundwater interactions frequently involve various forms of aquifers with significant storage capacity. Finally, most hydrology models do not have land cover which can respond to changes in climate. Thus, they too might suffer from inaccuracies if the climate changes enough to affect the relationship between land cover and runoff.

Three of the studies, Nash and Gleick (1993), Christensen et al. (2004) and Christensen and Lettenmaier (2006) used an operations model to project specific water system outcomes based on their future runoff results. Nash and Gleick (1993) utilized an older version of the USBR's CRSS model and the Christensen studies utilized a model (CRRM) created at the University of Washington. While the results of these two models are intriguing, it must be noted that numerous critical policy-laden decisions about how to operate the system under low flow conditions have never been addressed and thus these implementations either ignore these issues, or implement a solution that has no standing in the Law of the River. For example, neither the bookkeeping associated with Present Perfected Rights in the Upper Basin nor shortages in Upper Basin are present in these models. Hence, modeled reservoir storage and hydropower production are directly tied to modeling decisions which may be founded on unrealistic assumptions about the management and operational strategies that would be pursued in the face of severe drought. Assumptions about reservoir starting contents also can significantly alter results. Christensen et al. (2004) noted these problems and suggest that the operational results should only be used in a comparative sense. Thus, for the purposes of this document, these operational results should be of less interest than the findings for streamflow.

All recent studies specific to the basin (Christensen et al., 2004; Christensen and Lettenmaier, 2006; Hoerling and Eischeid, 2006,) and the Milly et al. study which later produced results specifically for the CRB[7] indicate that by mid- to late-21st Century, the central expectation is for decreased runoff in the Colorado River Basin. Furthermore, when precipitation is assumed to be constant or slightly decreased, an assumption consistent with the central projections of recent studies, all past studies (Stockton and Boggess, 1979; Revelle and Waggoner, 1983; Nash and Gleick, 1991, 1993) also indicate less future runoff. However, the range of results still spans increased to decreased runoff conditions through the late 21st century (e.g., Christensen and Lettenmaier, 2006).

If future precipitation remains approximately the same or decreases slightly, it seems likely that the basin will see less runoff. This leaves open the question of the magnitude of the decline. The two most recent studies have a very large range in future declines from -11% by 2100 by Christensen and Lettenmaier (2006) to -45% projected by Hoerling and Eischeid (2006) by about 2050. Although the Hoerling and Eischeid method can be questioned for using relatively crude techniques, its calibration and verification statistics are quite good. In contrast, the Christensen and Lettenmaier study (2006) is far more sophisticated and shows some results consistent with theories such as increased winter precipitation and increased summer and fall temperatures.

The Seager et al., and IPCC findings are both based on the recent AR4 climate models and at the large scale of these studies there is also general agreement that runoff in the “American Southwest” in the future will be reduced. It should be noted that the term “American Southwest” in the case of the IPCC is not defined, and in the case of Seager et al. covers far more area than is typically associated with the reference. While it is easy to criticize these studies for using GCMs which lack the sophistication seen by many to be necessary to model the complex topography and mid-continental location of the Colorado River basin[8], their collective findings are important for several reasons. These include the large number of models agreeing on the same projections as well as supporting theories on Hadley cell expansion, storm track movement and evidence from the paleoclimate record. At the least, these efforts suggest that additional research to understand the bases for model concurrence should be undertaken. This overall paradigm of projected future dryness in an existing dry subtropical area also has analogs in other parts world including the Mediterranean. This analog does fall short, however, in explaining how a relatively wet mountainous area close to an existing dry area should respond to future warming.

Finally, it is worth emphasizing that runoff and operations impacts in the CRB are highly sensitive to projected precipitation changes. It is notable that the sign and range of projected precipitation over the CRB (e.g., Christensen and Lettenmaier 2006, Appendices A1-A2 and Figure U-23) seems somewhat insensitive to future projection period, unlike sign and range

[7] Seager et al and the IPCC findings are excluded here because the Seager et al study did not include the Green River basin and the extent of the IPCC’s ‘Southwestern United States’ is not clear. Both of these studies did find reduced runoff likely in their respective study areas noted above.

[8] This point applies to Milly et al. as well.

of runoff change. This raises several questions. If precipitation change has no obvious trend related to warming, then what is driving the modeled period-to-period precipitation variability over the CRB? Put another way, what is the paradigm of CRB precipitation response to global and regional temperature increase? How does the fact that global atmospheric moisture should increase with global warming due to Clausius Clapyron physics apply in the CRB? The answers to both of these questions would provide a framework for analyzing GCM precipitation output. Without answers, we have limited basis for judging the band of precipitation projection uncertainty produced by GCMs. This band may be physically realistic, or it may be an artifact of having a diverse number of imprecise and adolescent GCM approaches & implementations. Section W.9.3 discusses these questions, additional current knowledge limitations and potential research paths forward.

U.7 Potential Methods for Relating Climate Change Information to Long-Term Reservoir Operations Analysis

Chapter W.5 presented impacts assessments that have been completed for the Colorado River basin. Those studies were conducted for a variety of climate change scenarios and using a number of different methodologies. This chapter categorizes method options for translating climate projections into operations response information. It then identifies analytical designs among those options that Reclamation's Lower Colorado region (LC) planning analysts might consider when using LC's planning model, CRSS (Section W.3). A number of design considerations are also discussed including climate scenario data availability, choice of runoff analysis tool, process simulation versus statistical methods for analyzing runoff response, treatment of natural water demands, and treatment of future precipitation assumptions.

U.7.1 Context

Following more recently developed methodologies discussed later in this section, a long-term operations analysis under assumed climate change would involve three core steps:

1) select a simulated climate scenario that overlaps with observed historical conditions and extends into a future planning horizon (e.g., a 1950-2100 time series), that has been bias-corrected during the historical overlap period (Section W.4.2.3), and has been spatially downscaled to a basin-relevant resolution necessary for planning;

2) relate downscaled climate conditions over the basin to natural runoff response; and

3) relate simulated natural runoff response to water supply and operations response.

Implementation of these steps follows the presumption that the tool development and validation has already been completed. More specifically, the hydrology model used in step (ii) and both the streamflow impairment scheme (if present) and operations model used in step (iii) have been calibrated, validated, and demonstrated to reproduce observed behavior of the system during some historical period. Implementation of these steps also implies that relations between runoff, precipitation, and air temperature are largely preserved as climate changes. Admittedly, climate will modulate conditions that affect these relations (e.g., potential evapotranspiration, land cover, etc), which introduces uncertainty into the analysis. Such uncertainties are discussed in Sections W.6.3 and W.6.6.

For convenience, steps (ii) and (iii) would be completed using one coupled model of basin hydrology and system operations. In practice, there is often a division between the hydrologic and operations modeling. The division exists for various reasons. Sometimes it is because hydrologic and operations models were developed relative to different historical periods. For example, runoff models are typically calibrated using reliable and recent meteorological input conditions, which typically mean calibrating models to conditions since approximately 1960. In contrast, operations models have often been developed relative to longer periods-of-record streamflow and water supply information. Sometimes geographical issues are a cause – e.g., where runoff simulations might be designed to simulate natural hydrology in a given watershed while the operations model might be developed to reflect a sub-area of the watershed where perimeter "system" inflows are affected by upstream impairments elsewhere in the watershed. An additional reason can relate to time-scale issues, where decisions in a given operations model (e.g., monthly) are made during time steps that are not consistent those necessary to simulate natural hydrologic processes, leading to challenges with model coupling. This all contributes to a likely situation of having to conduct steps (ii) and (iii) separately, with runoff simulation data being processed separately and input into the operations model.

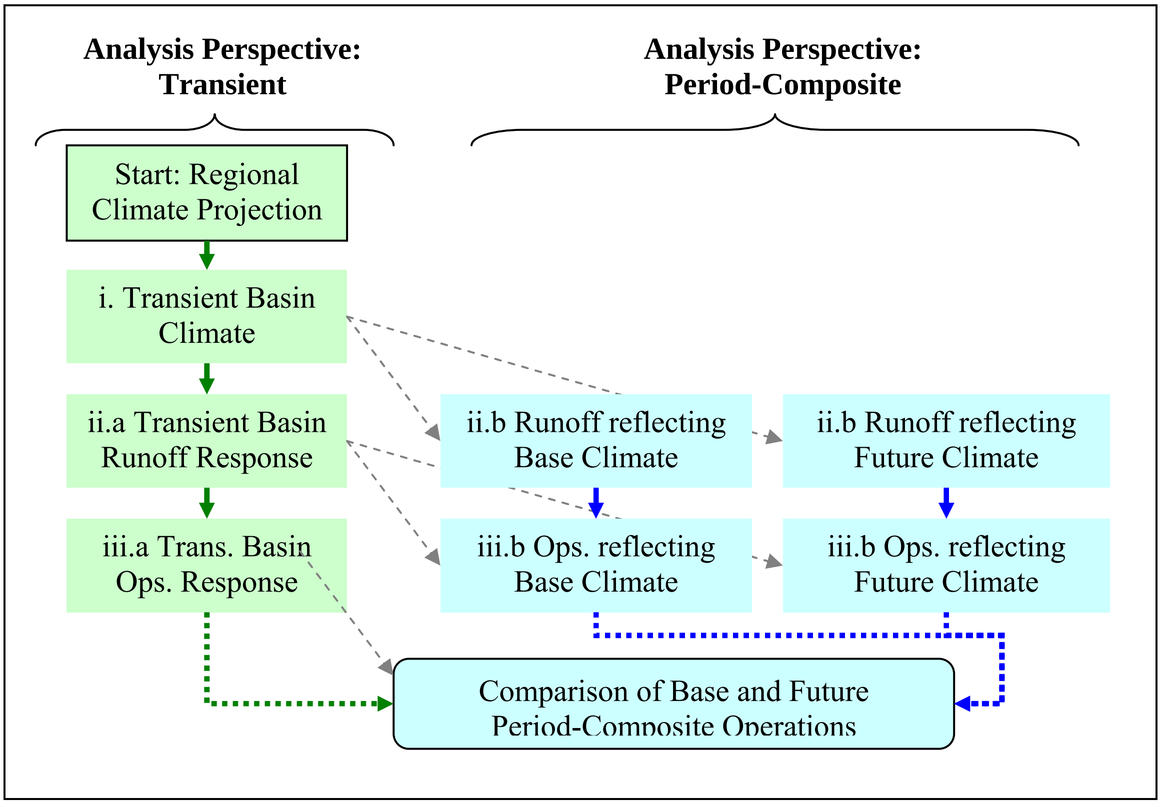
Within steps (ii) and (iii), several method options have been demonstrated in peer-review literature. For this discussion, the options are categorized under two analytical perspectives: transient or period-composite (Figure U-19). Under either perspective and considering a single-scenario analysis, the starting point is step (i) where an evolving simulated climate time-series is selected, describing historical to future evolution of climatic conditions over the basin of interest. The ending point after (iii) is comparative information describing period-composite performance of different operations variables during "recent historical" and "future" periods (e.g., variable being water deliveries to user group "A" and performance measured by long-term annual average amount). The main point is that the process starts with a transient perspective (step (i)), ends with a period-composite perspective (step (iii)), and that there are options for when to make the transition between perspectives (i.e. gray lines on Figure U-18).

U.7.2 Options for Analyzing Runoff and Operations Response

The transition can be made prior to runoff assessment, prior to operations assessment, or after operations assessment depending on the tools and methods used. Three-types of transitions are discussed in the following sections:

- Transient Runoff and Operations
- Transient Runoff and Period-composite Operations
- Period-composite Runoff and Operations

Figure U-18
Method Options for Relating Climate Change Scenario Information
to Long-Term Operations (Ops.) Response



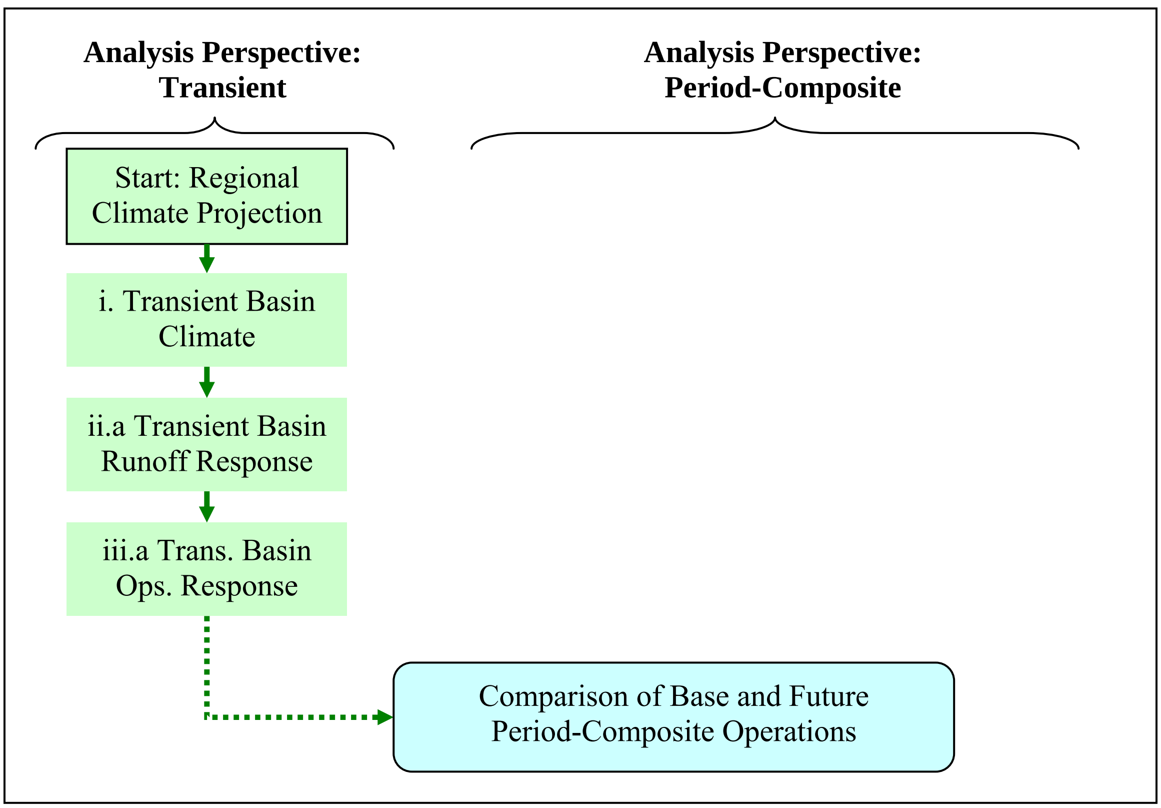
To illustrate each type, several examples from literature are highlighted in the following sections. Discussions in these sections all assume that step (ii) will be conducted using a process simulation of runoff rather than a statistical approach, although that may not be necessary, as will be discussed in Section W.6.3.

U.7.2.1 Transient Runoff and Operations

An example of this type was demonstrated by Christensen and Lettenmaier (2006), highlighted in Section W.5.1.6. Their study involved repeating steps (i)-(iii) for a 22-member ensemble of climate change scenarios. For each member, step (i) begins with a simulated climate time series having been bias-corrected relative to a 1950-1999 observed historical period and then spatially downscaled to 1/8 degree latitude-longitude resolution using methods described by Wood et al. (2004) and Maurer et al. (2007). Downscaled climate scenario time series are then converted into time series meteorological inputs for the runoff model used in the analysis, a Colorado River basin application of the Variable Infiltration Capacity (VIC) macroscale hydrology model (Liang et al. 1994; Nijssen et al. 1997). Runoff results from the VIC model were then routed to key reservoir inflow and system "gain" locations in a system simulation model analogous to the Colorado River Simulation System (CRSS) (Reclamation 1985), and aggregated into monthly values at these locations, providing time series inflow inputs for scenario operations analysis. Once complete, period-composite VIC runoff and CRSS operations statistics were computed to assess runoff and operations response to climate change by measuring statistics in future relative to "recent historical" periods.

Working within the options outlined in Figure U-18, the options selected by Christensen and Lettenmaier (2006) are indicated on Figure U-19. Implementation of these options generally involves a more intensive effort to develop meteorological inputs prior to runoff analysis, but a less intensive effort thereafter as full-period runoff information for a given scenario is well-aligned with operations model input. On developing scenario meteorological inputs for VIC, the step (i) output is already at a spatial resolution and position common to the runoff model. Given that the output is monthly time-step information for only precipitation and temperature conditions, additional data processing is required to translate the data into sub-monthly timestep conditions (daily) and other meteorological inputs required by VIC (e.g., wind speeds and surface radiative variables following methods described by Maurer et al. [2002]).

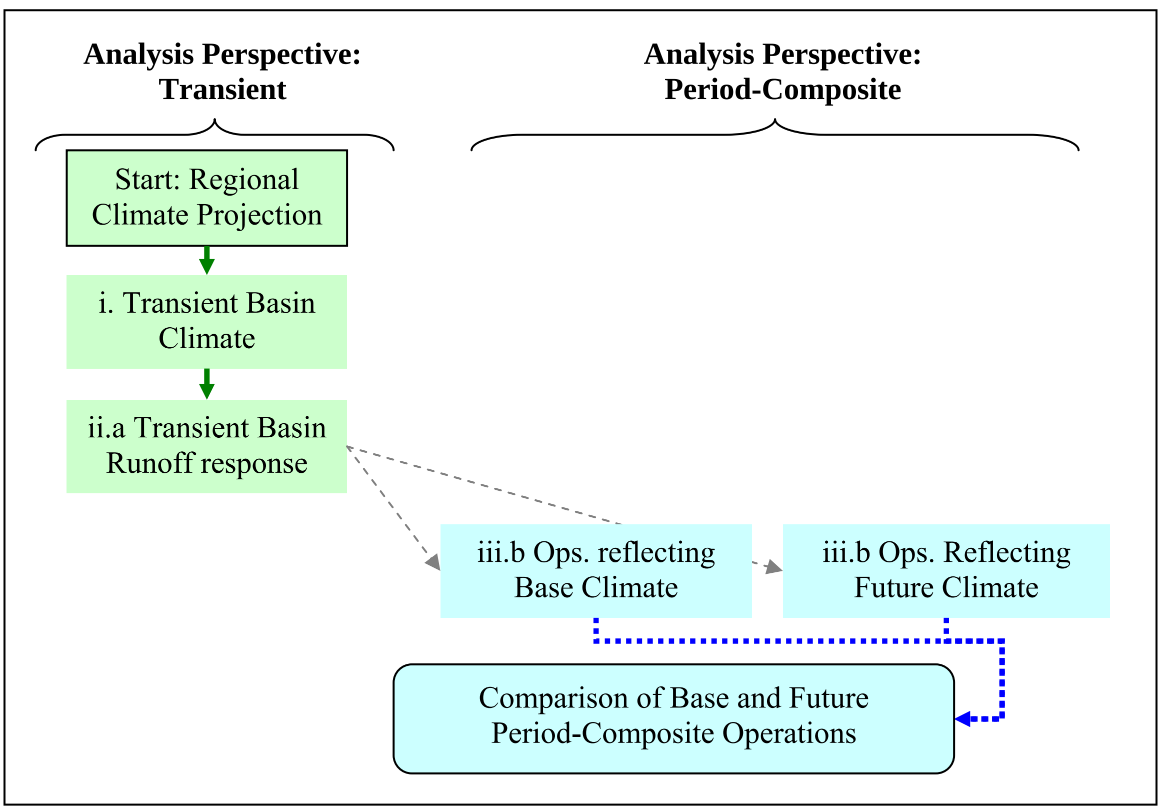
Figure U-19
Example Selection of Options following Christensen and Lettenmaier (2006)



U.7.2.2 Transient Runoff and Period-composite Operations

An example of this type was described in the California Department of Water Resources in their report "Progress on Incorporating Climate Change into Management of California's Water Resources" (CA DWR 2006). In their application, step (ii) reflected similar methods featured in Christensen and Lettenmaier (2006) and Maurer et al. (2007). Specifically, the runoff analysis was conducted using a California Central Valley application of VIC (Van Rheenan et al. 2004), and featured the same methods of preparing climate scenario meteorological inputs for the VIC application as described in Christensen and Lettenmaier (2006). The need to adopt a period-composite perspective for step (iii) was driven by the choice of operations model, which did not easily couple with the VIC application in several respects. For example, the VIC model simulated natural flow but not watershed impairments whereas the operations model simulated decisions relative to impaired river inflows at an interior sub-area of the watershed, located below other reservoir systems at higher elevation. The VIC model simulated natural flow during post-1950 conditions whereas the operations model featured a base inflow sequence coincided with observed weather during 1922-2003 and a study assumption was to continue using that historical sequence to reflect inflow variability. Consequently, rather than attempting to couple the VIC runoff model to the operations model, or adjust the base sequence of the latter, a perspective transition was implemented between steps (ii) and (iii) (Figure U-20).

Figure U-20
Example Selection of Options following CA DWR 2006



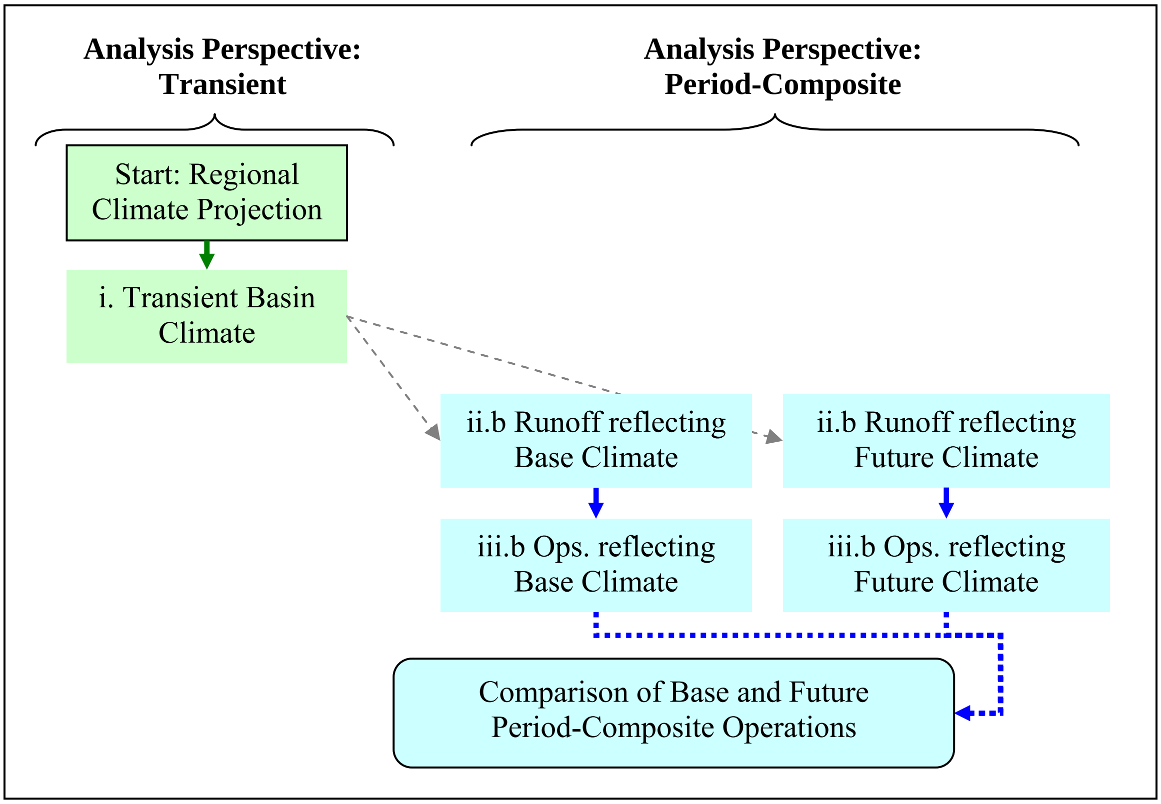
The mechanics of transition occurred using the following steps:

- Adopt "historical" and "future" periods of interest from the simulated runoff time series (CA DWR 2006 reports that simulated runoff during "1961-1990" and "2035-2065" periods were considered).
- Route VIC runoff results during these periods to key system inflow locations of the operations model.
- At each routed runoff location,
  - compute mean monthly runoff during each period.
  - compute month-specific inflow adjustment factors, defined as ratios of runoff, "future" divided by "historical" (i.e. natural runoff sensitivities).
  - adjust the operations model's "base case" inflow time series on a month-specific basis using the inflow adjustment factors. For example, at a given location, if the January ratio of runoff change is 1.2, inflate all January inflows in the operations model's input time series by +20%.
  - As it was applied, it is understood that this approach introduced discrepancy into the analysis since natural runoff responses were used to perturb "impaired" inflows in the operations model. However, such discrepancy may be unavoidable if water management decisions upstream of the operations model's geographic domain are not incorporated or cannot be feasibly incorporated into the operation model.

U.7.2.3 Period-composite Runoff and Operations

An example of this type is illustrated by the sequential analyses outlined in Miller et al. (2003) and Zhu et al. (2005). The operations analysis (step (iii)) by Zhu et al. (2005) follows a period-composite approach, similar to CA DWR 2006. However, the preceding runoff analysis (Miller et al 2003) also follows a period-composite perspective (Figure U-21).

Figure U-21
Example Selection of Options following Miller et al. (2003) and Zhu et al. (2005)



The starting points for the runoff analysis were (a) the simulated "monthly" climate time series over the given basin of interest, and (b) the "observed historical" basin meteorological time series at a 6-hour timestep used to calibrate the runoff model. The spatial resolution of (a) is not compatible with that of (b), requiring GIS data processing to develop monthly climate time series aggregated over the basin area. For example, in Miller et al. (2003), the information in (a) was downscaled during step (i) to a 10-km gridded resolution. These data had to be related to mean area "upper" and mean area "lower" basin areas for which the calibrated model had "observed historical" meteorological inputs. The need for this GIS exercise was set up by choice of runoff model (i.e. lumped basin applications of the Sacramento Soil Moisture Accounting (Burnash et al. 1973) and SNOW17 models (Anderson 1973) developed and provided by the National Weather Service CA-NV River Forecast Center). For these models, (b) consists of mean area "upper" (MAU) and mean area "lower" (MAL) precipitation and temperature observations from 1963-1992.

Given these starting points and a given basin, the transition from the transient to period-composite perspective in Miller et al. (2003) was accomplished as follows:

- Adopt "historical" and "future" periods in the simulated climate time series overlying the basins.

- From the simulated monthly climate time series aggregated to MAU and MAL boundaries, compute mean monthly temperature and precipitation during each period.
  - Compute month-specific shifts in temperature, future minus historical.
  - Compute month-specific ratios of precipitation change, future divided by historical.
- Create a "future period" meteorological input sequence for the given basin's runoff model by adjusting a duplicate version of that model's "observed historical" sequence on a month-specific basis according to mean monthly shift- or ratio-changes in temperature and precipitation, respectively. For example, given a future-minus-base January temperature change of +1.1 °C, all January time-step values in the "observed historical" sequence would be adjusted +1.1 °C. Likewise, for a given future-to-base December precipitation ratio of 1.2, all December time-step values in the "observed historical" precipitation sequence would be scaled 20% higher.

The basin's runoff model is then simulated for both the "historical" and "future" meteorological input sequences, producing runoff output that can be compared to compute monthly inflow adjustment factors as discussed in the preceding method (Section W.6.2.2). Subsequent procedures are unchanged relative to the preceding method.

U.7.3 Analysis Design Considerations

U.7.3.1 Climate Scenario Data Availability

The public and water resource analysts (including those at LC) can access a multitude of GCM "raw output" in the World Climate Research Programme's (WCRP's) Coupled Model Intercomparison Project phase 3 (CMIP3) multi-model dataset, which includes projection-specific datasets that vary by GCM and by greenhouse gas scenario simulated, as discussed in Section W.4. The multi-model dataset has been made available by the Program for Coupled Model Diagnosis and Intercomparison (PCMDI) at Lawrence Livermore National Laboratory (http://wwU-pcmdi.llnl.gov/) and WCRP's Working Group on Coupled Modeling. Support of this dataset is provided by the Office of Science, U.S. Department of Energy.

Projection-specific datasets are at "climate model" resolution, which is too coarse for hydrologic and operations studies conducted by LC analysts. Before such studies can be conducted, it is necessary to bias-correct and spatially downscale the climate model output into distributed climate conditions at more local resolution (Section W.4.2.3). The availability of downscaled climate projection datasets over the Colorado River basin is currently limited. LC might acquire such data through collaboration with research groups currently studying climate impacts in the region (e.g., NOAA-RISA centers at the University of Washington (Climate Impacts Group), University of Arizona (CLIMAS) or Colorado University (Western Water Assessment)). If studies of this nature are envisioned in the future, it might be useful for Reclamation to develop the ability to perform bias-correction and spatial downscaling procedures internally.

U.7.3.2 Choosing a Runoff Model

Runoff model options range from those supporting operational hydrologic forecasting services (e.g., Sacramento-Soil Moisture Accounting and SNOW17 applications (Sac-SMA) developed for Western U.S. basins by the National Weather Service River Forecast Centers) to hydrologic simulation tools used in research (e.g., the Variable Infiltration Capacity macroscale hydrologic model applications developed for various areas in the Western U.S. (e.g., the CA Central Valley application discussed by Maurer et al, 2007; the Columbia-Snake River Basin application discussed by Nijissen et al, 1997; or the Colorado River basin application discussed in Christensen and Lettenmaier, 2006). A common trait among process simulations is that they feature an interplay of lumped and linked watershed characteristics, where watershed processes are simulated in base level units (e.g., mean area upper or lower units in NWS RFC's Sac-SMA applications or regular grid cell units in VIC applications) and runoff between these units is governed by a routing scheme.

Any model option may be suitable as long as it has been well-calibrated in the basin of interest. Model familiarity, model access, and computing requirements are likely to be factors determining which hydrologic model is preferred. Some other distinguishing factors might relate to physical representations in the model. For example, in basins where there is significant elevation variability, a higher spatial resolution model might be able to more accurately show snowpack and snowmelt response to climate change. Likewise, in basins where groundwater baseflow contributes significantly to discharge conditions during low flow months, a model with a better treatment of subsurface hydrology might be preferred.

U.7.3.3 Analyzing Runoff Response Using Statistical Resampling

It has been suggested that step (ii) could be conducted using statistical techniques rather than runoff process simulation. There are several potential motivations for a statistical approach. First, operations analysts may not have easy access or have familiarity with the runoff models and data, particularly if the latter are maintained and operated by a separate agency (e.g., Reclamation operations analysts needing access and familiarity with models and data used by NWS RFC staff). Second, the computational requirements associated with runoff simulation and data handling may be an issue for some project situations. Finally, the step of translating natural runoff simulation response into adjusted "impaired system inflows" of an operation's models may introduce significant error (although this is not a concern for CRSS application, which is forced by natural system inflows; see Section W.3).

It has been proposed that such process modeling could be circumvented if a statistical model can be identified where an historical "inflows like-year" is selected as a function of climate parameters. For example, such a model might relate seasonal runoff volumes to antecedent or coincident season(s) temperature and/or precipitation. If such a model can be rationalized, then it would be possible to force such a model using a simulated climate time series (historical or projected) to determine lookup climate conditions from a historical database of paired climate and inflows data.

An attractive aspect of this approach is that the generated inflow time series complies with both (a) simulated climate conditions, and (b) the observed historical relationship between climate conditions and system inflows. For studies involving operations models that require "impaired system inflow" inputs, this would be an improvement over the process-based approaches to step (ii) featured in Section W.6.2, where natural runoff response to climate change from the runoff process modeling was taken as proxy information for the response of the operations model's impaired inflows.

Other advantages relate to implementation and compatibility with paleoclimate information. The statistical approach would seem to be cheaper and easier to implement, as it does not involve the model setup, or likely the computational and data processing requirements associated with runoff process simulation. It would also seem to offer an easily applied framework for developing "paleo" system inflows, where the observed historical inflows-climate relation is applied with reconstructed time series of paleoclimate conditions to produce paleo-inflows. That said, until the statistical relation between observed historical inflows and climate is established, it is uncertain which paleoclimate indicators would need to be surveyed and whether sufficient indicators could be identified. Nevertheless, paleoclimate reconstructions continue to be developed, and may be applicable to this conceptual framework. For example, summer season temperature reconstructions have been reconstructed from 1600-1983 for the general area of the Upper Colorado River basin (Briffa et al. 1992). A follow up summer season temperature reconstruction for a region just north of the Upper Colorado River basin dating back to 1350 is also under development (Connie Woodhouse, 6 March 2007, *personal communication*).

A potential disadvantage of the statistical approach is that it is limited to the assumption of persisting land cover conditions associated with the observed historical inflows-climate relation. However, runoff process simulations (Sac-SMA or VIC applications) are also limited by the same assumption (discussed in Section W.6.3.3). Additional model development would be required to identify time-changing model calibrations (i.e. model parameterizations) relative to time-changing land cover during the calibration period. It is not certain whether such time-changing model calibrations could be identified.

Another potential disadvantage of the statistical approach is that its application in this context has been less developed than approaches involving runoff process simulation that have been demonstrated in peer-review literature (e.g., Miller et al. 2003, Maurer et al. 2007, Christensen and Lettenmaier 2006). The approach has been primarily developed for shorter-term (seasonal) runoff-projection applications. For example, Regonda et al. (2006) developed a statistical resampling scheme conditioned on climate predictors and applied it to prediction of runoff conditions at multiple sites. Although their prediction look-ahead was only seasonal, the use of climate variables to condition the resampling would seem to be extensible to longer-term look-ahead horizons.

U.7.3.4 Treatment of Evapotranspiration and Land Cover

In many watersheds, the loss of water from the land surface via evapotranspiration (ET) is a significant term in the surface water budget. Treatment of this term in hydrologic process-models tends to vary. For example, in the Sac-SMA applications, evapotranspiration is simulated in response to simulated soil moisture conditions and input potential evapotranspiration demands. The latter demands are area-lumped historical average values that vary with month and day during the calendar year (NWS OHD 2005). In contrast, more recently developed hydrologic models such as VIC simulate evapotranspiration based on input land cover (bare soil to various vegetation classes) and input or derived meteorological forcings (temperature, wind speed, vapor pressure, shortwave radiation, and net longwave radiation).

As temperature and radiation increases, it is reasoned that potential ET would also increase. However, coincident changes in CO_2 (which affects plant stomata response) and other surface radiative variables introduce uncertainties on this ET response. Nevertheless, if process-simulation is selected for the runoff response analysis to climate change, it would seem that the more dynamic ET simulations of recently developed hydrologic models (e.g., VIC) would be preferred for capturing dynamic ET responses to meteorological changes. If the statistical approach of Section W.6.3.2 is selected, such dynamic ET responses would be implicitly represented when statistically selecting runoff conditions based on associated climate conditions.

When discussing natural ET response to climate change, it is also relevant to discuss potential land cover changes since the landscape composition also determines watershed ET. Most available hydrologic model applications (Sac-SMA, VIC, or otherwise) treat land cover as a static condition during model development and scenario simulation. In other words, while historical period climate and runoff observations are used to calibrate hydrologic process parameters (e.g., during 1960-2000), the coincidental land cover conditions in the watershed are either period-averaged or assumed to equal a recent land cover survey. The latter assumption is likely incorrect, understanding land cover has always evolved and will likely continue to do so in the future. This raises issues for step (ii) in the analytical sequence, whether it is done with process simulation or through the statistical concept of Section W.6.3.2. That said, land cover issues may be of secondary significance in simulation of seasonal-to-annual inflows, given that models like VIC have been used to explain a considerable majority of annual flow variance (Andrew Wood, 25 May 2007, *personal communication*).

Drivers of land cover change range from societal to natural. Our capabilities to project land cover in response to societal changes have received more research attention. For example, projections for Western U.S. land cover have been developed for the year 2040, and reflect an expectation that urban areas will occupy a greater proportion of the Western U.S. landscape during the coming decades (Travis et al. 2005). Capabilities in projecting land cover response to natural changes are less developed, but there have been attempts in recent years. For example, coarse models have been developed that simulate vegetation succession in response to climate change (Bachelet et al. 2001). Other studies have been conducted on potential vegetation responses to changes in atmospheric gases composition (Iverson and Prasad 2001; other references in the U.S. National Assessment of The Potential Consequences of Climate Variability and Change – Sector: Forests (USGCRP 2000)). However, questions remain surrounding land cover response to climate change, related to characterizing land-cover dynamics, drivers behind those dynamics, and the interactions between societal change, climate change, and land-cover dynamics (USCCSP 2003).

U.7.3.5 Treatment of Groundwater and Surface Water Interactions

Rivers and groundwater are intimately connected. That said, typical methods for studying runoff response to climate change (e.g., studies cited in Sections W.5 and W.6) have not featured direct simulation of groundwater response to surface climate changes. Ideally, analysis of surface water response to climate change would be performed with knowledge of how groundwater coincidentally responds, both in terms of migration and spatial/temporal distributions of aquifer stock. In contrast, typical methods for assessing runoff response to climate change feature use of models where groundwater interactions with surface water are more implied than prescribed.

Several areas of research must be advanced further in order to permit more definitive messages about how natural runoff will respond to climate change in the context of coincidental groundwater response. It will be necessary to understand the entire recharge process and its response to climate change. This in turn will require better understanding of groundwater recharge and movement at scales relevant to regional runoff analysis, and in turn require understanding on the aggregate process of mountain block recharge (K. Redmond, 2 June 2007, *personal communication*). Further, the role of root zone and riparian vegetation in mitigating this interaction will have to be better understood, which segues into questions already posed in Section W.6.3.4 about on how basin land cover and natural evapotranspirative demand will respond to climate change.

U.7.3.6 Treatment of Future Precipitation Assumptions

Current capabilities in projecting regional precipitation response to global climate change are limited. As discussed in Section W.4, raw GCM simulations of precipitation will likely put the precipitation in the wrong places, perhaps at the wrong time, and with wrong amounts. Bias-correction and spatial downscaling can be used to remove regional GCM biases (Section W.4.2.3). However, such data-processing does not provide more reliable information or increase confidence in a particular GCM scenario for climate change.

For planning studies, the problem with GCM-simulated precipitation projections is a matter of how to regard the data rather than how to use the data. Methods on how to use the data have been developed (Sections W.4.2.3 and W.6.2). The problem is that the variation among GCM-simulated precipitation projections can be quite broad for a given study region (e.g., Figure U-9a, b showing greater than +/- 50% change intervals for annual average precipitation over the Colorado River basin). Notably, a paradigm does exist suggesting that global precipitation should increase in response to global warming because increased temperatures cause a net-global increase in evaporation and subsequently precipitation. However, at a regional scale, there's no established paradigm suggesting *direction* or *limit* of precipitation change. Such a paradigm would have to factor in a multitude of drivers that affect the regional surface climate (e.g., for the

Colorado River basin: the influence of climate change on North Pacific storm track position, North American monsoon, tropical pacific variability related to ENSO, and other interannual/interdecadal climate phenomena that will be presented in Section W.8).

This issue is significant when conducting water management impacts analyses for storage-rich systems like the Colorado River basin. Storage-rich systems are sensitive to trends in mean-annual precipitation and runoff, more so than to changes in seasonal runoff patterns. An impact assessment conducted on such a system would produce a range of impacts significantly influenced by the range of precipitation changes considered (presumably from GCM results). Given that GCM-based precipitation changes can vary considerably (Figure U-9a, b) and may not exhibit consensus towards wetter or drier (Figure U-9a, b), some critical thought is invited as to whether the precipitation projections should be considered altogether at this stage in impacts study.

An alternative path forward might involve focus on only the more reliable aspects stemming from GCM-simulated climate projections (i.e. temperature changes), and combining this focus with either an assumption of no precipitation change or precipitation variability from some period of the observed or paleo-past (see Section W.7). Using this approach, any of the method options presented in Section W.6.2 could still be implemented, but instead with consideration limited to only GCM temperature projections and alternative methods used for defining future precipitation.

U.7.4 Potential Analysis Designs using Reclamation's CRSS

This section explores potential analytical designs that LC staff might consider, combining the use of LC's operations model, CRSS (Section W.3), with the method options discussed in Sections W.6.2 and W.6.3.

U.7.4.1 Transient Runoff and Period-composite Operations

This design would be similar to that implemented by CA DWR (2006), and illustrated in Figure U-21. It is assumed that the LC study might involve exploring how simulated operations are sensitive to a climate assumption (e.g., base versus future), or how operations alternatives vary under an assumed climate change scenario. The study might begin with selection of one or more of the scenarios and natural runoff simulation datasets recently documented in Christensen and Lettenmaier (2006). Scenario selections are subjective (e.g., choice of lower and higher rate-of-warming scenarios). CRSS inflow data preparations would follow, beginning with selection of "historical" and "future" climate periods. The results would be examined from a "period-composite" perspective, computing monthly mean runoff conditions near CRSS inflow locations during both "historical" and "future" periods. Ratios of monthly mean runoff would be computed, future relative to base period values, and be used as monthly runoff adjustment factors to scale the historical CRSS system inflows (month by month) into a future set of system inflows, reflecting observed inflow variability with means reflecting future climate.

Before developing the monthly runoff adjustment factors, the runoff datasets may need to be post-processed to report routed runoff at CRSS system inflow locations, and it may be necessary to bias-correct the routed natural runoff time series at these locations as it is possible that the modeled-historical and observed-historical natural runoff during the common historical overlap period will be different. A "distribution mapping" method could be used, similar to that discussed in section W.4.2.3 as it is used to bias-correct climate simulations (Wood et al, 2004).

U.7.4.2 Transient Runoff and Operations

This design is similar to the preceding design in that it uses the same starting points and potentially involves runoff-routing and bias-correction procedures during procedures to prepared CRSS inflow datasets. The only difference is that rather than adopt a period-composite perspective when relating Christensen and Lettenmaier (2006) runoff data to CRSS system inflows, a transient perspective is adopted instead. The time series of climate-scenario simulated runoff are routed to CRSS inflow locations (potentially bias-corrected) and used directly to force the CRSS simulation. This would permit the CRSS simulation to show how operations would evolving under evolving runoff conditions associated with the given climate scenario.

U.7.4.3 Transient Runoff and Operations with Statistical Runoff Analysis

This design would be similar to the preceding design, except that the transient runoff information under a given climate scenario would not be produced using hydrologic process simulation. Instead, statistical resampling schemes based on historical relations between observed inflows and climate variables, and driven by projected conditions for the climate variables, could be utilized to develop climate-scenario CRSS system inflows. The scenario starting points from the two preceding designs might be used here, aggregated into annual or monthly climate variable time series as required by the statistical resampling scheme. Generation of system inflows at the various CRSS inflow locations might be performed in direct relation to the climate conditions, or through an intermediate step of first relating the basin climate to Lees Ferry flow and then disaggregating spatially and temporally using procedures discussed in Prairie et al. (2007).

U.7.5 Potential Approach to First-Order Sensitivity Analysis for Near-Term Studies

For studies and decisions concerned with longer-term look-ahead horizons (e.g., greater than 20-years) and undergoing evaluation on the near-term, a *first-order* quantitative sensitivity analysis might be conducted on operations response to projected climate change. Such analysis would ideally reveal the significance of assumed climate in determining study results and informing decisions. Given Reclamation's current limited ability to easily conduct internally produced simulations of runoff response to climate change in the CRB, such near-term studies might be framed using literature-reported projections of climate <u>and</u> related runoff response.

For such studies evaluated on the near-term, it is recommended that scoping of sensitivity analysis begin with a "filtered" consideration of available literature. Rather than try to frame the analysis on all climate change and runoff impacts studies that have been conducted for the CRB (e.g., representing all studies listed in Table U-3), it is recommended that the following criteria be adopted to focus the analysis:

1) require that scenario climate change projections reflect the latest IPCC assessment on future greenhouse gas emissions pathways and climate science (i.e. the Fourth Assessment Report (AR4) from the IPCC (2007))

2) require that scenario climate change projections be produced by GCMs referenced in the latest IPCC assessment (i.e. coupled atmosphere-ocean GCMs listed in Table U-7 in IPCC (2007) report from Working Group 1, “The Physical Basis for Climate Change”).

3) require that an ensemble of GCM projections be considered, representing the range of available GCMs and future emission pathways reported by IPCC, and permitting consideration of uncertain climate change over the CRB and how that translates into uncertain runoff response.

4) require that GCM *projection* data be bias-corrected over the Colorado River Basin (CRB), accounting for GCM tendencies to be warmer, cooler, wetter, or drier when used to simulate 20th century (Section W.4.2.3.2, W.6.1).

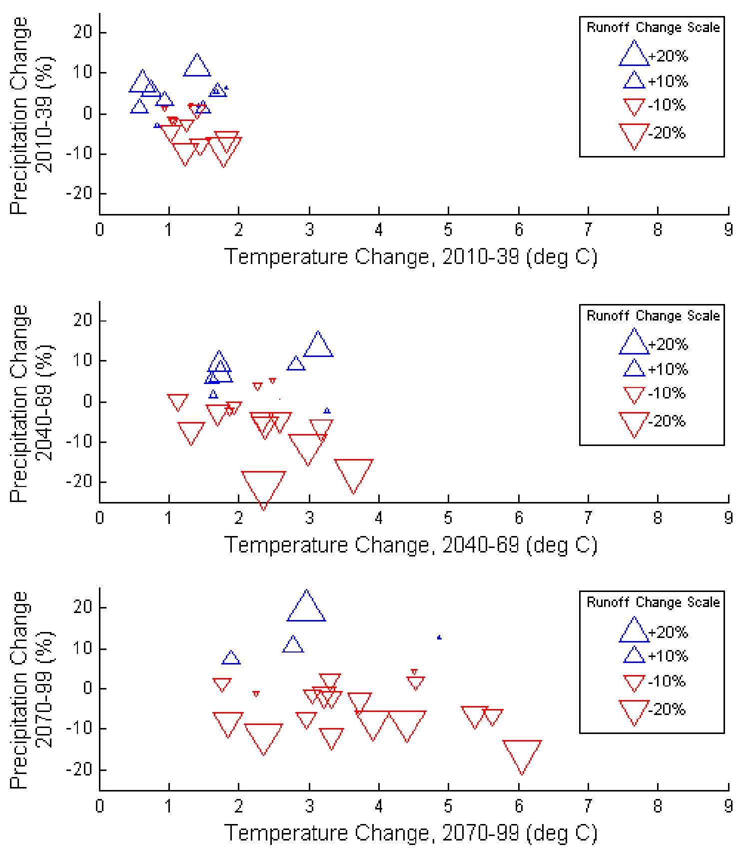
5) require that *bias-corrected GCM projection* data be spatially downscaled over the CRB, preserving larger- to smaller-scale climatic relations, and permitting more disaggregate consideration of runoff response to climate change distributed over the basin.

6) require that *bias-corrected and spatially downscaled (BCSD) GCM projection* data be translated into natural runoff response using a peer-reviewed methodologies.

Criteria 1 and 2 are meant to steer attention to the most recent understanding of climate change science and implications for the CRB. Criterion 3 recognizes that a survey of BCSD climate projections over CRB, representing multiple GCMs and emissions pathways, can reveal uncertainties of temperature and precipitation change as well as associated runoff change. Criterion 4 is based on the philosophy that simply starting from a multi-GCM projection ensemble is not sufficient, and that GCM-specific datasets should be adjusted to reflect the given GCM’s tendencies to give biased climate information (i.e. revealing how the given GCM has a tendency to be too wet, dry, cool or warm when simulating past conditions). Criterion 5 is based on the philosophy that studies consider spatially distributed climate change within the CRB are better prepared to indicate spatially distributed impacts to runoff, and how these impacts aggregate to upper basin inflow to the lower basin. And finally, criterion 6 recognizes that a philosophy that literature information framing these studies should have undergone peer-review within the scientific community and that use of multiple methodologies may be appropriate to reflect model uncertainty. As for the tool choice for modeling runoff response, options exist for using statistical or process simulation. Statistical modeling may have merit in its relative ease of implementation. Physical process simulation may offer more transparent accounting of how basin-distributed climate change impacts distributed runoff, soil moisture, and evapotranspiration, as well as how evapotranspiration interacts with computed soil moisture and climate forcing conditions.

Applying these criteria to the studies mentioned in Table U-3 leads to focus on the climate scenarios and runoff changes reported in Christensen & Lettenmaier (2006) (Figure U-22). Using this information to illustrate climate and runoff change scenarios, the next recommended step is to choose a projection period relevant to the management decision being informed by the operations study. For example, the purpose of the study may be to inform evaluation of how scenario operations affect other basin resources several decades from the present (e.g., Figure U-22, top panel showing changes for early 21st Century), or how scenario operations might translate into economic value during an even longer term service life (e.g., Figure U-22, middle and bottom panels, showing changes for middle and late 21st Century).

Figure U-22
Data from Christensen and Lettenmaier (2006), (Appendices A1 and A2) Change in 30-Year Mean Annual Runoff (%) from Historical (1950-1999), Given 22 Projections of Mean-Annual Climate Change Over the CRB, Sampled for Three Future Periods: 2010-39, 2040-69, and 2070-99



The 22 projections were simulated by 11 GCMs, each simulating either SRES A2 and B1 greenhouse gas emissions.

After filtering the literature information by the projection period of interest, the next step might involve characterizing distributional aspects of period-mean climate and runoff across projections considered in the literature (Figures U-23 through U-25). This step focuses attention on change in mean annual runoff as it relates to underlying scenarios of climate change. Change in *runoff seasonality* or *variability* is not the focus in this example, which may be appropriate for CRB studies that depend on assumptions of aggregate upper CRB runoff into Lake Powell, which is more sensitive to trend in mean annual runoff than trend in runoff seasonality.

Figure U-23
Histogram and Box-and-Whisker Distributions of 2010-39 Precipitation Change relative to Historical (1950-1999) Corresponding to Scenarios Represented on Figure U-23

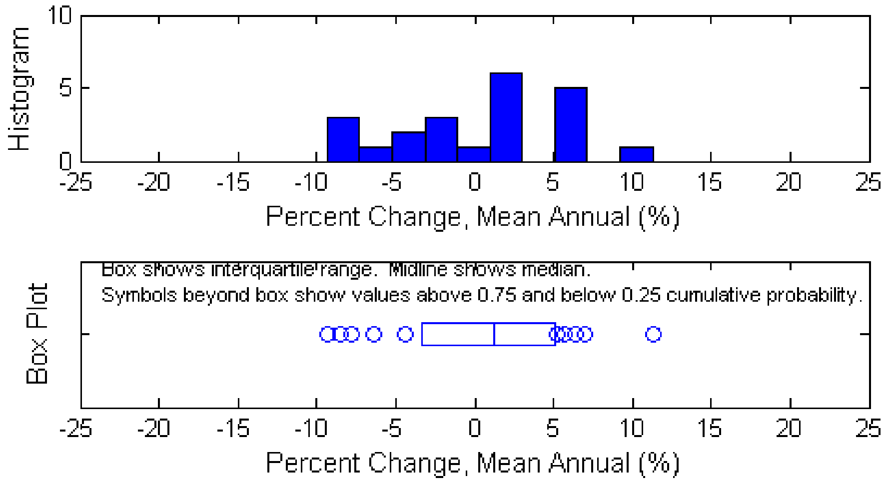


Figure U-24
Histogram and Box-and-Whisker Distributions of 2010-39 Temperature Change Relative to Historical (1950-1999) Corresponding to Scenarios Represented on Figure U-23

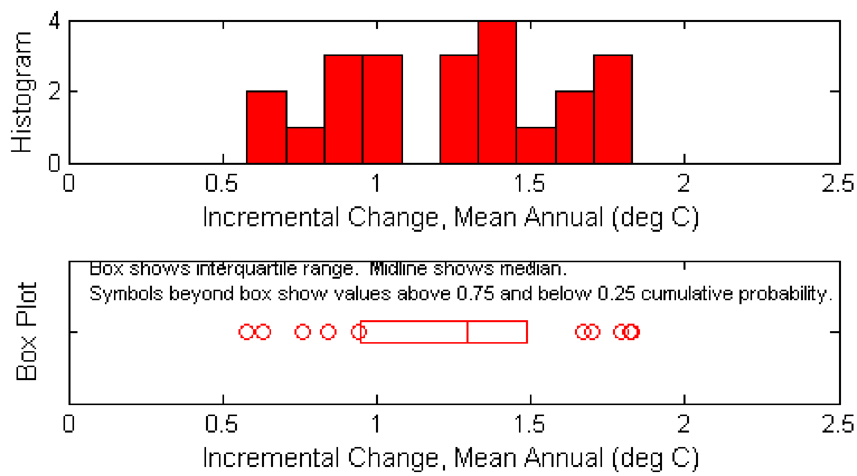

Figure U-25
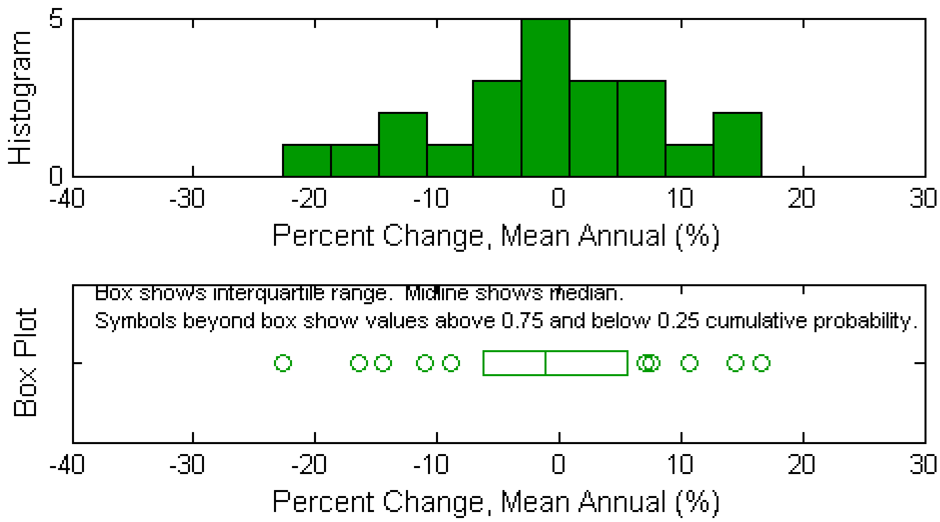
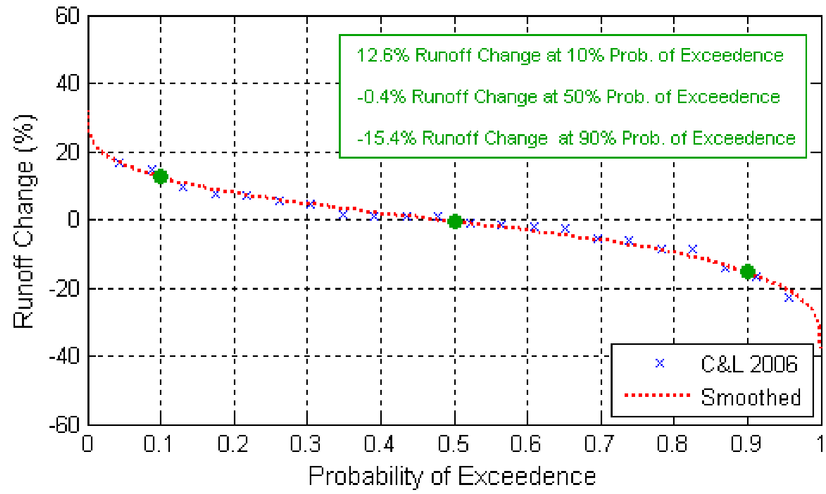
Histogram and Box-and-Whisker Distributions of 2010-39 Runoff Change relative to Historical (1950-1999) corresponding to Scenarios represented on Figure U-23



After identifying these period-mean changes, the final step in setting up the sensitivity analysis is to construct a (optionally smoothed) empirical distribution of period mean-annual runoff change (Figure U-26), and adopting "risk-perspective" threshold for sampling runoff change from the smoothed empirical distribution. On this latter step, a risk-neutral decision-maker might focus on median projected change in the distribution. A risk-averse decision-maker might focus on temperature change exceeded by only 10 percent of the projections, or precipitation change exceeded by 90 percent of the projections. Upon identifying threshold annual runoff changes, sensitivity analyses could be conducted where CRSS monthly inflows (Section W.3.1) are scaled by threshold scenario changes in period mean-annual runoff.

Figure U-26
Smoothed Empirical Distribution of 2010-39 Runoff Change (%) Relative to Historical (1950-1999), Fit to Scenario Runoff Changes Shown on Figure U-26 (labeled here as C&L 2006)



Three example thresholds of runoff change are shown (green circles), as sampled from the Smoothed Empirical Distribution, where smoothing was accomplished by fitting a nonparametric density function to the 22 cases fitting cases (C&L 2006). (Note: "Probability of Exceedence" in this case represents *relative* probability based on surveyed projections and runoff analyses, not *absolute* probability.)

U.7.6 Uncertainties

The process of relating projected climate change to operations response involves a number of uncertainties introduced by the methods outlined above. These uncertainties interact with those discussed in Chapter 4.0 concerning development of downscaled climate projections and simulated climate time series. Some key uncertainties associated with analyzing runoff and operations response include:

- Assumptions on how to convert simulated climate time series into a meteorological input sequence for runoff analysis. For process-simulation, this can involve temporal disaggregation and variable extrapolation depending on the hydrologic model used.

- Assumption on where to make the perspective transition from transient to period-composite (e.g., before step [ii], before step [iii], or after step [iii]).

- Assumptions on how to structure the hydrologic model used in the analysis, with suitability of structure indicated by model skill and calibration metrics produced during model development (e.g., the ability to reproduce observed runoff given observed weather conditions).

- Assumptions for relating climate change responses in natural runoff to adjusted "impaired system inflows" in operations analysis.

- ♦ Assumptions on how to structure the operations model used in the analysis, indicated by model verification efforts (e.g., the ability to approximate real-life decisions occurring on variable daily to weekly time-scales in the context of a decision model with a uniform daily or monthly time-scale).

- ♦ Assumptions on how to represent system operations within the operations model under a changing climate, understanding that climate changes may trigger different operational strategies and discretionary operational "rules" not present in the "present climate" rendition of the operations model.

- ♦ Assumptions that historical land covers underlying both runoff and operations model development will represent future period land cover, and that historical relations between the meteorological forcings and runoff will persist.

U.8 Paleoclimatic Information for the Colorado River Basin

With the growing recognition of the inadequacy of the gaged record as a baseline for planning, the use of paleoclimatic data has received increased interest in the water resources profession. Previous sections of this report (W.3.4.2. and W.3.4.4.) described the use of paleoclimatic data in Reclamation hydrologic analyses, capitalizing on the extended perspective on past hydrology provided by these data. In addition to "looking back" up to 500 years or more, there is potential for using these data to look forward and evaluate potential future hydrologic scenarios. This section summarizes the state of science for paleoclimatic information in the Colorado River basin and how this might be used with future climate projections.

U.8.1 Paleoclimate Indicators of Hydrology in the Colorado River basin

Paleoclimatic data from environmental records can be used to extend instrumental records back in time. Tree rings are the best source of high resolution, precisely-dated proxy records of hydroclimatology over the past centuries, and they have proven useful for reconstructing a range of hydroclimatic variables, including temperature, precipitation, and streamflow (Meko and Woodhouse, 2007). In the Upper Colorado River basin, tree-ring data have been used to reconstruct streamflow over the past five centuries and longer using dendrochronological techniques.

Research exploring the relationships between annual streamflow and tree growth began in the 1940s with Edmond Schulman whose early work investigated the feasibility of tree rings as a proxy for streamflow. He was motivated, in part, by the need for an extended record of Colorado River flow to assess the reliability of long term power generation, addressed in a 1942 report he authored for the Los Angeles Bureau of Power and Light entitled "A tree-ring history of runoff of the Colorado River, 1366-1941" (Schulman 1945, Stockton and Jacoby (1976). Later work expanded upon this (Schulman 1945, 1951, 1956).

The first reconstructions for the Colorado River based on a statistical calibration of tree-ring data with the natural flow records were undertaken by Stockton in 1975, and updated with additional tree-ring data by Stockton and Jacoby in 1976. Stockton and Jacoby (1976) generated three versions of a Lees Ferry reconstruction, based on two different gage records.

They considered an average of the two reconstructions based on the common time period 1914 to 1961 to be the most reliable estimate of past flow. This reconstruction, which extended from 1521-1961, was the basis for a set of multidisciplinary studies that assessed the impacts of a severe sustained drought on hydrologic, social, and economic impacts sectors (Young 1995 and others). Two more recent studies used similar sets of tree-ring data (all with the common tree-ring end date in the early 1960s) but different statistical approaches to reconstruct Lees Ferry flow. These resulted in reconstructions that shared the main features of Stockton and Jacoby's reconstruction but varied with regard to the magnitude of the high and low flows (Michaelsen et al. 1990, Hidalgo et al. 2000). (See Table U-6 for a summary)

Woodhouse et al. (2006) used an updated and expanded set of tree-ring data and a variety of data treatment and reconstruction approaches to reconstruct Lees Ferry flows extending from 1490-1997. Most recently, Meko et al. (2007) expanded the work of Woodhouse et al. (2006) to extend the reconstruction of Lees Ferry flow back to AD 762 using remnant material (stumps, logs, and standing dead trees) along with living tree chronologies using a nested reconstruction approach (See Figure U-27). This reconstruction, which extends seven centuries prior to any of the previous reconstructions, allows the first assessment of Colorado River flows during a period of time known as the Medieval Climate Anomaly (e.g., Cook et al, 2004). During this period, approximately AD 900-1300, the reconstruction documents a period of sustained low flow in the 1100s that includes a stretch of 62 years with a marked absence of any high flow years.

This set of reconstructions illustrates the robustness of the estimated flows with regard to the temporal pattern of flow over the past five centuries. One difference between the reconstructions is the long-term averages, which range from 13.0-14.7 maf, all of which are significantly less than the gage records average, 1906-1995, 15.2 maf.

U.8.1.1 Scientific Basis and Methodology

Tree-ring based reconstructions of Colorado River flow build upon the strong association between the annual ring widths of low elevation conifer species, (primarily *pinus ponderosa, pinus edulis,* and *pseudotsuga menzeseii*) and water year streamflow (Schulman 1956, Hidalgo et al. 2001). These conifers, particularly those growing on arid slopes with rocky soils, are sensitive to the same climate conditions that contribute to water year flows, primarily winter snowpack, but also precipitation and evapotranspiration over the course of the water year streamflow (for more detailed discussions on tree growth and streamflow, see Meko et al. 1995). In the field, careful site selection and sample replication (about 20 trees per site are cored, taking two cores per tree) further enhance the common signal, related to hydroclimatic variability, in the trees.

Table U-6
Summary of Lees Ferry Reconstructions

Reconstruction	Calibration years	Source of gauge data	Chronology type[c]	Regression approach[d]	Variance explained	Reconstruction years	Long-term mean[e] MAF
Stockton and Jacoby (1976)	a.1899-1961	Hely, 1969	Standard	PCA with lagged predictors	0.75	1512-1961	14.15
	b.1914-1961	Hely, 1969	Standard		0.78	1512-1961	13.9
	c.1914-1961	UCRSFIG, 1971	Standard		0.87	1511-1961	13.0
	Average of b and c					1520-1961	13.4
Michealsen et al. (1990)	1906-1962	Simulated flows[a]	Residual	Best subsets	0.83	1568-1962	13.8
Hidalgo et al. (2000)	1914-1962	USBR, see Hidalgo et al. 2000	Standard	Alt. PCA with lagged predictors	0.82	1493-1962	13.0
Woodhouse et al. (2006)							
Lees-A	1906-1995	USBR[b]	Residual	Stepwise	0.81	1490-1997	14.7
Lees-B	1906-1995		Standard	Stepwise	0.84	1490-1997	14.5
Lees-C	1906-1995		Residual	PCA	0.72	1490-1997	14.6
Lees-D	1906-1995		Standard	PCA	0.77	1490-1997	14.1
Meko et al. (2007)	1906-2003	USBR[b]	Residual	2-step regression with PCA	0.60	762-2003	14.7[f]
	1906-2002				0.74	1182-2002	
	1906-2002				0.77	1365-2002	
	1906-2004				0.57	1473-2005	

NOTES:

[a] Simulated flows developed from the U.S. Bureau of Reclamation's Colorado River Simulation System.

[b] J. Prairie, USBR, personal communication, 2004 (Woodhouse et al,), 2006 (Meko et al).

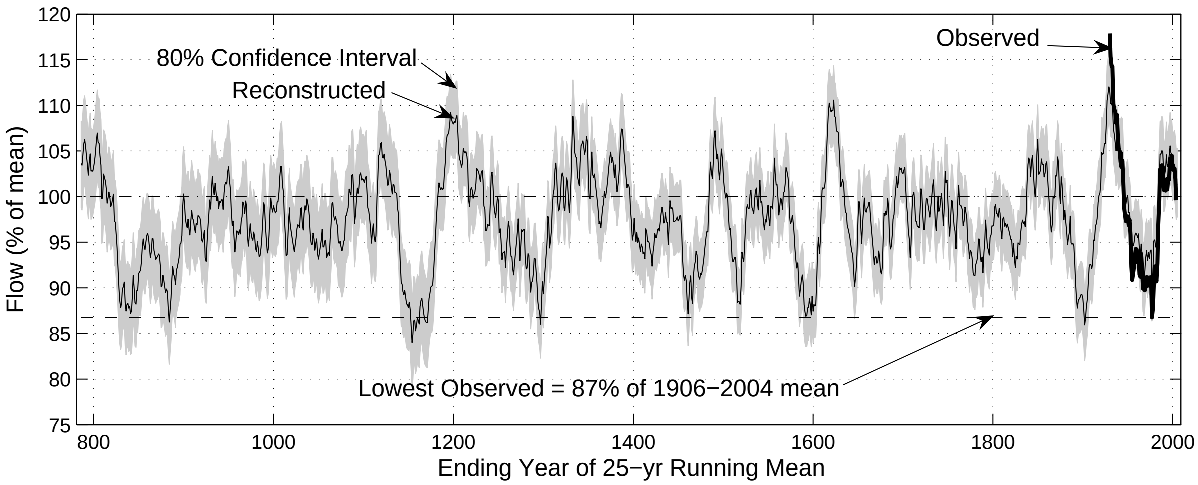
[c] Standard chronologies contain low order autocorrelation related to biological persistence; residual chronologies have been prewhitened and contain no low order autocorrelation.

[d] Regression approach: PCA is principle components regression. Best subsets is multiple linear regression, using Mallow's Cp to select best subset. Alternative PCA used an algorithm find the best subset of predictors on which to perform PCA for regression. Stepwise is forward stepwise regression.

[e] Long-term mean based on 1568-1961 except for Michaelsen et al., 1990, based on 1568-1962

[f] Long-term mean is from full nested reconstruction

Figure U-27
Reconstruction of Lees Ferry streamflow from Meko et al., 2007



A tree-ring chronology, which is derived from the average of the dated, measured, and standardized (to remove age/size related trends) tree-ring samples from a single site (Cook and Kairiukstis, 1990; Stokes and Smiley, 1968), is the basic unit used for streamflow reconstructions. Chronologies often contain significant low order autocorrelation, believed to be at least partially biological in origin, which may be removed through autoregressive modeling (chronologies with this persistence removed are residual chronologies, while those with persistence retained are standard chronologies). Tree-ring chronologies, which have been screened for a stable and significant relationship with streamflow, are calibrated with a natural flow record, typically using some type of multiple linear regression (see Loaciga et al., 1993 for a review of these approaches). Models generated through the calibration process are validated with independent data withheld from the calibration or through cross-validation, which tests the skill of the set of chronologies used rather than the specific model. Models are also evaluated to ensure results meet the assumptions of multiple linear regression.

A number of preliminary models may be generated using different data treatments (e.g., removal of persistence or not), different sets of predictor chronologies, and/or different regression approaches. The final model is selected on the basis of the amount of variance explained and the validation results. The full reconstruction is produced by applying the full-length chronologies to the selected regression equation.

U.8.1.2 Uncertainties

Uncertainty is inherent in the reconstruction because the tree-ring data are not perfect predictors of streamflow. The model uncertainty is the unexplained variance, and error bars for the reconstruction can be estimated from the average difference between the gage and estimated values. Model uncertainty is only one source of uncertainty. Other sources can come from changes in tree-ring sample size with time, the set of chronologies used as potential predictors, data treatment (including standardization which affects the preservation of low frequency information), modeling choices, the calibration period used, and the quality of the gage record. Uncertainty related to changes in tree-ring sample size over time can be reduced by truncating series when the strength of the common signal in the samples reaches a threshold, commonly 85%. The sensitivity of the reconstruction to data treatment, modeling choices, and calibration period can be assessed by comparing reconstructions generated in different ways (for an example of this, see Woodhouse et al. 2006, who evaluated reconstructions generated with different pools of chronologies, standard and residual chronologies, and stepwise and principle components regression). In addition, reconstructed flows that are higher or lower than the range of values in the gauge record may be based on tree-ring values beyond the "predictor space" on which the model is based and are thus potentially less reliable than other reconstructed values (Graumlich and Brubaker, 1986; Meko and Graybill, 1995; Meko et al., 1995).

U.8.1.3 Data Availability

Tree-ring data used in the reconstructions of the Colorado River at Lees Ferry are available through the National Climatic Data Center, Paleoclimatology Branch, International Tree-Ring Data Bank (http://www.ncdc.noaa.gov/paleo/treering.html) in both uncompiled ring width measurement files and the tree-ring chronologies. The reconstructions of Lees Ferry from Stockton and Jacoby (1976),Woodhouse et al. (2006), and Meko et al. (2007) are also archived in the NCDC Paleoclimatology Branch and are available online (http://www.ncdc.noaa.gov/paleo/recons.html#hydro).

U.8.2 Applications of Streamflow Reconstructions to Water Resource Management

Tree-ring based reconstructions of streamflow are being applied in a variety of ways to water resource management. These approaches correspond well to Ray's (2004) categorization of four types of use of climatic information: *consulted*, when information is received or looked up; *considere*d, when information is potentially influential to decisions; *incorporated*, when information is actually used in an operational model for decision-making; and *communication of risk*, when the information and its implications are conveyed to others to prompt or justify action. For example, the Denver Water Board is incorporating reconstructed streamflow data into their water system model to test the ability of the system to meet demands during a broad range of conditions. They have found that the most severe drought in the reconstruction would require level 4 conservation measures. At the other end of the spectrum, the Rio Grande Water Conservation District is still in the process of considering the information provided by the reconstruction, and this information may yet become a part of their decision-making process in assessing sustainable pumping. Other water providers are using the information to advise planning and prompt boards to recognize the potential risks of drought, based on the record of the past (Woodhouse and Lukas 2006).

Paleohydrologic reconstructions from tree rings provide a record of long-term natural variability, with a broader range of values, especially with regard to drought characteristics, than provided by the gage record alone. In addition, these reconstructions provide a richer variety of sequences of annual flows, that include a greater persistence of below or near average years than in the gage records, that particularly test water supply systems. Although the climate of the past is unlikely to be replicated in the future, there is no reason to believe that the range of variability and sequences that have occurred in the past could not recur in the future. The latest IPCC reports a widespread increase in extreme precipitation events and increases in evaporation across many areas of the U.S., along with drier conditions in the Southwest in the future (Christensen et al. 2007). Taken together, these conditions may lead to a broader range of hydroclimatic variability, in which case, the extended records of flow provide a useful analogue for future variability. Consequently, this information can play an important role in helping to anticipate the nature of future droughts.

Reclamation, recognizing that the gage record contains only a subset of the flow conditions that have occurred in the past, is utilizing the reconstructions of Colorado River at Lees Ferry in modeling studies of the Colorado River system. In one case, the broader variety of sequences of flow years in the reconstructed flow record, including longer dry spells, is being incorporated into model input (see section W.3.4.2). In another approach, the full range of reconstructed values as well as the sequences of flow are being used in the modeling (see section W.3.4.4.).

The low frequency (decadal to multidecadal) characteristics in the tree-ring based reconstructions, which represent long-term natural variability, may be exploited to project future flows. For example, Kwon et al. (2007) used spectral analysis to define dominant spectral peaks in reconstructions for southern Florida, and then extracted these using wavelet analysis. The spectral information was then combined with simulated flow projections based on the autocorrelation structure in the reconstructions to generate scenarios of future flows. This approach assumes that the underlying low frequency variability in the past flows will continue into the future, but as of yet, there is no reason to believe this is will not persist.

With regard to climate change projections, experiments that utilized tree-ring based reconstructions to run water supply models which are then altered to simulate warming are being performed (Smith et al. 2007). Incremental warming is added to test the ability of a water supply system to meet demands (in this case, the City of Boulder system). Increases are then compared to those projected for the region from range of general circulation models (GCMs). This approach utilizes the broader range of hydroclimatic variability that has occurred in the past and is likely to occur in the future, along with the certain increase in temperature due to the human-induced global warming. To date, models are not yet able to replicate regional precipitation very well, and model projections of the regional precipitation response to global warming are inconsistent. Consequently, combining the variability in the paleohydrologic records with the more certain future warming seems to be a productive approach for assessing possible future scenarios.

Seager et al. (2007) argue that model results indicate a consensus that a warmer climate will cause a general aridification of southwestern North America. Seager et al. hold that periodic droughts will still occur, precipitated by oscillations in climate conditions, but these will be perturbing a drier base state (See discussion in Section W.4.4.2). Seager et al.'s work provides support for using paleohydrologic reconstructions of streamflow as a proxy for the pattern of future inflows. Their notion that a drier base state will continue to be modulated by droughts caused by climate oscillations supports an assumption that the variability in streamflow captured by the paleohydrologic record can be used (with caution) as one proxy for the variability of future flows. Thus, an approach like the non-parametric paleo-conditioned method (NPC, described in Section W.3.4.2) could be adapted to synthesize streamflow data consistent with Seager et al.'s conclusions by scaling the flows to reflect the drier base state he projects will occur. Seager et al. estimate that precipitation minus evaporation (P-E) will decrease approximately 10% by the 2060-2080 timeframe. This is in the middle of the range of changes to streamflow projected by others, as summarized in Section W.5, and lends support to changes in streamflow of that magnitude.

U.9 Interannual/Interdecadal Climate Variability

There is an increasing awareness that in addition to gradual changes (long-term trends) in climate conditions, there is also a large degree of interannual and interdecadal variability in climate which may dominate the climate experienced in a basin in the short term (10-20 years in the future). This section describes the major modes of interannual/interdecadal variability, summarizes studies that have linked these to hydrologic variability in the Colorado River basin, and discuss the predictability of these phenomena.

U.9.1 Description of Major Modes of Climate Variability

The identification of major modes of interannual/interdecadal climate variability has been an ongoing area of research. Currently the NOAA Earth System Research Laboratory at (http://www.cdc.noaa.gov/ClimateIndices/List/) archives a wide range of climate indices representing oceanic and atmospheric variability. The major modes of interannual/interdecadal climate variability that have been investigated for possible linkages in the Colorado River Basin include the El Niño-Southern Oscillation (ENSO); the Pacific Decadal Oscillation (PDO); the Atlantic Multidecadal Oscillation (AMO); the Pacific North America, and the North Atlantic Oscillation (NAO). These phenomena have frequencies that vary from 2-80 years. Other climate indices may be significantly correlated with Colorado River Basin hydrology; however, there have not been studies to document these linkages.

ENSO is a contraction of names of two phenomena that were recognized to be different expressions of the same process: "El Niño" refers to anomalous strong warming of the surface waters of the eastern equatorial Pacific Ocean, while "Southern Oscillation" refers to concurrent changes in surface barometric pressure in the tropical Pacific. The ENSO phenomenon is now understood to span the equatorial Pacific and to have opposite phases with a 2-7 year periodicity, and with impacts that occur in many parts of the world. The warm phase of ENSO is called El Niño, while the cold phase is called La Niña (Philander 1990). Common indices used to describe ENSO conditions include the Southern Oscillation Index (SOI), equatorial Pacific sea surface temperatures (e.g., NINO12, NINO3), the Multivariate ENSO index (MEI), and the Oceanic Niño Index (ONI).

The **PDO** is a pattern of ocean variability in the North Pacific that is similar to ENSO in some respects, but has a much longer cycle (20 - 50 year) (Mantua et al., 1997, Mantua and Hare, 2002). Specifically, it is defined as the standardized difference between sea surface temperatures (SSTs) in the north-central Pacific and Gulf of Alaska.

The **AMO** is defined as the leading mode of low frequency, north Atlantic Ocean (0 to 70°N) sea surface temperature (SST) variability with a periodicity of 65 to 80 years (Kerr, 2000; Gray et al., 2003). Any linear trend in the data has been removed, so the time series represents a natural variability absent of long terms trend from global warming. Research has the AMO correlated with the number of tropical storms in the Atlantic and rainfall in Florida.

The **PNA** is one of the largest-scale ocean-atmosphere patterns that varies on seasonal, interannual, and interdecadal time scales. The PNA is a measure of atmospheric pressure anomalies at four locations in the northern hemisphere (Horel and Wallace 1981). The pressure near the Aleutian Islands and the southeastern U.S. have the same sign pressure anomaly, and the pressure near Hawaii and central Canada have the opposite sign pressure anomaly. The PNA index is a standardized measure of these pressure differences and is most pronounced in the winter and disappears in the summer months of June and July.

The **NAO** is an oscillation of pressure differences between the subtropical high pressure system located in the tropical Atlantic near the Azores and the subpolar low pressure system located near Iceland (Hurrell, 1995). The difference in surface pressure generally influences the surface winds and the steering of storms from west to east. The NAO has quasi-biennial and quasi-decadal periodicity (Hurrell and Van Loon, 1997).

U.9.2 Interannual/Interdecadal Signals in the Colorado River basin

The influence of interannual (e.g., ENSO) and interdecadal (e.g., PDO, AMO, NAO) variability on the hydrology of the Colorado River basin has been studied since the late 1980s. The linkages between these modes of variability and Colorado River Basin climate is a statistical relationships and the actual mechanisms still need to be understood.

A summary of the potential impacts are noted in Table U-7. First, the relationships between ENSO and western U.S. hydrology were studied by several researchers (e.g., Cayan and Peterson, 1989; Redmond and Koch, 1991; Cayan and Webb, 1992; Kayha and Dracup, 1993; Piechota and Dracup, 1996). In the Colorado River basin, El Niño events bring generally wetter conditions to the Lower Basin and La Niña events, drier conditions. The linkage of ENSO with conditions in the Upper Basin is not as clear. The wet/dry relationship does not hold true for all ENSO events and the strength of the event can influence the general relationship. For instance, the 1982/83 El Niño event was one of the strongest on record and much of the basin (upper and lower) experienced wet conditions. However, the recent 2002 El Niño event corresponded with dry conditions in much of the basin for 2002 and 2003. This was part of an ongoing drought that started in 2000.

Table U-7
Summary of Hydrologic Conditions During ENSO, PDO, AMO and NAO Phases
and Coupled Impacts for the Colorado River Basin

	ENSO Phase		PDO Phase		AMO Phase		NAO Phase	
	+	-	+	-	+	-	+	-
All Years	Dry	Wet	Wet	Dry	Dry	Wet		
El Niño (-)	--	--	Wet					
La Niña (+)	--	--		Dry	Dry	Wet	Wet	Dry
AMO +				Dry	--	--		
AMO -		Wet	Wet		--	--		

Blank boxes represent no significant impact to hydrologic conditions. Dashed boxes represent coupling that is not possible (e.g., AMO+ and AMO+)

More recently, researchers have investigated other oceanic/atmospheric phenomena such as the AMO, PDO, and NAO. The strongest relationships have been found with the AMO. When the AMO is in a positive phase, dry conditions were noted in the Colorado River basin, while the negative phase was associated with wet conditions (Enfield et al., 2001; McCabe et al., 2004; Hidalgo, 2004; Tootle et al., 2005; Hunter et al., 2006; McCabe et al., 2007). A weaker relationship is present between streamflow and the PDO. During the PDO positive phase, wet conditions occurred in the basin, and the negative phase had dry conditions (McCabe and Dettinger, 2002; Hidalgo and Dracup, 2003; McCabe et al., 2004; Hidalgo, 2004; Tootle et al., 2005; Hunter et al., 2006; and McCabe et al., 2007). A limitation in much of this research on AMO and PDO is that the analysis contains only 1-3 cycles of the multidecadal oscillations, so the confidence in the results is not as strong as ENSO studies. The use of paleoclimatic data may enhance the understanding of these multidecadal phenomena.

The coupled relationships between ENSO and the PDO, AMO, and NAO have also been evaluated. These studies focused on coupling the interannual variability present in ENSO with longer term (decadal) variability present in the PDO, AMO, and NAO. The coupling of ENSO and PDO has been shown to result in enhanced (diminished) wet conditions during El Niño events when PDO is positive (negative). Similarly, the dry conditions during La Niña are diminished (enhanced) when the PDO is positive (negative) (Gershunov and Barnett, 1998; Hidalgo and Dracup, 2003; Tootle et al., 2005; Hunter et al., 2006). However, Rajagopalan et al. (2000) examined the coupled effects of ENSO and PDO on summer season Palmer Drought Severity Index (PDSI) values for the U.S. and determined that PDO does not enhance (or dampen) ENSO's effect.

The coupling of ENSO and AMO has been studied by Tootle et al., (2005), and Hunter et al., (2006). During La Niña years with a positive AMO phase, dry conditions occurred in the basin. This could likely be enhancement of drought conditions since La Niña years and AMO positive years are both associated with dry conditions. During the La Niña years with a negative AMO phase, wet conditions were noted in the Upper Colorado River basin (Hunter et al., 2006). The reversing of La Niña impacts (dry) was also noted by Hunter et al., (2006) in SWE values during La Niña years that corresponded with NAO positive years. In addition, La Niña years associated with NAO negative years had dry conditions.

Lastly, AMO and PDO have been noted as possibly coupled and leading to enhanced or diminished impacts to hydrology. For instance, Hidalgo (2004), McCabe et al., (2004), and McCabe et al., (2007) found that dry conditions occurred during AMO + and PDO – phases. In addition, Hidalgo (2004) found that wet conditions occurred during AMO – and PDO + phases. This represents enhancement of wet or dry conditions when the PDO and AMO phases are opposite in sign.

A clear understanding of the dynamics behind the couplings between these circulation indices and between the indices and Colorado River basin climate is still lacking. More research is needed to better understand how these indices and the circulation features they describe impact the basin climate and hydrology.

U.9.3 Predictability of Intercadal/Interannual Variability

The increased research and develop of tools to predict phenomena such as ENSO, AMO, and PDO could lead to improved long-term forecasting of hydrologic conditions for the Colorado River basin. In general, the predictability of these phenomena are limited to 9-12 months in advance with decreasing skill as lead time increases. Currently, the National Weather Service (NWS) Climate Prediction Center (CPC) provides ENSO forecasts in the form of sea surface temperatures (SSTs) for the tropical Pacific up to nine (9) months in advance (http://www.cpc.ncep.noaa.gov/products/analysis_monitoring/lanina/ensoforecast.shtml). This may assist in forecasting streamflow conditions in Lower Basin tributaries, but does not help in the forecasting of Upper Basin streamflow.

Currently, there are no publicly available tools available to forecast AMO and PDO conditions. However, researchers have noted that the PDO is a red noise process [i.e., the autocorrelation (or memory) is proportional to the size the anomaly] forced by ENSO, so the predictability of PDO would follow that of ENSO forecasts (Philip Mote, personal communication, 2007). The potential for predicting the AMO may be more promising. Griffies and Bryan (1997) and Collins and Sinha (2003) have noted that Atlantic SSTs and the thermohaline circulation have potential predictability of one to two decades into the future.

It is also important to highlight the usefulness of interannual/interdecadal variations on water resources planning with a 20-year planning horizon. The ability of a phenomenon such as AMO to persist for 10-20 years suggests that in the short term, these phases should be closely watched and corresponding hydrologic impacts evaluated. This could be just as important as evaluating the impacts of climate change that may not really be noticed in the basin for 20-50 years.

U.9.4 Relevance to Hydrologic Scenarios for Planning

As noted earlier, the hydrologic scenarios used by Reclamation for planning over a 20-50 year time period include historical streamflow data from 1906 to the present and reconstructed streamflow data from about 1500 to the present. These scenarios include all years of data and encompass all phases of ENSO, AMO and PDO. In this section, the potential of using the phase of ENSO, AMO, or PDO is demonstrated for developing hydrologic scenarios.

Figure U-28 presents the average streamflow conditions at Lees Ferry during the different phases of AMO from 1906 to the present. Evaluating the average conditions during each phase (as represented by the box plots), there appears to be a shift in the monthly streamflow values where flows are higher during an AMO negative phase and lower during an AMO positive phase. These differences are further demonstrated in Figure U-29 where the historical traces of streamflow (light gray lines) during AMO positive and AMO negative phases are presented along with the long-term monthly average (dark line). These are hydrologic scenarios that could be used for long-range outlooks for streamflow.

Lastly, the relative change in streamflow conditions during the various phases of ENSO, PDO, and AMO are important to note in the context of projected changes in streamflow under climate change scenarios. Figure U-29 presents the distribution of the median streamflow for the Upper and Lower basins during the positive and negative phases of ENSO, PDO, and AMO, along with the projected changes in streamflow for the period 2010-2039 based on output from 11 climate models and 2 different climate change scenarios (Christensen and Lettenmaier, 2006). It is noteworthy that the changes in streamflow corresponding to interannual and interdecadal climate phenomenon is comparable (if not larger) than the projected changes in streamflow under climate change scenarios.

Figure U-28
Monthly Streamflow at Lees Ferry for AMO + and AMO – Phases from 1906 to the Present

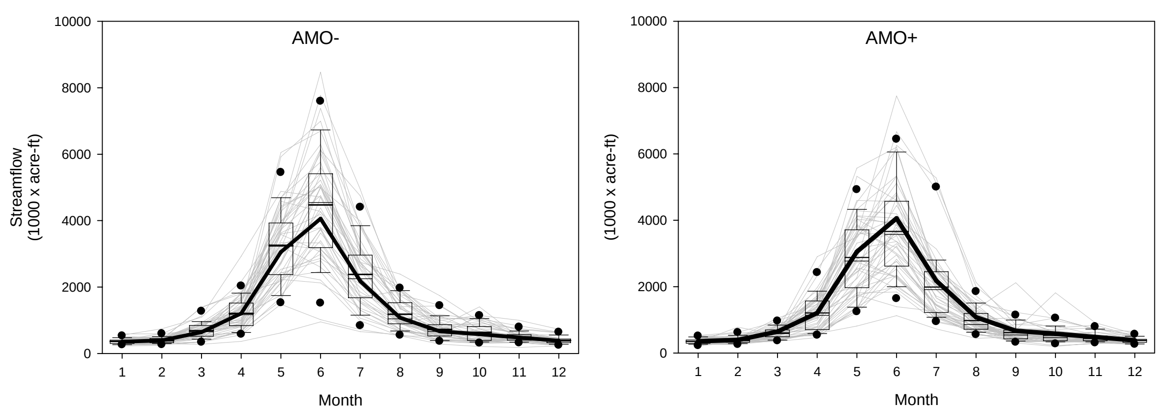


Figure U-29
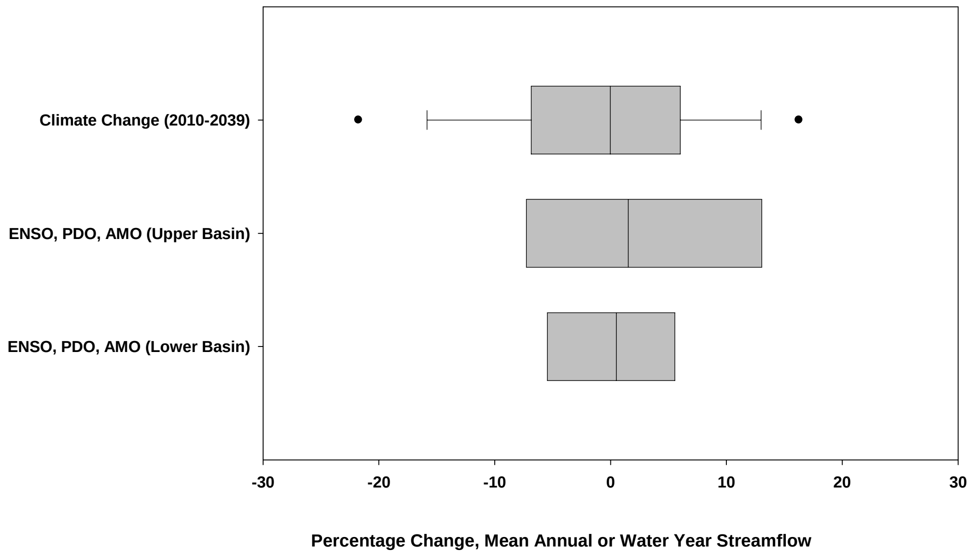
Box-and-Whisker Distributions of 2010-39 Runoff Change Relative to Historical (1950-1999) Corresponding to Various Climate Change Scenarios



The whiskers represent the 10th and 90th percentiles, the box represents the 25th and 75th percentiles, and the dots represent the outliers. In addition, distributions are provided of the runoff change during all phases (+ and -) of ENSO, PDO, and AMO for the Upper and Lower Colorado River Basin

U.10 Summary of Analysis Options and Future Needs

The information presented in this report highlight several important areas where Reclamation may use past and future climate information in the planning of water resources for the Colorado River basin.

U.10.1 Summary Points

- Climate models project that temperatures will increase globally by 1 to 2ºC in the next 20-60 years. The projections are fairly consistent for the next 20 years with a 1ºC increase, with larger uncertainty in the 40-year projections. The downscaling of global temperature increase to Colorado River Basin (CRB) climate change is less certain; however, it is expected that regional temperatures will also increase. Regional precipitation response is even less certain with comparable evidence suggesting wetter or drier conditions.

- The potential impacts of climate change on the CRB's water resources have been a subject of research for several decades. Initial studies related assumed regional climate change to region runoff response. Recent studies have been refined in several ways, including (a) how assumed climate changes are derived from global climate projections produced by various GCM simulations that reflect a range of global climate forcing scenarios, (b) how GCM output is bias-corrected and downscaled, and (c) how this output translated into region runoff response. Various analytical design options are represented by the survey of studies referenced in Section W.5 (Table U-3). Although an aggregate message from these studies may be that the *typical runoff response averaged across climate projections* spanning wetter to drier and less-warming to more-warming conditions is generally a mean annual decrease, the *range of runoff response across these same scenarios* is considerably broader and varies from increase to decrease. Note that due to advances in knowledge, technical abilities, and other factors, not all past studies retain the same significance today.

- Studies highlighted in Section W.5 show that system storage is very sensitive to changes in mean inflows as well as sequences of dry and wet years. This highlights the importance of properly investigating changes in both mean and variability in analyses of future system operations.

- Studies considered in Table U-3 feature varied treatment of projected climate *variability*, ranging from earlier studies where variability change was essentially not considered to more recent studies where GCM transient climatic conditions, bias-corrected or not, are used as input to the runoff response analysis. The significance of projected "change in climate variability" and its interaction with "change in climate norms" remains a question for research and affects ability to evaluate projected runoff uncertainty in the CRB.

- Paleoclimatic information suggests that long term average of natural flows from the upper CRB is 13.0 to 14.7 maf, compared to the gage record average of 15.2 maf. The paleoclimatic information may not necessarily represent future climate scenarios, but could be useful in framing assumed variability in future planning hydrologic sequences, with or without the joint consideration of future climate change. In particular, paleoclimate information offers evidence on drought spell potential beyond what has been experienced during the instrumental record, indicating a broader range of drought possibilities for the future.

- Interannual/interdecadal oscillation phenomena such as ENSO, PDO and/or AMO are *very significant* in the context of water resources planning within a 10- to 20-year horizon because such oscillations can persist in a given phase for a decade or longer. Evaluating the state of these oscillations and understanding their forcing mechanisms may be more important than evaluating impacts of projected climate change within a 10- to 20-year horizon.

U.10.2 Recommendations for Planning Studies

U.10.2.1 Shorter Look-Ahead Studies

For studies and management decisions involving shorter look-ahead horizons (e.g., less than 20 years), an appropriate level of analysis might involve a qualitative discussion of climate change and how interannual to decadal variability during the study's look-ahead horizon could be a more significant uncertainty than that associated with near-term projected climate change. This decision would be based on the limited projected change in climate trends over the near term and general inability to predict phase shifts in the interdecadal oscillations (e.g., AMO, PDO, etc.) that might overwhelm the trend signal during the same period. (See Figure U-29). Alternatively, if the role of shorter-term climate is critical to the study, the proposed qualitative discussion might be accompanied by a quantitative sensitivity analysis, where a range and distribution of 10- to 20-year hydrologic conditions are estimated based on instrumental record and paleoclimate evidence (in terms of mean, variance, and sequence; perhaps conditioned by understood relations with climate oscillations) and subsequently related to operations during the same look-ahead horizon.

U.10.2.2 Longer Look-Ahead Studies completed during the Near-Term

For studies and decisions concerned with greater than 20-year look-aheads and being evaluated on the near-term, it is suggested that a quantitative sensitivity analysis be conducted on operations response to projected climate change. By comparing system performance using projected climate change hydrology to historical hydrology, useful knowledge about system sensitivity should be ascertained. Given Reclamation's current limited ability to easily simulate runoff response to climate change in the CRB, which are highlighted in Section W.9.3, near-term studies should be framed using existing projections of climate and related runoff response. For such studies addressed during the near-term, scoping of sensitivity analysis should begin with a focused consideration of available literature. Rather than try to frame the analysis on all climate change and runoff impacts studies that have been conducted for the CRB (e.g., representing all studies listed in Table U-3), it is recommended that the criteria listed in Section W.6.5 be considered when reviewing available information.

U.10.2.3 Longer Look-Ahead Studies initiated beyond the Near-Term

Recommendations from section W.9.2.1 and Section W.6.5 are still relevant for studies that may be scoped beyond the near-term. However, we recommend that research and development be pursued as described in section W.9.3 to improve Reclamation's ability to consider and incorporate climate change information in future CRB studies. Some of the research and development can be pursued in-house, but much will need the broader assistance of scientists and engineers from the research and consulting communities.

U.10.3 Recommendations for Research and Development

- **Improved Availability and Temporal Resolution of Regional Climate Projection Datasets.** Currently, there is limited access to bias-corrected and downscaled climate projection datasets over the Colorado River basin. For example, there are more than 140 archived IPCC AR4, SRES A2, A1b, and B1 projections archived at LLNL PCMDI, compared to the 22 SRES A2 and B1 projections considered in Christensen and Lettenmaier (2006). Bias-correction and spatial downscaling procedures should be applied to the raw GCM outputs before they can be used to support regional to local hydrologic and water management impacts studies (see criteria in Section W.6.5)[9]. An archive of such data should be made available to researchers and the public. In addition, as dynamically downscaled datasets become available, these datasets should be added to the archive. Reclamation should encourage PCMDI and others to make daily and potentially sub-daily data available rather than the current monthly data which requires an additional and unnecessary temporal downscaling step for many hydrologic models.

- **Improved Ability to Model Runoff Under Climate Change.** Currently there are only a few runoff models available to generate CRB natural flow given climate inputs and Reclamation does not have easy access to these models. Reclamation needs to build internal staff expertise with available runoff model applications in the basin, and build coalitions with external groups that use such applications (e.g., working with groups familiar with UW's VIC hydrologic model, or NWSRFS). Ideally, such runoff applications would also report other hydrologic processes' response to climate change (e.g., soil moisture, evapotranspiration, groundwater interactions with surface water), which might involve development of applications that involve coupling of rainfall-runoff (e.g., NWSRFS) or land-surface model applications (e.g., VIC) with groundwater models (e.g., ModFlow). Several analytical designs (Section W.6.4) involve statistical methods that do not require runoff simulation. These methods should also be investigated by Reclamation.

- **Investigate Paradigm for Colorado River basin Precipitation Response.** While there is an evolving paradigm for how the American Southwest and other existing dry subtropical areas of the globe should respond to climate change, it is not clear how nearby relatively wet mountainous areas such as the Rockies should respond. In addition, the ability of GCMs to simulate future precipitation conditions at this spatial scale is questionable. Both the lack of a paradigm and current modeling capabilities constrain assumptions about future precipitation over the basin, and necessitate probabilistic or scenario-based approaches that explicitly recognize these uncertainties, to the extent that they might be quantified.

- **Diagnose and Improve Existing Climate Models Before Adding Additional Features.** Given known GCM limitations in simulating regional precipitation, climate research groups should focus a portion of their efforts on diagnosing and correcting biases in the current collection of IPCC AR4 AOGCMs, even though such efforts would compete for human and computational resources currently reserved for the development of new "Earth System Models" (i.e. ESMs, or AOGCMs modified to include interactive

---

[9] As of Summer 2007, Reclamation has begun working with research collaborators at Lawrence Livermore National Laboratory and Santa Clara University to produce an archive of bias-corrected and downscaled IPCC AR4 climate projections. The objective is to produce archived datasets featuring monthly 20th to 21st century time-series of surface air temperature and precipitation at eighth degree spatial resolution, and with geographic coverage spanning the contiguous United States (i.e. encompassing all of Reclamation's service areas). Bias-correction and downscaling procedures are being implemented using methods featured in Maurer (2007) and Christensen and Lettenmaier (2006). This effort may partially fulfill this need, but it is uncertain.

carbon cycle, chemistry, computed aerosols, and dynamic vegetation.)[10]. There is evidence that systematic errors in AR4 AOGCMs would still be present after coupling with additional ESM components and hence waiting for ESM models to solve existing problems is unlikely to be entirely satisfactory.

- **Investigate Changes in Modeled Climate Variability at Multiple Time Scales.** It is well appreciated that the Colorado River is sensitive to changes in mean flow. However, variability as represented by drought spells, wet refill periods, and extended decadal and longer periods of above and below average flow are also critical for determining system yield. Therefore, investigation of such variability in modeled sequences of precipitation, runoff and other climatic variables is critical. While future variability may not be similar to past variability, the variability in models should be characterized and explained both in the context of the historical record and the paleo record. In addition, the ability of the current generation of GCMs and the hydrology models to reproduce the historical variability of the CRB has not been studied.

- **Improve Understanding of Surface water, Groundwater and Land cover Interaction.** Because rivers and groundwater are intimately connected, understanding the entire recharge process and its response to climate change is critical. Hence, research is required on groundwater recharge and movement at scales relevant to regional runoff analysis, and this in turn requires understanding the aggregate process of mountain block recharge and the role of riparian and root zone vegetation. The latter leads to additional research questions on how basin land cover and natural evapotranspirative demand will respond to global climate change (Section W.6.3).

- **Improve Prediction of Interdecadal Oscillations.** The predictability of interdecadal climate oscillation phases (e.g., AMO, PDO) and their associated hydrologic impacts on the Colorado River basin are not well understood. Shorter-term planning may be more influenced by phase persistence and transition among these oscillations than by projected changes in climate means. Reclamation should actively support, either materially or otherwise (i.e., through partnerships and inter- or extra-agency interactions), efforts in the science and the applications community to advance knowledge in this area (i.e., 2- to 10-year climate prediction research).

- **Investigate use of Paleo Record to Inform Modeled Streamflow Variability.** Reclamation has funded some paleo-climate research on how to use information from the paleoclimate record in modeling studies. While the past will not repeat, the paleo record contains a wealth of information on natural variability that should not be ignored. For example, there may be valuable ways of combining paleo data with modeled and or historical data to modify the variability in these sequences in useful ways.

---

[10] (Jerry Meehl, 16 February 2007, presentation comments at WGNE/PCMDI Systematic Errors Workshop, 12-16 February 2007, San Francisco, CA; P. Chris Milly, 31 May 2007, personal communication)

- **Interact with Federal Climate Change Science Program and other Climate Change Research Initiatives.** Although Reclamation can pursue and fund some of the Research and Development work described above, many of these problems will require the assistance of the larger scientific and engineering community. The Department of the Interior is one of thirteen agency members of the approximately $2 billion per year federal Climate Change Science Program, the umbrella under which all federal climate change activity is pursued. In order to raise the profile of these issues and obtain resources to help solve them, Reclamation should engage the CCSP. In addition, Reclamation should collaborate with NOAA, the National Center for Atmospheric Research, and the University research community.

Jeff Lukas

Drafting Subcommittee

Levi Brekke, USBR
Brad Udall, NOAA/CIRES
David Yates, NCAR
Tom Piechota, University of Nevada, Las Vegas
Ben Harding, Hydrosphere
Connie Woodhouse, University of Arizona

Attachment 2: Glossary of Terms

Abrupt climate change: The nonlinearity of the climate system may lead to abrupt climate change, sometimes called rapid climate change, abrupt events or even surprises. The term abrupt often refers to time scales faster than the typical time scale of the responsible forcing. However, not all abrupt climate changes need be externally forced. Some possible abrupt events that have been proposed include a dramatic reorganization of the thermohaline circulation, rapid deglaciation and massive melting of permafrost or increases in soil respiration leading to fast changes in the carbon cycle. Others may be truly unexpected, resulting from a strong, rapidly changing forcing of a nonlinear system.

Atlantic Multi-Decadal Oscillation (AMO): The Atlantic Multi-Decadal Oscillation (AMO) is defined as the leading mode of low frequency, North Atlantic Ocean (0 to 70o) sea surface temperature (SST) variability with a periodicity of 65 to 80 years.

Analogue (or Analogs): Two observed states of the atmosphere that are very close by some measure, also applies to states of a model. Formal measures of closeness include anomaly correlation, root-mean-square distance, and covariance. Usually one expects analogs to occur only during the same time of year. Atmospheric analogs that are close compared to current levels of observational error are unlikely to be found unless one studies a single variable confined to a very small area, or otherwise reduced the degrees of freedom to a very small number.

Anthropogenic: Resulting from or produced by human beings.

Anthropogenic forcing: *Radiative* forcing resulting from or produced by human beings.

Atmosphere-Ocean General Circulation Model (AOGCM): Coupled Atmosphere-Ocean General Circulation Models (AOGCMs) provide a representation of the climate system that is near the most comprehensive end of the spectrum currently available. These models simulate atmosphere and ocean circulation and their interactions with each other, land, and cryospheric processes. Simulations are forced by several factors, including time series assumptions on atmospheric greenhouse gas and aerosol concentrations.

Baseflow: The sustained low flow of a stream, usually groundwater inflow to the stream channel.

Beneficial use: A use of water resulting in appreciable gain or benefit to the user, consistent with state law, which varies from one state to another.

Climate: Climate in a narrow sense is usually defined as the average weather, or more rigorously, as the statistical description in terms of the mean and variability of relevant quantities over a period of time ranging from months to thousands or millions of years. The classical period for averaging these variables is 30 years, as defined by the World Meteorological Organization. It is typically characterized in terms of suitable averages of the climate system over periods of a month or more, taking into consideration the variability in time of these averaged quantities. The relevant quantities are most often surface variables such as temperature, precipitation and wind.

Climatic classifications include the spatial variation of these time-averaged variables. Climate in a wider sense is the state, including a statistical description, of the climate system. Beginning with the view of local climate as little more than the annual course of long-term averages of surface temperature and precipitation, the concept of climate had broadened and evolved in recent decades in response to the increased understanding of the underlying processes that determine climate and its variability.

Climate change: Climate change refers to a change in the state of the climate that can be identified (e.g., by using statistical tests) by changes in the mean and/or the variability of its properties, and that persists for an extended period, typically decades or longer. Climate change may be due to natural internal processes or external forcings, or to persistent anthropogenic changes in the composition of the atmosphere or in land use. Note that the Framework Convention on Climate Change (UNFCCC), in its Article 1, defines climate change as: 'a change of climate which is attributed directly or indirectly to human activity that alters the composition of the global atmosphere and which is in addition to natural climate variability observed over comparable time periods'. The UNFCCC thus makes a distinction between climate change attributable to human activities altering the atmospheric composition, and climate variability attributable to natural causes. See also *Climate variability*.

Climate Model: A numerical representation of the climate system based on the physical, chemical and biological properties of its components, their interactions and feedback processes, and accounting for all or some of its known properties. The climate system can be represented by models of varying complexity, that is, for any one component or combination of components a spectrum or hierarchy of models can be identified, differing in such aspects as the number of spatial dimensions, the extent to which physical, chemical or biological processes are explicitly represented, or the level at which empirical parameterizations are involved. Climate models are applied as a research tool to study and simulate the climate, and for operational purposes, including monthly, seasonal and interannual climate predictions.

Climate variability: Climate variability refers to variations in the mean state and other statistics (such as standard deviations, the occurrence of extremes, etc.) of the climate on all spatial and temporal scales beyond that of individual weather events. Variability may be due to natural internal processes within the climate system (internal variability), or to variations in natural or *anthropogenic* or external *forcing* (external variability). See also *Climate change*.

Colorado River basin: The drainage basin of the Colorado River in the United States. The Colorado River watershed area encompasses over 246,000 square miles and is a primary water supply for residents in seven states including Colorado, Utah, Wyoming, New Mexico, Arizona, Nevada, and California.

Colorado River Compact: The Colorado River Compact is a 1922 agreement among seven U.S. states in the basin of the Colorado River in the American Southwest governing the allocation of the river's water. The compact divides the river basin into two areas, the Upper Basin (comprising Colorado, New Mexico, Utah and Wyoming) and the Lower Basin (Nevada, Arizona and California). The compact requires the Upper Basin states to deliver water at a rate of 7.5 million acre feet per year averaged over a moving ten-year average.

Colorado River Simulation System (CRSS): An operational model of the Colorado River system based on a monthly timestep. CRSS is a simulation model consisting of a database and a modeling code. The database describes the physical configuration of the natural and man-made features of the Colorado River system, the operating rules for the man-made features, the natural gains and losses of water that enter and leave the system, and the water used by or requested for use for human activities. The modeling code simulates the physical processes and institutional drivers that determine the system conditions, according to the data contained in the database.

Compact deliveries: Water allocations, diversions, and deliveries mandated under the Colorado River Compact of 1922.

Confidence: The level of confidence in the correctness of a result is expressed using probability confidence intervals.

Decadal: Occurring over a 10-year period.

Dendrochronology: The analysis of the annual growth rings of trees, leading to the calculation of significant indices of climate and general chronology of the past. The width of a tree-ring is determined by the temperature and/or moisture that prevailed during the year of its formation. Since stress from temperature and/or moisture variations reduces the width of the seasonal growth of a tree ring, dendrochronology has important application in the study of long-term climatic variations.

Domestic use: Also called residential water use or domestic withdrawals. Water used for household purposes, such as drinking, food preparation, bathing, washing clothes and dishes, flushing toilets, and water lawns and gardens. The water may be obtained from a public supply or may be self-supplied.

Direct Natural Flow Record (DNF): The Index Sequential Method (ISM) applied to the 1906 to 2004 Colorado River natural flow record.

Downscaling techniques: Techniques to generate climate scenarios at a point or watershed based on climate scenarios produced by global climate models at a larger spatial scale.

> **Bias-correction:** Simulations or forecasts of climate from dynamical models do not always correspond to reality (i.e., observations), thus, resulting in 'bias'. There are statistical methods to correct this and often referred to as 'bias correction' tools. Typically, they involve fitting a statistical model between the dynamical model simulations and the observations over a period. The fitted regression is used to correct future model simulations.
>
> **Disaggregation:** Breaking down a single indicator into subgroups variables. In section W.4 of this report, disaggregation is the second component of a downscaling technique where 2-degree lat-long climate projections are disaggregated into 1/8 degree projection data; and the second method, streamflow at an aggregate gauge (usually a gauge at the downstream) is disaggregated (or split) to flows at several upstream gauges - such that

the disaggregated flows add up to the flow at the aggregate gauge.(This enables the simulation of flow scenarios at all the required gauges in a parsimonious manner).

Drought: A period of abnormally dry weather sufficiently long enough to cause a serious hydrological imbalance. Drought is a relative term; therefore any discussion in terms or precipitation deficit must refer to the particular precipitation-related activity on a regional or continental scale.

Earth System Model (ESM): Models based on AOGCM (with various levels of simplification) that also include interactive carbon cycle, chemistry, computed aerosols, and dynamic vegetation. Earth System Models of Intermediate Complexity (EMIC) are discussed in the IPCC AR4 report from Working Group I, and are described as "reduced-resolution models that incorporate most of the processes represented by AOGCMs, albeit in a more parameterized form. They explicitly simulate the interactions between various components of the climate system. Similar to AOGCMs, but in contrast to simple climate models, the number of degrees of freedom of an EMIC exceeds the number of adjustable parameters by several orders of magnitude. ... like simple climate models, EMICs can explore the parameter space with some completeness and are thus appropriate for assessing uncertainty."

Empirical: Relying upon or derived from observation or experiment; Based on experimental data, not on a theory.

ENSO: A contraction of names of two phenomena that were recognized to be different expressions of the same process: “El Niño” refers to anomalous strong warming of the surface waters of the eastern equatorial Pacific Ocean, while “Southern Oscillation” refers to concurrent changes in surface barometric pressure in the tropical Pacific. The ENSO phenomenon is now understood to span the equatorial Pacific and to have opposite phases with a 2-7 year periodicity, and with impacts that occur in various parts of the world. The warm phase of ENSO is called El Niño, while the cold phase is called La Niña (Philander 1990). Common indices used to describe ENSO conditions include the Southern Oscillation Index (SOI), equatorial Pacific sea surface temperatures (e.g., NINO12, NINO3) and the Multivariate ENSO index (MEI).

Evapotranspiration: 1. The combined process through which water is transferred to the atmosphere from open water and ice surfaces, bare soil, and vegetation that make up the earth’s surface. 2. (Also called flyoff, water loss, total evaporation.) The total amount of water transferred from the earth to the atmosphere. This is the most general term for the result of this composite process; duty of water and consumptive use has more specific applications.

General Circulation Models (GCMs): *see climate model*.

Green house gases: Those gases, such as water vapor, carbon dioxide, ozone, methane, nitrous oxide, and chlorofluorocarbons, that are fairly transparent to the short wavelengths of solar radiation but efficient at absorbing the lower wavelengths of the infrared radiation emitted by the earth and atmosphere. The trapping of heat by these gases controls the earth’s surface temperature despite their presence in only trace concentrations in the atmosphere. Anthropogenic emissions are important additional sources for all except water vapor. Water vapor, the most important greenhouse gas, is thought to increases in concentration in response to increased concentrations of the other greenhouse gases as a result of feedbacks in the climate system.

Groundwater: Subsurface water that occupies the zone of saturation; thus, only the water below the water table, as distinguished from interflow and soil moisture.

Hydro-Climate Data Network (HCDN): USGS streamgages minimally affected by anthropogenic regulation or effects with sufficient periods of record.

Hydrology: The scientific study of the waters of the earth, especially with relation to the effects of precipitation and evaporation upon the occurrence and character of water in streams, lakes, and on or below the land surface.

Impaired inflows: In contrast to natural flows, these are reservoir or water system inflows affected by an upstream combination of natural runoff, human use, diversion, management, and/or allocation.

Indexed Sequential Method (ISM): A block bootstrap approach to resample a historic streamflow record. ISM cycles through each year in the natural flow record and extracts a sequence of flows beginning at that year and extending through the desired scenario length.

Inflow points: A specific location in which water flows into a body of water expressed in acre-feet per day or cubic feet per second.

Interim: Belonging to, serving during, or taking place during an intermediate interval of time; temporary: an interim agreement.

Interim shortage agreement: An interim shortage agreement in the context of this report is temporary operational guidelines for coordinated operation of Lakes Powell and Mead during times of shortage on the Colorado River.

Interpolation: The estimation of unknown intermediate values from known discrete values of a dependent variable.

IPCC: The Intergovernmental Panel on Climate Change (IPCC) established by World Meteorological Organization (WMO) and United Nations Environmental Programme (UNEP) provides an assessment of the state of knowledge on climate change based on peer-reviewed and published scientific/technical literature in regular time intervals.

IPCC Fourth Assessment Report: The Fourth Assessment Report "Climate Change 2007", also referred to as AR4 is a series of reports by the IPCC and provides an assessment of the current state of knowledge on climate change including the scientific aspects of climate change, impacts and vulnerabilities of human, natural, and managed systems, and adaptation and mitigation strategies.

Jet stream: Relatively strong winds concentrated within a narrow stream in the atmosphere. While this term may be applied to any such stream regards of direction (including vertical), it is coming more and more to mean only a quasi-horizontal jet stream of maximum winds embedded in the midlatitude westerlies, and concentrated in the high troposphere. Currently, in the analysis of upper-level charts, a jet stream is indicated wherever it is reliably determined that the wind speed equals or exceeds 50 knots.

Law of the River: The water law and appropriation requirements on the Colorado River mainstem and its tributaries.

Lees Ferry: A reference point in the Colorado River 1 mile below the mouth of the Paria River in Arizona which marks the Upper/Lower Colorado River Basins. Lees Ferry is the site of the USGS stream gage above the Paria River confluence.

Linear regression: Method dealing with a straight-line relationship between variables. It is in the form of y = a + bx, whereas nonlinear regression involves curvilinear relationships such as exponential and quadratic functions.

Long-wave radiation: In meteorology, a term used loosely to distinguish radiation at wavelengths longer than about 4 µm, usually of terrestrial origin, from those at shorter wavelengths (shortwave radiation), usually of solar origin.

Lower Basin: The part of the Colorado River watershed below Lees Ferry, Arizona; covers parts of Arizona, California, Nevada, New Mexico and Utah.

Million acre-feet (maf). The volume of water that would cover 1 million acres to a depth of 1 foot.

North Atlantic Oscillation (NAO): NAO is an oscillation of pressure differences between the subtropical high-pressure system located in the tropical Atlantic near the Azores and the subpolar low-pressure system located near Iceland (Hurrell, 1995). The difference in surface pressure generally influences the surface winds and the steering of storms from west to east. The NAO has quasi-biennial and quasi-decadal periodicity (Hurrell and Van Loon, 1997).

National Environmental Policy Act (NEPA): The National Environmental Policy Act (NEPA) requires federal agencies to integrate environmental values into their decision making processes by considering the environmental impacts of their proposed actions and reasonable alternatives to those actions. To meet this requirement, federal agencies prepare a detailed statement known as an Environmental Impact Statement (EIS). EPA reviews and comments on EISs prepared by other federal agencies, maintain a national filing system for all EISs, and assures that its own actions comply with NEPA.

Natural inflows: Inflows absent of any human use, diversion, management, or allocation; also called virgin flows.

Nonparametric: Problems for which a distribution curve cannot be drawn, either because the parameters of the equation are not known, or because there is no equation at all.

North American Monsoon: The North American monsoon (NA monsoon), variously known as the Southwest United States monsoon, the Mexican monsoon, or the Arizona monsoon, is experienced as a pronounced increase in rainfall from an extremely dry June to a rainy July over large areas of the southwestern United States and northwestern Mexico. These summer rains typically last until mid-September when a drier regime is reestablished over the region. Geographically, the NA monsoon precipitation region is centered over the Sierra Madre Occidental in the Mexican states of Sinaloa, Durango, Sonora and Chihuahua. The regime extends northward into the Arizona, New Mexico and Colorado. Typically, the NA Monsoon region is defined by sites that receive at least 50% of its annual precipitation in July, August and September.

Outflows: The amount of water passing a given point downstream of a structure, expressed in acre-feet per day or cubic feet per second. Water flowing out of a body of water.

Paleo-climate (or “Paleo”): Climate for periods prior to the development of measuring instruments, including historic and geologic time, for which only proxy climate records are available. (Paleoclimatolgoy: The study of past climate throughout geologic and historic time (paleoclimates), and the causes of their variations.

Paleo streamflow reconstruction: Using analyses from tree-ring reconstructions, streamflow volumes prior to the gage record can be estimated using a statistical model, which captures the relationship between tree growth and the gage record during their period of overlap. Then, this model is applied to the tree-ring data for the period prior to the gage record.

Palmer Drought Severity Index (PDSI): An index formulated by Palmer (1965) that compares the actual amount of precipitation received in an area during a specified period with the normal or average amount expected during that same period. The PDSI is based on a procedure of hydrologic or water balance account by which excesses or deficiencies in moisture are determined in relation to average climatic values. Values taken into account in the calculation of the index include precipitation, potential and actual evapotranspiration, infiltration, of water into a given soil zone, and runoff. This index builds on Thornthwaite’s work (1931, 1948), adding 1) soil depth zones to better represent regional change in soil water-holding capacity; and 2) movement between soil zones and, hence, plant moisture stress, that is, too wet or too dry.

Parts per million, ppm: Parts per million ("ppm") denotes one particle of a given substance for every 999,999 other particles.

Pacific Decadal Oscillation (PDO): The Pacific Decadal Oscillation (PDO) is a pattern of ocean variability in the North Pacific that is similar to ENSO in some respects, but has a much longer cycle (20 - 50 year) (Mantua et al., 1997, Mantua and Hare, 2002). Specifically, it is defined as the standardized difference between sea surface temperatures (SSTs) in the north-central Pacific and Gulf of Alaska.

Pacific North American pattern (PNA): The Pacific North America pattern (PNA) is one of the largest-scale ocean-atmosphere patterns that vary on seasonal, interannual, and interdecadal time scales. The PNA is a measure of atmospheric pressure anomalies at four locations in the northern hemisphere (Horel and Wallace 1981). The pressure near the Aleutian Islands and the southeastern U.S. have the same sign pressure anomaly, and the pressure near Hawaii and central Canada have the opposite sign pressure anomaly. The PNA index is a standardized measure of these pressure differences and is most pronounced in the winter and disappears in the summer months of June and July.

Present Perfected Rights: A water right to which the owner has applied for and obtained a permit, has complied with the conditions of the permit, and has obtained a license or certificate of appropriation. In the context of the Colorado River Compact (Compact), under Article VIII, "present perfected rights" refers to established beneficial use water rights prior to the Compact that will not be impaired.

Climate Projection: A projection of the response of the climate system to emission or concentration scenarios of greenhouse gases and aerosols, or radiative forcing scenarios, often based upon simulations by climate models. Climate projections are distinguished from climate predictions in order to emphasize that climate projections depend upon the emission/concentration/ radiative forcing scenario used, which are based on assumptions concerning, for example, future socioeconomic and technological developments that may or may not be realized and are therefore subject to substantial uncertainty.

Quantile: A generic term for any fraction that divides a collection of observations arranged in order of magnitude into two specific parts.

Return flows: The water that reaches a ground or surface water source after release from the point of use and thus becomes available for further use; water that re-enters the water system used further downstream.

Radiative forcing: In radiation, the net flux of radiation into or out of a system. As a consequence of radiative forcing there must be some change to the nonradiative energy states of the system (e.g., its temperature may change).

Rim inflows: Flows at the upper most gauges of tributaries and also the main stem.

Riparian: Of, on, or pertaining to the bank of a river, pond, or lake.

Scenario (Climate Scenario): A plausible and often simplified description of how the future may develop based on a coherent and internally consistent set of assumptions about driving forces and key relationships. Scenarios may be derived from projections, but are often based on additional information from other sources, sometimes combined with a narrative storyline.

Shortage: In a given watershed, a water supply deficit attributed to below average streamflow volumes due to natural or managerial attributions.

SNOTEL: Abbreviation for SNOwpack TELemetry. A west-wide system for obtaining snow water equivalent, precipitation, air temperature, and other hydrologic measurements from remote data sites via radio transmission.

SNOW17 snowmelt model: The SNOU-17 model is one of operations available in the National Weather Service River Forecast System (NWSRFS). It is a conceptual model in which each of the significant physical processes affecting snow accumulation and snowmelt is mathematically represented. The model uses air temperature as the sole index to energy exchange across the snoU-air interface and was developed to run in conjunction with a rainfall-runoff model. Developed by Anderson, (1973), (1976).

SnoU-water equivalent (SWE): The amount of water contained within the snowpack. It can be thought of as the depth of water that would theoretically result if you melted the entire snowpack instantaneously.

SRES scenarios: SRES scenarios are emission scenarios developed by Nakićenović and Swart (2000) and used, among others, as a basis for some of the climate projections shown in Chapter 10 of this report. The following terms are relevant for a better understanding of the structure and use of the set of SRES scenarios:

> **Scenario family:** Scenarios that have a similar demographic, societal, economic and technical change storyline. Four scenario families comprise the SRES scenario set: A1, A2, B1 and B2.
>
> **Illustrative Scenario:** A scenario that is illustrative for each of the six scenario groups reflected in the Summary for Policymakers of Nakićenović and Swart (2000). They include four revised scenario markers for the scenario groups A1B, A2, B1, B2, and two additional scenarios for the A1FI and A1T groups. All scenario groups are equally sound.
>
> **Marker Scenario:** A scenario that was originally posted in draft form on the SRES website to represent a given scenario family. The choice of markers was based on which of the initial quantifications best reflected the storyline, and the features of specific models. Markers are no more likely than other scenarios, but are considered by the SRES writing team as illustrative of a particular storyline. They are included in revised form in Nakićenović and Swart (2000). These scenarios received the closest scrutiny of the entire writing team and via the SRES open process. Scenarios were also selected to illustrate the other two scenario groups.
>
> **Storyline:** A narrative description of a scenario (or family of scenarios), highlighting the main scenario characteristics, relationships between key driving forces and the dynamics of their evolution.

Static: Fixed; stationary.

Stochastic hydrology: The science that pertains to the probabilistic description and modeling of the value of hydrologic phenomena, particularly the dynamic behavior and the statistical analysis of records of such phenomena.

Storage: The retention of water or delay of runoff either by planned operation, as in a reservoir, or by temporary filling of overflow areas, as in the progression of a flood wave through a natural stream channel.

r2: Statistical measure of how well a regression line approximates real data points; an r-squared of 1.0 (100%) indicates a perfect fit.

Temporal: Of, relating to, or limited by time, i.e. temporal boundaries.

Trajectories: see projection

Trigger: Procedure that is automatically executed in response to certain threshold events; event-driven programming.

Upper Basin: The part of the Colorado River watershed above Lees Ferry, Arizona; that covers parts of Arizona, Colorado, New Mexico, Utah and Wyoming.

Variable Infiltration Capacity (VIC) Model: VIC is a macroscale hydrologic model that solves full water and energy balances. VIC is a research model and in its various forms it has been applied to many watersheds including the Columbia River, the Ohio River, the Arkansas-Red Rivers, and the Upper Mississippi Rivers, as well as being applied globally.

Water balance (Water budget): An analytical tool whereby the sum of the system inflows equals the sum of the system outflows. A summation of inputs, outputs, and net changes to a particular water resource system over a fixed period.

Watershed: All the land and water within the confines of a certain water drainage area; the total area drained by a river and its tributaries.

Water supply: Process or activity by which a given amount of water is provided for some use, e.g., municipal, industrial, and agricultural.

Water year: A continuous 12-month period selected to present data relative to hydrologic or meteorological phenomena during which a complete annual hydrologic cycle normally occurs. The water year used by the U.S. Geological Survey runs from October 1 through September 30, and is designated by the year in which it ends.

PART 2 – PUBLIC HEARING TRANSCRIPTS

Introduction

The Bureau of Reclamation (Reclamation), acting on behalf of the Secretary of the Department of the Interior (Secretary), published a Notice of Availability (NOA) of a Draft Environmental Impact Statement (EIS) for Colorado River Interim Guidelines for Lower Basin Shortages and Coordinated Operations for Lake Powell and Lake Mead, and a schedule of public hearings, in the *Federal Register* on February 28, 2007 (72 Fed. Reg. 9026). The NOA commenced a public review period that ended on April 30, 2007.

Over 500 copies of the Draft EIS were distributed to interested federal, Tribal, state, and local entities and members of the general public for review; and the document was also available for public viewing at several local libraries and on Reclamation's Upper Colorado Region and Lower Colorado Region websites.

Three public hearings were held to receive oral comments on the Draft EIS during the month of April 2007. These three public hearings took place on April 3, 4, and 5, 2007 in Henderson, Nevada; Phoenix, Arizona; and Salt Lake City, Utah, respectively.

Two individuals provided oral comments during the public hearings. In addition to these oral comments, Reclamation received 78 letters with comments on the Draft EIS. The comment letters were submitted by a wide-range of interested parties that included businesses; federal, state and local agencies; Indian tribes; special interest groups; and individuals. Reclamation has reviewed all of the comments received during the Draft EIS public comment period.

As a result of Reclamation's review of comments received on the Draft EIS, and pursuant to the requirements of NEPA, Reclamation has prepared this Final EIS. Volume IV contains in Part I, reproductions of the letters and oral comments received, and Reclamation's responses to these comments; and in Part II copies of transcripts of the three public hearings.

Reclamation received a significant number of comments regarding climate change and hydrologic variability during the Draft EIS review period. In particular, questions were asked regarding the uncertainty of future inflow conditions and how this uncertainty was considered in the modeling of the alternatives. Reclamation believes that, it is appropriate to provide the following general response to the climate change and hydrologic variability questions.

General Response Pertaining to Climate Change and Hydrologic Variability

The potential impacts of climate change and hydrologic variability on the Colorado River have been subjects for discussion for many years. The continuing drought in the Colorado River Basin which began in 2000, coupled with recent advances in scientific knowledge regarding the potential impacts of climate change, has heightened this interest. The Fourth Assessment Report (Summary for Policymakers) of the Intergovernmental Panel on Climate Change (IPCC), published in April 2007, presented a selection of key findings regarding projected changes in precipitation and other climate variables as a result of a range of climate change scenarios projected by IPCC over the next century. Although annual average river runoff and water availability are projected to decrease by ten to 30 percent over some dry regions at mid-latitudes, information with regard to potential impacts on specific river basins is not included. Recently published projections of potential reductions in natural flow on the Colorado River Basin by the mid 21st century range from approximately 45 percent by Hoerling and Eischeid (2006), to approximately 6 percent by Christensen and Lettenmaier (2006). A recent analysis of future precipitation minus evaporation (a surrogate for runoff) in the basin suggests an "imminent transition to a more arid climate in southwestern North America" (Seager et al. 2006).

While these projections are of great interest, additional research is both needed and warranted to quantify the uncertainty of these estimates in terms of the actual uncertainty in the climate response as well as the uncertainty due to differences in methodological approaches and model biases in order to better understand the risks of current and future water resource management decisions.

Reclamation has been involved in a multi-faceted research and development program over the past three years to improve its risk assessment capabilities regarding projected climate change in the Colorado River Basin. Key components of this program include:

- Sponsorship of National Research Council's (NRC) Committee on the Scientific Bases of Colorado River Basin Water Management in collaboration with the California Department of Water Resources, the Metropolitan Water District of Southern California, the Southern Nevada Water Authority, and the NRC's Water Science and Technology Board.

  The above noted NRC study culminated in a report published in early 2007, titled *Colorado River Basin Water Management: Evaluating and Adjusting to Hydroclimatic Variability*. Among several conclusions and recommendations, this report concluded that the trend of increasing mean temperatures across the Colorado River Basin over the 20th century and into the 21st century is likely to continue, and although there is less consensus regarding future trends in precipitation and runoff, the preponderance of the scientific evidence suggests warmer future temperatures will reduce future streamflow and water supplies and contribute to increase the severity, frequency, and duration of future droughts. The executive summary of this report is included as Appendix T;

- Collaboration with several climate researchers to assess the state of knowledge regarding the potential impacts of climate change on the Colorado River Basin, to assess methodologies that would be appropriate to quantify future conditions, and to prioritize future research and development needs.

  This work culminated in a report titled *Review of Science and Methods for Incorporating Climate Change Information into Reclamation's Colorado River Basin Planning Studies.* Among several conclusions and recommendations, this report concluded that for shorter look-ahead horizons (e.g., less than 20 years), interannual and decadal variability is likely to be a more significant source of uncertainty than the uncertainty due to near-term climate change. Although paleoclimatic information may not necessarily represent future climate scenarios, this information may be useful in framing assumed variability in future hydrologic sequences, particularly with respect to drought potential. For longer look-ahead horizons (20+ years), further research and development is needed to translate climate projections from General Circulation Models (GCM) to the spatial scales necessary for use in Colorado River planning studies. This report is included in its entirety in Appendix U;

- ♦ Collaboration with several research partners including the United States Geological Survey (USGS), National Oceanic and Atmospheric Administration (NOAA), and various universities to improve the accuracy and spatial resolution of the output data from climate change models to enable use in Reclamation's planning model (CRSS); and

- ♦ Improvements to the decision-modeling framework (including the CRSS model and associated data handling and analysis tools).

Based on the current inability to precisely project future impacts of climate change to runoff throughout the Colorado River Basin at the spatial scale needed for CRSS, the primary hydrologic analysis for this Final EIS was based on the resampled historical record. However, in order to understand the potential effects of future inflow sequences outside the range of the historical flows (i.e., future sequences with increased variability including the severity, frequency, and duration of droughts), particularly during the 19-year period of the application of the proposed federal action, Reclamation analyzed the sensitivity of the hydrologic resources (including reservoir storage, reservoir releases, and river flows) to hydrologic scenarios derived from alternative methodologies. These methodologies, including stochastic hydrology methods and paleo-reconstruction methods and the analyses results were included in Appendix N of the Draft EIS. An additional analysis has been added to Appendix N in this Final EIS that incorporates newly published tree-ring reconstruction data (Meko et al. 2007) that extends the estimate of annual flow at Lees Ferry back to the year 762, a record length of 1,244 years.

Acknowledging the potential for impacts due to climate change and increased hydrologic variability, the Secretary proposes that these guidelines be interim in duration and extend through 2026, providing the opportunity to gain valuable operating experience for the management of Lake Powell and Lake Mead, particularly for low reservoir conditions, and improve the basis for making additional future operational decisions, whether during the interim period or thereafter. In addition, the Preferred Alternative has been crafted to include operational elements that would respond if potential impacts of climate change and increased hydrologic variability are realized. In particular, the Preferred Alternative includes a coordinated operation element that allows for the adjustment of Lake Powell's release to respond to low reservoir storage conditions in Lake Powell or Lake Mead as described in Section 2.7 and Section 2.3. In addition, the Preferred Alternative will enhance conservation opportunities in the Lower Basin and the retention of water in Lake Mead through adoption of the ICS mechanism. Finally, the Preferred Alternative includes a shortage strategy at Lake Mead that would result in additional shortages being considered, after appropriate consultation, if Lake Mead elevations drop below 1,025 feet msl.

This page intentionally left blank.

Part 1
Comments and Responses

This section contains copies of comment letters received by Reclamation in response to the public review of the Draft EIS. This section also includes two oral comments that were received during the public hearings. Finally, Reclamation's responses to each of the specific issues raised in the letters and comments are provided in this section. The contents of this section are organized as follows:

- ♦ Comment letters and the oral comments from the public meetings have been grouped according to their entity type (i.e., business; federal agency; special interest or non-governmental organization; individual; Indian tribe; local agency, city or water district; state agency; and oral comment). Comments were assigned a code and source identification according to the following method:
    - the grouped comments were assigned a letter code (i.e., business [B]; federal agency [F]; special interest or non-governmental organization [G]; individual [I]; Indian tribe [IT]; local agency, city or water district [L]; state agency [S]; and oral comment [PC]);
    - a number code was then assigned to identify the multiple comment letters within each grouping (e.g., the first letter in the local agency category is assigned code L-1 and the second letter is assigned code L-2); and
    - each comment letter has been further subdivided into issues which are marked with vertical lines and numbered sequentially within the right margin of the comment letter. The issue number is displayed after the comment letter group and number (e.g., L-1-1, L-1-2).
- ♦ Reclamation's response to each comment letter and oral comment immediately follows the respective letter and oral comment. The responses are numbered in the same method as the comment letter or oral comment and its respective issues.

Re: Draft EIS - Colorado River Interim Guidelines for Lower Basin Shortages and Coordinated Operations for Lake Powell and Lake Mead

The following comments are provided concerning the Draft Environmental Impact Statement (EIS) for the Colorado River Interim Guidelines for Lower Basin Shortages and Coordinated Operations for Lake Powell and Lake Mead.

On page ES-15 of the Executive Summary the statement is made that "With respect to other electrical power resource issues, the Water Supply Alternative has a higher potential for total loss of generation at the Glen Canyon Powerplant and the Hoover Powerplant than the other action alternatives and the No Action Alternative". This seems obvious for Glen Canyon; however, it isn't so obvious with respect to Hoover? The EIS should identify the basis for this statement. 1

Chapter 2 – Alternatives: The Draft EIS assesses four action alternatives: (1) Basin States Alternative, (2) Conservation Before Shortage Alternative, (3) Reservoir Storage Alternative, and (4) Water Supply Alternative. Each of these alternatives, with the exception of the Water Supply Alternative, includes a mechanism for the storage and delivery of conserved system and non-system water in Lake Mead (i.e., intentionally created surplus). The omission of a mechanism for storage and delivery under this alternative is arbitrary and does not allow this alternative to be evaluated on an equal basis against the other alternatives. This is particularly evident with respect to the probability distributions concerning shortage occurrences presented in Chapter 4, where had such a mechanism been included in the Water Supply Alternative even fewer shortages would likely occur. 2 The EIS should include an analysis of the Water Supply Alternative with a similar mechanism for the storage and delivery of water. Likewise, the No Action Alternative should also be evaluated with a similar mechanism for storage and delivery. 3

On page 2-5 in the discussion concerning the No Action Alternative, Table 2.2-1 shows that under a Stage II shortage California will take a 60-65 percent of the shortage. The basis for this conclusion or assumption should be identified in the EIS. 4

Similarly, on page 4-121, Table 4.4-11 shows different Lower Basin shortage volumes and the portion of the shortage that was assumed to be distributed to Arizona. 5 Similar tables are subsequently provided for California and Nevada. The basis for these assumptions should be identified in the EIS. 6

B-1

Bureau of Reclamation
Lower Colorado Region
April 30, 2007
Page 2 of 2

Beginning on page 5-7, the EIS briefly discusses a number of proposed water supply
projects of the SNWA that the proposed Colorado River Interim Guidelines would 7
presumably facilitate. A complete description of these projects is needed to adequately
assess the impact of the various shortage alternatives. Likewise, a more complete 8
description of the Systems Conveyance and Operations Program (SCOP) is needed. It is 9
unclear whether the water quality modeling performed in Chapter 4 of the EIS incorporates
the SNWA water supply proposals and the SCOP, which it should if the analysis is to
accurately assess the impacts of the various shortage alternatives.

Thank you for considering these comments.

Sincerely,

/c/ Craig W. Morgan

Reponses to Comment Letter B-1

B-1-1

Your comment is noted. The Executive Summary (Section ES 2.10) has been modified to more clearly summarize the results of the electrical power resources analysis (Section 4.10).

B-1-2

Reclamation does not concur with this comment. The action alternatives were developed to include different formulations of each of the four operational elements. The Water Supply Alternative was developed to analyze a scenario that would maximize water deliveries at the expense of retaining water in storage in the reservoir for future use (see description of Water Supply in Section 2.5 of the EIS).

B-1-3

Reclamation does not concur with this comment. Under NEPA, the No Action Alternative represents a projection of current conditions to the most reasonable future responses or conditions that would occur during the life of the proposed federal action without any action alternative being implemented (Section 2.2.2). Therefore, since a mechanism for the storage and delivery of conserved water currently does not exist, it would be inappropriate to include this in the No Action Alternative.

B-1-4

The information requested is provided in the EIS. Please refer to Section 2.2.2 of the EIS which explains the assumptions of how the distribution of water under Stage 1 and Stage 2 shortages is determined.

B-1-5

The information requested is provided in the EIS. Please refer to Section 2.2.2, Section 4.2, Appendix A, and Appendix G of the EIS for detailed explanations on the assumptions of how the distribution of water for Arizona under shortage conditions is determined.

B-1-6

The information requested is provided in the EIS. Please refer to Section 2.2.2, Section 4.2, Appendix A, and Appendix G of the EIS for detailed explanations on the assumptions of how the distribution of water for California and Nevada under shortage conditions is determined.

B-1-7

The information in the Draft EIS has been modified in the Final EIS (Section 4.16). More detailed information regarding the proposed SNWA projects has been included in Section 4.16 of the Final EIS and can also be found on SNWA's website at the following internet address: http://www.snwa.com/html/wr_instate.html

B-1-8

A description of the Systems Conveyance and Operations Program (SCOP) is provided in Section 4.5.2 and in Section 5.1.25 of the EIS. Additional information on the SCOP can be found at the Clean Water Coalition's website at the following internet address: http://www.cleanwatercoalition.com

B-1-9

The proposed SNWA water supply proposals are assumed to occur under the Basin States, Conservation Before Shortage, and Reservoir Storage alternatives, and under the Preferred Alternative, due to the assumed existence of a storage and delivery mechanism. Under the SCOP EIS preferred alternative, impacts to water quality are considered insignificant for Lake Mead elevations down to 1,000 feet msl (Section 4.5.2). For the Preferred Alternative (Section 4.3.4, Figure 4.3-24) under the assumptions described in Section 4.2, the probability of Lake Mead elevations below 1,000 feet msl is zero over the interim period.

APR 2 6 2007

CERTIFIED MAIL REQUESTED

Regional Director
Bureau of Reclamation
Lower Colorado Regional Office
P.O. Box 61470
Boulder City, NV 89006-1470

Dear Regional Director:

On February 28, 2007, the Bureau of Reclamation (Reclamation) published the Draft Environmental Impact Statement for the Colorado River Interim Guidelines for Lower Basin Shortages and Coordinated Operations for Lake Powell and Lake Mead (Draft EIS) and requested that comments on the Draft EIS be submitted no later than April 30, 2007. The Desert Southwest Region of the Western Area Power Administration (Western) would like to take this opportunity to provide comments in regard to the Draft EIS.

Western has the responsibility for the marketing of the generation from Federal hydropower in much of the Western United States, including generation on the Colorado River. The Desert Southwest Region has responsibility for projects on the Lower Colorado River including the Boulder Canyon (Hoover generation) and Parker-Davis Projects. Western has followed the development of the Draft EIS with great interest because of the potential impacts to our power customers for these projects. The power and benefits provided from these projects are currently distributed to millions of customers in Arizona, California, and Nevada. Due to the unique characteristics of hydropower generation, the Federal generation facilities on the Colorado River contribute greatly to the reliability of the entire interconnected electrical power system in the Southwest.

While our responsibility is for the marketing of federal hydropower, we recognize that Reclamation must manage the Colorado River, consistent with applicable federal laws, for all the affected resources including water supply, power, recreation, and environmental. Western's comments are therefore provided with consideration of all affected resources and are focused on issues that significantly affect the projected impacts of the alternatives analyzed and on the selection of a preferred alternative.

Comparison of Alternatives (by Operational Elements)

Reclamation has stated that it may combines aspects of more than one alternative in its preferred alternative, therefore we will provide comments on each of the Operational Elements presented in the Matrix of Alternative in Table 2.7-1.

F-1

Shortage Guidelines

The efficacy of the shortage guidelines for the alternatives may be demonstrated to a large extent
by the Lake Powell and Lake Mead elevation projections by the end of the interim guideline
period. The 50th percentile projection for lake elevations in 2026 show that for three (Basin
States, Conservation Before Shortage, and Water Supply) of the four action alternatives, the total
combined storage of the lakes are essentially unchanged or even lower than the initial storage at 1
the start of the study period and less than No Action. This is even with inflow projections that
we believe are overestimated as discussed in our comments on Modeling and Hydrologic
Resources. Only under the Reservoir Storage alternative is a substantial increase in the total
combined storage projected in 2026 at the 50th percentile, due primarily to the shortage 2
guidelines for this alternative. Water storage at the 10th percentile is also much higher for the
Reservoir Storage alternative.

It seems that shortage guidelines that do not show an appreciable increase in water storage in
almost 20 years (even with overly optimistic inflow projections) from relatively low levels 3
reached after a 7-year drought are inadequate. This would leave the reservoirs languishing in the
middle to lower range of storage during normal inflows and thus without sufficient storage to
handle significant drought periods without drastic cuts in water deliveries. The proposal under
the Basin States alternative for a re-consultation once Lake Mead drops below elevation 1025' 4
appears contrary to the purpose of having shortage guidelines. We believe that shortage
guidelines that do not address shortages at lower lake elevations do not fulfill the need set forth
in Purpose and Need "for more specific guidelines …to assist in the Secretary's determination
of annual water supply conditions in the Lower Basin under low reservoir conditions." Specific 5
guidelines would be absent at the lowest reservoir elevations at which they are most critical.

The shortage guidelines under the Reservoir Storage alternative result in much higher water
storage under the full range of probabilities. This would result in much better capability to meet
water demands during periods of drought which is a primary purpose for developing these 6
interim guidelines. In addition, other purposes for which these dams were built such as power 7
production and recreation will also benefit from these higher storage levels. We find the
shortage guidelines under the Reservoir Stage alternative are superior and recommend that they 8
be incorporated into the preferred alternative.

Coordinated Reservoir Operations

Coordinated releases from Lake Powell based upon the elevations or volumes at Lake Mead and 9
Lake Powell at lower elevations provides an overall benefit to the system resources. We do not
believe that there is an appreciable difference in the impacts based upon the triggers used in the
Basin States and Conservation Before Shortage alternatives versus the Reservoir Storage 10
triggers. We recommend either the Coordinated Reservoir Operations from the Basin States and
Conservation Before Shortage alternatives or the Reservoir Storage alternative be implemented. 11

F-1

Storage and Delivery of Conserved System or Non-System Water

We support the concept of Intentionally Created Surplus (ICS) mechanism for storage and 12
delivery of conserved water. The increase storage in Lake Mead resulting from the ICS would 13
provide positive impacts to many of the affected resources including power production. We
support the higher maximum levels of ICS in the Reservoir Storage alternative.

We strenuously oppose the proposal in the Conservation Before Shortage alternative that would
be funded in part by a surcharge assessed on the power rates for the Hoover electrical service 14
contractors and a Federal government contribution. As noted in the Draft EIS, this funding
proposal would be contrary to existing federal legislation and outside of the authority of 15
Reclamation.

Interim Surplus Guidelines (ISG)

We feel that it is counterproductive to provide for surplus deliveries not necessitated by the
potential of flood control releases when we are entering a period of time where the probability of 16
shortages is greatly increasing. While eliminating the Domestic Surplus provisions of the ISG
would only have a small effect on water storage, we still believe that this justifies elimination of 17
these surpluses. We support the Reservoir Storage proposal to eliminate the ISG Domestic
Surplus releases and make surplus releases only during Quantified and Flood Control conditions. 18

Environmental Consequences

Methodology and Hydrologic Resources

The first two stated purposes of the Draft EIS are to: 1) improve management of the Colorado River considering the tradeoffs between the frequency and magnitude of reductions of water deliveries and the effects on water storage, water supply, power production, recreation, and environmental resources; 2) provide Colorado River water users with a greater degree of predictability with respect to the amount of annual water deliveries in future years, particularly
under drought and low reservoir conditions. The most critical factor affecting the analysis of the
alternatives in regards to theses purposes is the water supply model. The reductions in water 20 19
deliveries and uncertainty in water deliveries are issues only as the reservoirs reach low levels
due to water deliveries that exceed the water supply over a period of years.

In the Draft EIS, Reclamation modeled the future inflows to the Colorado River Basin using 99 years of recorded data from 1906 through 2004 (Direct Natural Flow Record) and applying these years of inflows (or traces) and the projected initial conditions to models of the alternatives. The
use of historical recorded inflows for projection of future inflows has been used by Reclamation 21
in previous environmental impact studies and other analysis, however we believe that it is very
ill suited for the current Draft EIS.

As noted above, the primary purpose of the Draft EIS is to determine guidelines for operating at 22
low reservoir levels. We feel the use of this 99 year historical record of inflow data significantly

F-1

overstates the probable future inflows and therefore calls into question the validity of the analysis
of the alternatives. There are two factors that cause us to believe this use of recorded data would 22
overstate the probable future flows. First, the historical period includes the early 20th century, a
time of extraordinarily high inflows. All reconstructions of earlier inflows (through tree ring
analysis) have determined this to be the period of highest sustained inflows in the past 500 years.
By including and not adjusting for these abnormally high inflows results in an over-projection of
the probable inflows based on the full picture of historical inflows. Comprehensive analysis of
tree rings in the Colorado River Basin have shown average inflows over the past 500 years are 23
0.5 MAF to over 1.0 MAF less than the average inflows used in the Draft EIS. There is a
sensitivity analysis in Appendix A which did include one analysis (Direct Paleo) which used
such reconstructed water inflow data. The result was that at the 10th percentile in 2026, Lake
Powell elevation was about 50 feet lower for most alternatives and Lake Mead was about 20 feet
lower for the action alternatives when compared to the Direct Natural Flow Record used in the
body of the Draft EIS.

The second factor is the effects of climate change on the future inflows. There is almost
complete consensus in the scientific community in regards to increasing temperatures in the
Colorado River Basin as evidenced by the National Research Council report earlier this year.
Average temperatures in the Colorado River Basin have already increased over the last century
and higher average temperatures in the future will result in increased evaporative losses and 24
earlier snowmelts, reducing the future inflow. We have experienced this situation several years
in the current drought, where precipitation and snowpack levels were near average until about
March at which time warm, dry conditions ensued and resulted in runoff levels far below
average.

In addition, the current state of hydrologic conditions has changed substantially since the August
2006 data used in the analysis. Due to another poor snowpack in the Colorado River Basin, the 25
inflow for the current year will be far below the previous projections. This change would
significantly reduce the initial reservoir levels used in the Draft EIS.

In summary, we do not believe that the water supply model in the Draft EIS accurately portrays
the probabilities of future conditions due to overestimation of inflows and initial reservoir 26
conditions. It does not seem reasonable to us to analyze alternatives for creating guidelines to
address primarily the river operation during drought and low reservoir conditions using data that 27
would likely overestimate the available water supply. We suggest that the alternatives should be
re-analyzed using more conservative projected water inflows that would result from 28
incorporation of the information from recent scientific studies in this area, not solely the
recycling the limited period of recorded inflows.

Water Deliveries

Figure 4.4-6 demonstrates the impact on future deliveries that will likely occur because of
inadequate reductions of deliveries under all alternatives except for Reservoir Storage. Very 29
large shortages may be required immediately after the interim period in all the other alternatives
when the demands for water are only going to be greater. There does appear to be discrepancies 30

F-1

between Figure 4.4-6 and Table 4.4-10. The data points in the table do not match the corresponding data points in the figure. 30

Electrical Power Resources

The analysis in the Draft EIS presents a comparison of the impacts on power generation on an average basis and at various ranges of hydrologic conditions. The total economic values of the electrical power generation presented are greatly understated due to use of outdated (2004) data for the underlying prices and application of a net discount rate that reduced the value of generation in later years. 31 The comparison of impacts for each of the alternatives appears reasonable in terms of the change in electrical power production. This comparison shows that Hoover is the most impacted of the Federal generation facilities. The Reservoir Storage alternative provides for significantly higher power production at Hoover than the others alternatives as well as higher overall power production from the Colorado River generation facilities in total. 32

Recreation

We would just note that the Reservoir Storage clearly is the most beneficial alternative in terms of recreation at both Lake Powell and Lake Mead. 33 Each of the other alternatives has a negative impact on Lake Powell recreation compared to No Action. 34

Recommendation

In our review of the Draft EIS, we find that each of the alternatives, except Reservoir Storage, do not provide for adequate water storage on the Colorado River and therefore have negative impacts on resources, such as power and recreation, and leave future water deliveries vulnerable. 35 We believe these alternatives are likely to result in drastic reductions in water deliveries during or immediately after the interim period and/or result in the need to reconsider or modify the guidelines during the interim period. 36 Therefore, Western recommends that Reclamation selects Reservoir Storage as the preferred alternative in the Final Environmental Impact Statement based upon its most favorable impact to the resources and environment effected by the adoption of interim guidelines. 37

We thank you for this opportunity to comment on the Draft EIS. For any questions on this matter, please contact Mr. Brian Young at (602) 605-2594 or byoung@wapa.gov.

Sincerely,

Mary Oretta for

Deborah K. Emler

G6006:BYoung:x2594:wts:04-24-07:R:\Groups\G6000\BOR\Letter to USBR draft EIS 4-24-07.d042407_wts.doc

F-1

Reponses to Comment Letter F-1

F-1-1

Your comment is noted. No change to the Final EIS was necessary.

F-1-2

Your comment is noted. No change to the Final EIS was necessary.

F-1-3

Reclamation does not concur with this comment. The action alternatives were formulated to permit an evaluation of a wide range of operating conditions and to permit an evaluation of several trade-offs, including the trade-offs between water deliveries and retaining water in storage for future use.

F-1-4 and F-1-5

Reclamation does not concur with these comments. The Basin States Alternative and the Preferred Alternative include provisions for stepped water delivery reductions associated with specific Lake Mead elevations that begin at elevation 1,075 feet msl and continue down to elevation 1,025 feet msl. The re-consultation that would occur under these alternatives when the Lake Mead water level falls below elevation 1,025 feet msl is expected to consider among other factors, projected inflow conditions, the need for and magnitude of additional shortages, and the ability of water users to manage additional delivery reductions at that point in time. Therefore, the shortage guidelines provided in the Basin States Alternative and the Preferred Alternative meet the purpose and need of the proposed federal action.

F-1-6

Your comment is noted. No change to the Final EIS was necessary. The trade-offs between reducing water deliveries and retaining water in storage for future use is clearly demonstrated in the analysis of the alternatives.

F-1-7

Your comment is noted. No change to the Final EIS was necessary.

F-1-8

Your comment is noted. No change to the Final EIS was necessary.

F-1-9

Your comment is noted. No change to the Final EIS was necessary.

F-1-10

Your comment is noted. No change to the Final EIS was necessary.

F-1-11

Your comment is noted. No change to the Final EIS was necessary.

F-1-12

Your comment is noted. No change to the Final EIS was necessary.

F-1-13

Your comment is noted. No change to the Final EIS was necessary.

F-1-14

Your comment is noted. No change to the Final EIS was necessary.

F-1-15

Your comment is noted. No change to the Final EIS was necessary.

F-1-16 through F-1-18

Reclamation does not concur with this comment. Consistent with the purpose and need of the proposed federal action, Reclamation believes that it is important to provide operational guidelines that address the operation of the reservoirs throughout the full range of water levels. This includes the availability of surplus water when water levels in the reservoirs are in the upper range.

F-1-19

Your comment is noted. No change to the Final EIS was necessary.

F-1-20

Your comment is noted. No change to the Final EIS was necessary.

F-1-21

Reclamation does not concur with this comment. The foundation of the analysis in the EIS is a relative comparison between alternatives. Use of the historical record, tree-ring reconstructions and other techniques to project future inflows (Section 4.2 and Appendix N) provides a valid relative comparison of the alternatives.

F-1-22

See response to Comment No. F-1-21.

F-1-23

Your comment is noted. No change to the Final EIS was necessary.

F-1-24

Your comment is addressed in the general response pertaining to climate changes and hydrologic variability in the introduction to Volume IV of the Final EIS. Section 4.2 of the Final EIS has been enhanced and two new appendices (Appendix T and Appendix U) have been added to provide additional information regarding the potential impacts of climate change and hydrologic variability.

F-1-25

Reclamation concurs with this comment. Actual inflow from August 2006 through May 2007 was substantially lower than the projected inflow that was used in the hydrologic modeling that was conducted in the fall of 2006 for the Draft EIS. The modeling for the Final EIS was updated in June 2007 and incorporated the most current conditions and inflow projection information at that time. The different initial conditions that were used in the modeling for the Draft EIS and Final EIS are presented in Appendix A.

F-1-26 through F-1-28

See response to Comment No. F-1-21.

F-1-29

In the modeling of the alternatives, all action alternatives are assumed to revert back to the assumptions used to represent the No Action Alternative after in 2026. Figure 4.4-6 shows the maximum modeled shortage amounts in each year for all alternatives and the large maximum shortages occurring after 2026 are primarily the result of this assumption.

F-1-30

Reclamation concurs with this comment. The referenced table and figure have been revised in the Final EIS.

F-1-31

Reclamation concurs not concur with this comment. As noted in Section 4.11.1.3, the underlying hourly prices used in the analysis of economic values were based on 2004 price data. However, these prices were escalated by 2.2 percent per year to estimate 2008 prices. This escalation method is commonly used in the industry, was determined to be appropriate for this analysis, and provided results that could be used in the relative comparison of the action alternatives to the No Action Alternative.

F-1-32

Your comment is noted. No change to the Final EIS was necessary.

F-1-33

Your comment is noted. No change to the Final EIS was necessary.

F-1-34

Your comment is noted. No change to the Final EIS was necessary.

F-1-35

Your comment is noted. No change to the Final EIS was necessary.

F-1-36

See response to Comment No. F-1-3.

F-1-37

Your comment is noted. No change to the Final EIS was necessary.

Memorandum

To: Area Manager, Bureau of Reclamation, Boulder City, Nevada (Attn: Nan Yoder)

From: Field Supervisor

Subject: Draft Environmental Impact Statement (DEIS) on Colorado River Interim Guidelines for Lower Basin Shortages and Coordinated Operations of Lake Powell and Lake Mead – Comments

Thank you for the opportunity to assist as a Cooperating Agency in the development of this important DEIS. The Fish and Wildlife Service (FWS) provides the following comments for your consideration on the subject DEIS. We are providing these comments in accordance with the Council of Environmental Quality regulations addressing cooperating agency status (40C.F.R. 1501.6 & 1508.5).

We note that the FWS provided comments as a Cooperating Agency by memorandum dated January 19, 2007, and discussed these further at your January 22, 2007, meeting of Cooperating Agencies. We do not see acknowledgement of the following comments, even though during discussion of our written comments you did not express any concerns indicating that you could not use them. We therefore assumed that they were acceptable for incorporation into the EIS. We reiterate these comments and offer to discuss them if that would be helpful. 1

1) Page 1-13: Add Minute 306, December 12, 2000 to the Minutes noted in Table 1.7-1 for United States-Mexico Water Treaty of 1944, since it refers to collaborative efforts between the U.S. and Mexico to ensure use of water, i.e. quantity as noted for the 1944 Treaty on Page 1-12, lines 15 and 16, for ecological purposes in Reach 9. 2

2) Page 4-170, lines 10-29: The NIB-to-SIB, which is shared by the U.S. and Mexico, represents an important wildlife area, especially for migratory neotropical songbirds and waterfowl and other wetland birds. Also, various native and non-native fish species exist in the upper portion of the river that is maintained by sources including leakage at Morelos Dam, agricultural return drain flows, subsurface sources, and occasional releases. We continue to believe that effects to fish and wildlife resources should be addressed by this document in the NIB to SIB reach. 3 4

F-2

3) Page 6-5, lines 20-22: The FWS requests, pursuant to Executive Order 12114 as applied to the National Environmental Policy Act and development of this EIS, that our agency be included in investigations of the effects of this Federal action in the Colorado River delta area of Mexico due to our migratory bird and endangered species responsibilities. 5

The following are general comments as well as specific comments addressing specific sections, pages, and line numbers in the text.

Chapter 1

Page 1-3, lines 32-35: Reclamation should discuss what some of the anticipated future demands 6
might be that could result in low reservoir elevations. Increased water use in the Upper Colorado
River Basin is one likely cause. The reference to Colorado River Compact Article III(d) on page 7
1-15, lines 3-4 may also be appropriate to include.

Page 1-26, lines 22-26: While the LCR MSCP does provide "mitigation" for fish and wildlife
species in the LCR corridor that are not included as covered species, it is inaccurate to state that 8
effects to these un-covered species are fully mitigated. There are several land cover types that
provide habitat for these un-covered species that are affected by LCR operations, but are not 9
included in the conservation program.

Chapter 2

Page 2-2, lines 15-16: A definition of "system water" and "non-system water" would be 10
appropriately referenced here. Also, in lines 20-22, is it Reclamation's intent to have the
regulations part of the proposed action detailed in the FEIS, or will the regulations be published 11
separately?

Page 2-13, lines 12-13: Define "bypass flow". 12

Chapter 3

Page 3-29, lines 15-21: We understand that Reclamation cannot predict how shortage would be
managed by the water users in Arizona; although Arizona has provided some details in their 13
Drought Preparedness Plan. However, since an obvious method would be to temporarily lease
water from agricultural users in the Yuma area for delivery to Phoenix and Tucson, that would
result in a decrease in the application of water to fields in the Yuma area. With less water on the 14
fields, the amount of groundwater flowing into the river might be reduced. We suggest an
explanation here (or reference to one in an Appendix) of why groundwater amounts are not 15
likely to change due to the Federal action.

Page 3-71, Table 3.8-7: Bluehead suckers are probably not found in or below Lake Mead. The 16 17
correct spelling of the species name for Yuma clapper rail is *Longirostris yumanensis*.

Chapter 4

F-2

Page 4-4, lines 35-40: Most available climate models project that the southwestern United States will experience a significantly more arid period in the 21st century, with a transition, which is now underway, to a more arid climate, dominated by a pattern similar to the current drought. We 18
recommend that Reclamation add a section discussing this information and its implications in the context of Reclamation's analysis of future hydrology.

Page 4-7, lines 1-5: The LCR MSCP includes provision for the transfer of up to 1.574 maf from downriver agricultural users to more upriver urban users. This concept is not included within the 19
common assumptions. We understand that a portion of the intent of the modeling is to show effects of the shortage alternatives and that those effects can be incorporated within the change in 20
1.574 maf, but this may not be clear to other readers. This is especially important when discussing the groundwater changes later in the section.

Page 4-8, lines 24-26: We believe it is important to include the rationale for the Drop 2 structure 21
to be in place and operating. If the environmental compliance has been completed for this project, inclusion may be appropriate. If not, please explain why Reclamation believes this 22
project has certainty.

Page 4-58, lines 6-10: This paragraph is an example of where a discussion of what is meant by 23
"non-system water" would be helpful in understanding the closing statement. How would SNWA development of non-system supplies affect the releases from Hoover Dam? 24

Page 4-65, lines 8-13: In the introduction to this section (4.3.7), it might be worthwhile noting that in the event of a Phase 1 or Phase 2 shortage, the two major entities that would receive less 25
water are CAP and MWD. Given that fact, flows entering and leaving Lake Havasu under 26
shortage conditions would be largely the same (allowing for some minor depletions). Perhaps some explanation here on that subject would be useful. Also, flows below Parker Dam may, over the course of the 50-year life of the LCR MSCP, be reduced as much as 1.574 maf due to 27
water transfers from agricultural users to the urban areas. How is that factored into the modeling?

Page 4-68, lines 7-15: Perhaps it would have been better to use the flows below Headgate Rock Dam (which would reflect diversions to CRIT) than to use those above which don't show any 28
real difference from the Parker Dam releases. Unless the major water users below Parker Dam provide leased water for use by CAP and MWD during times of shortage, one would not expect 29
these high-priority users to change their water use. Differences between the alternatives, particularly in terms of groundwater levels, are related to this.

Page 4-79, lines 6-13: Although this begins the discussion of SNWA's creation of new sources, it still does not relate how those sources would provide existing users with alternative water so 30
that SNWA could take more river water. For example, desalinization plants would have to be 31
operated near a source of non-Colorado River water in order to later affect an exchange.

Page 4-79, lines 30-40: Please explain the statement that the change in point of diversion effects 32
under the LCR MSCP are not additive to the changes due to shortage.

F-2

Page 4-94, lines 1-6: Since storage of water is a factor in reducing shortages through
maintenance of lake elevations, perhaps a discussion of how that stored water being used during
a potential shortage situation affects lake levels. Similarly, for the surplus discussion on page 4- 33
99, lines 1-13.

Page 4-162, lines 11-15: Perhaps it should be noted here that the LCR MSCP provides coverage 34
for changes in points of diversion up to 1.574 maf/year. The amount of potential shortage is
higher than that figure. It should be explained how the conservation for the LCR MSCP relates 35
to the shortage amounts, particularly in light of the increase in amount of water that had a change
in point of diversion over the 50-year life of the LCR MSCP.

Page 4-163, line 14: The summary in this section should focus on the changes in median flows
and the relationship to groundwater levels. The amount of vegetation affected is directly related 36
to those groundwater changes. The discussion should also address the frequency and multi-year
potential for these reduced flows. This should be included in the discussions in subsections 37
4.8.3.4 and 4.8.3.5. It is the changes in groundwater that may be most relevant to an effects 38
analysis since those changes can alter the vegetation structure and wildlife use.

Page 4-182, line 38- Page 4-185, line 35: This analysis would be more clear if it were organized
either by alternative, or by percentile elevations. Based on figure P-81 (on page P-88) it appears
that, at the 50th percentile, Glen Canyon Dam release temperatures would generally be colder for 39
all alternatives compared to the no action , but the effects of this are not considered in the
analysis.

Page 4-189, lines 33-34: If MacNeils sooty-wing skipper can be considered present in the lower
Grand Canyon due to known records at the Muddy River, it seems inappropriate to state that this 40
species does not occur at Lake Mead. Please review this information.

Page 4-192, lines 8-9: The woundfin is also not known from Lake Mead. 41

Page 4-194, lines 11-12 and page 4-197, lines 21-28: The Colorado River cotton rat is found
from the vicinity of Needles south to at least Ehrenburg. Please examine the data on this species 42
locations and revise these sections.

Page 5-11, lines 21-25: The Long-Term Experimental Plan for the Operation of Glen Canyon
Dam will further modify the proposed action of the DEIS by potentially altering the daily and 43
seasonal pattern of dam releases at Glen Canyon Dam which could have cumulative effects
relative to the proposed action of the DEIS.

We look forward to continuing to work with you on this important effort. Our contacts are as follows: Sam Spiller (Lower Colorado River Coordinator, Tel: 602/841-5329, Email: sam_spiller@fws.gov) as the primary contact and for National Wildlife Refuge and Mexico delta resources; Glen Knowles (Biologist, Tel: 602/242-0210 x233, Email: glen_knowles@fws.gov) for Glen Canyon Dam and associated operations (generally downriver from Glen Canyon Dam to upper Lake Mead); and Lesley Fitzpatrick (Biologist, Tel: 602/242-0210 x236, Email: Lesley_fitzpatrick@fws.gov) for the Lower Colorado River Multi-Species Conservation

F-2

Program and associated operations (generally from upper Lake Mead downriver to the Southerly International Boundary).

F-2

This page intentionally left blank.

Reponses to Comment Letter F-2

F-2-1

Reclamation reviewed the comments submitted in January 2007 and as appropriate, modified the Draft EIS that was published in February 2007.

F-2-2

Reclamation concurs with this comment. A citation of Minute 306 has been added to Table 1.7-1.

F-2-3 and F-2-4

Your comments are noted. Potential impacts of the proposed federal action to fish and wildlife resources in the NIB to SIB reach are analyzed (Section 4.8).

F-2-5

Reclamation has complied with Executive Order No. 12114 and Public Law 109-432 by informing the Department of State of the proposed federal action and by providing technical support to the United States Section of the International Boundary and Water Commission (USIBWC) for its consultation with Mexico. The Final EIS incorporates appropriate information regarding potential hydrologic and water quality impacts to Mexico (at the appropriate Treaty delivery point) that have been prepared after coordination with the USIBWC, as well as with representatives of the Department of State.

F-2-6

The information requested is provided in the EIS. Reclamation's modeling of the alternatives considered various factors that could affect future reservoir water levels. These factors include future water demands, hydrologic variability, the coordinated operation for Lake Powell and Lake Mead, and the storage and delivery of conserved water via the proposed Lake Mead storage and delivery mechanism.

F-2-7

Your comment is noted. No change to the Final EIS was necessary.

F-2-8 and F-2-9

Reclamation concurs with these comments. The referenced statement in Section 1.8.5 regarding mitigation for un-covered species has been modified.

F-2-10

Reclamation concurs with this comment. The terms “system water” and “non-system water” have been defined in the glossary of the Final EIS.

F-2-11

Reclamation has included draft operational guidelines in the Final EIS (Appendix S).

F-2-12

The term “bypass flows” has been defined in the glossary of the Final EIS.

F-2-13 through F-2-15

Your comments are noted. Any presumption of temporary or long-term water transfers between specific agricultural and municipal interests is speculative since it is unknown which entities might participate and at what level of participation. Given the speculative nature of agricultural to urban transfers, it is not possible to make a quantitative assessment of the potential impacts of these types of actions on groundwater or other resources.

F-2-16

Reclamation concurs with this comment. Table 3.8-7 has been corrected in the Final EIS.

F-2-17

Reclamation concurs with this comment. Table 3.8-7 has been corrected in the Final EIS.

F-2-18

Your comment is addressed in the general response pertaining to climate changes and hydrologic variability in the introduction to Volume IV of the Final EIS. Section 4.2 of the Final EIS has been enhanced and two new appendices (Appendix T and Appendix U) have been added to provide additional information regarding the potential impacts of climate change and hydrologic variability.

F-2-19 and F-2-20

Potential flow reductions resulting from shortages and changes to points of diversion (e.g. due to existing or planned water transfers, conservation activities postulated for the storage and delivery mechanism, etc.) were modeled for each alternative and the modeling assumptions are detailed in Section 4.2, Appendix A, Appendix D, and Appendix M. The groundwater analysis in the Davis Dam to Parker Dam and Parker Dam to Imperial Dam reaches was based on a relative comparison of the median flows for each alternative, including potential flow reductions as modeled.

Consistency of the Preferred Alternative with the LCR MSCP will be analyzed and submitted separately to the Fish and Wildlife Service.

F-2-21 and F-2-22

Legislation passed by Congress in late 2006 (Public Law 109-432) requires that the Secretary proceed "without delay" with the "construction, operation and maintenance" of the Drop 2 Storage Reservoir. Reclamation published a Final EA on the Drop 2 Storage Reservoir project on June 20, 2007 (http://www.usbr.gov/lc/yuma/environmental_docs/environ_docs.html). Construction is scheduled to begin in 2008 and is expected to be operational by 2010. Therefore, the inclusion of this project as part of the No Action Alternative and the action alternatives is consistent with NEPA guidelines.

F-2-23

See response to Comment No. F-2-10.

F-2-24

The effect that individual future SNWA non-system water projects will have on Hoover Dam releases will vary depending on whether the source of supply for the individual projects is located upstream or downstream of Hoover Dam. Since SNWA's intakes are in Lake Mead, non-system water projects originating upstream of Hoover Dam would have no effect on Hoover Dam releases. SNWA non-system water projects originating downstream of Hoover Dam, however, could potentially result in a reduction in Hoover Dam releases. Such projects would likely involve a water "exchange" with another agency where the other agency would take possession of the new non-system water supply developed by SNWA in exchange for an equivalent portion of the other agency's Colorado River water supply yet to be released from Lake Mead. The analysis of the storage and delivery mechanism in the EIS considered non-system water projects originating upstream and downstream of Hoover Dam.

F-2-25

Your comment is noted. No change to the Final EIS was necessary.

F-2-26

The analysis of the potential changes in flows in each reach is detailed in Section 4.3.

F-2-27

See responses to Comment Nos. F-2-19 and F-2-20.

F-2-28

Your comment is noted. No change in the Final EIS was necessary.

F-2-29

See responses to Comments Nos. F-2-13 through F-2-15.

F-2-30 and F-2-31

Conservation projects (including canal lining, desalination, etc.) would result in additional water supplies. Those projects would not necessarily need to be near a source of Colorado River water to affect an exchange.

F-2-32

This comment does not accurately reflect the information published by Reclamation in the Draft EIS. The referenced section on Page 4-79 of the Draft EIS states "The river flow reductions that were observed for the river reaches downstream of Hoover Dam under the action alternatives were similar to those previously analyzed in the LCRMSCP Final EIS and LCR MSCP BA/BO".

Also see responses to Comment Nos. F-2-19 and F-2-20.

F-2-33

Reclamation has included draft operational guidelines in the Final EIS (Appendix S) that discuss the creation and delivery of Intentionally Created Surplus (ICS) for all Lower Basin water supply conditions (including during a Shortage Condition and a Surplus Condition).

F-2-34

Reclamation concurs with this comment. The text in Section 1.8.5 and Section 4.8.1.2 has been modified.

F-2-35

See responses to Comment Nos. F-2-19 and F-2-20.

F-2-36 through F-2-38

The discussion of the potential impacts on vegetation has been expanded in the Final EIS to more directly address the connection between changes in annual median flows, groundwater levels, and riparian and marsh vegetation impacts. Sections 4.8.3.4 and 4.8.3.5 have also been modified in the Final EIS to include discussions of the magnitude, frequency, and duration of annual median flow differences under all alternatives and the anticipated effects on riparian groundwater levels and vegetation.

F-2-39

Information presented in the Draft EIS has been modified in the Final EIS to clarify this issue. Reclamation identified that the temperature graphs used in the Draft EIS (presented in Appendix P) could be clarified by establishing a single temperature output for each month at the three Lake

Powell elevation percentiles. Accordingly, for the Final EIS, the average monthly temperature for each month at the 10th, 50th and 90th percentile were used rather than the range provided in the Draft EIS. Based on this revision, the average temperature for some of the action alternatives does fall lower than the No Action Alternative. As a result, Reclamation added additional discussion on these potential impacts to fishery resources in the Final EIS. Please refer to Chapter 4.8 for discussion of the results of these analyses.

F-2-40

Information presented in the Draft EIS has been modified in the Final EIS (see Section 4.8.4.3 and Table 4.8-5) to clarify this issue. The FEIS includes a discussion and analysis of McNeill's sooty-winged skipper and its habitat at Lake Mead.

F-2-41

The discussion regarding woundfin at Lake Mead in the Draft EIS was related to those individuals that may move downstream from the Virgin River into Lake Mead as the lake level drops and more riverine habitat is exposed in the inflow area upstream of Lake Mead and is not intended to indicate that woundfin regularly inhabit Lake Mead under current conditions.

F-2-42

Reclamation concurs with this comment. A discussion on potential impacts to the Colorado River Cotton Rat has been added to the Special Status Species discussion in Chapter 4.8 of the Final EIS and addresses the area from Davis Dam to Lake Havasu.

F-2-43

It is anticipated that the ROD for this EIS will implement guidelines for the coordinated management of the Lake Powell and Lake Mead. These guidelines will be used in the AOP process to inform the Secretary's decisions with regard to the annual release from Lake Powell for each year. The Long-term Experimental Plan (LTEP) for the operation of Glen Canyon Dam is primarily focused on implementing a structured, long-term program of experimentation (including dam operations, as well as other potential management actions such as removal of non-native fish species). Dam operations considered by LTEP will not modify Lake Powell's annual release. Potential changes to daily and seasonal patterns of release relative to the assumptions in this EIS may occur due to LTEP; however, those changes anticipated to be addressed in the LTEP EIS or other appropriate decision making processes.

San Francisco, CA 94105-3901

April 30, 2007

Robert W. Johnson
Regional Director
Lower Colorado Region
Bureau of Reclamation
Attn: BC00-1000
P.O. Box 61470
Boulder City, NV 89006-1470

Subject: Draft Environmental Impact Statement for Lower Basin Shortage Guidelines and Coordinated Management Strategies for Lake Powell and Lake Mead Under Low Reservoir Conditions, Lower Colorado River Basin

The U.S. Environmental Protection Agency (EPA) has reviewed the above-referenced document pursuant to the National Environmental Policy Act (NEPA), Council on Environmental Quality (CEQ) regulations (40 CFR Parts 1500-1508), and our NEPA review authority under Section 309 of the Clean Air Act. Our detailed comments are enclosed.

EPA supports the development of shortage guidelines which will provide specific criteria for reductions in annual water deliveries during low reservoir conditions. The beneficial uses of the Lower Colorado River are diverse, providing vital environmental, economic, and public health benefits for Arizona, California and Nevada (Lower Basin States). Unpredictable, large disruptions in water deliveries or sudden changes in Lake Mead and Lake Powell operations could have significant adverse impacts on these beneficial uses. The draft environmental impact statement (DEIS) makes clear that action is required to address future shortages. All of the action alternatives would reduce the probability of shortages and increase the flexibility to operate the Colorado River water supply system for multiple purposes.

We commend the Bureau of Reclamation (Reclamation) and cooperating agencies
for evaluating a range of alternatives that define the trade-offs between different users and
benefits, such as water supply, hydropower generation, and recreation. We recognize that
Reclamation is convening a workgroup of climate change experts to evaluate the water
supply implications of climate change, and we support the consideration of this 1
information in your final decision-making on this project. EPA supports the overall
approach as proposed in the Conservation Before Shortage and Basin States alternatives,
in particular the concepts of voluntary shortages prior to involuntary shortages and the 2
storage and delivery of conserved system and non-system water (water banking).

F-3
Printed on Recycled Paper

Based upon our review, we have rated this DEIS, and the proposed action
alternatives, Environmental Concerns - Insufficient Information (EC-2) (A *Summary of* 3
EPA Rating Definitions is enclosed) due to concerns with potential adverse effects to
beneficial uses and the need for additional information regarding the effects of climate
change, banking of conserved water, and monitoring. EPA is concerned that long-term 4
reduction of water quantities and availability due to drought, shortage declarations,
climate change, and increasing growth and water demand will result in adverse impacts to 5
in-stream resources (riparian habitat, fish and wildlife), water quality, water supply
management flexibility and associated cumulative impacts. Additional information on
changing climatic conditions and water management mechanisms will contribute to more 6
systematic water resources planning and further explain key components of proposed
actions.

We recommend Reclamation develop a comprehensive, annotated list of water
management tools available to Colorado River users to further enhance the Colorado 7
River system flexibility and the benefits of the proposed approach. In that regard, we
recommend the final environmental impact statement (FEIS) include a description of, and
commitment to, a detailed monitoring, adaptive management, and water banking 8
accounting plan. The shortage guidelines should be based upon the principles of: 1)
collaboration, partnerships, and a transparent public involvement process; 2) protection of
the environment, human health, and beneficial uses of the Colorado River; 3) 9
minimization of involuntary reductions; and 4) mitigation of direct, indirect, and
cumulative impacts. EPA supports system management for small, predictable reductions
in annual water use versus large, involuntary disruptions in water supply service and 10
Colorado River flows.

We appreciate Reclamation's February 5, 2007 presentation to EPA on this project and the opportunity to provide comments on the DEIS. We would be glad to set up a conference call to discuss the enclosed recommendations. We look forward to continued participation in this process as more information becomes available. When the FEIS is released for public review, please send <u>two</u> copies to the address above (mail code: CED-2). If you have any questions, please contact me or Laura Fujii, the lead reviewer for this project. Laura can be reached at 415-972-3852 or fujii.laura@epa.gov.

Sincerely,

for Enrique Manzanilla, Director
Communities and Ecosystems Division

U.S. Environmental Protection Agency Rating System for Draft Environmental Impact Statements Definitions and Follow-Up Action*

__Environmental Impact of the Action__

LO – Lack of Objections

The U.S. Environmental Protection Agency (EPA) review has not identified any potential environmental impacts requiring substantive changes to the proposal. The review may have disclosed opportunities for application of mitigation measures that could be accomplished with no more than minor changes to the proposal.

EC – Environmental Concerns

EPA review has identified environmental impacts that should be avoided in order to fully protect the environment. Corrective measures may require changes to the preferred alternative or application of mitigation measures that can reduce these impacts.

EO – Environmental Objections

EPA review has identified significant environmental impacts that should be avoided in order to provide adequate protection for the environment. Corrective measures may require substantial changes to the preferred alternative or consideration of some other project alternative (including the no-action alternative or a new alternative). EPA intends to work with the lead agency to reduce these impacts.

EU – Environmentally Unsatisfactory

EPA review has identified adverse environmental impacts that are of sufficient magnitude that they are unsatisfactory from the standpoint of public health or welfare or environmental quality. EPA intends to work with the lead agency to reduce these impacts. If the potential unsatisfactory impacts are not corrected at the final EIS stage, this proposal will be recommended for referral to the Council on Environmental Quality (CEQ).

__Adequacy of the Impact Statement__

Category 1 – Adequate

EPA believes the draft EIS adequately sets forth the environmental impact(s) of the preferred alternative and those of the alternatives reasonably available to the project or action. No further analysis of data collection is necessary, but the reviewer may suggest the addition of clarifying language or information.

Category 2 – Insufficient Information

The draft EIS does not contain sufficient information for EPA to fully assess environmental impacts that should be avoided in order to fully protect the environment, or the EPA reviewer has identified new reasonably available alternatives that are within the spectrum of alternatives analyzed in the draft EIS, which could reduce the environmental impacts of the action. The identified additional information, data, analyses or discussion should be included in the final EIS.

Category 3 – Inadequate

EPA does not believe that the draft EIS adequately assesses potentially significant environmental impacts of the action, or the EPA reviewer has identified new, reasonably available alternatives that are outside of the spectrum of alternatives analyzed in the draft EIS, which should be analyzed in order to reduce the potentially significant environmental impacts. EPA believes that the identified additional information, data, analyses, or discussions are of such a magnitude that they should have full public review at a draft stage. EPA does not believe that the draft EIS is adequate for the purposes of the National Environmental Policy Act and or Section 309 review, and thus should be formally revised and made available for public comment in a supplemental or revised draft EIS. On the basis of the potential significant impacts involved, this proposal could be a candidate for referral to the CEQ.

* From EPA __Manual 1640 Policy and Procedures for the Review of Federal Actions Impacting the Environment__. February, 1987.

APR-30-2007 MON 12:12 PM U.S.E.P.A. FAX NO. 4159478026 P. 05

EPA DETAILED DEIS COMMENTS LOWER BASIN SHORTAGE GUIDELINES AND COORDINATED MANAGEMENT STRATEGIES FOR LAKE POWELL AND LAKE MEAD UNDER LOW RESERVOIR CONDITIONS, LOWER COLORADO RIVER BASIN, CA, AZ, NV, APRIL 30, 2007

Conservation and Water Use Efficiency

The Basin States and Conservation Before Shortage alternatives include water management tools which would enhance the management flexibility of the Colorado River system. EPA strongly supports the implementation of these tools to maximize water conservation and water use efficiencies – key components of supply and demand management – if adverse effects on third parties (e.g., downstream users, in-stream beneficial uses) are minor. Innovative and aggressive supply and demand management is essential in assuring a long-term, sustainable balance between available water supplies, demand, and ecosystem and public health. Efforts to improve system flexibility, conservation, and water use efficiencies are even more urgent given the projected growth in the Lower Colorado River Basin, the adverse effects of the multi-year drought, and the potential adverse effects of climate change on scarce water supplies.

Recommendations:

We urge the Bureau of Reclamation (Reclamation) to include a detailed tool kit of supply and demand management measures in an appendix in the Final Environmental Impact Statement (FEIS). This appendix could serve as an extension of any of the action alternatives; further enhancing Colorado River system flexibility and the benefits of the proposed management approach. The list of tools could also serve as a resource for Colorado River water providers (e.g., water districts, irrigation districts) who wish to maximize the effective use of their water supplies. The appendix should describe the full range of tools available to users to improve water quality and reuse, maximize water use efficiencies, balance supply and demand, and avoid and minimize adverse effects to third parties. The description of these tools should include a report of each tool's potential adverse third party effects, its ability to enhance water management flexibility, mitigation opportunities, and the most appropriate entities to use the tool. 11

As recommended by the Water Science and Technology Board (National Academy of Sciences)[1], we urge Reclamation to work with Colorado River users to conduct a comprehensive, action-oriented study of Colorado River region urban and agricultural water practices and changing patterns of demand. If integrated with the proposed shortage guidelines, this study could provide a more systematic basis for water resources planning across the region. We recommend the FEIS address the need for this study and how and when the study could be conducted. 12

[1] Colorado River Basin Water Management: Evaluating and Adjusting to Hydroclimatic Variability (2007), p. 9. Water Science and Technology Board, National Academy of Sciences, 500 Fifth St. N.W., Washington, D.C. 20001.

1

F-3

APR-30-2007 MON 12:13 PM U.S.E.P.A. FAX NO. 4159478026 P. 06

Efficient water use can be influenced by development, infrastructure, and drinking water policies. We recommend the FEIS explore the linkages between these different factors and describe potential mechanisms to align them in order to better protect water resources. We recommend the FEIS provide a short discussion of who could best implement the identified mechanisms. The following reports may be of assistance as a starting point for your evaluation:

- Growing Toward More Efficient Water Use: Linking Development, Infrastructure, and Drinking Water Policies. EPA Publication 230-R-06-001, EPA National Service Center for Environmental Publications, (800) 490-9198 or nscep@bps-lmit.com.
- Protecting Water Resources with Higher-Density Development. EPA publication 231-R-06-001. EPA National Service Center for Environmental Publications, (800) 490-9198 or nscep@bps-lmit.com.

We recommend the Affected Environment chapter of the FEIS describe the current efforts to increase conservation, water use efficiencies, water supplies, and management flexibility for the Colorado River system. For instance, provide a summary of Arizona's Drought Management Plan, efforts by California to ensure adequate water supplies for southern California, and the conservation and use measures being taken by the Southern Nevada Water Authority (SNWA). 13

Storage and Delivery of Conserved Water (Water Banking in Lake Mead)
The DEIS analysis clearly demonstrates the benefits of the storage and delivery of conserved water (water banking). These benefits include the reduced probability of shortages, increased Colorado River management flexibility, and increased probability for flows below Morelos Diversion Dam, under some alternatives, that could benefit the complex riparian ecosystem of the Limitrophe Reach (Northern International Boundary to the Southern International Boundary) (p. ES-14, p. 4-76) and Colorado River Delta.

Recommendations:
The Basin States alternative limits the use of water banking in Lake Mead to the Lower Basin States while the Conservation Before Shortage alternative allows other entities, including Mexico, to utilize this water bank. The allowable total amount of stored conserved water also varies between alternatives. In order to fully realize management flexibility through water banking, EPA recommends the selected alternative maximize the use of water banking by allowing a broad range of users and ample storage capacity for conserved water. 14

The Conservation Before Shortage alternative includes the concept of compensated voluntary water reductions, triggered by specific Lake Mead elevations and financed through a compensation program. Under this concept willing Lower Basin users, including Mexico, would be paid to voluntarily and temporarily reduce their water use (p. 4-82). To facilitate regional efforts to optimize water use, we recommend the FEIS provide additional information on 15

2

F-3

APR-30-2007 MON 12:13 PM U.S.E.P.A. FAX NO. 4159478026 P. 07

Lake Mead elevation triggers, funding mechanisms, and management of the compensated voluntary water reduction program. 15

We recommend the FEIS include a detailed description of the accounting procedures and conserved water validation process for the storage and delivery of conserved water in Lake Mead. 16

Monitoring and Adaptive Management Plan

The DEIS analysis depends heavily on probabilistic models based upon a number of assumptions regarding precipitation, climate, water supply depletion rates, water supply policy and trends, and conservation programs. We recommend that existing conditions be monitored and model assumptions validated.

Recommendation:

Given the assumptions and uncertainties surrounding probabilistic models, we recommend Reclamation develop and commit to a detailed monitoring and adaptive management plan as part of the FEIS. We recommend the plan include details on what, who, and when to monitor; the process used to ensure monitoring results feed into the management decision process, and how monitoring can be used to help verify model assumptions. 17

The ability to monitor the hydrology of the Colorado River is provided by the U.S. Geological Survey's Colorado River Streamflow Gaging Network. As stated by the Water Science and Technology Board,[2] financial support for these stream gaging stations has been inconsistent and limited in recent years. The loss of stations with long periods of record (greater than 30 years) is of concern because they provide key data for understanding Colorado River hydrology and water quality (e.g., downstream perchlorate contamination, temperatures, sedimentation) and thus for Colorado River water management.

Recommendation:

We recommend the FEIS describe how Reclamation and other users of the Colorado River can ensure resources are available to maintain and expand the Colorado River Streamflow Gaging Network. 18

Climate Change

A number of studies specific to the Colorado River Basin have indicated the potential for significant environmental impacts as a result of changing temperatures and precipitation.[3] While we commend the inclusion of the hydrologic sensitivity analysis to determine model results with a wider range of hydrologic variability (Appendix N), we believe that

---

[2] Water Science and Technology Board, pps 4-5.

[3] For example, Colorado River Basin Water Management: Evaluating and Adjusting to Hydroclimatic Variability (2007); The Colorado River Basin and Climatic Change, Linda L. Nash & Peter H. Gleick (1993) (EPA Publication 230-R-93-009).

APR-30-2007 MON 12:14 PM U.S.E.P.A. FAX NO. 4159478026 P. 08

a more extensive discussion of climate change and its potential effects on the proposed action would better serve long-term, Basin-wide water management planning.

Recommendation:
We recommend the FEIS include a separate discussion of climate change and its
potential effects on the proposed action and the action's impacts. We recommend 19
this discussion provide a short summary of climate change studies specific to the
Colorado River Basin, including their findings on potential environmental and
water supply effects and their recommendations for addressing these effects.
Potential effects to examine include the incremental effects on shortage
allocations and land use. For example, if there is a projected 10-20% reduction in
precipitation for the Colorado River[4], we would recommend the FEIS describe the
effect on potential shortages, whether California would experience a higher
probability of shortages, and whether adverse land use effects, in addition to 20
temporary agricultural fallowing, could occur under a shortage determination.

Tribal Impacts

The DEIS provides a limited description of the Cocopah Indian Reservation (p. 3-84), the Limitrophe Reach, and potential cultural resources in this region. Twelve miles of the Limitrophe Reach lie within the Cocopah Indian Nation. This reach includes a complex riparian ecosystem that supports a wide variety of birds and wildlife. The multi-agency effort, in cooperation with the Cocopah Indian Nation, to restore 350 acres of this habitat signifies the ecological importance of the Limitrophe Reach. We also note that the Cocopah Indian Nation and their cultural interests extend down to the Colorado River Delta.

Recommendations:
We recommend the FEIS include a more detailed description of the ecological
resources of the Limitrophe Reach and of cultural resources below Imperial Dam 21
to the Southern International Boundary. Potential impacts to these resources
should be fully evaluated and described in the FEIS. We recommend the FEIS 22
include a description of the Cocopah Indian Nation, including a description of
their tribal interests and concerns down to the Colorado River Delta and potential 23
effects on these tribal interests.

Power Generation

Although the action alternatives would have minor impacts on the economic value of electrical power generation at Glen Canyon and Hoover Dams, the total loss of electrical power generation capabilities would have a substantial effect on the Basin Power Funds which rely on power revenues (pps. 4-230, 4-241). These funds provide key support for Colorado River environmental programs, the Colorado River Salinity Control Program, and projects to address Tribal water right settlements.

[4] Nash and Gleick, p. ix.

4

F-3

APR-30-2007 MON 12:14 PM U.S.E.P.A. FAX NO. 4159478026 P. 09

Recommendation:

EPA is concerned with the potential reduction of the Basin Power Funds. We 24 recommend the FEIS describe potential mitigation measures that could be included in the selected alternative to offset or replace these revenue reductions. 25

5

F-3

Reponses to Comment Letter F-3

F-3-1

Your comment is addressed in the general response pertaining to climate changes and hydrologic variability in the introduction to Volume IV of the Final EIS. Section 4.2 of the Final EIS has been enhanced and two new appendices (Appendix T and Appendix U) have been added to provide additional information regarding the potential impacts of climate change and hydrologic variability.

F-3-2

Your comment is noted. No change to the Final EIS was necessary.

F-3-3 and F-3-4

Your comment is noted. The content of the Final EIS has been modified as appropriate.

F-3-5

Your comment is noted. The content of the Final EIS has been modified as appropriate.

F-3-6

Your comment is noted. The content of the Final EIS has been modified as appropriate.

F-3-7

Water supply planning and water supply management occurs at the federal, state, regional and local levels. Most states, regional agencies, local agencies, and communities already have or are in the process of preparing water resources management plans and/or drought management plans that address varying water demand and water supply management issues. The proposed guidelines are intended to, among other benefits, provide mainstream United States users of Colorado River water, particularly those in the Lower Division states, a greater degree of certainty with respect to the amount of annual water deliveries in future years, particularly under drought and low reservoir conditions and provide additional mechanisms for the storage and delivery of water supplies in Lake Mead. Additionally, the proposed water storage and delivery mechanism is expected to be used by agencies to increase their flexibility in meeting water use needs from Lake Mead. Implementation of these guidelines will be highly beneficial to water supply planners and will provide added water supply management options that can be used by agencies to develop more comprehensive plans to meet their water use needs, particularly during drought or low reservoir conditions.

F-3-8

Your comment is noted. Reclamation has included draft operational guidelines in the Final EIS (Appendix S) that address the administration of the ICS mechanism.

F-3-9 and F-3-10

Reclamation concurs with these comments. No change to the Final EIS was necessary.

F-3-11

See response to Comment No. F-3-7.

F-3-12

Your comment is noted. No change to the Final EIS was necessary.

F-3-13

Your comment is noted. Additional information with respect to the drought response and water supply management plans of Arizona, MWD, and SNWA have been included in Section 4.14 in the Final EIS.

F-3-14

Your comment is noted. The environmental impacts of a mechanism allowing ICS of up to 4.2 maf have been analyzed for the Preferred Alternative identified in the Final EIS.

F-3-15

Information presented in the Draft EIS has been modified in the Final EIS pursuant to this specific comment, as well as other public comments. Section H.6. of the Final EIS includes an additional assessment that considers the impacts of a compensated voluntary conservation program. Additionally as noted in Section 2.4.5 of the EIS, the Conservation Before Shortage proposal postulated several potential funding sources which the Department currently does not have the authority to implement in their entirety absent additional legislation. The viability of this funding proposal is not known at this time and therefore there is some uncertainty as to whether all of the elements of the Conservation Before Shortage proposal can be implemented.

F-3-16

See response to Comment No. F-3-8.

F-3-17

Your comment is noted. No change to the Final EIS was necessary.

F-3-18

The United States Geological Survey (USGS), in cooperation with Reclamation and other regional and local agencies, maintains a stream flow gaging system throughout the Colorado

River Basin. Reclamation also maintains additional gages in the Lower Basin. The data from these systems is used to monitor and record flows throughout the mainstream and tributaries of the Colorado River. Although Reclamation is committed to maintaining its gaging network in addition to assisting the USGS, ensuring that resources are available to expand and maintain these networks is beyond the scope of this EIS.

F-3-19 and F-3-20

Your comment is addressed in the general response pertaining to climate changes and hydrologic variability in the introduction to Volume IV of the Final EIS. Section 4.2 of the Final EIS has been enhanced and two new appendices (Appendix T and Appendix U) have been added to provide additional information regarding the potential impacts of climate change and hydrologic variability.

F-3-21 and F-3-22

The information requested regarding ecological resources in the NIB to SIB reach (limitrophe) is provided in the Draft and Final EIS. Section 3.8 provides a discussion of the vegetation and wildlife species present in the study area by river reach, including the NIB to SIB reach. Additional information on the existing endangered and listed species that are found in the NIB to SIB reach can be found in the LCR MSCP EIS (Reclamation 2004). Section 4.8 describes the potential effects of the proposed action, again by river reach including the NIB to SIB reach.

As noted in Section 3.9, there is little to no data relative to the existence of historic properties within the river channel for the river reach that extends from Imperial Dam to the SIB. Nevertheless, any known or as yet undiscovered cultural resources within this reach of the River will not be affected by the No Action Alternative or action alternatives because the current river operations will continue into the future

F-3-23

Section 3.10 provides a description of Indian Trust Assets (ITA), including those of the Cocopah Indian Reservation. Potential impacts to ITAs as a result of the proposed federal action are discussed in Section 4.10.

F-3-24 and F-3-25

Section 4.11 provides a description of electrical power resources, including the Basin Funds. Potential impacts to the Basin Funds as a result of the proposed federal action are discussed in Section 4.11.

This page intentionally left blank.

BC00-1000
1003

INTERNATIONAL BOUNDARY AND WATER COMMISSION
UNITED STATES AND MEXICO

OFFICE OF THE COMMISSIONER
UNITED STATES SECTION

APR 27 2007

Bureau of Reclamation
Attention: BC00-1000
P.O. Box 61470
Boulder City, NV 89006-1470

Dear Bureau Staff:

Thank you for providing the opportunity to review the Draft Environmental Impact Statement, titled *Colorado River Interim Guidelines for Lower Basin Shortages and Coordinated Operations for Lake Powell and Lake Mead* (DEIS). The United States Section, International Boundary and Water Commission (USIBWC) is charged through various treaties and international agreements to evaluate the relationship of projects to international obligations of the United States. The following and attached review comments are for your consideration and use.

The International Boundary and Water Commission (IBWC) is responsible for applying the boundary and water treaties between the two countries and settling differences that arise in the application of the treaties. The United States Section carries out the activities in the United States resulting from obligations and rights assumed with the Government of Mexico in accordance with these treaties and related agreements. The USIBWC duties include review of projects on resources in the United States and effects potentially crossing into Mexico.

The IBWC has agreements that pertain to issues within the Colorado River watershed, the Treaty Relating to the Utilization of Waters of the Colorado and Tijuana Rivers and of the Rio Grande, and supplementary protocol, November 1, 1944 Untied States-Mexico (1944 Water Treaty), the Treaty to Resolve Pending Differences and Maintain the Rio Grande and Colorado River as the International Boundary Between the United States and Mexico, signed at Mexico November 23, 1970 (1970 Boundary Treaty), and several related agreements that merit consideration.

In accordance with the 1944 Water Treaty, the United States delivers 1.5 million acre-feet of Colorado River water annually to Mexico. The treaty also states that when there is water surplus to United States uses, an additional volume of up to 200,000 acre-feet/year may be delivered. The two Governments entrusted the IBWC to give attention to salinity control. Minute No. 242, a binding agreement of the United States and Mexican Governments, controls the salinity of Colorado River water delivered to Mexico. The Minute also provides for limits on groundwater pumping within five miles of the international boundary near San Luis, Arizona, and for consultations between the two countries prior to undertaking any new development of the surface or groundwater resources, or undertaking substantial modifications of present developments in the border area, that might adversely impact the other country. Commission Minute No. 306 provides for cooperation between the two countries in the development of studies and recommendations regarding the ecology of the Colorado River limitrophe and delta. The 1970

F-4

The Commons, Building C, Suite 100 • 4171 N. Mesa Street • El Paso, Texas 79902
(915) 832-4100 • (FAX) (915) 832-4190 • http://www.ibwc.state.gov

Boundary Treaty includes providing for the preservation of the Colorado River as the international boundary.

These agreements are all available on the USIBWC web page at www.ibwc.state.gov.

The USIBWC is the primary federal agency responsible for promoting the identification, investigation, and resolution of transboundary and boundary water and border technical issues along the United States and Mexico boundary region. The USIBWC carries out its statutory responsibilities through binational cooperation and in partnership with other entities. The United States Government gives limited technical investigative authority to the USIBWC.

Thank you again for the opportunity to review and comment on the DEIS. If you have any questions regarding these comments, please call me at (915) 832-4702 or contact R. Steve Fox, Environmental Protection Specialist, at (915) 832-4736.

Sincerely,

Gilbert G. Anaya
Supervisory Environmental Protection Specialist
Environmental Management Division

F-4

DRAFT Review Comments, United States Section, International Boundary and Water Commission, April 2007, on the *Draft Environmental Impact Statement Colorado River Interim Guidelines for Lower Basin Shortages and Coordinated Operations for Lake Powell and Lake Mead*, February 2007, Bureau of Reclamation

General Comment.

The Draft Environmental Impact Statement (Draft EIS) seems to be on water management and deliveries.

Specific Comments.

Page TOC-viii, Section 6.8. Revise to "Consultation with Government of Mexico Agencies" or "Consultation with Agencies of Mexico." 1

Page 1-3, line 34, delete "drought and" 2

Page 2-4, line 34. Revise to "In addition, the determination of shortages to Mexico does not fall under the authority of the Secretary, and therefore is not a part of the proposed federal action. 3
Such determination would be made in accordance with the 1944 Treaty" (Section 1.7). Page 2-4, 4
line 36. Specify the Subsection of the stated "(Section 1.7)," as the Section is broad.

Page 2-15. Line 22. Add a sentence or footnote to indicate that potential future Mexican participation in a storage and delivery mechanism is assumed to be included within the range for the "Unassigned" category in Table 2.6-1. 5

Page 3-3, Section 3.2. Please comment on the following. Based on the Section and Chapter 4, there could be effects to the services of MWD. MWD provides assistance to the IBWC on the "emergency transfer of a part of Mexico's Colorado River water through the Southern California aqueduct system to the emergency water connection at Otay Mesa for deliveries to Tijuana, Baja California, Mexico." Minute 310 was signed in 2003. The USIBWC FONSI notes that the agreement is for five year. 6

Page 3-46, line 1. Specify the Subsection of the stated "(Section 3.4)." Section 3.4 is referenced in line 1 of the Draft EIS in the context of salinity yet the Section is on water quantity, not quality. Recommended is stating such. 7

Page 4-8, lines 31-37 and Page 4-9, lines 1-2. This paragraph is confusing. It should be rewritten 8
for clarification. The statement "replacement of bypassed water is not assumed to occur in the
future" is particularly confusing. What does this mean in terms of modeling deliveries to Mexico 9
or why was that assumption made?

Page 4-119, lines 1-3. The sentence: "The occurrences of deliveries greater than 1.5 mafy reflect both times when additional water up to 200 kafy is made available during Flood Control conditions." After the word "available" insert the word "and." 10

F-4

3

Page 4-119, Figure 4.4-32 and others. The Figure and other charts in this Section label the y-axis as "Annual Depletions." Recommended is changing those labels to "Annual Deliveries," though they are depletions from the system. 11

Page 4-131, Section 4.5. Subsections 4.5.2.1 and 4.5.3 are on salinity. It is suggested that the Draft EIS describe the Minute 242 requirements regarding the applicable salinity differential for water deliveries to Mexico, and reference Section 3.5.1, page 3-46, on salinity. 12 It is also suggested that the Draft EIS state what the alternatives' effect would be on the salinity of waters delivered to Mexico and Minute 242 compliance. 13

Page 6-5, line 16. The Draft EIS states "IBWC and Mexico National Water Commission Meetings with representatives of Mexico…" Revise to "IBWC, the Mexico National Water Commission, and Mexico Secretariat of Foreign Relations meetings with agencies of Mexico …" 14

Page 6-8. Delete "**United Mexican States Agencies**" and insert "**Government of Mexico Agencies**." 15

Page B-32, line 2. Delete "… approximately 25 miles …" and insert "… 23.7 miles …" 16

Page B-32, line 11. Insert "The current design flood flow in the limitrophe is 140,000 cfs." 17

Page B-32, line 26. Insert after the words "The reach of" the word "the." 18

Page B-32, line 33, after "up to" insert "an additional."
With this change, it would read, "Mexico is allowed to schedule up to an additional 200 kaf pursuant to the 1944 Treaty during flood control years…." 19

Page I-1, Table I-1, U.S. Department of State. Insert after the stated "Various planning meetings" the punctuation and date "; 6/23/06." 20

Page I-2. Delete "**United Mexican States Agencies**" and insert either "**Government of Mexico Agencies**," or "**Agencies of Mexico**." 21

Page I-2, Table I-1, International Boundary and Water Commission, Mexican Section. Insert after the stated date "2/8/06," the words and punctuation "including the shortage issues and EIS,". 22 Also, insert after the stated "9/25-29/06" the words and punctuation "; including Upper Basin Tour." 23 Finally, insert, in bold in column one, another category at the end of the table, and title it "International Boundary and Water Commission (IBWC)." In column two of the same new entry, insert the words and meeting date "IBWC and Reclamation, meetings, including 6/23/06." 24

Page I-2. Table I-1. It is recommended to add additional meeting dates that occurred in February and March 2007 with the Mexican representatives. 25

Page M-8, lines 10-18. This paragraph is confusing, especially the last sentence on lines 16-18. It is suggested that this concept be clarified. If the storage credits were assumed to be generated 26

F-4

4

via extraordinary conservation within Mexico, then how could they be used by the United States to be counted toward replacement of the bypass flows to the Cienega de Santa Clara in Mexico? 26
Does this assume that U.S. entities would pay to acquire some of Mexico's water? If so, then it raises significant treaty compliance issues. 27

F-4

This page intentionally left blank.

Reponses to Comment Letter F-4

F-4-1

Your comment is noted. The TOC and Section 6.8 have been revised in the final EIS to reflect the suggested changes.

F-4-2

Reclamation does not concur with this comment. No change to the Final EIS was made.

F-4-3

Your comment is noted. No change to the Final EIS was necessary. The Draft EIS and the Final EIS include statements throughout clearly stating that determinations regarding water deliveries to Mexico would be made in accordance with the 1944 Treaty and are therefore not part of the proposed federal action.

F-4-4

Your comment is noted. The reference has been changed from Section 1.7 to Section 1.7.2.3.

F-4-5

Your comment is noted. No change to the Final EIS was necessary. As noted in Appendix M, at this time, it is unknown which entities might participate in a Lake Mead mechanism that allows the storage and delivery of conserved system and non-system water. However, modeling assumptions with respect to the entities that might participate and their respective level of participation were needed to enable the evaluation of the mechanism and its potential effects on environmental resources, particularly to reservoir storage and river flows below Lake Mead. Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 Treaty or to represent current United States policy or a determination of future United States policy regarding deliveries to Mexico.

F-4-6

Under the current modeling assumptions, the probability of shortages to California and MWD is zero over the interim period for the Preferred Alternative (Section 4.4.7.2 of the Final EIS).

F-4-7

Your comment is noted. The reference has been changed from Section 3.4 to Section 3.4.5 in the Final EIS.

F-4-8

Your comment is noted. Information presented in the EIS in Section 4.2.7 accurately reflects the modeling assumptions that are common to the No Action Alternative and the action alternatives. No change to the Final EIS was necessary with regard to expanding or clarifying the paragraph referenced in the comment. However, although not part of the comment, there was an omission in the first sentence of this paragraph. The first sentence in this paragraph has been revised in the Final EIS.

F-4-9

As discussed in Section 4.2.7 of the Final EIS, the bypass of return flows from the Welton-Mohawk Irrigation and Drainage District to the Cienega de Santa Clara in Mexico is assumed to be 109 kafy (the historical average for the period 1990 through 2005). This water is not counted as part of the 1944 Treaty delivery.

Except under the Conservation Before Shortage and Reservoir Storage alternatives, replacement of the bypassed water is not assumed to occur in the future. Under those alternatives, replacement of the bypass flows was assumed to be part of activities related to the storage and delivery mechanism.

The United States recognizes that it has an obligation to replace, as appropriate, the bypass flows and the assumptions made herein, for modeling purposes; do not necessarily represent the policy that Reclamation will adopt for replacement of bypass flows. The assumptions made with respect to modeling the bypass flows are intended only to provide a thorough and comprehensive accounting of the Lower Basin water supply. The United States is exploring options for replacement of the bypass flows, including options that would not require operation of the Yuma Desalting Plant. For modeling purposes only, the Yuma Desalting Plant is not assumed to operate over the modeling period.

F-4-10

Your comment is noted. No change to the Final EIS was made.

F-4-11

Your comment is noted. No change to the Final EIS was made. The term “depletions” is used throughout the EIS and is defined in the Glossary.

F-4-12 and F-4-13

Your comment is noted. Additional language has been added to Section 3.5.1 and Section 4.5.3 in the Final EIS.

F-4-14

Your comment is noted. The referenced sentence in Section 6.8 has been modified in the Final EIS.

F-4-15

Your comment is noted. The referenced entry in Table 6.9-1 has been modified in the Final EIS.

F-4-16

Your comment is noted. The referenced sentence in Section B.2.8 has been modified in the Final EIS.

F-4-17

Your comment is noted. No change to the Final EIS was necessary. The design capacity of the limitrophe reach is already noted in the second paragraph in Section B.2.8.

F-4-18

Your comment is noted. The referenced sentence in Section B.2.8 has been modified in the Final EIS.

F-4-19

Your comment is noted. The referenced sentence in Section B.2.8 has been modified in the Final EIS.

F-4-20

Your comment is noted. No change to the Final EIS was made.

F-4-21

Your comment is noted. The referenced entry in Table I-1 has been modified in the Final EIS.

F-4-22 through F-4-24

Your comment is noted. No change to the Final EIS was made.

F-4-25

Your comment is noted. The appropriate information in Table I-1 has been updated in the Final EIS.

F-4-26 and F-4-27

INTERNATIONAL BOUNDARY AND WATER COMMISSION
UNITED STATES AND MEXICO

OFFICE OF THE COMMISSIONER
UNITED STATES SECTION

April 30, 2007

Bureau of Reclamation
Attention: BCOO-1000
PO Box 61470
Boulder City, NV 89006-1470

Dear Bureau Staff:

The U.S. Section of the International Boundary and Water Commission provided a copy of the Draft Environmental Impact Statement on Colorado River Interim Guidelines for Lower Basin Shortages and Coordinated Operations for Lake Powell and Lake Mead to the Mexican Section of the Commission and invited comment from the Mexican Section. The Mexican Section provided detailed comments by means of a letter dated April 25, 2007. By means of this letter, I wish to communicate the Mexican Section's views to the Bureau in English. 1

The Mexican Section indicates that its comments of April 25 supplement initial views presented in a letter on March 29, 2007. That initial letter expressed the following views:

The Mexican Commissioner has indicated that any proposal for basin operations that affects Mexico's allocation needs to be approved bilaterally within the framework of the IBWC, particularly any alternatives that imply an interpretation or application of the extraordinary drought clause of the 1944 Water Treaty. Any reduction in the allocation of water to Mexico shall be done in strict conformance with the terms of the Treaty. As stated in the meetings, Mexico views that the reduction applicable to Mexico in the event of extraordinary drought should be proportional to consumptive uses in all of the basin states, not just those of the lower basin. 2 3 4

He also expresses Mexico's interest in being informed about and participating in discussions about sustainable use of the basin and, as appropriate, for Mexico to be a proportional beneficiary of conservation measures that could affect water availability in the main channel of the Colorado River. 5

Moreover, he states concern that operations under the shortage criteria could affect the salinity of Colorado River water delivered to Mexico, reduce the likelihood of surplus waters being delivered to Mexico in excess of the 1.5 million acre-foot annual allotment, and reduce environmental flows to the Colorado River Delta. 6 7 8

The Mexican Section is also concerned that the Draft Environmental Impact Statement (EIS) includes aspects related to Mexico that have not been agreed upon by the IBWC, which could generate false expectations regarding application of shortage criteria in Mexico. The Commissioner expresses his strong disagreement that alternatives that include Mexico do not take into account the concept of extraordinary drought as required by the 1944 Water Treaty in order to reduce allotments to Mexico. He is concerned that a perception has been created that Mexico has accepted the reduced allotments modeled in the alternatives – alternatives that do not conform to the 1944 Water Treaty. 9 10 11

End of the Mexican Section's March 29 comments

The Commons, Building C, Suite 100 • 4171 N. Mesa Street • El Paso, Texas 79902

F-5

In the letter of April 25, 2007, the Mexican Section expresses the following:

Any proposal for basin operations that affects allotments to Mexico must be agreed upon within the IBWC.

The EIS proposes conditions under which reductions of water allotments to users in the lower basin, including Mexico, will be undertaken. It clarifies that the modeling assumptions do not constitute an interpretation of the 1944 Water Treaty nor do they establish operating policies with regard to water deliveries to Mexico and that any determination about such deliveries will be made in accordance with the 1944 Water Treaty. Nevertheless, the use of modeling assumptions in relation to Mexico generates false expectations that those assumptions will be or must be accepted by Mexico and by having been recorded, they could be used in the future as a restriction or limiting factor in negotiations with Mexico.

We are concerned that in spite of the repeated statements from Mexico, the document that was released to the public presents assumptions that were not previously accepted by Mexico (timing, conditions, and proportion of the reductions to Mexico). 12

The reduction in the allotments of water to Mexico must be under the terms of the Treaty and proportional to consumption of all states in the basin.

The policy of reductions in the lower basin of the Colorado River and Mexico is maintained throughout the document but it does not include the upper basin, which means that Mexico bears a greater percentage of reduction (16.67%) than if proportional reductions were considered for all consumptive uses in the upper and lower basin (9.1%). 13

In the modeling of the reductions, Mexico is always included with Arizona and Nevada, while California is not included until level 2 is reached, and the upper basin is never included. This generates false expectations as to the timing and conditions under which there would be reductions to Mexico as well as the implicit acceptance by Mexico of those reductions. 14

Even the No Action alternative, which should not include implementation of any actions, contains strategies of cuts for Mexico.

After applying any of the four action alternatives, it reverts back to the No Action alternative, which is a de facto policy of cuts that significantly affect Mexico. 15

In this context, even the No Action alternative, as addressed in the EIS, is not acceptable to Mexico, yet the language implies that should none of the four alternatives be accepted, or once their period of application ends, Mexico would not object to the No Action alternative.

Consistent with the above, all of the alternatives show reductions to Mexico of various frequencies and quantities of water and none of them is acceptable in how issues related to Mexico are addressed. 16

The interest of Mexico in knowing about and participating in discussions of sustainable use of the basin and, as appropriate, being a proportional beneficiary of the conservation measures that could result in the modification of water availability in the main stem.

F-5

The EIS considers a conserved volume for Mexico charged to its allotment that is designated for
environmental use only and not for irrigation, its principal use in Mexico. Also, the delivery is not made 17
when Mexico needs it (situation of scarcity or normal conditions), but rather only in surplus conditions.
This type of voluntary conservation is of no use to Mexico. 18

No alternative was modeled in which Mexico could voluntarily conserve water to use it when it needs it.

Effect on the levels of salinity of the waters that Mexico receives.

In the analysis of the alternatives, only the quantity of water is evaluated, and not the quality of it. Given 19
the time to undertake these analyses with the sets of rules delivered during the current month of April, it is 20
assumed that the U.S. will comply with the salinity parameters agreed upon by the IBWC.

In the table shown on page ES18 it is observed that for three of the alternatives, increases in salinity levels
are recorded at Imperial Dam (5-20 ppm), which consequently would represent an increase in the salinity 21
of waters at Morelos Dam, since both are linked in conformance with Minute 242.

Limit on access to the surplus deliveries to Mexico.

Partial and total surpluses are allotted to U.S. users depending on reservoir storage and forecasts.
Nevertheless, these additional allotments could have as a consequence the reduction in the levels of the 22
dams that are indicators for declaring shortage. In this context, Mexico is excluded from distribution of
surpluses but included during a shortage declaration, which is unacceptable to Mexico. 23

Reduction in the occurrence of environmental flows required by the Colorado River Delta.

In Chapter 3 of the EIS (Page 3-29) it is mentioned that due to potential changes in reservoir storage that
occurs under the different action alternatives, the frequency and magnitude of flood control flows, which
are those that generate surplus deliveries to Mexico, could be affected. This represents an impact to 24
Mexico in both access to surplus deliveries as well as the occurrence of environmental flows in the Delta.

Around 16 species of fish and a list of bird species that live in the limitrophe reach are identified that
could be affected by application of the proposed federal action (Table 3.8-7). 25

As part of the cumulative impacts, it is noteworthy that the Drop 2 storage project will reduce the
volumes of over deliveries to Mexico and will have hydrologic effects in Mexican territory. 26

By allotting to the U.S. more frequent and greater quantities of surpluses, it leaves less water in Mead, so
that when Mead spills (less frequently) it is of a lesser volume and, as a result, less water arrives in 27
Mexico.

Inclusion of aspects that have not been agreed upon by IBWC that, by being made public in the U.S., generate false expectations on this issue.

During the binational meetings, Mexico questioned certain modeling assumptions related to Mexico;
nevertheless, in spite of the repeated questioning by Mexico, the document that was released to the public 28

F-5

presents assumptions that previously were not accepted by Mexico (timing and conditions of reductions to Mexico, proportion of the reductions to Mexico).

The inclusion of these assumptions will have an effect on the talks to define the term of extraordinary drought referred to in the Treaty or at the time when both governments set about to define the timing and conditions for making reductions, as well as the consultations that Mexico undertakes with its users. 28

Although the EIS is a document for domestic use in the United States, it is not acceptable that aspects related to Mexico are presented about which Mexico repeatedly expressed its disagreement and, as previously stated, any proposal for operating the basin that affects Mexico's allotments must be agreed upon within the IBWC under the terms of the 1944 Water Treaty. 29

End Mexican Section's comments of April 25

In addition to the above comments presented by the Mexican Section of the International Boundary and Water Commission, the U.S. Section has received observations from Mexico's National Water Commission (CNA). CNA's comments are as follows:

The Draft EIS presents five alternatives for operating the Colorado River basin from 2008-2026. The alternatives are presented as four federal action alternatives and one for reference, called the No Action alternative, which should lack any implementation of actions; nevertheless it contemplates strategies (reasonable ones in accordance with the draft EIS) of cutbacks to Mexico. In this sense, there is no control scenario where water would continue to be distributed as it is today. Although the EIS is for the purpose of internal analysis in the U.S., in fact it means there is already a de facto policy of cuts that significantly affects Mexico since, following the period of application of one of the four action alternatives, it reverts to the No Action alternative. This concerns the National Water Commission because, if none of the other four alternatives is accepted, it could be construed that Mexico would not object to the No Action alternative because it supposedly represents current conditions. 30 31 32

In the meeting held March 14, 2007, representatives of the U.S. Bureau of Reclamation explained to Mexican personnel from the IBWC and CNA that the draft EIS has been opened for public comment in the U.S. and to the opinion of Mexico until the end of April.

The minutes of that meeting confirm that the U.S. Bureau of Reclamation would provide to Mexico during the week of March 19 additional information requested by CNA so that CNA could provide its opinion on time. Nevertheless, it was not until April 10 that CNA received from the Mexican Section the agreed upon information, forcing us to review it under much pressure and it still has not been completely examined. 33

Upon conducting an analysis of the EIS, it is observed that at all times a policy of reduction in the lower part of the Colorado River basin and to Mexico is maintained. During the meetings it was mentioned that this was due to the fact that the states of the upper basin have natural reductions due to the fact that the flow of the river is insufficient for the required demand. It was also commented that the droughts in the upper basin are more frequent than in the lower basin. First, it must be reiterated that, according to the 1944 Water Treaty, the first step consists of declaring an extraordinary drought and, based on that, proportional reductions will be applied according to consumption in both countries, meaning the upper and lower basin together. Additionally, the term "consumption" implies that of current users and not to 34 35

F-5

APR-30-2007 MON 04:05 PM IBWC EL PASO FAX NO. 915 832 4191 P. 06/08

the volumes allotted that are still not utilized in the upper basin. From the analysis of drought undertaken 35
in the upper basin, it can be seen that its frequency and severity is not significant, and as such does not 36
constitute an argument to exclude the upper basin. It is observed in most cases that California is not 37
reduced until reaching a level 2. In any case, if the U.S. decides not to reduce California in any of the
alternatives, that is its decision. However, the reduction to Mexico should have been modeled only when
reductions were applied to the entire American basin, in conformance with the 1944 Water Treaty.
Mexico reiterates its concern that this modeling will generate false expectations and misinformation about
the timing and conditions under which there would be reductions in Mexico as well as Mexico's implicit 38
acceptance. This has great relevance when it comes time for both countries to evaluate the terms under
which cuts in allotments will have to be made, to define the term extraordinary drought, or for Mexico to
undertake consultations with its users. Until extraordinary drought is defined and declared, the U.S. must
comply with water deliveries to Mexico under the terms of the 1944 Water Treaty. What the EIS
proposes is a "goodwill" agreement.

An additional analysis performed on the Colorado River basin to verify that the upper basin is more
affected than the lower basin shows that the annual historic precipitation (1908-2006) has diminished less
than runoff. This could be due to three possible factors: 1) the basin could be dry in a year prior to a wet 39
year and part of the volume of water is lost due to seepage; 2) over pumping of groundwater reduces the
aquifer's contribution to base flow and, in extreme cases, suctions the flow from the streams; 3) rainwater
could seep into local sinkholes (natural or induced). In any event, more information is required,
especially regarding supply and demand of groundwater, in order to reach a possible conclusion. What is
certain is that the analyses show a noticeable reduction in rainfall and runoff. The fact that runoff has 40
been reduced with respect to water allotted in the Colorado River Compact, added to the presence of more
frequent droughts in the last two decades (the most recent since 2002) according to our analysis, indicates
that we must prepare ourselves for an imminent situation of periods of less runoff.

In the EIS (Appendix M) (*U.S. Section comment – we believe this is actually a reference to Appendix N*)
it appears that it is indicated that in 2026 the levels of Lake Mead will be stabilized because it will receive
a constant delivery from Lake Powell and because of that it won't fluctuate as much as during the interim
period for some of the alternatives studied. It is not clear what is meant by a stable situation for 2026
given that in the same Appendix M: 1) the graph of probability of shortages shows that they will exist
beyond 2026 and they will not have low values; 2) in 2010 there are cuts in the Reservoir Storage 41
alternative; 3) in 2017 there are lesser cuts to 1.0 maf; 4) in 2026 the majority are reductions of less than
1.0 maf but there are many at other levels; 5) in 2060 the majority of the cuts are of 500 kaf.

In conducting an analysis of the five alternatives and their effects on allotments to Mexico, the one that 42
seems to have fewer negative impacts on Mexico is Conservation Before Shortage. That is because U.S.
users would make voluntary efforts to maintain high levels in Powell. Nevertheless, the EIS refers to
voluntary conservation. In this scenario, conservation is managed as a voluntary reduction, but for
modeling purposes the U.S. Bureau of Reclamation ran suggested reductions. It must be noted that that
conserved waters are accounted for and charged to the users' allotments and the conserved volume could
be used later (discounting evaporation and a 5% charge for the benefit of the basin). In the case of
Mexico, the conserved volume at the expense of the allotment (1.5 maf) is designated for environmental 43
use only and not for irrigation (Mexico's main use). Also, the delivery is made not when it is required
(situation of scarcity or normal conditions) but rather only in a situation of abundance (modeled every
five years). Voluntary conservation in this manner is not useful for Mexico as a consumptive use.

F-5

Likewise, the EIS has a table in Appendix M with an error in that it shows that Mexico receives more water than conserved. (*U.S. Section comment – we are unclear from Mexico's comments which specific table is referenced.*) This is not possible from the physical point of view. The conserved volume is identical to the volume released in various examples on the table M4; but it should be less. 44

What is not modeled in the alternative is that Mexico would voluntarily conserve water to use when 45
needed. One aspect still pending is that, should this scenario take effect, and if it is in Mexico's best
interest, the U.S. government would need to take internal steps so that Mexico could store its conserved 46
volume. Additionally, Mexico would have to evaluate the legal impact of this measure. 47

In conclusion, this alternative only could be attractive for Mexico, in alliance with U.S. environmental organizations, if economic support from the U.S. is provided to make technical improvements to irrigation in Mexico. Otherwise, this is not considered a viable option for Mexico. 48

To better evaluate the behavior of the alternatives, analysis was done extending the interim period for 20 years before the No Action alternative entered into operation and sequences 23 and 46 were applied to this interim period, modeling the least favorable conditions that have occurred in the basin. These analyses show that for Mexico (in case it is obligated to choose from these five alternatives) the Water Supply alternative guarantees its complete allotment during the entire simulated period before the No Action alternative enters into force. Nevertheless, there exists the risk that once the No Action alternative enters into force, storage in the reservoirs would be so low that there would automatically be severe cuts 49
for Mexico. Given the recent climatic variability of the Colorado River basin, it would need to be
evaluated if this strategy of reductions after the interim period or a strategy of smaller shortages 50
distributed over the period would be beneficial to Mexico. Perhaps the decision could be supported with
U.S. funding to make technical improvements to irrigation systems in Mexico. 51

If the existing level of the reservoirs will be the indicator for making decisions, then there is no pressure on users that take water upstream of the reservoirs. This can be appreciated in the Basin States alternative where the volumes from the dams in the upper basin (including Powell) are high and the support to Mead is only produced when it reaches near the level of 1000. 52

For all the alternatives, it would be recommended that the U.S. establish a program to monitor volumes allotted, used, and returned and report on water conservation measures. 53

Finally, it must be mentioned that when comparing the results of the No Action and Water Supply alternatives, it is noted that Mexico receives less surplus water in the No Action alternative. The interpretation is that this alternative assigns surplus waters to the U.S. more frequently and in greater quantity than in the Water Supply alternative and leaves less water in Mead such that when Mead spills (less frequently) it is of a lesser volume and, as a result, less is provided to Mexico. 54

In summary, except for the considerations of the Water Supply and Conservation Before Shortage alternatives, the rest of the alternatives always show reductions to Mexico of various frequencies and quantities of water. It is evident that none of these options is appropriate for Mexico. 55

The CRSS model provided recently still has values of 10 acre-feet in some segments; this does not correspond to environmental flow. The requirement of a minimum flow of 10 acre-feet/month for each segment was used in the original model for salinity calculations. To avoid dividing by zero in calculating 56

F-5

APR-30-2007 MON 04:06 PM IBWC EL PASO FAX NO. 915 832 4191 P. 08/08

salinity, in case there were an upstream segment with zero flow, the original CRSS model limited flow to a minimum of 10 acre-feet/month. In the analysis of the alternatives, only the quantity of the water and not its quality is considered. Given the amount of time to undertake these analyses with the set of rules delivered in April, one is left with the assumption that the U.S. will comply with the Minutes undertaken within the terms of the 1944 Water Treaty in relation to the salinity parameters. It is also assumed that the modeling of quantity is more linked to the reality of the basin and the quality model has many more assumptions and considerations that would have to be discussed in specific meetings. Additionally, if the allotted volumes are complied with, the salinity in the lower part should not be a problem in the alternatives. 57 58 59 60

In the alternatives modeled, it is observed that in the reservoirs much care is taken to leave space for flood control; Mexico has no objection to this. 61

With the model, by running the alternatives with drier runoff scenarios (23 and 46), it is observed that the reservoirs upstream of Powell are emptied. The table of results shows negative values which physically is not possible. Perhaps the model would have to consider a minimum level (dead storage) to avoid that situation of generating erroneous results allotting water that does not exist. 62

Another observation about the model is that since it does not model groundwater, it could cause water that doesn't exist to be allotted to meet demand downstream of the sources, as well as overstated inflows to the lower dams. This is derived from the possible losses in the channels caused by overexploitation in the areas of groundwater use. 63

End CNA comments

I appreciate the opportunity the U.S. Bureau of Reclamation has afforded the International Boundary and Water Commission to share the international view of the Draft EIS. I also appreciate the Bureau's willingness to engage in meaningful technical discussions with Mexico through the Commission.

Should you have any questions, please do not hesitate to contact me at 915-832-4702.

Sincerely

Gilbert Anaya
Supervisory Environmental Protection Specialist
Environmental Management Division

Reponses to Comment Letter F-5

Responses to Mexico's Comments:

Allotment of Colorado River water to Mexico is governed by the 1944 Treaty. The proposed federal action is a domestic action for the purpose of adopting additional operational guidelines to improve the Department's annual management and operation of key Colorado River reservoirs for an interim period through 2026. Certain modeling assumptions are used in this EIS in order to assess the potential effects to environmental resources of the proposed federal action. This assessment includes, but is not limited to, potential effects to water quantity, water quality, and fish and wildlife, particularly at the borders between the United States and Mexico. Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 Treaty or to represent current United States policy or a determination of future United States policy regarding deliveries to Mexico.

The United States has provided information to Mexico throughout the NEPA process through the United States and Mexican sections of the IBWC as detailed in Chapter 6. The United States will conduct all necessary and appropriate discussions regarding the proposed federal action and implementation of the 1944 Treaty with Mexico through the IBWC in consultation with the Department of State.

F-5-1

Comments transmitted in letters dated March 29, 2007 and April 25, 2007 have been addressed in this Final EIS.

F-5-2

Allotment of Colorado River water to Mexico is governed by the 1944 Treaty. The proposed federal action is a domestic action for the purpose of adopting additional operational guidelines to improve the Department's annual management and operation of key Colorado River reservoirs for an interim period through 2026. The proposed federal action is a domestic action. However, in order to assess the potential effects of the proposed federal action in this Final EIS, certain modeling assumptions (discussed in Section 2.2.1, Section 4.2, Appendix A, and Appendix M) are used that display projected water deliveries to Mexico. These modeling assumptions are common to all of the alternatives studied and are not intended to constitute an interpretation or application of the 1944 Treaty or to represent current United States policy or a determination of future United States policy regarding deliveries to Mexico. The United States will conduct all necessary and appropriate discussions regarding the proposed federal action and implementation of the 1944 Treaty with Mexico through the IBWC in consultation with the Department of State.

F-5-3

As noted in Section 1.7.2.3, allotment of Colorado River water to Mexico is governed by the 1944 Treaty. Determination of deliveries to Mexico would be made in accordance with the 1944 Treaty. The United States will conduct all necessary and appropriate discussions regarding the implementation of the 1944 Treaty with Mexico through the IBWC in consultation with the Department of State.

F-5-4

The modeling assumption used in this EIS assumes future water delivery reductions to Mexico are proportional to future reductions to United States users in the Lower Basin. Based upon comments provided by Mexico regarding this assumption, a sensitivity analysis was conducted and included as Appendix Q, Modeling Assumptions with Regard to Future Water Deliveries to Mexico, Sensitivity Analysis, of this Final EIS. This analysis examines the sensitivity of the hydrologic resources to a different modeling assumption that assumes future water reductions to Mexico are in the same proportion as water delivery reductions to all United States users, in both the Upper and Lower Basin.

F-5-5

The governments of Mexico and the United States expressed their intention to cooperate and collaborate on issues related to the lower Colorado River in a joint statement issued on August 13, 2007. In that statement, United States and Mexican authorities stated that cooperative, innovative and holistic measures should be considered to ensure that the Colorado River is able to continue to meet environmental, agricultural and urban demands of both nations. Opportunities for water conservation, storage and supply augmentation, and more efficient Colorado River water deliveries to Mexico are among the issues expected to be addressed in discussions held under the auspices of the IBWC.

F-5-6

The Colorado River Basin Salinity Control Act of 1974 authorized implementation of desalting and salinity control projects to improve river water quality. Salinity control projects have and continue to be implemented throughout the basin including projects to control irrigation seepage and reduce transport of salt loads to the Colorado River. As shown in Section 4.5 of the Final EIS, relative changes in salinity at Imperial Dam under all alternatives are expected to be minor (approximately one to three percent).

IBWC Minute 242 (Section 3.5) was developed in 1973. Minute 242 limits the differential in annual salinity between Imperial Dam and the NIB to 115 parts per million (ppm) ± 30 ppm. The United States will continue to undertake activities to ensure compliance with the salinity provisions of Minute 242 and these activities will not be affected by the proposed federal action.

F-5-7

During flood control operations at Lake Mead, releases are made from Hoover Dam as specified by the flood control criteria established with the USACE (Section 3.3.4). Under current practice (Section 2.2.4.1), Mexico is allowed to schedule up to an additional 200 kaf pursuant to the 1944 Treaty during flood control years when water supplies exceed those required for use in the United States.

As described in Section 4.2.7, modeling assumptions common to all alternatives included deliveries to Mexico of up to 1.7 maf during flood control years. The probability of flood control surplus deliveries to the Lower Basin states for all alternatives is shown in Figure 4.4-16. Given the modeling assumption that deliveries to Mexico of up to 1.7 mafy would be made under these conditions, this figure also shows the likelihood of Mexico receiving surplus water under the 1944 Treaty. As shown in Figure 4.4-16, the likelihood of flood control releases under all alternatives is nearly the same (ranging from between zero and approximately 20 percent for all alternatives over the interim period), with the exception of the Reservoir Storage Alternative which is higher (up to a maximum of eight percent higher in 2015) over much of the interim period due to the larger volumes of shortages that are applied under that alternative which tend to keep the reservoir higher.

F-5-8

As discussed in Section 3.3.10, Mexico diverts the majority of its Colorado River water allotment at Morelos Diversion Dam resulting in limited volumes of water flowing in the NIB to SIB (limitrophe) reach and to the Colorado River Delta. The more frequent and smaller volumes of water (up to but typically less than 50,000 afy) are primarily the result of seepage from Morelos Diversion Dam, irrigation return flows and groundwater from Mexico and the United States, and water in excess of Mexico’s scheduled delivery due to cancelled orders in the United States. The proposed federal action would not affect these smaller volumes of water.

Larger, less frequent volumes of water may occur below Morelos Diversion Dam as a result of flood control releases from Hoover Dam (Section 3.3.10) that are not diverted at Morelos Diversion Dam. As shown in Figure 4.3-44 (Section 4.3.9), the probability of larger flows under all alternatives during the interim period are approximately nine to ten percent, with the exception of the Reservoir Storage Alternative which shows probabilities of about twelve percent, as well as somewhat higher magnitudes when the flows occur. The somewhat higher frequencies and larger volumes under the Reservoir Storage Alternative are primarily due to the larger volumes of shortages that are applied which tend to keep the reservoir higher.

Although the Conservation Before Shortage Alternative and Reservoir Storage Alternative assumed that conserved water would be delivered on a periodic basis to Mexico through the NIB to the SIB reach, these modeling assumptions were used only to model the alternative proponent’s recommendations and to analyze the potential impacts to resources of a larger storage and delivery mechanism. Use of these modeling assumptions does not represent any determination by Reclamation as to whether, or how, these releases could be made under current management of the Colorado River.

F-5-17

As discussed in Appendix M, the Conservation Before Shortage Alternative and the Reservoir Storage Alternative assumed that storage credits would be generated and used for environmental purposes. These and other modeling assumptions were utilized in the Final EIS in order to analyze the potential impacts to environmental resources of the storage and delivery mechanism, particularly with regard to reservoir elevations and river flow impacts.

The use of these modeling assumptions does not represent any determination by Reclamation as to whether, or how, these releases could be made under current administration of the river. Furthermore, notwithstanding the lack of an existing mechanism to implement such modeling assumptions, Reclamation utilized these assumptions for a number of reasons, including the following: (1) a larger volume of potential storage in Lake Mead is identified, (2) the maximum potential impacts on river flows below Hoover Dam are identified, (3) the Conservation Before Shortage Alternative proponent’s recommendations as to participating entities and levels of participation are modeled, (4) the arbitrary assignment of water conservation amounts to entities in the Lower Basin states is avoided, and (5) modeling impacts of a program of potential future cooperation between the United States and Mexico are identified.

F-5-18

The proposed federal action only involves domestic determinations and actions and does not address prospective voluntary arrangements that may be agreed upon by the United States and Mexico. The governments of Mexico and the United States expressed their intention to cooperate and collaborate on issues related to the lower Colorado River in a joint statement issued on August 13, 2007. In that statement, United States and Mexican authorities stated that cooperative, innovative and holistic measures should be considered to ensure that the Colorado River is able to continue to meet environmental, agricultural and urban demands of both nations.

Opportunities for water conservation, storage and supply augmentation, and more efficient Colorado River water deliveries to Mexico are among the issues expected to be addressed in discussions held under the auspices of the IBWC. The inclusion of the modeled information is appropriate in Reclamation's view, because, at this time, it is unknown which entities might participate in a Lake Mead mechanism that allows the storage and delivery of conserved system and non-system water and the timing and magnitude of the storage and delivery of conserved water is unknown. Certain modeling assumptions with respect to the entities that might participate and their respective level of participation were needed to enable the evaluation of the mechanism and its potential effects on environmental resources, particularly to reservoir storage and river flows below Lake Mead.

See also response to Comment F-5-17.

F-5-19 through F-5-21

See response to Comment No. F-5-6.

F-5-22

The proposed federal action builds upon the prudent water management approaches contained in the Interim Surplus Guidelines adopted by the Secretary of the Interior in 2001. These Guidelines had the effect of reducing demand on limited Colorado River water supplies through efforts to allow (and require) California to reduce its reliance on Colorado River supplies in excess of 4.4 mafy These Guidelines link availability to water supplies to the elevation of Lake Mead. The proposed federal action will adopt operational guidelines for the operation of Lake Mead for a full range of reservoir operations, including surplus, normal, and shortage conditions. This approach is integral to the prudent development of new low-reservoir operational guidelines, as the approach and management of these reservoirs at higher elevations has a direct impact on available storage, thereby affecting the likelihood and severity of potential future shortages.

F-5-23

Reclamation does not concur with Mexico's position as expressed in this comment. Under current practice (Section 3.3.4), Mexico can schedule up to an additional 200 kaf during flood control years when the water supply exceeds the needs of Colorado River water users in the United States. The modeling assumptions used in the EIS, particularly with regard to water reductions to Mexico, are common to all alternatives, are used only to display projected water deliveries to Mexico, and are not intended to constitute an interpretation or application of the 1944 Treaty.

See also response to Comments F-5-2 and F-5-7.

F-5-24

See responses to Comment Nos. F-5-7 and F-5-8.

F-5-25

Reclamation concurs with this comment. Table 3.8.7 identified 16 species of fish, primarily non-native, that may be found in NIB to SIB (limitrophe) reach. The analysis of potential impacts to vegetation and wildlife for this reach is presented in Section 4.8.3.7. It is also noted that an analysis of potential impacts to special status species for the NIB to SIB reach is also presented in Section 4.8.4.7.

F-5-26

As discussed in Section 4.2 and Section 4.16.2, the Drop 2 Storage Reservoir Project was included in the hydrologic modeling for all alternatives for Lake Mead and the Colorado River conducted for this EIS. Potential impacts are included in the analysis in Sections 4.3 and 4.4, particularly to larger flows in the NIB to SIB (limitrophe) reach resulting from flood control releases (see response to Comment No. F-5-8). The Lower Colorado River Drop 2 Storage Project Environmental Assessment analyzed the potential hydrologic impacts of the project on smaller (non-flood release) flows in the limitrophe reach.

F-5-27

The alternatives analyzed in the EIS considered a range of methodologies for determining surplus conditions in the United States. Specifically, the Basin States Alternative, the Conservation Before Shortage Alternative, and the Preferred Alternative assume that the more permissive provision of the Interim Surplus Guidelines (i.e., Partial Domestic Surplus) is eliminated in 2008. See also response to Comment No. F-5-7.

F-5-28

See responses to Comment Nos. F-5-2 and F-5-5.

F-5-29 through F-5-30

See response to Comment No. F-5-2.

F-5-31 and F-5-32

As noted in Section 2.2, a reasonable representation of future conditions under the No Action Alternative is needed for comparison to each action alternative. The modeling assumptions used for this representation are consistent with assumptions used in previous environmental compliance documents for the ISG, the Colorado River Water Delivery Agreement, and the LCR MSCP (Section 1.8). However, as noted in the response to Comment No. F-5-2, the assumptions used in the No Action Alternative are not intended to constitute an interpretation or application of the 1944 Treaty or to represent current United States policy or a determination of future United States policy regarding deliveries to Mexico. The United States will conduct all necessary and appropriate discussions regarding the proposed federal action and implementation of the 1944 Treaty with Mexico through the IBWC in consultation with the Department of State.

F-5-33

Reclamation conducted a modeling workshop to facilitate an understanding of the technical details of the modeling conducted for the Draft EIS. This workshop was held in Henderson Nevada on March 6, 2007 for all interested parties, including Mexico. One participant from Mexico attended. In the spirit of comity, Reclamation offered to repeat the workshop in Juarez Mexico on March 14, 2007 for the convenience of other interested parties in Mexico. Additional information was requested by the Mexican participants at that time and Reclamation provided, through the USIBWC, all available information in the timeliest manner possible.

F-5-34

See response to Comment No. F-5-4.

F-5-35

As discussed in Section 4.2, modeling future Colorado River conditions requires the input of a large amount of information, including the future depletion (consumption) schedules for the Basin States and for Mexico. The depletion schedules for future use in the Upper Basin were provided by the Upper Colorado River Commission (Section 3.4 and Appendix C).

F-5-36

The United States does not concur with Mexico's statement that drought in the Upper Basin has been "not significant." Provisional calculations of natural flow for the Colorado River at Lees Ferry, Arizona, show that the average flow over the past eight years (2000 through 2007 inclusive) was the lowest eight-year average in 100 years of record-keeping. United States users throughout the Upper Basin have incurred shortages throughout this period.

With respect to the inclusion of the Upper Basin in calculations of modeled water reductions, see response to Comment F-5-4.

F-5-37

The modeling assumptions used in this EIS regarding shortage-sharing between the Lower Division states are consistent with the Consolidated Decree and federal law, in particular the 1968 Colorado River Basin Project Act (the CRBPA). Specifically, the CRBPA states that satisfaction of all PPRs and California's 4.4 maf apportionment would have priority over CAP and other post-1968 water delivery contracts (contracts with approval dates after September 30, 1968). It also states that Nevada shall not be required to bear shortages in any proportion greater than would have been imposed in the absence of the CRBPA (Section 3.4.3).

F-5-38

See responses to Comment Nos. F-5-2 and F-5-4.

F-5-39

Your comment is noted. Reclamation agrees that a complete understanding of the relationships between precipitation and runoff throughout the Basin would require a large amount of data and further study.

F-5-40

Your comment is noted. In addition, the Department concurs that recent hydrologic trends indicate a strong likelihood of ongoing and imminent periods of less runoff. These concerns are highlighted by inclusion of information in the Final EIS regarding considerations of paleohydrology and possible global climate change impacts. It is precisely these concerns and realities (along with precipitously decreasing reservoir levels) that informed the decision to proceed with this NEPA process. The uncertainty in future hydrologic conditions warrant more efficient use of the available water supply throughout the basin. This process to develop additional operational guidelines for Lake Powell and Lake Mead is being undertaken to address this concern.

F-5-41

If the reference is assumed to be Appendix N (as suggested by USIBWC), it should be noted that the elevations shown for example in Figure N-3, do not represent actual traces, but rather the ranking of each year's data from the 100 traces for the conditions modeled. Future reservoir levels would fluctuate from year to year and would depend on the future variation in basin runoff conditions. As noted in Section 4.3, these presentations are best used for comparing the relative differences in the general lake level trends that result from the simulation of the different alternatives. Under the No Action Alternative, the 50th percentile or median elevations at Lake Mead remain relatively stable over time primarily due to the increasing probability of shortage.

F-5-42

Your comment is noted; however, Reclamation notes that the Conservation Before Shortage Alternative would have users make efforts to maintain high levels in Lake Mead not Lake Powell as referenced in your comment.

F-5-43

See responses to Comment F-5-17 and Comment F-5-18.

F-5-44

Although it is unclear the specific table that is being referenced, the model assumes that conserved water can only be delivered if sufficient credits exist. The credits may be created in the same year or they may be available because they were created in previous years. The model performs an accounting of the credit balance in each year as detailed in Appendix M.

F-5-45

See responses to Comment Nos. F-5-17, F-5-18, and F-5-2.

F-5-46

See responses to Comment Nos. F-5-5, F-5-18, and F-5-2.

F-5-47

Your comment is noted. See also response to Comment F-5-18.

F-5-48

Your comment is noted.

F-5-49

Reclamation fully concurs with this comment. The example presented clearly shows that there are tradeoffs between incurring more manageable yet more frequent water delivery reductions versus incurring no water delivery reductions for some period of time resulting in an increased risk of incurring much larger, severe and less manageable water delivery reductions at a later date.

F-5-50

An analyses of the trade-offs between incurring more manageable yet more frequent water delivery reductions versus incurring no water delivery reductions for some period of time resulting in an increased risk of much larger, severe and less manageable water delivery reductions at a later date has been performed through the comparison of the alternatives that have been studied in the EIS. With respect to these trade-offs for purpose of this domestic action, Reclamation's determination is manifested through its identification of the Preferred Alternative, which selects more frequent, less severe reductions in water deliveries, potentially avoiding the need for larger more severe reductions (depending on hydrology). These analyses included the potential impacts to water deliveries to Mexico (Section 4.4.6). The sensitivity of the hydrologic resources to increased hydrologic variability has been analyzed in Appendix N.

F-5-51

Your comment is noted. See response to F-5-5.

F-5-52

Reclamation does not concur with this statement and does not believe it is an accurate description of the information presented in the Draft (and Final) EIS. The Basin States and Conservation Before Shortage Alternatives and the Preferred Alternative have a common coordinated operation element whereby the annual release from Lake Powell is determined by the storage in both Lake Powell and Lake Mead (Chapter 2 and Table 2.8-2). For example, under these alternatives, if Lake Powell is below the Equalization Line and Lake Mead is below 1,075 feet msl, the Upper Level Balancing operation can result in annual releases from Lake Powell of up to 9.0 mafy.

F-5-53

The Consolidated Decree stipulates that the United States shall prepare and maintain complete, detailed, and accurate records of diversions, return flows and consumptive use throughout the Lower Basin on an annual or more frequent basis. The Lower Colorado Region has an on-going program to meet this stipulation and the annual reports are available at http://www.usbr.gov/lc/region/g4000/wtracct.html. These reports also include various supplemental information including water conservation and water transfers. Furthermore, Reclamation has expanded that program to provide, on a daily basis, estimates throughout the year of use-to-date and forecasted use through the end of the calendar year for all users throughout the Lower Basin that consume greater than 2,000 afy, totaling approximately 98 percent of all water used in the Lower Division states.

F-5-54

Reclamation does not concur with this comment. As described in the response to Comment No. F-5-7, Figure 4.4-16 presents the probability of flood control surplus conditions, and given the modeling assumption that deliveries to Mexico of up to 1.7 mafy would be made under these conditions. This figure also shows the likelihood of Mexico receiving surplus water under the 1944 Treaty. Although the likelihood of flood control releases under the all alternatives is nearly the same (with the exception of the Reservoir Storage Alternative), the probability of flood control releases under the No Action Alternative is not less than the probability under the Water Supply Alternative throughout the Interim Period.

F-5 55

Your comment is noted.

F-5-56

As discussed in the modeling workshop in Juarez Mexico held on March 14, 2007, certain Upper Basin reaches experience zero flow during simulation under the driest hydrologic sequences in the CRSS model. To prevent division by zero when performing salinity calculations, a minimum flow constraint of ten af per month is applied in each Upper Basin reach. This situation occurs infrequently.

F-5-57

Reclamation does not concur with this comment. Section 3.5 describes the water quality constituents that may be potentially affected by the proposed federal action and Section 4.5 describes those potential impacts. In particular, the potential impacts to salinity are considered in both sections (see response to Comment No. F-5-6).

F-5-58

The United States will continue to comply with the Minutes undertaken within the terms of the 1944 Water Treaty, including with regard to the salinity differential pursuant to Minute 242, described in Section 3.5 (see response to Comment No. F-5-6).

F-5-59

Your comment is noted. Reclamation welcomes the opportunity to meet with representatives from Mexico to discuss the various assumptions and considerations that are used in the CRSS salinity module.

F-5-60

See response to Comment No. F-5-58.

F-5-61

Your comment is noted.

F-5-62

Reclamation investigated this observation, but did not find negative storage or release values at any reservoir. Reclamation welcomes the opportunity to meet with representatives from Mexico to discuss modeling results from CRSS.

F-5-63

Groundwater aquifers in direct connection to the Colorado River could act as either water sources or sinks depending upon the hydraulic gradient. In many areas, the hydraulic gradients are quite variable and can change rapidly. As noted in the response to Comment No. F-5-39, the interactions between surface and groundwater are complex and require a large amount of site-specific data. The necessary data is not currently available throughout the Colorado River Basin.

April 30, 2007

Dr. Terrance Fulp
Regional Director, Lower Colorado Region
Bureau of Reclamation
Attn: BCOO-1000
P.O. Box 61470
Boulder City, NV 89006-1470

Dear Dr. Fulp

Thank you for the opportunity to comment on the recent Draft EIS on Proposed Guidelines for Managing the Colorado River During Drought Conditions.

We are pleased to see that Reclamation is taking steps to include the effects of climate variability
in its evaluation of management strategies for low reservoir operations of Lake Mead and
Powell. We encourage Reclamation to work further to consider how climate change may impact 1
water availability and environmental conditions in the Basin.

As discussed in our scoping comments for this EIS, we recommended that management
strategies for low reservoir operations of Lake Mead and Powell should include the effects of
climate variability and long-term trends in climate. We suggested that Reclamation should
consider including information on long-term climate variability (such as paleoreconstructions of 2
flows from tree rings), potential climate change impacts the potential of ENSO-based seasonal
forecasts and intraseasonal forecasts to contribute to reservoir management. Reclamation has
made some effort to incorporate our scoping comments (e.g. Appendix N), but we believe more
could be done.

Since the Scoping process, several studies have been released which can provide information to
assist in incorporating the potential impacts of climate change in the evaluation of alternatives.
These include the Summaries for Policymakers of the Intergovernmental Panel on Climate
Change (IPCC 2007a,b), the IPCC Regional Climate Projections (Christensen et al., 2007) a 3
National Academy of Sciences report, *Colorado River Basin water management: Evaluating and
adjusting to hydroclimatic variability* (NAS, 2007), and several journal articles including, *Global
pattern of trends in streamflow and water availability in a changing climate* (Milly et al., 2005),
*Model projections of an imminent transition to a more arid climate in Southwestern North
America: A multimodel ensemble approach to assessment of climate change impacts on the*

F-6

hydrology and water resources of the Colorado River basin (Christensen and Lettenmaier, 2007), and a special issue of Southwest Hydrology including an article by Hoerling and Eischeid (2007), *Past peak water in the southwest?*.

Some of the key findings are summarized below.

The IPCC international panel of experts finds observed changes in climate including:

- An increase in the rate of global average temperature rise to 0.74°C (1.3°F) [range 0.56 - 0.92°C, 1.08 - 1.6°F] for 1906-2005.
- Discernible human influences now extend to other aspects of climate, including ocean warming, continental-average temperatures, temperature extremes and wind patterns. 4
- Widespread changes in extreme temperatures have been observed, including less frequent cold days, cold nights and frost, and more frequent hot days, hot nights, and heat waves.

Future impacts relevant to the Western U.S. and the Colorado River Basin include:

- Over North America, annual mean warming is likely to exceed the global average. Over western North America, median temperatures are projected to increase by 3.5°C, 4°C, and 5°C by 2100 under the B1, A1B, and the A2 emissions scenarios, respectively.
- In the southwestern U.S., warming is likely to be the largest in summer
- Warmer and fewer cold days and nights are virtually certain as are warmer/more frequent hot days and nights over most land areas 5
- Warm spells and heat waves are very likely to increase over most land areas
- There is very high confidence that high elevation warming is projected to cause decreased snowpack, more winter flooding, and reduced summer flows
- Annual mean precipitation is likely to decrease in the southwestern U.S.
- The area affected by drought is likely to increase, with more widespread water stress and water shortages and reduced hydropower generation potential
- The global models likely underestimate the warming at high altitudes due to the snow-albedo feedback.
- Snow season length and snow depth are very likely to decrease over most of North America.

The NAS report notes that temperature records and climate model projections both suggest that temperatures across the Western U.S. will continue to rise in the foreseeable future. The NAS report, Hoerling and Eischeid (2007), and Christensen and Lettenmaier (2007) all point to the negative impacts of higher temperatures on water supply in the West. The IPCC 2007 findings also point to the impacts of rising temperature on water supplies in already arid areas, and note that areas like the U.S. West are particularly vulnerable because its economies are closely linked with climate-sensitive resources, its rising population, urbanization, and dependence on already highly utilized water resources.

It is noteworthy that the IPCC 2007 model runs consistently show a reduction in water supplies in the American Southwest even when precipitation stays approximately the same. This is due to temperature increases and the resultant widespread drying. The results in Milly et al (2005), 6

Hoerling and Eischeid (2006), Christensen and Lettenmaier (2007), and Seager and et al. (2007) 7
all indicate a reduction in water supplies, albeit with some significant differences in magnitude.
Models used in the IPCC Third Assessment Report in 2001 (IPCC 2001) and the National
Assessment of the Potential Consequences of Climate Variability and Change in (USGCRP, 8
2000) showed no such consistency with some models indicating more precipitation and some
less.

These and other recent studies are showing that the use of historical hydrology for the Colorado 9
River cannot adequately capture the likely future variability of water supply. We strongly
encourage Reclamation to consider ways to generate hydrology representative of likely future 10
conditions and to continue to utilize the paleo record to investigate climate variability outside
that of the historical period.

We have been pleased to participate in a panel of experts convened to consult with Reclamation and assist in addressing these questions. The NOAA and the NOAA-University of Colorado Western Water Assessment are happy to continue to work with Reclamation, to assess the potential effects of climate variability and change, as well as the opportunities for the use of seasonal climate forecasts, in studying how best to operate Lakes Powell and Mead during low reservoir conditions

Sincerely,

Andrea J. Ray, Ph.D.
NOAA Earth Systems Research Laboratory and
NOAA-University of Colorado Western Water Assessment

Brad Udall
University of Colorado and
NOAA-University of Colorado Western Water Assessment

Reponses to Comment Letter F-6

F-6-1 through F-6-10

Your comment is addressed in the general response pertaining to climate changes and hydrologic variability in the introduction to Volume IV of the Final EIS. Section 4.2 of the Final EIS has been enhanced and two new appendices (Appendix T and Appendix U) have been added to provide additional information regarding the potential impacts of climate change and hydrologic variability.

Subject: Comment on Colorado River drought plan

Dear Sir or Madam,
I have not had time to read the plan but I did want to comment on it.
I live in the Phoenix area. The future water shortage situation has been talked about for years here but nothing has been done about it. Arizona and Nevada are two of the biggest growth areas in the nation. Arizona has the added burden of illegal aliens pouring in along with the people from other parts of the U.S.. This crazy growth has to stop or at least slow down. We are going to have enough problems sharing the water with the existing population.
I realize this is a state issue, not a federal issue, but nobody from the governor on down wants to talk about it I guess because growth means money to the various state and local governments and their buddies. The builders are just going nuts out here and absolutely nobody wants to slow them down. The Phoenix area could someday be the biggest ghost town in the world. The repercussions would be devastating. Is there any way to talk some sense into these representatives from Arizona to start looking into growth control? 1

Thanks for letting me rant,
Totally Frustrated Mike

Reponses to Comment Letter I-1

I-1-1

Your comment is noted. No change to the Final EIS was necessary. As noted in Section 3.4 and Section 4.4, water supply planning and water supply management occurs at the federal, state, regional and local levels. Most states, regional agencies, local agencies, and communities have already or are in the process of preparing water resources management plans and or drought management plans that address varying water demand and water supply management issues.

Subject: CO River Interim Guidelines DEIS
Mr. Fulp,

I am writing to express my support of the "Conservation Before Shortage" Alternative for the draft EIS of the Colorado River Interim Guidelines for Lower Basin Shortages and Coordinated Operations for Lake Powell and Lake Mead. 1

I feel that this alternative would meet the purpose and need of the project without limiting the recreational opportunities of these lakes and without being economically detrimental. 2 While I understand new legislation would have to be passed to provide funding to implement this project, I feel that the Basin States would be willing to support such an action. 3

I do however, feel that such an action should be considered for the long term viability of operations and not merely used as "interim guidelines". 4 With the increasing growth in Basin states, it is important that the Bureau of Reclamation plan for not only the near future but for the long term productivity of the Colorado River. 5

Thank you,

Brianne Emery

I-2-1

Your comment is noted. No change to the Final EIS was necessary.

I-2-2 and I-2-3

Your comment is noted. See also response to Comment No. G-1-4.

I-2-4 and I-2-5

Reclamation does not concur with this comment. The interim nature of the guidelines is intended to provide an opportunity to evaluate how the guidelines work. In addition, opportunities for review of the effectiveness of the guidelines are anticipated to be available both throughout the proposed interim period and at intervals during the interim period. Such reviews would provide a basis for possible further federal actions and decisions at the end of the interim period. Reclamation anticipates that a review of the guidelines will be conducted at a time prior to the end of the interim that would allow the Department, and the public, to assess the effectiveness of the guidelines and to determine the most appropriate course of action for the post-interim period.

Subject: Colorado River drought plan

The Scottsdale, Arizona, City Government continues its profligate disregard for water resources by ignoring poorly designed, inappropriate, and mismanaged landscaping, which allows water to pour into our streets. I can only imagine the amount of water that has been wasted over the years and how so many other countries and people could be maintained with just our irresponsibly wasted water. 1

I fear for our lowered, beautiful, Colorado River systems.

Thank you for your environmental effort.

Subject: Colorado River Interim Guidelines for Lower Basin Shortages and Coordinated Oper
CITIZEN INPUT on Colorado River Interim Guidelines for Lower Basin Shortages and Coordinated Operations for Lake Powell and Lake Mead

In Stage I:

It appears that the math used to arrive at the shortage assignments differs from case to case, no doubt the result of the 60s agreement that optimistically took responsibility for all shortages on the river unto Arizona. 1

I now ask what the incentive for all those water users in California to conserve might be? I believe this antiquated agreement that penalizes Arizona water users unduly while cutting no allocations for others leads to profligate development and wastage of water. 2

As a native Arizonan, I deplore this unfair distribution of water shortage 'allocations'. This ill-conceived agreement should be renegotiated.

Another problem is the cutting off of agriculture in favor of bedroom communities and ever continuing development is strategically foolish. Agriculture recharges the water table, provides human food and fodder for livestock and is a viable business in Arizona. I know the assumption is that food can be shipped in with less cost than the value of the water used in agriculture, but making sure that the population of Arizona is totally dependent on supplies brought in using fossil fuels is poor future planning. Fossil fuel is not going to ever be cheaper and this policy insures that the people of Arizona will be paying inflated food prices on all foodstuffs. I have a problem with this kind of shortsighted planning. Of course, the developers promote this destructive plan since they can then sop up the last of the Arizona allocation in more homes. As of now, Tucson has over 9,000 housing units for sale at inflated prices. 3

I do believe that prohibiting further water hookups, cutting water to golf courses and other water saving measures should be required of all communities using Colorado River water before this shortage allocation plan be implemented. 4

The economic problems generated by a cessation of raw development are real and can be predicted in terms of construction related unemployment. All of the communities using Colorado River water must aim for sustainability in water resources, which will force a lifestyle change among the water users. 5

I know that the present allocations were assigned during flood times on the Colorado, as corroborated by data from 1500-2000 AD. The 'new' average river flow will not sustain the current populations at their level of water use. 6

I-6

I suggest that mandatory conservation and cessation of new water hookups be required of all communities using Colorado River water. A refusal to conserve water and a refusal to deny new water hookups should result in immediate cuts of Colorado River water deliveries. All communities should share in the results of drought conditions. 7

Opinions and Facts!

Reponses to Comment Letter I-6

I-6-1

This comment fails to accurately reflect the information published by Reclamation in the Draft EIS. As noted in Chapter 2, the different alternatives considered alternative criteria for determining when and by how much water deliveries to the Lower Division states may be reduced during drought and low reservoir conditions. The purpose for considering the different criteria was to evaluate, among other things, the trade-offs between water deliveries and retaining water in storage for future use.

I-6-2

See responses to Comment Nos. L-17-17 through L-17-19.

I-6-3

Your comment is noted. No change to the Final EIS was necessary. Please note that the shortages within individual states are assumed to be distributed in the order of priorities within in each respective state and distributed proportionally between the water users with the same priority right. The modeling assumption that distributes water delivery reductions among the equal priorities within individual states does not necessarily distinguish between water user type.

I-6-4 and I-6-5

See response to Comment No. I-1-1.

I-6-6

Your comment is addressed in the general response pertaining to climate changes and hydrologic variability in the introduction to Volume IV of the Final EIS. Section 4.2 of the Final EIS has been enhanced and two new appendices (Appendix T and Appendix U) have been added to provide additional information regarding the potential impacts of climate change and hydrologic variability.

Subject: Comments for Operations at Lake Powell & Lake Mead under Low Reservoir Conditions

Dear Mr. Johnson and Mr. Gold:
Lake Powell and Lake Mead lose 17 percent of the water that flows into them through
evaporation. Vacant space in underground aquifers near existing Colorado River water
recharge facilities could store more water than these two reservoirs combined. Upwards 1
of 810,000 acre-feet of water annually could be saved by eliminating Lake Powell and
operating Lake Mead principally for distribution to groundwater recharge facilities.

After more than 40 years of operation, it was not until the fall of 2004 that Lake Powell's
water storage actually augmented downstream water use. And with the impacts of climate
change and rising water consumption, it is unlikely that there will be sufficient surplus 2
water to fill Lake Powell again. Even should surplus water accumulate, Lake Mead alone
could provide sufficient storage.

Between Lake Powell and Lake Mead lies Grand Canyon National Park. The operation of
both these reservoirs has impacted the Canyon, but Glen Canyon Dam at Lake Powell has 3
been far more devastating. Since the dam's completion four of eight native fish have 4
gone extinct and the dam has trapped the sediment necessary to maintain habitat and 5
beaches for wildlife and recreation, as well as the stabilization of archeological sites.

Sediment is a major unresolved problem threatening the long-term operations of Lake
Powell and Lake Mead. Ultimately, sediment must be removed to ensure public safety. 6
Removing sediment from Lake Mead downstream, rather than Lake Powell upstream is
the most technically feasible, least costly and environmentally advantageous approach.

The Colorado River Compact of 1922, which largely governs the operations of Lake
Powell for Lake Mead, cannot meet its intended purpose of equitably sharing Colorado
River water between the Upper and Lower Basin states. With River flows expected to 7
decline 18 percent by 2040, this inequity will worsen, furthering the need for Compact
amendments while highlighting the benefits of eliminating Lake Powell to fulfill the
Compact's primary objective.

BC00-1000 - page 2 of 2
ENV-6.00

Powers of the Authority should include:

1) Use of eminent domain to reallocate water from farmers or others, both on and off Indian reservations, for urban purposes. There should be one-time compensation to anyone giving up water. (Reservation Indians are citizens of the U.S. and should be treated as all other citizens, i.e., the special privileges awarded reservation Indians by the U.S. Congress at the expense of other citizens should end.)

2) Own and operate the river dams.

3) Construct additional dams and diversion works.

4) Augment the river supply.

Other considerations:

The Authority should urge the U.S. Congress to:

1) Repeal the U.S. Supreme Court's "practicably irrigable acreage" (PIA) ruling as the measure of water for Indian reservations (PIA ignores reality, from climate to location, and awards excessive quantities of water to some tribes. See footnote for two such tribes in Arizona).[2]

2) Repeal language in Section 5, Boulder Canyon Project Act, which the U.S. Supreme Court purposefully misinterpreted to give the U.S. secretary of the Interior power to distribute water to Arizona, California and Nevada, and to users within these states.

3) Repeal all laws based upon PIA.

4) Repeal all laws that conflict with powers given the Colorado River Basin Authority.

5) End the reservation system for Indians and assure "the equal protection of the laws" for all citizens as provided in the 14th Amendment to the U.S. Constitution.

Correction: "The Gila River Reservation," according to Chapter 3, 3-88, lines 38-39, Draft EIS, "Reclamation, Managing Water in the West," "*was established by executive order* in 1859..." (emphasis supplied). Not so. The reservation was created February 28, 1859, **by an act of the U.S. Congress**. 3

---

[2] With implementation of the Arizona Water Settlements Act of 2004, two Arizona Indian reservations, with less than one-half of 1% of Arizona's 5,130,632 people in 2000, are supposed to have yearly almost 1 million acre-feet of Arizona's Colorado River water entitlement. These two are the Gila River Indian Community (GRIC), 328,800 acre-feet (including 17,000 acre-feet from ASARCO, Inc., that remains unsettled), and the Colorado River Indian Tribes, 662,402 acre-feet. With fewer than 19,000 residents, these two reservations will have 991,202 acre-feet (including the 17,000 acre-feet). Add in the Gila River tribe's other water, and the two reservations yearly will have 1,315,902 acre-feet. Not morally, ethically, or historically are these tribes entitled to that much water. These tribes no doubt will be founding members of the Organization of Water Exporting Tribes (OWET).

To: Regional Director, Lower Colorado Region, Bureau of Reclamation, Attention: BCOO-1000, Box 61470, Boulder City, Nevada 89006-1470
From: Earl Zarbin, 3803 E. St. Catherine Ave., Phoenix, AZ 85042-5013 - (no home Internet or fax reception)
Re: BCOO-1000 - Response to Draft EIS - Colorado River Interim ENV-6.00 Guidelines for Lower Basin Shortages, etc.

Best alternative: Given Arizona's growing population, the U.S. secretary of the Interior should adopt as a guideline for Lower (Colorado River) Basin Shortages the alternative calculated to do the least harm to the sufficiency of the Central Arizona Project water supply. 1

Preferred action: Because it is preposterous and illogical to lock into perpetuity a system of water distribution that ignores population shifts and other Colorado River Basin changes, and,

Because the present system unjustly enriches or enables some people at the expense of others, and,

Because there exists a need to restore reason, common sense, and sanity to management of the Colorado River,

The areas of the seven Basin States and the Republic of Mexico within the Colorado River Basin should seek to create a new entity administratively independent of their federal and state governments and other special interests. To accomplish this, the seven Basin States: 2

Should create, using **Section 19** of the Boulder Canyon Project Act, a Colorado River Basin Authority or other entity independent of the U.S. secretary of the Interior, and invite Mexican water users to cooperate.[1]

(Should the Basin States meet to create a Colorado River Basin Authority, Section 19 permits the U.S. president to name a representative to "participate" and to "report to Congress of the proceedings and of any compact or agreements entered into." The States and the Congress have to approve any agreement, but the Interior secretary has no role unless named by the president. The Interior secretary should not be named.)

[1] Ideally, as noted by John Wesley Powell, river basins should be operated as a unit. For the Colorado River Basin, options include: 1) The U.S. should acquire the portion of Mexico receiving Colorado River water; 2) Mexico should acquire areas of the seven states within the basin; 3) the Colorado River Basin, including the area in the U.S. and Mexico, should create an independent Colorado River Basin Republic. None of these are likely to occur, which means the present messy management of the river will continue unless the seven Basin States unite and act to change the system.

I-11

Reponses to Comment Letter I-11

I-11-1

Your comment is noted. No change to the Final EIS was necessary.

I-11-2

Your comment is noted. No change to the Final EIS was necessary. The creation of a new entity that is administratively independent of federal/state governments and special interests groups to manage river and water and reallocate water is outside the scope of the subject EIS.

I-11-3

Information presented in the Draft EIS has been modified in the Final EIS (see Section 3.10.2.2) pursuant to this specific comment, as well as other public comments. Section 3.10.2.2 of the Final EIS has been revised to reflect this comment. This revision does not significantly change the impact analysis or results presented in the Draft EIS.

Subject: My comments on Colorado River DEIS

April 30, 2007

Dear Bureau of Reclamation officials:

Please accept this letter with my comments on the Colorado River water allocations DEIS.

I strongly support and urge you to adopt and implement the "Conservation Before 1
Shortage Alternative". I believe that this alternative best reflects the changes that are 2
needed to address exponential human growth combined with declining water supplies.
Communities in the arid Southwest must learn to be much more aggressive and effective
in achieving water conservation and reclamation. Groundwater recharge is also 3
preferable to reservoir storage because of the latter's excessive evaporation losses. Water
pricing must reflect true market demands and delivery costs, without any subsidies. 4
Greater use of tiered water pricing can reward conservation and punish wasteful
practices.

With global warming and the prospects for more severe droughts, the continuation of status quo management of the Colorado River would be irresponsible and dangerous. Strong reforms are needed now, in anticipation of the more serious shortages to come. We need only to look at Australia this year to see what the future may hold for us.

Please have the foresight and courage to implement these necessary reforms in the public interest.

Thank you very much for your consideration.

Sincerely,

Richard Spotts

Regional Director
Bureau of Reclamation, Lower Colorado Region
Attn: BCOO-1000
P.O. Box 61470
Boulder City, Nevada 89006-1470

09 April 2007

Dear Director,

Thank you for the review copy of the Draft Environmental Impact Statement (DEIS) – Colorado River Interim Guidelines for Lower Basin Shortages and Coordinated Operations for Lake Powell and Lake Mead. Please retain my name on the mailing list.

Specific Comments to the text of the DEIS

1. Page 4.16

   I don't understand why Lake Powell Traces 1, 21, and 48 presented in Figure 4.3-1 were based on hydrologic sequences beginning in years 1906, 1926, and 1953 respectively when Lake Powell didn't even exist then. What do these data mean? 1

2. General Comment

   I see no assessment of the potential for reduced seepage and evaporation at Lake Powell if storage is concentrated at Lake Mead. Studies should be done to determine if system-wide seepage and evaporation losses could be reduced in this manner. This could improve the benefits of the Water Supply Alternative. 2

I-14

Page 1 of 2

Recommended Alternative

1. The primary purpose of the Colorado River Storage Project is to deliver water to the holders of water rights. The Water Supply alternative is the only alternative that focuses 3 on this purpose. To protect the SNWA the alternative should be amended to protect the 1,000 feet MSL level consistent with the proposed SNWA Lake Mead Intake No. 3 4 Project noted on page 5-8. With this change the Water Supply Alternative best meets the 5 primary purpose of the system.

Thank you for the opportunity to participate in this process,

I-14

Reponses to Comment Letter I-14

I-14-1

The information requested is provided in the Draft EIS. As noted in Section 4.3.2 of the Draft EIS, these traces represent the results of three of the 100 model runs. These distinct traces were provided only to illustrate what was actually simulated under the various traces and respective hydrologic sequences and to highlight that the 90^{th}, 50^{th}, and 10^{th} percentile lines do not represent actual traces, but rather the ranking of each year's data from the 100 traces for the conditions modeled. The traces also illustrate the variability among the different traces and that the reservoir levels could temporarily decline below the 10^{th} percentile line.

I-14-2

See response to Comment No. G-8-32.

I-14-3

Your comment is noted. No change to the Final EIS was necessary.

I-14-4 and I-14-5

Your support for the Water Supply Alternative is noted. No change to the Final EIS was necessary. As noted in Chapter 2, the No Action Alternative and the Conservation Before Shortage Alternative were the only two alternatives that considered absolute protection of Lake Mead water surface elevation 1,000 feet msl. The other action alternatives assumed that SNWA deliveries would be zero at Lake Water surface elevation below 1,000 feet msl. As noted in the response to Comment No. I-14-3, the other action alternatives were formulated to permit an evaluation of a wide range of operating conditions and to permit an evaluation of the trade-offs between water deliveries and retaining water in storage for future use. These other action alternatives, amongst other things, facilitated an evaluation with regard to how often and by how much SNWA may receive water deliveries below their annual entitlement due to Lake Mead water levels dropping below elevation 1,000 feet msl.

RE:

DRAFT EIS: Colorado River Interim Guidelines for Lower Basin Shortages and Coordinated Operations for Lake Powell and Lake Mead

This comment is regarding the Draft Environmental Impact Statement (DEIS) prepared by the Bureau of Reclamation (Reclamation) for the Secretary of the United States Department of the Interior (Secretary) in support of a proposal to adopt specific interim guidelines for the Colorado River Lower Basin (Lower Basin) shortages and coordinated operations for Lake Powell and Lake Mead, particularly under drought and low reservoir conditions. The bulk of these comments are related to how the Interim Shortage Guidelines (ISG) will affect the Navajo Nation.

SUMMARY of COMMENTS

In general the DEIS fails

(1) to include the Upper Basin usage or Management into the any of the plans; the Final Environmental Impact Statement should be a programmatic EIS that includes the shortage plan for the entire basin so that the shortage can be equally shared across all stakeholders; 1

(2) to address the issue of Federal Indian Reserve Water Rights particularly the lack of adequate culinary water available to members of the Navajo Nation; 2

(3) to address the storage capabilities of CAP, the MWD Aquaduct, and the alternatives of using aquifers for storage to reduce the evaporative loss in the reservoirs; and 3

(4) to include contingencies to react to actual global warming projections. 4

I-15

1

Background of the Navajo Nation

The Navajo Nation includes the largest geographic area of any reservation in the United States.[1] The reservation is approximately 27,000 square miles.[2] As of the year 2000 census there are currently 298,215 members of the Navajo Nation, of which an estimated 173,987 currently live within the Navajo Nation reservation.[3] The majority of the Navajo Nation is geographically located in the Lower Basin state of Arizona. However, there are portions of the Navajo Nation in New Mexico and Utah. As of the 2000 census 63,500 members of the Navajo Nation were without domestic culinary water in their homes and had to haul water from community wells. [4] Additionally, the Navajo Nation will likely continue a transition from livestock herding to an agricultural based economy. In order to meet the future demands of the Navajo Nation a substantial quantity of water will be required.

The Supreme Court recently decreed in the Consolidated Decree that the Colorado River Indian Reservation, located in Arizona and California, had a prior perfected right to 662,402 acre feet (af) of Lower Basin.[5] This allocation is based on water that can be diverted and put to a consumptive use on the reservation.[6] However, the Decree does not actually restrict the use to which that water can be applied, so long as it is a beneficial use under the meaning in the decree.[7] Additionally, under the Consolidated Decree allocations to the tribes are charged to the state within which the consumptive use is made.[8] Although, there are members of the Navajo Nation homesteading on the Colorado River Indian Reservation, the bulk of the Nation's

2

members remain within the Navajo Nation reservation. Unfortunately, the Consolidated Decree does not identify an apportionment from the Lower Basin's apportionment to the Navajo Nation.

Approximately one third of the Navajo Nation reservation is in the state of New Mexico. The fact that the Navajo Nation is split between states and between the Upper and Lower Basins has severely complicated any claims by the Navajo Nation for water. Although Congress granted the Navajo Nation 508,000 af of Upper Basin water in the Navajo Indian irrigation project, the Navajo Nation has never realized that amount.[9] Instead, after decades of litigation and controversy, the Navajo Nation has agreed to settle with the State of New Mexico for 56% of New Mexico's entire allocation and with priority dates starting in 1868.[10] However, that settlement is still pending congressional approval. Furthermore, only one third of the Navajo Nation will be serviced from the water in the settlement if it is approved.

The balance of the Navajo Nation is in Arizona, 18,119.2 square miles, and Utah. The Navajo Nation has the right to demand sufficient water to put the all of the irrigable land on the reservation to a beneficial use. Unfortunately, the amount of irrigable land is still heavily contested. There are 11,601,856 acres of Navajo Nation Land within Arizona, under the precedent in the Consolidated Decree the Navajo Nation could claim an average of 6 af per irrigable acre on the reservation.[11] Under the Law of the River the water would be charged against Arizona's allocation. Furthermore, the Consolidated Decree has determined that anywhere between thirty and seventy percent of a tribe's reservation may be irrigable.[12] However, Public Law (87-483) designated 110,630 acres of the Navajo Nation reservation

I-15

3

located in New Mexico as irrigable, or roughly, two percent, a more realistic number when looking at the Navajo Nation.[13] Therefore, if the Navajo Nation can prove that 232,037 of the total reservation in Arizona is irrigable then the Navajo Nation could claim as much as 1.4 maf, or approximately one half of Arizona's total apportionment under the BCPA.[14]

COMMENTS

FACT SHEET

1. The Fact Sheet states that four action alternatives and a no-action alternative are included in the DEIS. Additionally, the Fact Sheet states that two of the four action alternatives were developed based on comments from parties outside the Bureau of Reclamations. Please identify the cooperating agencies, stakeholders, and other interested parties that are mentioned as providing input for the two action alternatives. Other stakeholders and interested parties would be more likely to provide meaningful input into the DEIS if it was clear who had already participated in the drafting process. 5

2. The Fact Sheet also states that the purposes of the proposed federal actions are to: (1) improve Reclamation's management of the Colorado River by considering the tradeoffs between the frequency and magnitude of reductions of water deliveries, and considering the effects on water storage in Lake Powell and Lake Mead, water supply, power production, recreation, and other environmental resources; 2) provide mainstream U.S. users of Colorado River water, particularly those in the Lower Division states, a greater degree of predictability with respect to the amount of annual water deliveries in future years, particularly under drought and low reservoir conditions; and, 3) provide additional mechanisms for the storage and delivery of water supplies in Lake Mead. With the increase in demand on water use projected in the Upper Basin

[13] Navajo Indian Irrigation Project, Public Law 87-483, (1962).
[14] Boulder Canyon Project Act of 1928

I-15

4

states and pending determinations of Tribal reserve water rights, the purpose should include identification and resolution of those issues to avoid future conflicts during times of drought. 6

CHAPTER 1: PURPOSE AND NEED

1. Section 1.3 Purpose of and Need for Action. The DEIS statements for the need for action fail to mention anything about the known effects of climate change on the future supply of water for the Colorado River Basin. The harms associated with global climate change were recently recognized in by the Supreme Court in *Massachusetts v. EPA*.[15] Among the known harms that will directly affect any shortage plan in the Colorado River Basins is a significant reduction in winter snowpack in the Rocky Mountains.[16] 7

2. Additionally, Section 1.3 fails to account for the recent 9th Circuit decision that vacated an injunction against lining the All American Canal to reduce seepage into Mexico.[17] Under the *Mexicali* decision the seepage water that currently enters Mexico from the canal will be reclaimed for use in the Imperial Valley Irrigation District. This will further reduce the amount of water that enters Mexico to meet treaty obligations.[18] Although it was assumed that this seepage water was not part of the treaty allocation it has become relied upon by Mexico and will have to be replaced from another source in the Lower Basin. Additionally, where the seepage has replaced the in-stream flows into Mexico it may have the original priority date set by the treaty of 1944.[19] 8

3. Section 1.5.1 Affected Region and Interests: limits the scope of the DEIS to the Lower Basin. It is well documented that there is a hydrological nexus between the Upper and Lower

I-15

5

Basin States.[20] If the interim guidelines for Lower Basin shortage operations are based on the 9
assumption that a minimum of 8.23 maf of water will be available for release annually from Glen
Canyon Dam then the affected region includes all of the Upper Basin states. Under current and
future projected precipitation the total per annum flow through the basin is, and will continue to
be, less than 15 maf.[21]

CHAPTER 2: DESCRIPTION OF ALTERNATIVES

1. Section 2.1 Development of Alternatives: Although there is discussion of encouraging
conservation under one of the four action alternatives, there is no inter-basin strategy to reduce 10
demand for water resources through an increased emphasis on conservation. With a growing
demand and diminishing supply the Conservation Before Shortage Alternative is the only
alternative that realistically attempts to address the larger problem. However, without an inter-
basin coordinated management alternative any savings realized in the Lower Basin will be lost to 11
the ever decreasing supply available from the Upper Basin. Furthermore, all published
alternatives require an unrealistic minimum annual inter-basin transfer of 8.23 maf through Lee's 12
Ferry and follow the same Shortage priority

2. Section 2.2.1 Shortage Guidelines: The DEIS discusses the Secretary's current options under the Law of the River as placing California's claims ahead of Arizona. In effect, under this interpretation, California would not incur a shortage until all Arizona post 1968 contracts were
reduced completely, including the Central Arizona Project. However, there is no discussion of
allocation to the tribes and specifically the Navajo Nation during a shortage. The Navajo Nation 13

6

has a water right as of September 9, 1850.[22] Under the *Winters' Doctrine* the Supreme Court
recognized the water rights of the tribes as the time that the reservation was created under the
treaty.[23] Additionally, the Supreme Court quantified the right as an amount sufficient to make
use of the reserved land in the manner for which they are reserved.[24] However, the actual acre
feet reserved to the Navajo Nation has yet to be determined. Any interim or long term shortage 14
strategy must include an accurate accounting of the water available to the Upper and Lower
Basin states after the prior perfected rights are quantified and apportioned. Finally, in 1922 the
Colorado River Compact solidified that the Indian reserve water rights were not to be affected by 15
the Compact or later statutes or decisions.[25]

CHAPTER 3: AFFECTED ENVIRONMENT

1. Section 3.4.1 Apportionments to Upper Basin States: explains the apportionment to the
Upper Basin states by percentage. Appendix C includes a depletion schedule projected through
2060 based on current and projected uses. Section 3.2.1.1 identifies that the Navajo Nation is
riparian to a portion of Reach 1 defined as Gypsum Canyon to Glen Canyon Dam. Section 3.3.2
Lake Powell and Glen Canyon Dam: states that the Navajo Generating Station takes water
directly from the Lake Powell for use as cooling water. The depletion schedule in Appendix C
limits use within Arizona to 50 kaf. The amount currently used by the Navajo Generating
Station is 34,100 af. The balance of the 50 kaf is already allocated to beneficial uses within the 16
portion of the Navajo Nation in the Upper Basin. The Navajo Nation has agreed not to make
demands additional demands against Arizona's Upper Basin apportionment greater than 50 kaf

I-15
7

before 2018.[26] However, this amount does not account for the total prior perfected right of the 16
Navajo Nation in the Upper or Lower Basin.

CHAPTER 4: ENVIRONMENTAL CONSEQUENCES

1. Section 4.15 Environmental Justice: explains the methodology and consequences of the ISG on the 9 identified Environmental Justice counties within the Lower Basin states. Because the alternatives all follow the same priority for reductions in deliveries to the respective water users there is no significant difference to the environmental justice communities under any alternative. However, Executive Order 12898 directs agencies to identify and address, as appropriate, disproportionately high and adverse human health and environmental impacts of their programs, policies, and activities on minority and low-income populations.[27] The tribes have historically been left out of the discussions regarding allocations of water throughout the basin. Any plan that does not take into account the Indian reserve water rights, and specifically the reserve water rights of the Navajo Nation, will ultimately have a disproportionately high and 17
adverse impact on the low-income populations on the reservations. By failing to identify and secure the water rights of the Navajo Nation now the agency is effectively maintaining the 18
status-quo by allowing junior water-rights holders to continue to appropriate water ahead of their priority date. Additionally, the longer the agency waits to rule on the quantity due to the Navajo Nation the more severe the impact and the greater the estoppel argument against the prior perfected rights of the Navajo Nation. 19
Without a final decision the junior appropriators are far more likely to continue to litigate the matter as long as they can and are allowed to use the water during litigation. The ISG should take into account the amount of water that the Navajo Nation can put to a beneficial use on the existing reservations.

---

[26] *See* Navajo Nation Council Resolution CD-108-68.
[27] Federal Actions To Address Environmental Justice in Minority Populations and Low-Income Populations, **59 FR 7629(1994).**

CONCLUSION

None of the proposed alternatives have significant differences to environmental impacts or on environmental justice issues. There are no alternatives relating to the actual significant government action that is affecting the human environment, specifically the Interim Shortage Guidelines and the priority of imposing shortages is the substantially the same in each alternative. Essentially, all of the current alternatives follow the same shortage sharing modeling assumptions. The ISG then imposes shortages in the same priority without any regard for the actual quantity of available water after consideration of the Federal Reserve Indian Water rights of the Navajo Nation. 20 Finally, the Scope of the Environmental Impact Statement needs to be reevaluated to adequately address the effects of the ISG on minority and low-income populations that stand to be affected by the Federal Action in accordance with EO 12898. 21

Reponses to Comment Letter I-15

I-15-1

As noted in Section 3.2 reservoirs located upstream of Lake Powell and operate independently of Lake Powell would not be affected by changes in the operations of Lake Powell and Lake Mead or consequently the proposed federal action.

I-15-2

Your comment is noted. To the extent that additional Tribal water rights are developed, established or quantified during the interim period of the proposed federal action, the United States will manage Colorado River facilities to deliver water consistent with such additional water rights, if any, pursuant to federal law. Thus, modifications to system operation, in accordance with pertinent legal requirements, will be considered as Tribal water rights and will be exercised in accordance with applicable law.

I-15-3

See response to Comment No. G-8-33.

I-15-4

Your comment is addressed in the general response pertaining to climate changes and hydrologic variability in the introduction to Volume IV of the Final EIS. Section 4.2 of the Final EIS has been enhanced and two new appendices (Appendix T and Appendix U) have been added to provide additional information regarding the potential impacts of climate change and hydrologic variability.

I-15-5

The information requested is provided in the Draft and Final EIS. Please refer to Section 1.4 for a listing of the cooperating agencies and Chapter 2 for details on the involvement of other stakeholders in the development of the alternatives.

I-15-6

See response to Comment No. IT-15-2.

I-15-7

Your comment is addressed in the general response pertaining to climate changes and hydrologic variability in the introduction to Volume IV of the Final EIS. Section 4.2 of the Final EIS has been enhanced and two new appendices (Appendix T and Appendix U) have been added to provide additional information regarding the potential impacts of climate change and hydrologic variability.

I-15-8

The All-American Canal Lining Project is not a part of this proposed federal action but is considered an interrelated project. A description of this project has been added to Chapter 5 (Other Considerations and Cumulative Impacts) in the Final EIS.

I-15-9

Your comment is addressed in the general response pertaining to climate changes and hydrologic variability in the introduction to Volume IV of the Final EIS. Section 4.2 of the Final EIS has been enhanced and two new appendices (Appendix T and Appendix U) have been added to provide additional information regarding the potential impacts of climate change and hydrologic variability. See also response to Comment No. G-5-44.

I-15-10 through I-15-12

As noted in Section 3.2 reservoirs located upstream of Lake Powell and operate independently of Lake Powell would not be affected by changes in the operations of Lake Powell and Lake Mead or consequently the proposed Federal Action. Your comment is also addressed in the general response pertaining to climate changes and hydrologic variability in the introduction to Volume IV of the Final EIS. Section 4.2 of the Final EIS has been enhanced and two new appendices (Appendix T and Appendix U) have been added to provide additional information regarding the potential impacts of climate change and hydrologic variability.

See response to Comment No. I-15-2.

I-15-16

Your comment is noted. See response to Comment No. I-15-2.

I-15-17 through I-15-20

Reclamation recognized federal reserved water rights of tribes on pages 3-81 to 3-89 and on 4-213 of the Draft EIS. Given that no effect is anticipated to Indian water rights, there would be no resulting environmental justice impacts. See also response to Comment No. I-15-2.

I-15-21

The information requested is provided in the Draft EIS. Please refer Section 4.14, Section 4.15, and Appendix H in the Draft and Final EIS for information on the potential impacts on minority and low-income populations which includes Indian tribes.

>>> Lana Jones <lana.jones@arizona.edu> 04/23/07 03:07PM >>>
Dear Bureau of Reclamation:

I'm writing to comment on the Draft EIS Interim Guidelines for Lower Basin Shortages.

In Chapter 4, page 4-265, lines 35-37 the range for reduced consumptive use of
4.2 to 6.9 af per acre is attributed to Colby et. al. 2006 but there is no entry for Colby in the References Cited, 1

page Ref-4.

In Colby B., K. Pittenger and L. Jones. "Voluntary Irrigation Forbearance to Mitigate Drought Impacts: Economic

Considerations" water application rates range from 3.5 to 5.8 af/acre. These rates comes from "Estimated Quantity of

2

Water Applied and Method of Distribution by Selected Crops Harvested:
2003 and
1998." 2003 Farm and Ranch Irrigation Survey Census of Agriculture,
2002 Census
of Agriculture,
http://www.nass.usda.gov/census/census02/fris/tables/fris03_28.pdf.

In brief, the range of consumptive use reduction in the dEIS seems high compared to the application rates found in the 3

irrigation survey.

Best regards,
Lana Jones
Graduate Research Assistant
Agricultural & Resource Economics
University of Arizona

This page intentionally left blank.

Reponses to Comment Letter I-16

I-16-1 and I-16-2

Information presented in the Draft EIS has been modified in the Final EIS pursuant to this specific comment, as well as other public comments. The appropriate citation has been added to the References Cited (bibliography). This revision does not significantly change the impact analysis or results presented in the DEIS.

I-16-3

Your comment is noted. No change to the Final EIS was necessary. The range of consumptive use reductions considered in the Draft EIS are attributed to the references cited. Although these rates may vary by region and more specifically by the local soils type, crops grown, and irrigation methods, amongst other factors; the methodology in the Draft EIS addressed this issue in an appropriate fashion since the information was used consistently between alternatives and appropriately lent itself in the relative comparison of the alternatives.

This page intentionally left blank.

Bureau of Reclamation

Re: Comments on Shortage Guideline Matters

1. I request that your use of the term "extraordinary conservation" be changed to **extraordinary measures** which includes:
   a. **Extraordinary conservation** based on doing something using less water and thereby generating **conserved wet water.** 1
   b. **Fallowing and crop rotation** based on "not farming for a period of a year or more" or "not farming for a period which is less than a year" and generating **saved wet water.**

   Making this distinction is important for:
   (1) **Conservation** has a positive socioeconomic impact
   (2) **Not farming** has a negative socioeconomic impact

2. I support Reclamation directly managing the ICS program based on: 2
   a. The Lower Basin States submitting their ideas
   b. Reclamation proposing and establishing policies and procedures
   c. Reclamation managing the ICS program in accordance with its policies and procedures

Because the Seven Basin State and lower Basin State meetings and the Technical Committee meetings are closed to the public, I request that Reclamation will be available to discuss the management of the ICS program further upon request. 3

Cc: Bird, Mark
Subject: river DEIS

Hi:

I am responding the DEIS for the Colorado River. I believe options to be considered should include:

1. The Secretary of the Interior reducing water to all river states by 5 percent. 1
2. Converting farm water to city water. 2
3. Increasing by a factor of three the amount of money for desalting research and development. 3
4. U.S. efforts at reducing global warming gases at a national and international level. 4

These options are further discussed in the following newspaper article relating to the Colorado River. Please include a copy of this article as a part of my reply. Also, can you tell me whether or not you can include the following article? 5

Thanks,

Mark Bird

I-18

Is California headed toward economic collapse?

By Mark Bird
March 9, 2007

California has been using over 100 percent of its allocation of the Colorado River and over 100 percent of its annual renewable groundwater. Nearly 100 percent of the water used in metro San Diego and metro Los Angeles flows from hundreds of miles away.

There is a virtual 100 percent probability global warming is occurring and will intensify. Solutions will be thwarted by a near 100 percent certainty of litigation.

The Colorado River is the most critical water source for Southern California, Arizona and Nevada. In the next 30 years, the population of these two latter states will increase by 100 percent. Wyoming, Colorado, Utah and New Mexico will all also be using more Colorado River water in the next decade.

Lake Mead, on the Colorado River, is the largest reservoir in North America. Relative to its designed storage capacity, Lake Mead is now 15 percent silt, 37 percent water and 48 percent empty. A California economic collapse would commence if Lake Mead loses as little as another 20 percent of its storage capacity.

Additional hydrological factors include the absence of any large lake or river that is entirely within Southern California, the urban heat island effect, the tree-ring record suggesting the 20th century was a wet century, aging water infrastructure and an absence of regulations addressing shortage conditions on the Colorado River.

Additional sociological factors include water speculators buying water rights, bureaucratic inertia, an anti-science disposition relative to present trends, unfriendly relations with other states, and the complexity of approximately a thousand water districts and water-regulating entities in California. These factors are certain to intensify water scarcity in the near future.

But global warming is probably the most significant factor. In about 150 years of measurement, the 10 warmest years have all occurred after 1989. Statistically, one would not expect this pattern in over a million samples of picking 10 random years from a box.

For metro Los Angeles, 86 percent of its water derives from aqueducts supplying water from the Colorado River or the Sierra Nevada mountains in Northern California. Global warming is likely to continue to mean less snow being created, upstream soil absorbing more water, more evaporation from all reservoirs, less water entering the over 2,000 miles of concrete canals in California and more evaporation from these canals. At the same time, due to the warming, all farms will need more water to grow the same quantity of food.

It would be difficult to quantify, but perhaps the 43 non-Colorado River states and about 200 nations in the world are now annually "using," in terms of global warming evaporation, an amount of California water equal to the annual water usage of San Diego.

Over a few years, the contours of a collapse may feature a 50 percent increase in water bills, a 50 percent increase in power bills from electricity from Colorado River dams, and a 50 percent increase in the cost of food grown in Southern California. Such a scenario would send ripples of unemployment, crime and civil

I-18

unrest throughout the Golden State.

Given these trends, what are four key solutions?

Perhaps the most immediate solution is for the federal government to promptly reduce water deliveries by 5 percent for all seven Colorado River states. This could be in effect until the water level of Lake Mead reaches, say, 75 percent of capacity.

Likewise, California should institute water-based financial rewards and penalties for all farms and cities.

As there are three theoretical techniques that may each reduce desalting costs by 75 percent, the federal government should triple funds for desalting research and development, with a focus on desalting powered by solar, wind, tidal or other sources.

To further prepare for certain lean water years, the federal government should assume a far more energetic leadership role in reducing global warming gases.

Without major water policy shifts, an economic collapse of California could start as early as 2008. Otherwise, as California has eight times as many people as Louisiana in 2004, an economic collapse could be more financially devastating than Hurricane Katrina.

Reponses to Comment Letter I-18

I-18-1

Your comment is noted. No change to the Final EIS was necessary. The Secretary is vested with the responsibility to manage the mainstream waters of the Lower Basin pursuant to applicable federal law. The responsibility is carried out consistent with a body of documents referred to as the Law of the River. The Law of the River comprises numerous operating criteria, regulations, and administrative decisions included in federal and state statutes, interstate compacts, court decisions and decrees, an international treaty, and contracts with the Secretary. This body of documents also sets forth the quantity and priority of water rights from the Colorado River. The Secretary has the responsibility to observe the priority of water rights and cannot arbitrarily implement delivery reductions that do not comport to the established rights, and the elements of the legal framework for allocation and delivery of Colorado River water, including the Supreme Court Consolidated Decree.

I-18-2

Your comment is noted. No change to the Final EIS was necessary.

I-18-3

Your comment is noted. No change to the Final EIS was necessary.

I-18-4

Your comment is noted. No change to the Final EIS was necessary. Please note that the identification and evaluation of the methods to reduce warming gasses is outside the scope of this EIS.

I-18-5

Your comment is noted.

>water shortage. The results of that EIS are
practically useless and, if implemented, will put the public interest at risk. My reasons 1
for this statement are as follows:

>Essentially, they use a river/reservoir model forced by 50 years chunks
>of actual Colorado River flow. These runs under different river flow
>scenarios are used to estimate the likely range of future levels of
>Lake Mead (say); the probability the Lake will be full or empty. In
>fact, their simulations show a disturbingly large range of
>possibilities from full pool to a level near dead pool. Just how the
>Lake is operated depends on these probabilistic estimates of future
>elevation.
>
> But the analysis done by USBR to date and the one on which the
>EIS is omits one huge factor. Essentially, their analysis to date
>assumes the past climatic variations in rainfall, snow levels,
>evaporation, etc are good estimates of what the future will be 2
>like··past river flows are good estimates of future river flows. In
>their case, this is a fatal error that, in my view, negates the basis
>of the EIS.
>Numerous studies over the last 10 years have shown the climate of the
>Colorado drainage will change markedly in the next few decades (it is
>already!). There will be less rain, snow pack will disappear earlier, 3
>increase temperatures will increase evaporation, etc. In short, the
>EIS is defined for the past, not the future. As such it is largely
>unreliable for decision makers.
>
> I believe the model forcing changes could be estimated from
>existing information. They could be added to the existing simulations
>and the whole probability structure of future possibilities be made
>available to decision makers·.at least then we would be taking a fairly 4
>realistic look at the future of the Colorado system under the climate
>change scenario. Given that the system is uncomfortably close to
>failure now, we need the best look at what to expect.

I-19

>
>   One other item along the same lines:
>while USBR talks about inflow, outflow, etc in the EIS, they never
>factor in increasing population. The 20 million more folks expected to
>rely on Colorado water by 2030 will need something like 3 maf MORE than 5
>is required today. This is order 20-30% the typical inflow to Lake
>Powell today. And as we have seen, numerous studies all show that
>inflow will decrease in a greenhouse world. So where does that extra
>water come from?

Thank you for your consideration. Dr. Tim Barnett, Climate research Div, Scripps Inst Oceanography, La Jolla, CA

Reponses to Comment Letter I-19

I-19-1

Your comment is noted. No change to the Final EIS was necessary.

I-19-2 through I-19-4

Your comment is addressed in the general response pertaining to climate changes and hydrologic variability in the introduction to Volume IV of the Final EIS. Section 4.2 of the Final EIS has been enhanced and two new appendices (Appendix T and Appendix U) have been added to provide additional information regarding the potential impacts of climate change and hydrologic variability.

I-19-5

The information requested is provided in the Draft EIS. Please refer to Section 3.4 (Water Deliveries) for details on the water depletion schedules that were used in the modeling of the alternatives. As noted in this section, the Upper Basin depletion schedules have factored the projected increased water demands that are associated with increased use of domestic water supplies to meet the projected population growth in the Upper Division states. In the Lower Basin, all of the Lower Division states are currently using the full amount of their entitlement of Colorado River water and therefore, their respective entitlements limit their use of water from the Colorado River. Managing future population growth within the constraints of available water supply is primarily a local responsibility.

Mr. Rick Gold
Regional Director, Bureau of Reclamation Upper Colorado Region
Attn: UC-402
125 South state St
Salt Lake City, Utah 84138-1147

Dear Mr. Gold,

I applaud the Bureau's acknowledgment of the critical water problems for the people of the southwest in the face of continuing long-term drought as well as the efforts to devise a strategy to deal with the problem.

Of the four alternatives listed in the DEIS, Conservation before Shortage provides the best solution for providing for the water and electricity needs of the southwest cities while also protecting the Colorado's riverine ecosystem. 1

A particularly attractive feature of Conservation Before Shortage that is not included in the Basin States Alternative is that users who give up water in response to a conservation trigger are compensated. 2 The Basin States alternative does not provide such compensation but strictly follows first in time, first in right western water law. This feature of Conservation Before Shortage is attractive for its obvious fairness and is particularly meaningful in that it alters the traditional way of dealing with water shortage in the West.

There are significant potential advantages to the use of voluntary, market-based conservation as an alternative to and as a means of mitigating against involuntary shortages. 3

In addition, in the Conservation Before Shortage Alternative, Mexico is allowed to participate in the ICS. That is Mexico can create surplus and bank it in Mead. This feature has many beneficial possibilities for the Delta. Initial indications are that all the potential players, including the powers in Mexico, find the potential attractive. 4

- Based on extensive modeling performed for the Lower Basin states, reductions of 400,000, 500,000 and 600,000 acre-feet at Lake Mead elevations 1075 feet, 1050 feet and 1025 feet, respectively, appear to provide optimal results in preventing larger involuntary shortages that perform better than the 200,000, 400,000, and 600,000 acre-foot reductions proposed in the original CBS proposal. 5

- It is desirable to protect the elevation of Lake Mead at no less than 1000 feet under any condition to protect Southern Nevada Water Authority's lower intake structures, as well as the new minimum power pool if proposed low-pressure turbines are installed at Hoover Dam. 6

I-20

- It is preferable for Lower Basin water users to voluntarily engage in predictable, small-scale reductions in use – and receive compensation for those reductions – rather than face large-scale, involuntary and uncompensated disruptions in water deliveries that could cut into municipal and agricultural water supplies and create unmitigated economic impacts. 7

- There is a large volume of Colorado River water which could be temporarily conserved through voluntary, market-based mechanisms such as part-year fallowing or forbearance agreements, dry year options, or other similar arrangements to reduce Lower Basin consumptive use on an occasional, temporary basis as an alternative to involuntary shortages to low-priority users.

- Users of Colorado River water in Mexico may wish to participate in short-term, voluntary and compensated conservation agreements, to reduce the probability of larger, uncompensated future reductions due to a declaration of shortage under the 1944 Treaty with Mexico. 8

For the reasons listed above, I urge the Bureau to adopt the Conservation before Shortage Alternative as the preferred alternative.

Thank you.

Stacey Hamburg

>>> Melanie Florence <smskflor@yahoo.com> 04/27/07 12:42PM >>>
Dear Bureau of Reclamation,

I live in St. George, Utah, a place that will be affected by future water policies on the Colorado River. I have read the four alternatives and feel like the best one is the conservation before shortage initiative. 1

St. George right now uses a lot of water--about 300 gallons per person per day--and is pursuing building a Lake Powell to get even more. Most of the water is used on house lawns and golf courses--even during the summer when the snowbirds have left for cooler temperatures. Sprinklers all over town go off during the hot times of the day, in strong winds, and many areas overwatered. Even the city does not appear to be curbing water conservation in parks, school grounds, etc. Although St. George and Washington County in general has a desert climate, very few homes and businesses are xeriscaped in the front yards.

I feel like the only way to force the city and county to look toward future water shortages and encourage water conservation practices now is by imposing it from the outside somehow. I hope the conservation before shortage alternative will do that. 2

Sincerely,
Melanie Florence

>>> "Crista Worthy" <cristaworthy@hotmail.com> 03/01/07 10:47 AM >>>

Thank you for the opportunity to comment:Due to climate change, which has already
begun, it seems inevitable that those who depend on the Colorado River for their water 1
supply will receive less and less in the future. This makes it all the more ridiculous to
continue the existence of "Lake" Powell. Although I am one of those who has enjoyed
boating on this reservoir, I also know that it wastes an obscene quantity of water each 2
year, through evaporation and seepage--enough to supply the entire state of Nevada! The
Glen Canyon Dam, just upstream from the Grand Canyon, not only prevents sediment
from entering that National Park, but drastically lowers the water temperature, causing 3
the extinction of a number of fish, and near-extinction of others, contrary to Federal Law.

Lake Powell should be drained, the dam decommissioned, and the West will instantly
have enormously more water, which can be taken directly from the river or stored, if 4
necessary, in the Lake Mead reservoir. The small amount of electricity generated at the
Glen Canyon Dam can be replaced by building wind and solar generators nearby. The
Grand Canyon river ecosystem, unique in all the world, will be saved. The muck and 5
scum of "Lake" Powell that now fills the main channel of the Colorado River through
Glen Canyon will clean itself out within a decade or so through natural forces, and Glen 6
Canyon will once again be what it was: the true heart of the Southwest, an oasis with
more wildlife than all the thousands of square miles of desert surrounding it put together.

Subject: Comments for Operations at Lake Powell & Lake Mead under Low Reservoir Conditions

Dear Mr. Johnson and Mr. Gold:
Lake Powell and Lake Mead lose 17 percent of the water that flows into them through
evaporation. Vacant space in underground aquifers near existing Colorado River water
recharge facilities could store more water than these two reservoirs combined. Upwards 1
of 810,000 acre-feet of water annually could be saved by eliminating Lake Powell and
operating Lake Mead principally for distribution to groundwater recharge facilities.

After more than 40 years of operation, it was not until the fall of 2004 that Lake Powell's
water storage actually augmented downstream water use. And with the impacts of climate
change and rising water consumption, it is unlikely that there will be sufficient surplus 2
water to fill Lake Powell again. Even should surplus water accumulate, Lake Mead alone
could provide sufficient storage.

Between Lake Powell and Lake Mead lies Grand Canyon National Park. The operation of
both these reservoirs has impacted the Canyon, but Glen Canyon Dam at Lake Powell has 3
been far more devastating. Since the dam's completion four of eight native fish have 4
gone extinct and the dam has trapped the sediment necessary to maintain habitat and 5
beaches for wildlife and recreation, as well as the stabilization of archeological sites.

Sediment is a major unresolved problem threatening the long-term operations of Lake
Powell and Lake Mead. Ultimately, sediment must be removed to ensure public safety. 6
Removing sediment from Lake Mead downstream, rather than Lake Powell upstream is
the most technically feasible, least costly and environmentally advantageous approach.

The Colorado River Compact of 1922, which largely governs the operations of Lake
Powell for Lake Mead, cannot meet its intended purpose of equitably sharing Colorado
River water between the Upper and Lower Basin states. With River flows expected to 7
decline 18 percent by 2040, this inequity will worsen, furthering the need for Compact
amendments while highlighting the benefits of eliminating Lake Powell to fulfill the
Compact's primary objective.

To Whom It May Concern:

INTRODUCTION

The Mohave County Water Authority (MCWA) submits the following comments to the Colorado River Interim Guidelines for Lower Basin Shortages and Coordinated Operations for Lake Powell and Lake Mead, Draft Environmental Impact Statement (February 2007). MCWA is comprised of members representing Bullhead City (BHC), Lake Havasu City (LHC), Mohave Water Conservation District (MWCD), Mohave Valley Irrigation and Drainage District (MVIDD), Golden Shores Water Conservation District (GSWCD), City of Kingman and Mohave County. BHC, LHC, MWCD, MVIDD and GSWCD represent the first (and probably only) municipal / industrial users in the State of Arizona to be significantly and immediately impacted by projected shortages during the interim period. Because of our unique position in the State of Arizona, we renew our previously denied request for consultation on this matter as the draft EIS makes it abundantly clear that no one with whom Reclamation consulted was adequately representing the interests of Arizona's 4th priority on river users.

THE SEVEN BASIN STATES ALTERNATIVE

MCWA recognizes Arizona worked diligently with the other Basin states to achieve agreement on the Basin States' Preliminary Proposal recommended to the Secretary of Interior on February 3, 2006 following the publication of the Draft EIS, and that Arizona has continued to work closely with the other states to refine and improve the Basin States' Preliminary Proposal and to develop one set of comments to the Draft EIS on behalf of all of the states ("Basin States Comments"). We understand the Basin States will be submitting the Basin States' Comments, together with the Basin States'

1

"As you drink the water, remember the spring."
– Chinese proverb –

L-1

Proposal, which will include the Basin States' Agreement, Proposed Interim Guidelines for Colorado River Operations, draft Forebearance Agreement and Arizona-Nevada Shortage Sharing Agreement (Basin States Proposal). While MCWA has some significant reservations regarding the Basin States Alternative we join in Arizona's letter submitted this date recommending the Secretary choose the Basin States alternative as the preferred alternative in the FEIS and adopt an ROD with the guidelines and criteria necessary to implement the Basin States Alternative in substantial conformance with the carefully negotiated Basin States Proposal provided such ROD adopts Arizona Department of Water Resources' Director's Shortage Sharing Workshop Recommendations, October 24, 2006 (Revised) Final attached hereto as Exhibit 1. 1

COMMENTS TO ADDRESS CONCERNS SPECIFIC TO MCWA

1. <u>No Action Alternative</u>:
   This alternative would provide no guidance to the on river 4th priority users in planning for shortages. Our members could suffer 30% shortages in both M&I and agricultural supplies as early as 2011. It gives no guidance as to how and when shortages would be imposed. It also assumes (a) the existing 602(a) interpretation would stand (see Arizona's letter for further discussion) and (b) the CRBPA requires on river agricultural and municipal/industrial users to be shorted immediately when CAWCD suffers shortages. This conclusion is not compelled by either the language in our contracts nor the CRBPA. This alternative leaves too many unanswered questions both among the Basin States and within Arizona to be acceptable to MCWA. 2

2. <u>Water Supply Alternative</u>
   The DEIS indicates that there would likely be no shortages in Arizona during the interim period under this alternative. In the short term this is clearly the best alternative for us, but we recognize the potential long term adverse consequences of this alternative and the likely conflicts it would cause among the Basin States. The compromises encompassed within the Basin States Proposal benefit the entire system and its long term benefits are reasons we support the Basin States Alternative versus the Water Supply Alternative. 3

3. <u>Reservoir Storage Alternative</u>
   The modeling provided in the DEIS shows that this alternative would have a significant negative impact on the river communities in Mohave County. 4 While the Reservoir Storage Alternative proposes to offset some of its impact with increased intentionally created surplus (ICS) the Arizona cities most immediately and severely impacted by this proposal, i.e., Lake Havasu City and Bullhead City, would be unlikely to benefit from an ICS program without a legal battle within Arizona. 5

   MCWA for the above reasons, as well as the reasons set forth in Arizona's letter, strongly objects to the Reservoir Storage Alternative. 6

2

L-1

4. <u>CBS Alternative</u>
MCWA believes the concept of voluntary fallowing, as well as the opportunity for
participation by all parties (including Arizona's on river 4th priority users and
Mexico) in the ICS program are laudable goals and request the FEIS adopt the 7
Basin States Alternative as the preferred alternative but discuss further the steps
which could be taken, within the Law of the River, to get the benefits likely to
result from a voluntary fallowing program (which would put fallowing contracts in
place NOW for future shortages) and to broaden participation in the ICS
program. Representing the communities in which Arizona will take the first, and
most significant, reductions in times of shortage we consider it incumbent upon
the Secretary to take all reasonable steps to mitigate the impacts of shortage by 8
supplementing the mitigation efforts we already have in place.

5. <u>Additional Comments on the DEIS</u>
   A. <u>ICS</u>
   Reclamation should, in the Final EIS, accurately describe ICS as a
   category of surplus, include a description of the forebearance necessary
   for the delivery of ICS to the entity that created the Surplus, and, in the 9
   record of Decision, adopt guidelines for the creation and delivery of ICS as
   set forth in the Proposed Interim Guidelines contained in the Basin States'
   Proposal. Reclamation should also take reasonable steps to provide that
   the benefits of ICS are available to all users particularly those immediately 10
   and significantly impacted by projected shortages, i.e., our members.

   B. <u>On River 4th Priority Agricultural Users</u>
   The draft EIS includes the following statement: "Key to the impact analysis
   is the assumption that the most conservative way to estimate impacts is to
   assume that, if a shortage occurs, farmers would react by fallowing
   irrigated lands." (p.4-263) This is an adequate approach for analyzing
   shortage reductions expected to last for a single year. However, we 11
   disagree with the assumption that this approach captures the expected
   impact for multiple consecutive-year storage reductions. Since fourth
   priority agricultural water users in Mohave County, Arizona have no
   reasonably available replacement water supply, a long term shortage will 12
   likely result in the permanent loss of production for some lands.

   The DEIS also fails to adequately address the impact on the economies of
   the impacted communities of this loss of agriculture by comparing the
   impact to the State and County overall (see, e.g., p.4-261 which totally 13
   ignores on river agricultural impacts in Arizona). This serves to very much
   dilute the direct and immediate impact on the on river 4th priority user
   communities.

   C. <u>On River 4th Priority Municipal and Industrial Users</u>

3

L-1

- As with on river agricultural users, the DEIS fails in any manner to
  address the direct and immediate impact of the projected shortages 14
  and cumulative shortages on municipal users of 4th priority on river
  users (see, e.g., p.3-129) and, again, lumps the communities
  together by County which significantly dilutes the local impact.

- The DEIS depletion schedules (Appendix D) underestimate by 25-
  35% on river M&I water use (as compared, e.g., to Reclamation's
  own 2006 water use report) which again, serves to underestimate
  the extent and effect of shortages and makes it difficult to determine 15
  the actual shortage amounts we would be expected to suffer based
  on the DEIS hydrologic modeling.

- The DEIS fails to address the significant costs borne by our
  members to date, and the even higher costs to be borne in the
  future, of the mitigation efforts taken to date (primarily participation 16
  in the Arizona Water Banking Authority (AWBA) program which
  costs include water, delivery, storage, recovery and replacement of
  any water used in times of shortage). The significant economic
  hardship of using AWBA water in times of shortage, particularly in
  multiple year shortage occurrences, is totally ignored by the DEIS. 17
  The DEIS also ignores the hundreds of millions of dollars our
  communities have spent/are spending to convert from septic to
  wastewater treatment systems in order to generate effluent to offset
  the impacts of shortage.

- Future estimated shortage reductions to mainstream users,
  including Lake Havasu City and Bullhead City, run as high as 30%
  of entitlement over a number of consecutive years. Despite the
  conclusion in the DEIS that no permanent changes in land use are
  expected (p.4-270) it is highly unlikely that such significant cutbacks 18
  in supply, and as early as 2011, would not alter land use patterns in
  the affected communities.

- The DEIS goes to great lengths to address impacts in Nevada
  (ostensibly in support of the extreme measures be proposed to
  solve both its long term and shortage supply needs) and the
  Central Arizona Project area while totally ignoring that Arizona's on
  river 4th priority users are in a far worse position than either of these 19
  areas for a number of reasons including:

(1) Neither our agricultural nor M&I users have a readily available alternative source of water to offset shortage reductions; e.g., no adjacent tributaries, no non Colorado River related surface water flows,

4

L-1

nor (based on Reclamation's current interpretation of Article V accounting under the Consolidated Decree in *Arizona and California*) is there any locally available, non-Colorado River groundwater..

(2) The small (relative, e.g., to the SNWA and CAP service areas) population in the area, and the large geographic distances separating the on river P4 users, make financing of any water importation project unlikely at best.

(3) Fallowing agreements, e.g. with farmers or tribes, as are available to Central Arizona Project communities are not available to on river P4 users for a variety of reasons including the trading of our priority for the CAP (which did not benefit, and arguably harmed, on river users), on river tribes in Mohave and LaPaz settling their claims before our communities existed and thus such settlements make no provision for leasing to adjacent municipalities, and the apparent position of Arizona and CAP that ICS in any form is not available to us without forebearance by Arizona and CAP.

(4) Limited, if any (investigation is ongoing) adjacent basins unconnected to the River in which recharge, and recovery, could occur (i.e., our own banking program).

- The ROD needs to include the Arizona/Nevada shortage sharing agreement as submitted with the Basin States Proposal and a provision that the proceeds of that agreement are to first be used to hold the on river P4 M&I users, the first impacted by this "deal", harmless (i.e., as to water and money) from the impact of this sharing agreement. Arizona has verbally indicated to MCWA that this is the intent but due to the immediate and detrimental impact of the Arizona/Nevada agreement MCWA takes the position this commitment should be recognized in the ROD. 20

D. Additional Comments

- An agreement with Mexico is a critical component of the Basin States Proposal and MCWA's support of same. The impacts of a failure to reach such an agreement are not modeled in the DEIS but would no doubt have a significant impact on our members 21
- MCWA, its members, and Arizona as a whole appear to be penalized in the DEIS for its active planning for drought for decades (p.4-282). 22 The DEIS dismisses the significant economic impact of the investments made to date, and projected into the future, by coming to the erroneous conclusion that due to Arizona's drought planning, there is no real impact on its M&I users. 23

5

L-1

- The projected depletion schedules and shortage impact tables in the DEIS do not accurately portray the various contracts and contract amounts held by MCWA and its various subcontractors. This should be corrected in the FEIS. 24

- Because a shortage has not been declared to date on the River, and because our M&I users take the most immediate and significant and disproportionate reductions, the FEIS should include a program for monitoring the economic, land use and public policy impacts of any declared shortage during the proposed interim period. 25

- Operation of the YDP at full capacity should commence as soon as possible in order to stop the loss of water now occurring as a result of the bypass flows to the Cienega de Santa Clara. 26

- Reclamation should immediately undertake programs and projects to augment system flows. 27

- Final shortage guidelines should be flexible in order to allow the appropriate response to changing conditions including, but not limited to, improved hydrologic conditions during the year(s) in which a shortage is declared and catastrophic conditions requiring cuts in excess of 600,00 a/f. 28

CONCLUSION

Subject to Arizona's comments as submitted by ADWR, and our comments as noted above, the Mohave County Water Authority strongly recommends that the Secretary choose the Basin States Alternative as the preferred alternative in the FEIS and adopt a ROD with the guidelines and criteria necessary to implement the Basin States Alternative in substantial conformance with the carefully negotiated Basin States' Proposal. 29

Sincerely,

Maureen R. George

Director's Shortage Sharing
Workgroup
Recommendation

October 24, 2006
(Revised)
Final

In 2005, the Director established the Arizona Shortage Sharing Stakeholder Workgroup (Workgroup). The Workgroup had two specific goals:

1. Develop a recommendation to the Director regarding the appropriate volume and implementation strategy for implementing future Colorado River shortages in the lower basin.
2. Develop a recommendation to the Director for allocating shortages between the Central Arizona Project (CAP) and equivalent priority mainstream Colorado River water users.

The Workgroup effort supports a larger Bureau of Reclamation (Reclamation) Environmental Impact Analysis process to develop lower basin shortage criteria and conjunctive management strategies for the operation of Lakes Powell and Mead. Reclamation currently plans to issue a Record of Decision in December 2007.

Shortage Volume and Implementation Strategy

The Workgroup developed the following recommendation for implementing lower basin shortages:

1. At or below Lake Mead elevation 1075 feet, 400,000 acre-feet shortage
2. Below elevation 1050 feet, 500,000 acre-feet shortage
3. Below elevation 1025 to 1000 feet, 600,000 acre-feet shortage
4. Below elevation 1000 feet, reconsultation with Reclamation and the states

The recommendation assumes that the first step will be to reduce water deliveries to Mexico and the next step will be to calculate shortage sharing with Nevada. Hydrologic conditions that necessitate reductions in excess of 600,000 acre-feet will trigger a Secretarial consultation process to determine how to implement additional reductions in the least damaging and most equitable manner possible. That consultation process has not been defined, but should be developed with input from the basin states.

The Director forwarded this recommendation to the other Colorado River basin states, and it has been incorporated into the *Seven Basin States' Preliminary Proposal Regarding Colorado River Interim Operations, February 3, 2006,* with one modification, that reconsultation would be triggered at elevation 1025.

Shortage Allocation Between CAP and Fourth Priority Mainstream Entitlements

The Workgroup analyzed methods for allocating shortage reductions between CAP and fourth priority mainstream water users. The CAP has an established priority system for implementing shortage reductions. Excess water supplies are reduced first. If additional reductions are needed, non-Indian agricultural priority water supplies are reduced until gone, and finally municipal/industrial/Indian uses are reduced according to the formula in the Gila River Indian Community Water Rights Settlement L-1

Agreement. There is no equivalent shortage implementation system for fourth priority mainstream water users. Fourth priority mainstream uses (agricultural and municipal) will be reduced proportionately as soon as Arizona Colorado River shortage reductions are implemented. Future estimated shortage reductions to mainstream users including Lake Havasu and Bullhead City run as high as 30 percent. Under Reclamation's current interpretation for Article V accounting, there is no locally available, non-Colorado River water supply to offset these shortage reductions.

The Director requested that a small technical subgroup of Workgroup stakeholders begin working with the Department to develop a shortage allocation recommendation. The technical group established principals to guide a shortage allocation strategy:

1. Define a method for the Secretary to utilize when allocating shortages to Arizona users
2. Beneficiaries bear the costs of shortage protections
3. Shortages must be allocated in a reasonable manner based on existing contracts and agreements
4. To the extent possible, treat similar users groups equitably

The Mohave County Water Authority (MCWA) presented a recommendation for proportional shortage reductions to fourth priority mainstream water supplies based on entitlement. Shortage reductions to mainstream domestic water supplies could be mitigated by the Arizona Water Banking Authority. The Department completed additional technical analysis of the proposal, which was endorsed by the technical group. The technical group recommends that Arizona fourth priority shortages be allocated as follows:

1. Determine shortage amount and allocation to Mexico. Allocate the remaining shortage amount first to Nevada, and the remainder to Arizona. The enclosed spreadsheet first allocates 16.7% of the shortage to Mexico. The remaining shortage amount is then allocated 7.4% to Nevada and the remainder to Arizona.
2. Determine the estimated priority 1-3 consumptive use amount based on the last non-shortage year use. Determine the **Total Water Supply Available for Fourth Priority Diversion**. Subtract the priority 1-3 consumptive use amount from the Arizona Colorado River water allocation of 2,800,000 acre-feet.
3. Determine the **Fourth Priority Mainstream Shortage Percentage**. Divide the fourth priority mainstream diversion entitlement, 164,652 acre-feet, by the Total Water Supply Available for Fourth Priority Diversion (#2).
4. Determine the total water supply **Available for Fourth Priority Diversion after Shortage Reduction**. Subtract the Arizona portion of lower basin shortage from Total Water Supply Available for Fourth Priority Diversion amount (#2).
5. Determine the **Fourth Priority Mainstream Shortage Reduced Water Supply**. Multiply the Available for Fourth Priority Diversion after Shortage Reduction (#4) water supply by the Fourth Priority Mainstream Shortage Percentage (#3).
6. Determine the remaining, CAP water supply. The Total Water Supply Available for Fourth Priority Diversion amount is based on estimated priority 1-3 water use. Actual use may be higher than estimated, and could result in an inadvertent CAP overrun. The CAP has agreed to be responsible for payback, under the Inadvertent Overrun and Payback Policy, up to the amount of the water user's entitlement. Actual use may be lower than estimated, resulting in an increased water supply for CAP.

L-1

Director's Shortage Sharing Workgroup Recommendation
October 24, 2006
(Revised)
Final

Since there is a fixed maximum diversion entitlement for fourth priority mainstream water users, as noted in the *Contract Between the United States and the Central Arizona Water Conservation District for Delivery of Water and Repayment of Costs of the Central Arizona Project, December 1, 1988*, the mainstream fourth priority water supply has been calculated based on that entitlement. After determining the mainstream fourth priority water supply, the remaining water supply is available for diversion by the CAP, including any available return flow from mainstream water uses.

The shortage allocation recommendation includes the opportunity for mainstream municipal water users to firm 100 percent of their individual municipal/industrial entitlements. Based on updated population projections (2003) the AWBA would need between 450,000 and 525,000 acre-feet of credits for fourth priority mainstream municipal and industrial water users. As AWBA credits are used and replaced, the new credits will be earmarked in the name of the entity that replaced the credits, thereby creating a revolving fund. The AWBA has not foreclosed the opportunity for any fourth priority mainstream entitlement holder to contract with the AWBA for firming.

ENDNOTES

1 Source: Arizona Department of Water Resources 2003 mainstem Colorado River water use projections.

2 An amount of 72,000 acre-feet has also been deducted to account for higher priority Ak-Chin and Salt River Pima-Maricopa Indian settlement water.

3 This amount is determined by first deducting Mexico's share (16.7%) of the total Lower Basin shortage. The remaining shortage volume is apportioned first to Nevada (7.4%) and the remainder to Arizona.

Reponses to Comment Letter L-1

L-1-1

Your comment is noted. No change to the Final EIS was necessary.

L-1-2

Your comment is noted. No change to the Final EIS was necessary.

L-1-3

Your comment is noted. No change to the Final EIS was necessary.

L-1-4 through L-1-6

Your comment is noted. No change to the Final EIS was necessary.

L-1-7 and L-1-8

Your comment is noted. See also response to Comment No. G-5-93.

L-1-9

ICS is the proposed mechanism for the storage and delivery of conserved system and non-system water in the Preferred Alternative. In addition, Draft Operational Guidelines have been included in Appendix S of the Final EIS that provide reviewers with an understanding of Reclamation's current assessment of the likely proposed format and content of the proposed interim guidelines which includes ICS administration.

L-1-10

See responses to Comment Nos. G-5-93 and L-1-9.

L-1-11 and L-1-12

Your comment is noted. The content of the Final EIS has been modified to reflect this public input. A discussion of the probabilities and socioeconomic effects of multi-year shortages has been added to Section 4.4 and 4.14 of the Final EIS. The effect of such a multi-year shortage on land use would depend on how these shortages were allocated among individual farmers within the water agency service area, or which lands within a single farming operation were fallowed. Given these unknowns, Reclamation did not conclude that the same acres would be fallowed each year, and did not identify socioeconomic impacts from permanent land use changes.

L-1-13

As indicated in the EIS, losses in employment, income, and tax revenues that may be experienced during a shortage represent a small percentage of employment, income, and tax revenues within Arizona and the counties that may be directly affected. Reclamation's assessment of the relative effects of shortages occurring at the county-level determined that no individual county in Arizona would see losses in employment, income, or tax revenues greater than one percent of the total generated within that county. The analysis for impacts to the agricultural economy did include the counties along the river where agriculture would be affected, including Mohave County.

L-1-14

The Draft EIS did address socioeconomic impacts to the agricultural sector at the County level, including impacts along the Colorado River mainstream, including Mohave County. Reclamation concurs that fourth priority municipal contractors such as Lake Havasu City and Bullhead City will be affected by shortages, and additional information has been added to the Final EIS to acknowledge this. The specific reductions distributed to affected Arizona M&I users under specific shortage determinations is included in Appendix G. See also response to Comment No. L-1-13.

L-1-15

Reclamation concurs with this comment. In the Draft EIS, the depletion schedules for three entities, Bullhead City, Lake Havasu City and Mohave Water Conservation District, consisted of the portion of water related to their water delivery contract with the Secretary; but did not include subcontracted water from the Mohave County Water Authority (MCWA). Instead the schedules were related to the MCWA water delivery contract with the Secretary. For the Final EIS, the schedules for these three entities were increased to include subcontracted water with MCWA. Therefore the depletion schedules and modeling for the Final EIS now correctly reflects the water supply conditions of these three entities.

L-1-16 and L-1-17

See response to Comment No. G-1-25.

L-1-18

See responses to Comment Nos. L-1-11 and L-1-13.

L-1-19

See response to Comment No. L-1-14.

L-1-20

The content of the Final EIS has been modified to reflect this public input. The modeling assumptions in Section 4.2.7.1 of the Final EIS and resulting analyses are consistent with the Arizona and Nevada Shortage Sharing Agreement. The use of the proceeds of the shortage sharing agreement are beyond the scope of this EIS.

L-1-21

Your comment is noted. No change to the Final EIS was necessary.

L-1-22 and L-1-23

See response to Comment No. G-1-25.

L-1-24

See response to Comment No. L-1-15.

L-1-25

Reclamation does not concur with this comment. The interim nature of the guidelines is intended to provide an opportunity to evaluate how the guidelines work. In addition, opportunities for review of the effectiveness of the guidelines are anticipated to be available both throughout the proposed interim period and at intervals during the interim period. Such reviews would provide a basis for possible further federal actions and decisions at the end of the interim period. Reclamation anticipates that a review of the guidelines will be conducted at a time prior to the end of the interim that would allow the Department, and the public, to assess the effectiveness of the guidelines and to determine the most appropriate course of action for the post-interim period..

City of Phoenix
OFFICE OF THE CITY MANAGER

April 30, 2007

Regional Director
Lower Colorado Region
Bureau of Reclamation, Attention BCOO-1000
P.O. Box 61470
Boulder City, NV 89006-1470

Re: Notice of Availability and Notice of Public Hearings for the Draft Environmental Impact ("EIS") Statement for the Colorado River Interim Guidelines for Lower Basin Shortages and Coordinated Operations for Lake Powell and Lake Mead.

Dear Director,

The City of Phoenix ("City") submits its comments to the Draft EIS for the Colorado River Interim Guidelines for Lower Basin Shortages and Coordinated Operations for Lake Powell and Lake Mead (72 Fed. Reg. 9026 dated February 28, 2007). The City is keenly interested in the outcome of the shortage criteria and coordinated operations for Lake Powell and Lake Mead. The City has previously commented during the scoping process pursuant to the Notice of Intent to prepare the EIS. Likewise, the City has directly participated in the negotiations between the Seven Colorado River Basin States culminating in the Seven Basin States proposal to the Secretary of the Interior dated February 3, 2006 and in stakeholder meetings within the State of Arizona resulting in shortage criteria proposed to Reclamation by the Arizona Department of Water Resources and agreed upon by all the Basin States. Phoenix' commitment to these processes is a necessary outgrowth of its reliance upon Colorado River water, delivered through the Central Arizona Project ("CAP"). The City serves over 1.4 million people and Colorado River water currently supplies over 35% of its total water demand. The City's CAP water supplies include sources with a variety of priorities, and its exposure to shortages varies accordingly. The City holds subcontracts for Municipal and Industrial priority water and leases for Indian priority water. The City also holds a contract for a substantial volume of lower-priority non-Indian agricultural CAP water. As a result, the City must consider many potential drought scenarios that the majority of the municipalities relying upon CAP water do not need to be concerned with.

The City's plight is further complicated by the fact that the CAP is the major junior priority user under the Law of the River. It is imperative that the Secretary of the Interior ("Secretary") be mindful of this factor when selecting and implementing a preferred alternative. Thus, Arizona water users face the greatest risks when a shortage declaration is made and the preferred alternative must recognize and minimize impacts to those water users. 1

Page 2

The City has a long-standing track record of sound water resources management including diversifying its water resources portfolio, building integrated infrastructure to allow efficient use of those resources, reusing reclaimed water, a strong water conservation program that has been in place for over two decades that has resulted in declining rates of water use and a drought management program that allows for the imposition of mandatory demand reductions. Despite all these efforts by the City, catastrophic shortages on the Colorado River could pose serious problems to the City's ability to continue to fully serve its customers.

The Proposed Alternatives

The Final EIS Should Designate the Basin States Alternative as the Preferred 2
Alternative
The Basin States Alternative provides the greatest degree of certainty for the City of 3
Phoenix because it is consistent with the agreement reached by the Basin States and
can be implemented upon approval of the Record of Decision ("ROD") without the need 4
for additional action. This alternative best meets the goals of the proposed action
discussed in the February 28, 2007 Federal Register Notice, i.e., "[T]his action is
proposed in order to provide a greater degree of certainty to U. S. Colorado River water
users and managers of the Colorado River Basin by providing detailed and objective
guidelines for the operations of Lake Powell and Lake Mead, thereby allowing water
managers and water users in the Lower Basin to know when, and by how much, water
deliveries will be reduced in drought or other low reservoir conditions." (72 Fed. Reg.
9027 dated February 28, 2007.) Moreover, certainty provided by the Basin States
Alternative goes well beyond the actual criteria and numbers. The Agreement reached 5
by the Basin States, and reflected in the Basin States Alternative, creates an increased
level of confidence that legal issues over the interpretation and implementation of the
Colorado River Compact, the Mexican Treaty, accounting under the Arizona v.
California Decree, and equalization of Lake Mead and Lake Powell will not result in
costly and divisive litigation with an uncertain outcome for water users. The value of 5
collaboration by the Basin States can not be overstated.

Another unique attribute of the Basin States Alternative is that it provides flexibility
within the system and a mechanism, that can be immediately implemented upon 6
execution of the ROD, for maximizing the efficiency of the system by allowing for the
intentional creation of surplus ("ICS") in Lake Mead by a Lower Colorado River
Mainstem contractor and release of that surplus for use within the state that created it,
with the forbearance of the other Lower Division States. The State of Arizona recently
enacted legislation that allows the State to forbear ICS water if the Secretary "adopts 7
substantially the same concepts as contained in the proposal of the seven basin states
for shortage guidelines and conjunctive management of lakes Mead and Powell,"
clearing the way, at least from Arizona's perspective, for ICS to be implemented if that
alternative is memorialized in the ROD.

L-2

Regional Director
April 30, 2007
Page 3

Certainty for water users and the ability of the Basin States Alternative to be
immediately implemented is also enhanced by the fact that the Lower Colorado River
Multi-Species Conservation Plan ("MSCP") provides compliance with the Endangered
Species Act ("ESA") given the reductions of flow proposed in the Basin States
alternative and the reductions analyzed in the MSCP. Additional ESA consultation that 8
may be required under other alternatives raises uncertainties regarding the
implementation schedule for those alternatives.

The Basin States Alternative is the only alternative that allows for the extension and 9
modification of the existing Interim Surplus Guidelines ("ISG") without the need for
further action. The package submitted to the Secretary by the Seven Basin States on
February 3, 2006 includes provisions to amend the ISG by agreement of all the States.
The Basin States Alternative adopts those amendments.

Finally, the Basin States Alternative is the only alternative that meets all the criteria 10
discussed in Section 1.1 of the Draft EIS that states, "[T]he Secretary intends to
consider, adopt and implement the proposed federal action consistent with applicable
federal law and judicial decisions, and, further, in a manner that will not require any
additional statutory authorization." (DEIS at p. 1-1).

<u>The No Action and Water Supply Alternatives</u>
The No Action and Water Supply Alternatives analyze a broad range of environmental 11
impacts but fall short of meeting the goals of the proposed action by failing to provide
certainty for the timing and extent of shortages in the Lower Basin and by failing to
propose viable criteria for the coordinated management of Lake Powell and Lake Mead.
These two alternatives do not allow for the creation or use of ICS thus limiting flexibility 12
in the operation of the system and creating greater risk and uncertainty regarding
shortages for water users in the Lower Basin.

<u>The Reservoir Storage Alternative</u>
The Reservoir Storage Alternative ("RSA") proposes levels of shortages starting at
600,000 AF and increasing to 1,200,000 AF and the magnitude of the average shortage
volumes during the interim period are the highest under this alternative. (DEIS at p. ES-
10). Shortage levels beyond 600,000 AF (including 17% for Mexico or 500,000 AF just 13
for the Lower Basin) are draconian in nature for Arizona water users on their face, and
their adoption can not be justified when compared to reductions of 400,000 AF, 500,000
AF and 600,000 AF (including 17% for Mexico or 300,000 AF, 400,000 AF and 500,000
AF just for the Lower Basin) proposed under the Basin States Alternative. The Basin
States recognized the harsh nature of shortages greater than 600,000 AF (including 14
17% for Mexico or 500,000 AF just for the Lower Basin) and have agreed to consult with
the Secretary if shortages are projected to exceed this volume (Seven Basin States
Letter to Secretary Norton, February 3, 2006, Attachment A., at p.6). The RSA does not 15
meet the goal stated in the Federal Register Notice, i.e., "to (1) Improve Reclamation's
management of the Colorado River by considering the trade-offs between the *frequency*

L-2

Regional Director
April 30, 2007
Page 4

and magnitude of reductions of water deliveries…" (72 Fed. Reg. 9027 dated February 28, 2007. emphasis added). Furthermore, this alternative would require changes to the Law of the River prior to its implementation. 16

The Conservation Before Shortage Alternative

The Conservation Before Shortage Alternative ("CBS") also falls short of meeting the certainty provisions of the proposed action as evidenced in Table ES-1, Matrix of Alternatives. 17 Column one of that table states that for the CBS alternative, "shortages are implemented in any given year to keep Lake Mead above SNWA's lower intake at elevation 1000' (absolute protect of elevation 1,000)." Water users in the Lower Basin will be left to the whims of the Annual Operating Plan for determining when and how much of a shortage will be declared under this alternative. This greatly reduces certainty for water users like Phoenix. 18

This alternative is also dependent upon the creation and use of ICS but reliance upon ICS would require changes to the Law of the River prior to this part of the alternative being implemented. 19 In addition to this inherent fatal flaw, the City also points out that this alternative essentially would allow 4.2 million AF to be stored in Lake Mead compared to a maximum storage of 2.1 million AF under the Basin States Alternative. Creating ICS of this magnitude could create too much risk for losing expensive ICS water to spills in wet years and earmark too much Lake Mead water for a particular water use, rather than for the system. 20

Two additional drawbacks of the CBS alternative are: (1) no funding mechanism for creation of ICS currently exists; 21 and (2) including ICS by the Republic of Mexico may necessitate amending the 1944 Treaty to allow for the creation and delivery of ICS water to Mexico. 22 Reclamation recognizes the limitations of the CBS alternative by stating, "[T]he viability of the Conservation Before Shortage program funding proposal is not known at this time. Reclamation currently does not have authority to implement all facets of this proposal and additional legislation would be necessary to gain such authority." (Draft EIS at p. 2). 23

Summary

When weighing the proposed alternatives against one another it is evident that the Basin States Proposal is superior to any of the other alternatives because it provides the greatest degree of certainty to water users, avoids potential litigation, creates shortage criteria that are reasonable in magnitude and are readily predictable based upon elevations at Lake Mead, and present a package that can be implemented without the need for further legislation or ESA compliance. 24

Furthermore, the Basin States Alternative best meets all the aspects of the purpose and need for the action and has the support of the Basin States which will enhance the Secretary's ability to manage the Colorado River system in a collaborative manner. The City of Phoenix urges the Secretary to adopt the Basin States Proposal as the preferred alternative in the Final EIS.

L-2

Regional Director
April 30, 2007
Page 5

Conjunctive Operation of Lake Mead and Lake Powell

The Basin States Alternative creates the ability to more effectively balance the contents of Lake Mead and Lake Powell in a way that dampens the large fluctuations in reservoir elevations during extended periods of low inflow into the system. 25 That alternative also removes potential issues over the methodology for equalizing the contents of Lake Mead and Lake Powell under other proposed alternatives.

Currently equalization is largely governed by the Interim 602(a) Storage Guideline for Management of the Colorado River which contains a 14.85 million acre-feet storage 26 requirement. That guideline artificially limits equalization and has a detrimental effect on storage in Lake Mead and thus on the City of Phoenix. While the current guideline was also part of a package agreed to by the Seven Basin States as part of the ISG process, it essentially provides for greater protection for power production at Lake Powell than is otherwise authorized under the Law of the River. 27 The Basin States Alternative replaces this equalization requirement in favor of a strategy that is not as onerous for the City.

As stated in the City's scoping comments dated November 30, 2005, water supply has a higher priority than hydro-generation and water users in Phoenix should not be subject 28 to shortages for the benefit of hydropower production. Absent the adoption of the Basin States Alternative (and after the expiration of the ISG in 2016) the City believes the Secretary must adhere to the following: (1) the 602(a) storage algorithm must be reviewed and revamped so that it accurately reflects the requirements of Section 602(a) of the Colorado River Basin Project Act of 1968; (2) the algorithm should be changed so that the current storage in Lake Powell of an additional amount over 5 million acre-feet to protect hydropower production is no longer included in the operating criteria; (3) 29 actual Upper Basin depletions and a measurable realistic projection of new depletions to calculate the 602(a) storage requirement must be incorporated into the algorithm. The use of overstated depletion schedules results in significant increases in Lake Powell storage before equalization occurs; and (4) review the methodology that determines available storage in reservoirs authorized by the Colorado River Storage Project Act to determine whether forecasted active storage in the Upper Basin is greater than the Section 602(a) storage requirement under subarticle II(3) of the Coordinated Long-Range Operation of Colorado River System Reservoirs to insure that active storage in the Upper Basin is being properly calculated.

If the Basin States Alternative is adopted and implemented in the guidelines set out in the ROD, at the end of the interim period in 2026 or if the guidelines are changed, whichever comes first, Reclamation can not revert to its current interpretation of the 30 602a requirements. In that case, Reclamation must consult on the modification of the guidelines to make them consistent with the legal priorities established by the Law of the River.

For these reasons and because the coordinated operations of Lake Powell and Lake Mead are essential components to shortage criteria, the Secretary should adopt the Basin States Alternative.

L-2

Regional Director
April 30, 2007
Page 6

The Record of Decision and Implementation of the Preferred Alternative

The City supports the Basin States Alternative as the preferred alternative and
recommends that it be incorporated into the Record of Decision ("ROD") in a way that
parallels the Interim Surplus Guidelines ROD. The City believes that the Secretary
should work with the Basin States to create specific implementation criteria and
guidelines consistent with the adoption of the Basin States Alternative as the preferred
alternative. That document will serve as a road map that the City can then rely upon to
better manage its water supplies and to better prepare for shortages. To effectuate
those guidelines and criteria so that the certainty outlined in the proposed action is
achieved, the City urges the Secretary to include a statement in the ROD that "during
the effective period of the guidelines the Secretary shall utilize the established process 31
for development of the Annual Operating Plan for the Colorado River System
Reservoirs (AOP) and shall use those guidelines to make determinations regarding
normal, surplus and shortage conditions for the operation of Lake Mead and for the
coordinated management of Lake Mead and Lake Powell."

Cumulative Impacts of Shortages in Arizona

The DEIS has only attempted to analyze the socio-economic impacts for shortages in a
single year. Analysis by the State of Arizona indicates a high probability that multi-year
shortages will occur. The socio-economic impacts of multi-year shortages should be 32
analyzed and incorporated into the Final EIS for all of the alternatives.

Socioeconomic Impacts to Municipal Water Users in Arizona

The DEIS does not adequately analyze and describe the impacts to municipal water 33
users in Arizona or to the City of Phoenix in particular. The DEIS states, "Implementing
statewide and local demand-side and supply-side strategies are expected to minimize
adverse socioeconomic effects occurring during the maximum M&I shortage." This
statement accurately reflects the strategies that Phoenix has historically used, and
continues to use for determining its long-term need for water supplies, including
supplies to help offset shortages. Likewise demand restrictions are also part of the
City's plan for dealing with actual shortages. Phoenix' goal is to minimize the impacts
on its citizens and on its economy. However, neither demand-side nor supply-side
strategies and actions come without a substantial price. The DEIS does not analyze
quantitatively, or even qualitatively, the costs associated with shortages. This is a 34
glaring omission in the DEIS.

Arizona municipal water providers and the City of Phoenix have already expended
substantial sums of money in anticipation of shortages on the Colorado River.
Municipal water users in Arizona, including the City of Phoenix, will rely in part on
recovery of water stored underground by the Arizona Water Banking Authority to make
up for shortfalls due to Colorado River shortages. Through calendar year 2006, the 35
Arizona Water Banking Authority ("Bank") has stored about 2,243,000 AF of water at a
cost of about $101 million. More appropriately for the City, about 1,158,000 AF of water
at a cost of about $63 million dollars has been stored in the Phoenix Active
Management Area. Funding for the Bank comes primarily from a property tax in
Maricopa, Pinal and Pima Counties, from a pump tax paid by groundwater users in

L-2

Regional Director
April 30, 2007
Page 7

those counties and some appropriations by the Arizona Legislature. To prepare for the onset of Colorado River shortages through supply-side protection, significant sums have already been expended. Additional sums will be need to be expended to store additional water underground to meet the goals of the Bank, to replace the banked water when it is used, or for access to other supplies to make up shortfalls.

Because the City's municipal priority CAP water may not be fully replaced by the Bank and because the City uses non-agricultural priority CAP water and Indian lease water not eligible to receive water from the Bank during shortages, the City is pursuing the acquisition and use of drought back up water supplies and the infrastructure necessary to use those supplies. To date the City has stored 171,600 acre-feet at a cost of about $7 million (excluding the capital costs of the facilities to store or treat water). Additionally, the City has embarked on a two year planning study to identify other options for supply enhancement for shortages. The cost of that study is estimated at about $1.8 million and the implementation costs, once options are chosen, is expected to be in the range of $50-100 million for both drought supplies and new supplies to meet normal demands. 35

Through the City's water resources planning function, a water resources plan is completed and published about every five years. The latest plan, the Water Resources Plan, 2005 Update, concludes that in extreme drought supply enhancement will not be sufficient to deal with shortages. During moderate and extreme drought conditions the City will also implement its Drought Management Plan, first promulgated in 1993. That Plan, and the City ordinances implementing it, allow for mandatory reductions in deliveries to customers and thus require cut backs in water use. There is an additional cost, over the $1.5 million the City is spending annually on its water conservation efforts, associated with implementing mandatory water user restrictions. In 2003 and 2004, in the midst of water allocations reductions by the Salt River Project, the City explored the costs associated with implementing Stage II of its Drought Management Plan which contains relatively benign mandatory water use restrictions. The estimated cost of implementing that program, at that time, was about $1.5 million per year. Implementing Stage III and Stage IV restrictions would necessitate incurring even higher costs.

As the prior discussion clearly illustrates socioeconomic impacts on municipal water users in Arizona and on the City of Phoenix due to Colorado River shortages are significant and should be documented in the Final EIS.

<u>Comments to Specific Portions of the EIS</u>

The City offers the following comments to specific language included in the DEIS:

1. Section 2.3.1, line 28: The Seven Basin States proposal dated February 3, 2006 goes beyond "suggesting" that consultation occur when shortages greater than 600,000 AF are projected to occur. Because of the impacts on Arizona water users that will likely occur, that provision is an integral part of that proposed package. 36
2. P. 3-39, Section 3.4.6.1,

L-2

Regional Director
April 30, 2007
Page 8

a. Lines 11-16: It should be noted that the AWBA also provides for banked water to be use by municipal water users of Colorado River water both within and outside of the CAP service area. 37

b. Lines 28-30: The Final EIS should incorporate the recommendation submitted to the Bureau of Reclamation on October 24, 2006 that presents shortage sharing criteria between on-river P4 water users in Arizona and CAP water users. 38

3. P. 3-40, Lines 3-5: The DEIS does not provide enough detail to address Arizona water users' efforts to prepare for drought. Individual water users adopted drought Plans over a decade before the statewide drought plan was created. The Arizona Groundwater Management Act, the Arizona Water Banking Authority and other state-wide and local government actions all contribute to Arizona's drought preparedness. 39
4. P. 3-42, Lines 1-6: The Final EIS should incorporate the terms of the Arizona-Nevada Shortage Sharing Agreement. 40
5. P. 3-87, Line 37: The City's lease for CAP water with the Salt River Pima-Maricopa Indian Community is for a term of 99 years, not 100 years. 41
6. P. 3-89, Lines 5-17: The Final EIS should clarify that the EIS assumed that the Gila River Community Indian Water Rights Settlement is in effect. The statement that "CAP water has already been leased to Phoenix area cities" is only correct if that assumption is made clear since the leases can not be consummated until the enforceability date of the Settlement. 42
7. P. 4-8, Lines 7-9: The Final EIS should recognize that the Southern Nevada Water Authority has plans to complete new intakes at Lake Mead to elevation 856' by 2011 and thus the "limitations" on SNWA's ability to pump from Lake Mead, or form the Colorado River, at that point in time will not be 1000'. 43
8. P. 4-8, Lines 31-36: The discussion of the bypass flows is confusing regarding the extent of the "obligation" to replace those flows. If a legal obligation to replace those flows exists, the Final EIS should cite to the controlling law, contracts, treaties or other legal instruments evidencing the obligation. 44
9. P. 4-9, Lines 3-4: The City continues to support the operation of the Yuma Desalting Plant at its full capacity to maximize the efficiency of Lower Colorado River operations. 45
10. P. 4-238, Lines 21-24: Any "benefits" of increased power revenues on the const of CAP water would likely be more than offset by increased delivery charges ("OM&R") to CAP water users when CAP deliveries are reduced because of shortages. The delivery rate paid by CAP water users will greatly increase because fixed OM&R, the numerator in the rate equation will remain the same, while water deliveries, the denominator in the rate equation, will be less. While the CAP Board of Director's may chose to artificially hold rates down to minimize "rate shock", there is still a negative economic consequence because the funds to hold down the rates will likely come from the tax payers or rate payers within the CAP. 46
11. P. 4-264, Lines 17-19: The Final EIS should recognize that the cost of water used in this analysis, the "price of excess water pools" for agricultural use is a subsidized water rate. The tax payers of Maricopa, Pinal and Pima counties pay 47

L-2

Regional Director

Page 9

an ad valorem property tax set by the CAP Board of Director's. One of the uses for that tax is to lower the cost of water for the agricultural pool.

12. P. 6-3, Lines 3-9. The Final EIS should expand its discussion of Section 8 of the ESA so that it is clear that consultation through the Secretary of State is a voluntary and not a mandatory function. 48

Conclusion

The City of Phoenix reiterates that the Basin States Alternative is the only alternative that meets all the criteria defined in the proposed action for the EIS. The City urges that the Final EIS adopt the Basin States Alternative as the preferred alternative and that a Record of Decision be signed incorporating the terms of the Basin States Alternative.

Sincerely

Tom Buschatzke
Water Advisor

Reponses to Comment Letter L-2

L-2-1

Your comment is noted. The Preferred Alternative is formulated to provide more frequent yet lower magnitude shortages that are more manageable as compared to less frequent but higher magnitude shortages.

L-2-2 through L-2-4

Your comments are noted. No change to the Final EIS was necessary.

L-2-5

Your comment is noted. No change to the Final EIS was necessary.

L-2-6 and L-2-7

Your comments are noted. No change to the Final EIS was necessary.

L-2-8

Your comment is noted. Reclamation has prepared a Biological Assessment (Appendix R of the Final EIS) in compliance with Section 7 of the Endangered Species Act. As part of this assessment, Reclamation evaluated whether the Preferred Alternative would exceed the flow reductions analyzed and covered by the LCR MSCP. It was determined that the effects of the Preferred Alternative are within the range of effects analyzed in the MSCP, and no additional consultation under Section 7 is needed for the areas of effect within the LCR MSCP geographic area.

L-2-9

Your comment is noted.

L-2-10

Your comment is noted. No change to the Final EIS was necessary.

L-2-11 and L-2-12

Your comments are noted. No change to the Final EIS was necessary.

L-2-13 through L-2-16

Your comments are noted. No change to the Final EIS was necessary.

L-2-17 through L-2-23

Your comments are noted. No change to the Final EIS was necessary.

L-2-24

Your comment is noted. No change to the Final EIS was necessary.

L-2-25

Your comment is noted.

L-2-26

Your comment is noted.

L-2-27

Your comment is noted. As discussed in Section 2.3.2.1, the Basin States Alternative and the Preferred Alternative use an elevation schedule (a specified elevation for each year through 2026) to determine when equalization releases would be made from Lake Powell.

L-2-28

Your comment is noted.

L-2-29

Your comment is noted.

L-2-30

Your comment is noted. No change to the Final EIS was necessary.

L-2-31

The information requested is provided in Appendix S of the Final EIS. Reclamation has developed draft operational guidelines that are included in Appendix S of the Final EIS. The guidelines are anticipated to be finalized and adopted through the Record of Decision for this action. Following publication of this Final EIS, additional and updated information regarding the content and development of guidelines is anticipated to be provided to the public through the dedicated project website, (http://www.usbr.gov/lc/region/programs/strategies.html).

L-2-32

See response to Comment No. L-1-11

L-2-33 through L-2-35

See response to Comment No. G-1-25.

L-2-36

See response to Comment No. G-1-13.

L-2-37

Reclamation concurs with this comment. The requested change has been made in Section 3.4.6.

L-2-38

See response to Comment No. G-1-15.

L-2-39

See response to Comment No. G-1-25.

L-2-40

See response to Comment No. G-1-14.

L-2-41

Reclamation concurs with this comment and the requested correction has been made in the Final EIS.

L-2-42

Your comment is noted. The suggested clarification has been added to Section 3.10.2.2 of the Final EIS

L-2-43

See response to Comment No. G-1-31.

L-2-44

See response to Comment F-4-9.

L-2-45

Your comment is noted. No change to the Final EIS was necessary.

L-2-46

Your comment is noted. Rate setting decisions by the CAP Board of Directors are outside the scope of this EIS.

L-2-47

The quantitative evaluation of the socioeconomic effects (employment, income, and tax revenues) as a result of losses in agricultural production in Arizona was based on changes in the value of crop production measured at the farm gate. These estimates were made through application of Reclamation's shortage allocation model and spreadsheet model that estimates the acreage and crop types that would be affected. IMPLAN, the tool used to quantify these effects, does not take into account water subsidies. Taxpayers in Maricopa, Pinal, and Pima residents may benefit as a result of not paying these subsidies. However, this increase would be expected to be small when spread among all taxpayers within the three counties.

L-2-48

Your comment is noted. Sections 5.1.19, 6.3.2 and 6.8 of the Final EIS have been updated in the Final EIS.

RE: City of Scottsdale, Arizona Comments Regarding the *Colorado River Interim Guidelines for Lower Basin Shortages and Coordinated Operations for Lake Powell and Lake Mead, Draft Environmental Impact Statement*

Dear Sir or Madam:

The City of Scottsdale, Arizona ("Scottsdale") hereby submits its comments regarding the "Draft Environmental Impact Statement for Colorado River Interim Guidelines for Lower Basin Shortages and Coordinated Operations for Lake Powell and Lake Mead" (DEIS). Additionally, Scottsdale understands that the Arizona Department of Water Resources and the Arizona Municipal Water Users' Association ("AMWUA") will be also be providing comments on this issue. Scottsdale supports those comments.

More than 240,000 people rely on the City of Scottsdale to provide safe, reliable drinking water supplies and Central Arizona Project ("CAP") water is a key component of the City's long-term water resources strategy. Nearly two-thirds of Scottsdale's water supply needs are currently met with varying types of CAP water. Scottsdale has subcontracts for M&I priority water, non-Indian agricultural water, and excess CAP water. We also lease CAP water from three Native American communities. Because of our high reliance on CAP to meet our water needs, the preferred alternative that is selected for implementation by the Bureau is of critical interest to the City of Scottsdale.

Scottsdale Supports the Basin States Alternative as the Preferred Alternative

Scottsdale supports selection of the Basin States Alternative as the preferred alternative in the final environmental impact statement and supports implementation of the Basin States Alternative through the final record of decision. This alternative is a compromise alternative acceptable to each of the seven Colorado River Basin States. In selecting the pre- 1

Phone (480) 312-5685 • Fax (480) 312-5615

ferred alternative and finalizing the record of decision, the Secretary of the Interior (Secretary) should recognize the value of this unique compromise. 2

Furthermore, the Basin States Alternative does not require any additional statutory authorization and is the only alternative that can be implemented immediately after the Secretary issues the final record of decision. 3 Implementation of the other alternatives, particularly the Conservation Before Shortage and the Reservoir Storage Alternatives, would require substantive changes to the Law of the River. 4

Water Management Considerations

For decades Scottsdale has been actively planning and preparing to address water shortages. The City has taken proactive steps toward achieving long-term water supply sustainability, including the following:

- implementation of enhanced water conservation programs;
- reclaimed effluent reuse by the golf courses in north Scottsdale;
- recharging the groundwater table using highly treated effluent; and
- groundwater recharge of potable CAP water using dual purpose aquifer storage and recovery ("ASR") wells.

Adoption of the Basin States Alternative as the preferred alternative in the final environmental impact statement will provide the certainty necessary for Scottsdale to continue the responsible planning necessary to address the adverse impacts that could occur during Colorado River shortages. 5

Scottsdale has developed an extensive water conservation customer outreach program. Our five full-time staff positions are supplemented by a group of active volunteers. The City is an active participant in the "Water - Use It Wisely" program, which is a regional water conservation public information campaign. The water conservation staff also participates in regional public exhibits, fairs, and festivals. In addition, the City provides a number of financial incentives for conservation, including for example offering rebates to encourage turf removal.

Golf courses are a large water user in Scottsdale. Therefore, Scottsdale has developed strategies to minimize the impact they have on our potable water supplies. Scottsdale reclaims wastewater at our Water Campus facility, treating the water for use for golf course irrigation. This water is delivered through Scottsdale's Reclaimed Water Delivery System (RWDS), which is the largest reclaimed water reuse system in the Valley. The RWDS delivers reclaimed water to twenty three golf courses in north Scottsdale. In addition, the City's Council-adopted golf course policy requires that any future golf courses must provide their own renewable surface water supply in order to locate in Scottsdale.

Scottsdale is also a leader in the Phoenix area in increasing the long term sustainability of our groundwater through artificial groundwater recharge. The City is replenishing our groundwater supply by +recharging reclaimed water at our Water Campus facility in North Scottsdale. In 2005, this groundwater recharge added over 2-1/4 billion gallons of water to our underground aquifers. Water stored in these aquifers is an important part of Scottsdale's overall water supply management strategy.

Scottsdale is also implementing groundwater recharge/recovery throughout the City by injecting treated CAP water directly into the aquifer through specially designed wells. These wells are used to recharge during the winter low water use demand periods, and supplement the water supply during the high demand summer months.

Record of Decision Guidelines

Scottsdale expects and needs the final record of decision to clearly and unambiguously set forth the guidelines that the Secretary will use to declare a shortage in the lower basin. The record of decision should identify and adopt guidelines consistent with implementation of the Basin States Alternative that the Secretary must follow in formulating each of the annual operating plans through 2026. 6

The Basin States Alternative requires that the record of decision acknowledge that the lower basin States must agree to the terms and conditions for forbearing, if necessary, their rights to delivery of Colorado River water in order to allow for the development, storage and delivery of any Intentionally Created Surplus (ICS) as defined by the DEIS. 7 Scottsdale would object if the Secretary issued a unilateral authorization that allowed for the creation of ICS without this agreement by the States. 8
