Mission Statement

The mission of the Department of the Interior is to protect and provide access to our Nation's natural and cultural heritage and honor our trust responsibilities to Indian Tribes and our commitments to island communities.

The mission of the Bureau of Reclamation is to manage, develop, and protect water and related resources in an environmentally and economically sound manner in the interest of the American public.

Colorado River Interim Guidelines for Lower Basin Shortages and Coordinated Operations for Lake Powell and Lake Mead
Final Environmental Impact Statement

Lead Agency:

United States Department of the Interior
Bureau of Reclamation
Upper and Lower Colorado Regions

Cooperating Agencies:

Bureau of Indian Affairs
National Park Service
Western Area Power Administration
United States Fish and Wildlife Service
United States Section of the International Boundary and Water Commission

Abstract:

The Secretary of the Department of the Interior (Department), acting through the Bureau of Reclamation, proposes adoption of specific Colorado River Lower Basin (Lower Basin) shortage guidelines and coordinated reservoir management strategies to address operations of Lake Powell and Lake Mead, particularly under drought and low reservoir conditions. This action is proposed in order to provide a greater degree of certainty to United States Colorado River water users and managers of the Colorado River Basin by providing detailed and objective guidelines for the operations of Lake Powell and Lake Mead, thereby allowing water users in the Lower Basin to know when, and by how much, water deliveries will be reduced in drought and other low reservoir conditions. The Department proposes that these guidelines be interim in duration and extend through 2026.

This Final EIS has been prepared pursuant to the National Environmental Policy Act to address the formulation and evaluation of specific interim criteria and to identify the potential environmental impacts of implementing such criteria.

Executive Summary

ES.1 Background

The Secretary of the Department of the Interior (Secretary), acting through the Bureau of Reclamation (Reclamation), proposes to adopt specific interim guidelines for Colorado River Lower Basin (Lower Basin) shortages and coordinated operations for Lake Powell and Lake Mead, particularly under drought and low reservoir conditions.

Reclamation, as the agency that is designated to act on the Secretary's behalf with respect to operation of Glen Canyon Dam and Hoover Dam and managing the mainstream waters of the lower Colorado River pursuant to federal law, is the lead federal agency for the purposes of compliance pursuant to the National Environmental Policy Act of 1969 (NEPA), as amended, for the development and implementation of the proposed interim guidelines. Five federal agencies are cooperating for purposes of assisting with environmental analysis and preparation of this Environmental Impact Statement (EIS). The cooperating agencies are the Bureau of Indian Affairs (BIA), United States Fish and Wildlife Service (FWS), National Park Service (NPS), Western Area Power Administration (Western), and the United States Section of the International Boundary and Water Commission (USIBWC).

Volume I of the Final EIS includes six chapters as outlined below:

- Chapter 1: Purpose and Need;
- Chapter 2: Description of Alternatives;
- Chapter 3: Affected Environment;
- Chapter 4: Environmental Consequences;
- Chapter 5: Other Considerations and Cumulative Impacts; and
- Chapter 6: Consultation and Coordination.

In addition to the above, Volumes II and III contain appendices which are comprised of documents and other supporting materials concerning the proposed federal action. Volume IV contains reproductions of letters received from the public review of the Draft EIS, and Reclamation's responses to comments received.

ES.1.1 Purpose and Need for Action

The eight-year period from 2000 through 2007 was the driest eight-year period in the 100-year historical record of the Colorado River. This drought in the Colorado River Basin has reduced Colorado River system storage, while demands for Colorado River water supplies have continued to increase. From October 1, 1999 through September 30, 2007, storage in Colorado River reservoirs decreased from 55.8 maf (approximately 94 percent of capacity) to 32.1 maf (approximately 54 percent of capacity), and was as low as 29.7 maf (approximately 52 percent of capacity) in 2004. Currently, the Department of the Interior (Department) does not have specific operational guidelines in place to address the operations of Lake Powell and Lake Mead during drought and low reservoir conditions.

The purpose of the proposed federal action is to: 1) improve Reclamation's management of the Colorado River by considering trade-offs between the frequency and magnitude of reductions of water deliveries, and considering the effects on water storage in Lake Powell and Lake Mead, and on water supply, power production, recreation, and other environmental resources; 2) provide mainstream United States users of Colorado River water, particularly those in the Lower Division states, a greater degree of predictability with respect to the amount of annual water deliveries in future years, particularly under drought and low reservoir conditions; and 3) provide additional mechanisms for the storage and delivery of water supplies in Lake Mead to increase the flexibility of meeting water use needs from Lake Mead, particularly under drought and low reservoir conditions.

ES.1.2 Proposed Federal Action

The proposed federal action includes the adoption of specific interim guidelines for Lower Basin shortages and coordinated operations for Lake Powell and Lake Mead. These interim guidelines would remain in effect for determinations to be made through 2025 regarding water supply and reservoir operating decisions through 2026 and would provide guidance each year in development of the Annual Operating Plan for Colorado River Reservoirs (AOP). This proposed federal action considers four operational elements that collectively are designed to address the purpose and need for the proposed federal action.

The interim guidelines would be used by the Secretary to:

- determine those circumstances under which the Secretary would reduce the annual amount of water available for consumptive use from Lake Mead to the Colorado River Lower Division states (Arizona, California, and Nevada) below 7.5 million acre-feet (maf) (a ''Shortage'') pursuant to Article II(B)(3) of the United States Supreme Court Decree in the case of *Arizona v. California*, 547 U.S. 150 (2006) (Consolidated Decree);

- define the coordinated operation of Lake Powell and Lake Mead to provide improved operation of these two reservoirs, particularly under low reservoir conditions;

- allow for the storage and delivery, pursuant to applicable federal law, of conserved Colorado River system and non-system water in Lake Mead to increase the flexibility of meeting water use needs from Lake Mead, particularly under drought and low reservoir conditions; and

- determine those conditions under which the Secretary may declare the availability of surplus water for use within the Lower Division states. The proposed federal action would modify the substance of the existing Interim Surplus Guidelines (ISG), published in the Federal Register on January 25, 2001 (66 Fed. Reg. 7772), and the term of the ISG from 2016 to 2026.

ES.1.3 Geographic Scope

The geographic region that could potentially be affected by the proposed federal action begins with Lake Powell and extends downstream along the Colorado River floodplain to the Southerly International Boundary (SIB) with Mexico. In addition to the potential impacts that may occur within the river corridor, the alternatives may also affect the water supply that is available to specific Colorado River water users in the Lower Basin. The following water agency service areas are also included in the appropriate affected environment discussions:

- Arizona water users, particularly the lower priority water users located in the Central Arizona Project service area;
- the Southern Nevada Water Authority (SNWA) service area; and
- the Metropolitan Water District of Southern California (MWD) service area.

Figure ES-1 shows the geographic scope for the Final EIS.

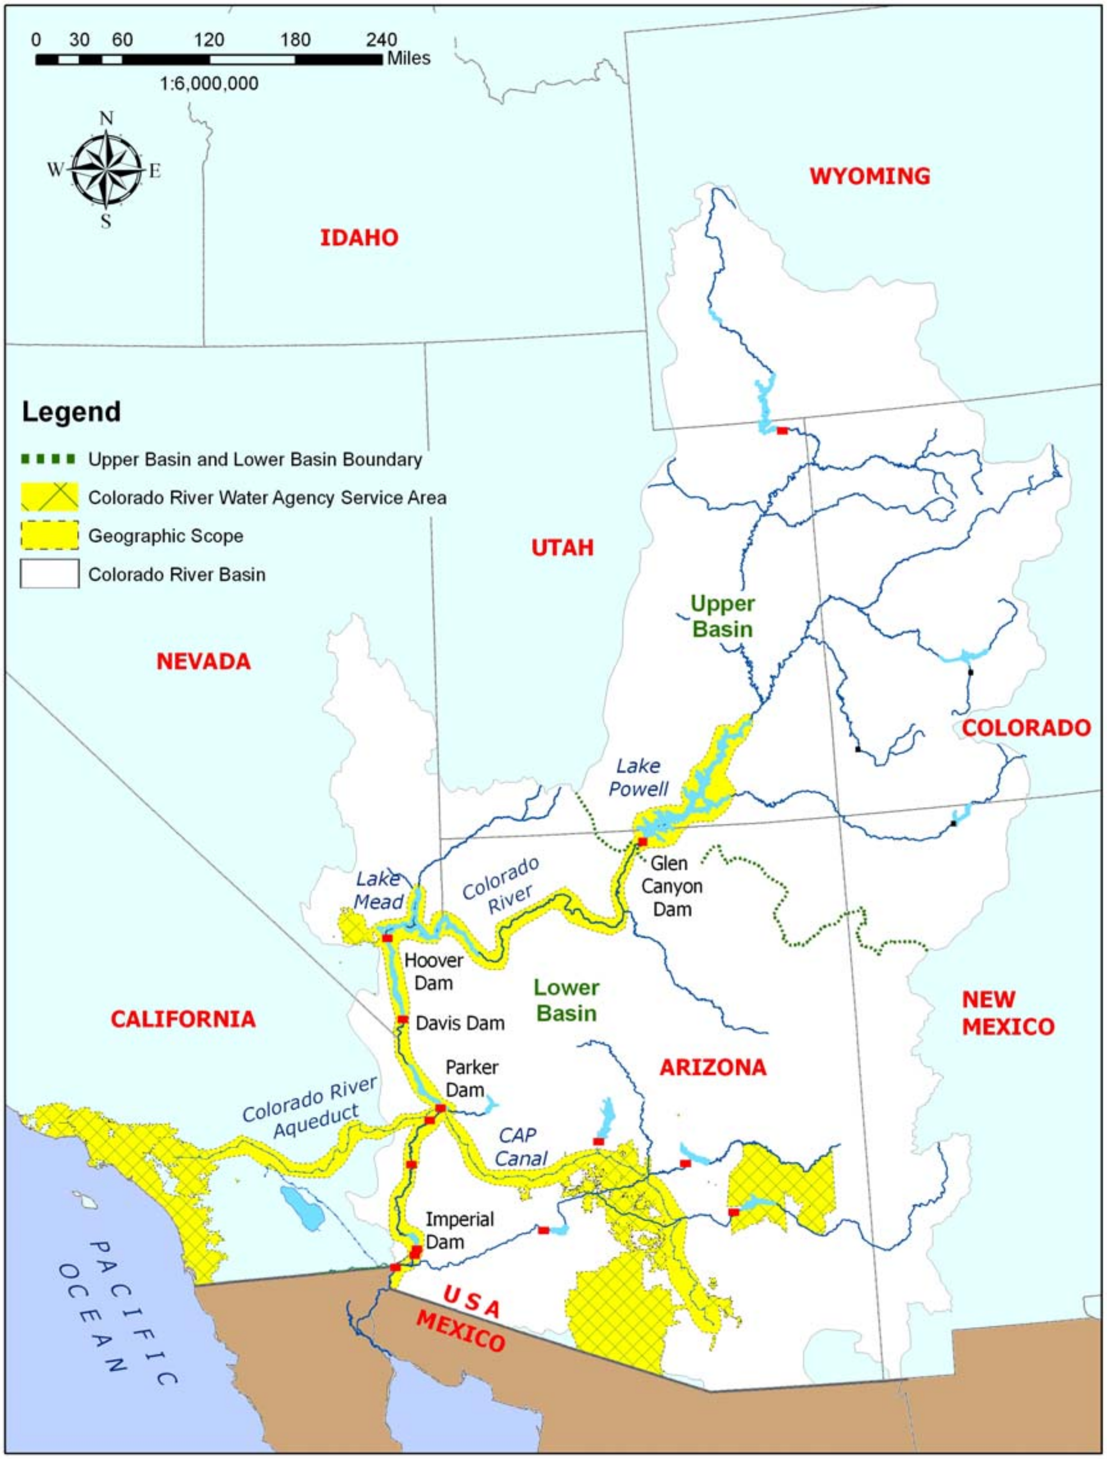
ES.1.4 Alternatives

Six alternatives are considered and analyzed in this Final EIS. The alternatives consist of a No Action Alternative and five action alternatives. The five action alternatives are: Basin States Alternative, Conservation Before Shortage Alternative, Water Supply Alternative, Reservoir Storage Alternative, and the Preferred Alternative. The action alternatives reflect input from Reclamation staff, the cooperating agencies, stakeholders, and other interested parties.

Reclamation received two written proposals for alternatives that met the purpose and need of the proposed federal action, one from the seven Colorado River Basin States (Basin States) and another from a consortium of environmental non-governmental organizations (NGO). These proposals were used by Reclamation to formulate two of the alternatives considered and analyzed in the Final EIS (Basin States Alternative and Conservation Before Shortage Alternative). A third alternative (Water Supply Alternative) was developed by Reclamation, and a fourth alternative (Reservoir Storage Alternative) was developed by Reclamation in coordination with the NPS and Western. The No Action Alternative and the action alternatives analyzed in the Draft EIS were posted on Reclamation's website (http://www.usbr.gov/lc/region/programs/strategies.html) on June 30, 2006.

A fifth alternative, the Preferred Alternative, was developed after consideration of the comments received on the Draft EIS and further analysis. The Preferred Alternative was posted on Reclamation's website (same website address as above) on June 15, 2007 and is composed of operational elements from the action alternatives identified and analyzed in the Draft EIS.

Figure ES-1
Geographic Scope



The Preferred Alternative is the most reasonable and feasible alternative; all environmental effects of this alternative, as well as the No Action Alternative and the remaining four action alternatives have been fully analyzed in this Final EIS. The identified environmental effects of the Preferred Alternative are well within the range of anticipated effects of the alternatives presented in the Draft EIS and do not affect the environment in a manner not already considered in the Draft EIS.

Reclamation selected from among the four key operational elements disclosed in the Draft EIS to formulate the Preferred Alternative. Reclamation has determined that the four operational elements selected under this alternative best meet all aspects of the purpose and need of the proposed federal action. Additionally, Reclamation has developed draft operational guidelines describing how the Preferred Alternative could be implemented during the interim period.

Summary descriptions of the No Action Alternative and the five action alternatives considered and evaluated in the Final EIS are provided below and in Table ES-1.

ES.1.4.1 No Action Alternative

The No Action Alternative provides a baseline for comparison of each of the action alternatives. The No Action Alternative represents a projection of future conditions that could occur during the life of the proposed federal action without an action alternative being implemented.

Pursuant to the Criteria for Coordinated Long-Range Operation of Colorado River Reservoirs Pursuant to the Colorado River Basin Project Act of September 30, 1968, or Long-Range Operating Criteria (LROC), the Secretary makes a number of determinations at the beginning of each operating year through the development and execution of the AOP, including the water supply available to users in the Lower Basin and the annual release from Lake Powell. However, the LROC currently does not include specific guidelines for such determinations. Furthermore, there is no actual operating experience under low reservoir conditions, i.e., there has never been a shortage determination in the Lower Basin. Therefore, in the absence of specific guidelines, the outcome of the annual determination in any particular year in the future cannot be precisely known. However, a reasonable representation of future conditions under the No Action Alternative is needed for comparison to each action alternative. The modeling assumptions used for this representation are consistent with the assumptions used in previous environmental compliance documents for the ISG, the Colorado River Water Delivery Agreement, and the Lower Colorado River Multi-Species Conservation Program (LCR MSCP). However, the assumptions used in the No Action Alternative are not intended to limit or predetermine these decisions in any future AOP determination.

Table ES-1
Matrix of Alternatives

Alternatives	Shortage Guidelines to Reduce Deliveries from Lake Mead (elevation in feet msl)	Coordinated Reservoir Operations (Lake Mead & Lake Powell) (elevation in feet msl)	Lake Mead Storage and Delivery of Conserved System and Non-system Water	Interim Surplus Guidelines (ISG) for Deliveries/Releases from Lake Mead
No Action	▪ Determination made through the AOP process, absent shortage guidelines ▪ Reasonably represented by a two-level shortage strategy - probabilistic protection of Lake Mead elevation 1,050 and absolute protection of Lake Mead elevation 1,000	▪ Minimum objective release of 8.23 maf from Lake Powell unless storage equalization releases are required ▪ Operation at low reservoir levels reasonably represented by a 8.23 maf release from Lake Powell down to Lake Powell dead pool	▪ No water management mechanism for storage and delivery of conserved system and non-system water	▪ No modification or extension of the ISG which end in 2016 ▪ After 2016, determination made through the AOP process, absent surplus guidelines; reasonably represented by the spill avoidance (referred to as the 70R) strategy
Basin States	▪ Shortages (i.e., reduced deliveries in the United States) of 333, 417, and 500 kaf from Lake Mead at elevations 1,075, 1,050, and 1,025 respectively [1] ▪ Initiate efforts to develop additional guidelines for shortages if Lake Mead falls below elevation 1,025 (Note: includes consultation with Basin States)	▪ Under high reservoir conditions, minimum objective release of 8.23 maf from Lake Powell unless storage equalization releases are required ▪ Under lower reservoir conditions, either reduce Lake Powell release or balance volumes depending upon elevations at Lake Powell and Lake Mead	▪ Creation, accounting, and delivery of ICS ▪ Maximum total ICS of 2.1 maf ▪ System assessment of 5% when ICS is created	▪ Modification of ISG to eliminate Partial Domestic Surplus condition ▪ Extension of the modified guidelines through 2026
Conservation Before Shortage	▪ Shortages are implemented in any given year when necessary to keep Lake Mead above SNWA's lower intake at elevation of 1,000 (absolute protection of elevation 1,000)	▪ Under high reservoir conditions, minimum objective release of 8.23 maf from Lake Powell unless storage equalization releases are required ▪ Under lower reservoir conditions, either reduce Lake Powell release or balance volumes depending upon elevations at Lake Powell and Lake Mead	▪ Prior to shortage, conservation of different volumes of water tied to Lake Mead elevation ▪ Creation, accounting, and delivery of ICS ▪ Water for environmental uses ▪ Maximum total ICS of up to 4.2 maf ▪ System assessment of 5% when ICS is created	▪ Modification of ISG to eliminate Partial Domestic Surplus condition ▪ Extension of the modified guidelines through 2026
Water Supply	▪ Release full annual entitlement amounts until Lake Mead is drawn down to dead pool (elevation 895)	▪ Minimum objective release of 8.23 maf from Lake Powell unless storage equalization releases are required ▪ Balancing if Lake Powell is below elevation 3,575 or Lake Mead is below elevation 1,075	▪ No water management mechanism for storage and delivery of conserved system and non-system water	▪ Extension of the existing ISG through 2026
Reservoir Storage	▪ Shortages (i.e., reduced deliveries in the United States) of 500, 667, 833, and 1,000 kaf from Lake Mead at elevations 1,100, 1,075, 1,050, and 1,025 respectively[1]	▪ Minimum objective release of 8.23 maf from Lake Powell if Lake Powell is above elevation 3,595 unless storage equalization releases are required ▪ 7.8 maf release from Lake Powell between Lake Powell elevations of 3,560 and 3,595 ▪ Balancing below Lake Powell elevation 3,560	▪ Storage and delivery of conserved system and non-system water ▪ Maximum total storage of conserved system and non-system water of 3.05 maf ▪ System assessment of 10% of stored conserved system and non-system water	▪ Provisions of existing ISG terminate after 2007, and during period from 2008-2026, surplus determinations are limited to 70R and Flood Control conditions
Preferred Alternative	▪ Shortages (i.e., reduced deliveries in the United States) of 333, 417, and 500 kaf from Lake Mead at elevations 1,075, 1,050, and 1,025 respectively[1] ▪ Initiate efforts to develop additional guidelines for shortages if Lake Mead falls below elevation 1,025 (Note: Includes consultation)	▪ Under high reservoir conditions, minimum objective release of 8.23 maf from Lake Powell unless storage equalization releases are required ▪ Under lower reservoir conditions, either reduce Lake Powell release or balance volumes depending upon elevations at Lake Powell and Lake Mead	▪ Creation, accounting, and delivery of ICS ▪ Maximum total ICS in Lake Mead of up to 4.2 maf ▪ System assessment of 5% when ICS is created	▪ Modification of ISG to eliminate Partial Domestic Surplus condition ▪ Extension of the modified guidelines through 2026

[1] These are amounts of shortage (i.e., reduced deliveries in the United States). As in the Draft EIS, the Final EIS includes modeling assumptions that identify water deliveries to Mexico pursuant to the 1944 Treaty.

ES.1.4.2 Basin States Alternative

The Basin States Alternative was developed by the Basin States and proposes a coordinated operation of Lake Powell and Lake Mead that would minimize shortages in the Lower Basin and avoid risk of curtailments of Colorado River water use in the Upper Basin. This alternative includes shortages to conserve reservoir storage; coordinated operations of Lake Powell and Lake Mead determined by specified reservoir conditions; a mechanism (i.e., Intentionally Created Surplus or ICS) for the creation, accounting, and delivery of conserved system and non-system water; and a modification and extension of the ISG through 2026.

ES.1.4.3 Conservation Before Shortage Alternative

The Conservation Before Shortage Alternative was developed by a consortium of environmental non-governmental organization (NGOs), and includes voluntary, compensated reductions (shortages) in water use to minimize involuntary shortages in the Lower Basin and to avoid risk of curtailments of Colorado River water use in the Upper Basin. This alternative includes voluntary shortages prior to involuntary shortages; coordinated operations of Lake Powell and Lake Mead determined by specified reservoir conditions; an expanded ICS mechanism for the creation, accounting, and delivery of conserved system and non-system water, including water for environmental uses; and modification and extension of the ISG through 2026.

ES.1.4.4 Water Supply Alternative

The Water Supply Alternative maximizes water deliveries at the expense of retaining water in storage in the reservoirs for future use. This alternative would reduce water deliveries only when insufficient water to meet entitlements is available in Lake Mead. When reservoir elevations are relatively low, Lake Powell and Lake Mead would share water (“balance contents”). This alternative does not include a mechanism for the creation, accounting, and delivery of conserved system and non-system water in Lake Mead. The existing ISG would be extended through 2026.

ES.1.4.5 Reservoir Storage Alternative

The Reservoir Storage Alternative was developed in coordination with the cooperating agencies and other stakeholders, primarily Western and the NPS. This alternative would keep more water in storage in Lake Powell and Lake Mead by reducing water deliveries and by increasing shortages to retain more water in storage and thereby, benefit power and recreational interests. This alternative includes larger, more frequent shortages that serve to conserve reservoir storage; coordinated operations of Lake Powell and Lake Mead determined by specified reservoir conditions (more water would be held in Lake Powell than under the Basin States Alternative); and an expanded mechanism for the creation, accounting, and delivery of conserved system and non-system water in Lake Mead. The existing ISG would be terminated after 2007.

ES.1.4.6 Preferred Alternative

The Preferred Alternative incorporates operational elements identified in the Basin States and Conservation Before Shortage alternatives. This alternative includes shortages to conserve reservoir storage; a coordinated operation of Lake Powell and Lake Mead determined by specified reservoir conditions that would minimize shortages in the Lower Basin and avoid risk of curtailments of use in the Upper Basin; and also adopts the ICS mechanism for promoting water conservation in the Lower Basin. It is anticipated that the maximum cumulative amount of ICS would be 2.1 maf; however, the potential effects of a maximum cumulative amount of ICS of up to 4.2 maf have been analyzed in the Final EIS. This alternative also includes modification and extension of the ISG through 2026.

ES.2 Summary of Potential Environmental Effects

ES.2.1 Methodology

Hydrologic modeling of the Colorado River system was conducted to determine the potential hydrologic effects of the alternatives. Modeling provides projections of potential future Colorado River system conditions (i.e., reservoir elevations, reservoir releases, river flows) for comparison of those conditions under the No Action Alternative to conditions under each action alternative. Due to the uncertainty with regard to future inflows into the system, multiple simulations were performed in order to quantify the uncertainties of future conditions and as such, the modeling results are typically expressed in probabilistic terms.

Hydrologic modeling also provides the basis for the analysis of the potential effects of each alternative on other environmental resources such as recreation, biology, and electrical power. The potential effects to specific resources are identified and analyzed for each action alternative and compared to the potential effects to that resource under the No Action Alternative. These comparisons are typically expressed in terms of the relative differences in probabilities between the No Action Alternative and the action alternatives.

ES.2.2 Hydrologic Resources

ES.2.2.1 Reservoir Storage

Lake Powell. Under the No Action Alternative and the action alternatives, the elevations of Lake Powell are projected to fluctuate between full and lower levels during the period of analysis (2008 through 2060). At the 90th percentile Lake Powell end-of-July elevation values, the action alternatives and the No Action Alternative are projected to be similar over the period of analysis.

Lake Powell elevations are generally lower under the Water Supply Alternative relative to the No Action Alternative. Conversely, Lake Powell elevations are generally higher under the Reservoir Storage Alternative relative to the No Action Alternative. Lake Powell elevations under the Basin States and Conservation Before Shortage alternatives, and the Preferred Alternative, are similar to each other because these alternatives assume the same operation at Lake Powell. At the 50th percentile, Lake Powell elevations under the Preferred Alternative are approximately ten feet lower than under the No Action Alternative in 2026; at the10th percentile, Lake Powell elevations are nearly the same in 2026.

The probabilities of Lake Powell elevations less than 3,560 feet msl (the approximate minimum elevation for operation of several launch ramps) are higher under the Water Supply Alternative and lower under the Reservoir Storage Alternative relative to all other alternatives including the No Action Alternative. Probabilities under the Basin States and Conservation Before Shortage alternatives and the Preferred Alternative are similar, with a probability of about five percent in 2016. The probability of Lake Powell elevations less than 3,490 feet msl (the approximate minimum elevation for operation of the Glen Canyon Dam Powerplant) is low (three percent or less) for the Preferred Alternative.

Lake Mead. Under the No Action Alternative and the action alternatives, the elevation of Lake Mead is projected to fluctuate between full pool and lower elevations during the period of analysis (2008 through 2060). At the 90th percentile Lake Mead end-of-December elevation values, the Basin States, Conservation Before Shortage, and Water Supply alternatives, the Preferred Alternative, and the No Action Alternative are projected to be similar over the period of analysis. The 90th percentile Lake Mead end-of-December elevation values under the Reservoir Storage Alternative are slightly higher than under the other alternatives.

At the 50th and 10th percentiles, Lake Mead elevations are generally higher under the Reservoir Storage Alternative relative to the No Action Alternative. Lake Mead 50th percentile elevations under the Water Supply Alternative are generally lower than those under the No Action Alternative. However, the Lake Mead 10th percentile elevations under the Water Supply Alternative vary and are sometimes higher and sometimes lower than those under the No Action Alternative. Lake Mead elevations under the Basin States and Conservation Before Shortage alternatives, and the Preferred Alternative are similar to each other at the 50th and 10th percentiles. At the 50th percentile, Lake Mead elevations under the Preferred Alternative are approximately 16 feet lower relative to the No Action Alternative; however, at the 10th percentile, Lake Mead elevations are approximately 20 feet higher.

The probabilities of Lake Mead elevations less than 1,050 feet msl (the approximate minimum elevation for operation of the Hoover Dam Powerplant and the operation of SNWA's upper intake) are higher under the Water Supply Alternative and lower under the Reservoir Storage Alternative relative to all other action alternatives. Probabilities under the Basin States and Conservation Before Shortage alternatives and the Preferred Alternative are similar, with a probability of approximately 15 to 17 percent in 2016.

The probability of Lake Mead elevations below 1,000 feet msl (the minimum elevation for operation of SNWA's lower intake) is low (between zero and two percent) for all alternatives except for the Water Supply Alternative (up to 12 percent).

Lake Mohave and Lake Havasu. Lake Mohave and Lake Havasu are operated on rule curves and have target end-of-month elevations. This manner of operation for the two reservoirs will continue in the future and would apply to operations under the No Action Alternative and the action alternatives. Therefore, future Lake Mohave and Lake Havasu elevations would not be affected by the proposed federal action.

ES.2.2.2 Reservoir Releases

During the interim period (2008 through 2026), Glen Canyon Dam releases less than the annual minimum objective release of 8.23 maf occurred less than one percent of the time under the No Action Alternative, approximately ten percent of the time under the Basin States, Conservation Before Shortage, and Water Supply alternatives, and the Preferred Alternative, and approximately 17 percent of the time under the Reservoir Storage Alternative. During the interim period, releases greater than the annual minimum objective release of 8.23 maf occurred approximately 42 percent of the time under the No Action Alternative, approximately 62 percent of the time under the Basin States and Conservation Before Shortage alternatives, 69 percent of the time under the Water Supply Alternative, 44 percent of the time under the Reservoir Storage Alternative, and 59 percent of the time under the Preferred Alternative.

During the interim period (2008 through 2060), the observed minimum and maximum Hoover Dam annual releases under the No Action Alternative are 7.46 maf and 17.13 maf, respectively. By comparison, the minimum annual release under the action alternatives is 7.3 maf and occurs under the Conservation Before Shortage Alternative. The maximum annual release of 17.16 maf occurs under the Basin States, Conservation Before Shortage, and Reservoir Storage alternatives, and the Preferred Alternative. In general, the observed annual release volumes under the Basin States, Conservation Before Shortage, and Reservoir Storage alternatives, and the Preferred Alternative are similar to those observed under the No Action Alternative. The Hoover Dam annual releases observed under the Water Supply Alternative are generally higher than those observed under the No Action Alternative. The Hoover Dam annual releases observed under the Reservoir Storage Alternative are generally lower than those observed under the No Action Alternative.

Releases from Davis Dam and Parker Dam generally reflect the same pattern of releases under the different action alternatives as those from Hoover Dam. The differences in the release volumes are mostly attributed to the depletions that occur upstream of each respective dam.

ES.2.2.3 Groundwater

Differences in Colorado River flows downstream of Hoover Dam are similar between the action alternatives and the No Action Alternative and these differences are relatively minor. Corresponding effects of the action alternatives relative to the No Action Alternative on groundwater will also be relatively minor.

ES.2.3 Water Deliveries

All of the action alternatives increase the probability that Normal Condition deliveries will be met over the interim period relative to the No Action Alternative. The differences between the action alternatives and the No Action Alternative, in terms of the probability of occurrence for water supply deliveries under a Normal Condition, range from about 15 to 40 percent over the interim period.

The Water Supply Alternative exhibits the same probability of Surplus Condition deliveries as the No Action Alternative (between about 30 to 40 percent) between 2008 and 2016 due to identical assumptions regarding surplus during this period. The ISG provisions terminate under the No Action Alternative in 2016. However, these provisions are retained in the Water Supply Alternative through 2026 and therefore this alternative consistently exhibits the highest probability of surplus deliveries during the interim period. The Reservoir Storage Alternative exhibits the lowest probabilities (between about ten to 20 percent) during the interim period because surplus determinations are limited to Quantified and Flood Control Surplus Conditions beginning in 2008. The surplus provisions under the Basin States and the Conservation Before Shortage alternatives, and under the Preferred Alternative, are similar and the probability of a Surplus Condition from 2010 through 2016 is slightly less than under the No Action Alternative due to the absence of the Partial Domestic Surplus provision in these three alternatives. After the end of the interim period in 2026, the probability for all alternatives converges to between ten and 20 percent.

The storage and delivery mechanism and related storage and delivery of conserved system and non-system water were modeled under the Basin States, Conservation Before Shortage, and Reservoir Storage alternatives, and the Preferred Alternative. This mechanism has the effect of increasing the probability of occurrence of a Surplus Condition since more water is retained in Lake Mead relative to the No Action Alternative. The maximum increase in the probability of occurrence of a Surplus Condition is seven percent, occuring in two years under the Preferred Alternative.

During most of the interim period, the probability of an involuntary and voluntary shortage is less under all of the action alternatives than under the No Action Alternative; however, after 2026, the Water Supply Alternative has the highest probability of shortage due to the relatively depleted storage conditions and the assumption that the operations revert back to the assumptions used in the modeling of the No Action Alternative after 2026. The probability of occurrence of shortages under the Reservoir Storage Alternative is slightly higher than under the No Action Alternative between 2008 and 2013; however, after 2013 shortages under the Reservoir Storage Alternative occur less frequently as compared to the No Action Alternative. The probability of occurrence of shortages under the Basin States and Conservation Before Shortage alternatives and the Preferred Alternative are lower relative to the No Action Alternative throughout the interim period, ranging from 15 to 20 percent lower.

In terms of magnitude, the average shortage volumes during the interim period are lowest under the Water Supply Alternative (between zero and 240 kafy) and highest under the Reservoir Storage Alternative (between 600 and 750 kafy). The average shortage volumes for the Preferred Alternative (between 400 and 530 kafy) are less than the average shortage volumes for the No Action Alternative (between 500 and 610 kafy) during the interim period.

Multi-year shortages with annual shortage volumes equal to or greater than 400 kaf are likely for all alternatives with the exception of the Water Supply Alternative, with the Conservation Before Shortage Alternative and the Preferred Alternative exhibiting probabilities of between ten and 30 percent over the interim period for durations of two or more years. Multi-year shortages with annual shortage volumes equal to or greater than 500 kafy are more likely to occur under the Reservoir Storage Alternative with probabilities of approximately 35 percent for durations of two or more years and 26 percent for durations of five or more years. Multi-year shortages with annual shortage volumes equal to or greater than 600 kafy are likely only for the Reservoir Storage Alternative. No alternatives exhibited shortages of greater than or equal to 1.0 mafy for any duration.

The storage and delivery mechanism and related storage and delivery of conserved system and non-system water were modeled under the Basin States, Conservation Before Shortage, and Reservoir Storage alternatives and the Preferred Alternative. This mechanism has the effect of decreasing the occurrence of shortages. Due to the assumptions of increased participation in the storage and delivery mechanism, the greatest differences (up to a ten percent reduction in shortage probability during the interim period) were observed under the Reservoir Storage Alternative and under the Preferred Alternative.

ES.2.4 Water Quality

The future average annual salinity levels under the different action alternatives are not expected to exceed the numeric criteria for salinity at Hoover Dam, Parker Dam and Imperial Dam, established by the Colorado River Basin Salinity Control Forum. The difference between all alternative is less than three percent relative to the No Action Alternative. The ability for the United States to continue to meet the salinity differential at the Northerly International Boundary with Mexico pursuant to Minute 242 will not be affected.

The temperature range for Glen Canyon Dam releases under the Water Supply Alternative could potentially be warmer due to lower Lake Powell reservoir elevations. The Reservoir Storage Alternative generally results in cooler temperatures for Glen Canyon Dam releases since this alternative generally results in higher Lake Powell elevations. The temperature of Glen Canyon Dam releases under the Basin States and Conservation Before Shortage Alternatives, and the Preferred Alternative, are similar to those under the No Action Alternative.

Hydrologic and water quality modeling for Lake Mead for the Boulder Islands North Alternative, the preferred alternative published in the System Conveyance and Operations Program Final EIS (Clean Water Coalition 2006), shows that drawing down Lake Mead elevation to 1,000 feet msl would not have a significant effect on water quality in Lake Mead. The probability that Lake Mead will be drawn down to elevations below 1,000 feet msl over the interim period is low for all alternatives, except the Water Supply Alternative. Therefore, potential effects of the alternatives on Lake Mead water temperatures are considered to be negligible.

ES.2.5 Air Quality

As reservoir elevation decreases and shoreline is exposed, the potential for increased fugitive dust increases. The projected exposed shoreline acreage under the Basin States and Conservation Before Shortage alternatives, and the Preferred Alternative, are similar (i.e., from zero to five percent for the year 2025) to that projected under the No Action Alternative at Lake Powell. In general, the greatest increase in exposed shoreline acreage (i.e., about 30 percent for the year 2025) compared to the No Action Alternative at Lake Powell is projected under the Water Supply Alternative; the greatest reduction (i.e., about 15 percent for the year 2025) is projected under the Reservoir Storage Alternative.

Except for the Reservoir Storage Alternative, all of the action alternatives are projected to have similar or decreased shoreline exposure (i.e., from a less than one percent increase to a nine percent decrease) compared to the No Action Alternative for Lake Mead, and for Glen Canyon Dam to Lake Mead reach (Lake Mead delta). There is a greater potential for reduction in shoreline acreage exposure (i.e., 18 percent for the year 2025) under the Reservoir Storage Alternative and this potential is generally consistent for all years.

As reservoir elevation decreases and more shoreline is exposed, the potential for increased fugitive dust emission increases. However, an increase in fugitive emissions as a result of increased exposed shoreline would be limited at Lake Powell because the increased exposure of acreage would be comprised largely of sandstone.

ES.2.6 Visual Resources

The probability of exposing Cathedral in the Desert ranged from three to 17 percent under the alternatives. The Water Supply Alternative would offer the greatest chance of exposure, while the Reservoir Storage Alternative offers the least chance. There would be no visual effects on attraction features at Lake Mead.

At Lake Powell, the maximum height of calcium carbonate rings ranged from 192 feet under the Water Supply Alternative to 148 feet under the Basin States and Conservation Before Shortage alternatives, the Preferred Alternative, and the No Action Alternative, and to 128 feet under the Reservoir Storage Alternative. At Lake Mead, the maximum height of calcium carbonate rings ranged from 170 feet under the Reservoir Storage Alternative to 221 feet under the Water Supply Alternative, similar to the 218 foot height under the No Action Alternative. The calcium carbonate ring height under the Basin States and Conservation Before Storage alternatives, and the Preferred Alternative was approximately 197 feet. For both reservoirs, the presence of the calcium carbonate ring produces an effect regardless of its height. Therefore, while there are numeric differences in the projected height of the rings, the overall difference in visual impact among the alternatives is not considered significant.

At the inflow areas to both Lake Powell and Lake Mead, sediment deltas will continue to build up over time and be visible under all alternatives. Their relative exposure and visibility are directly related to reservoir elevations. The differences among all alternatives are negligible for both Lake Powell and Lake Mead.

ES.2.7 Biological Resources

ES.2.7.1 Vegetation and Wildlife

Lake Powell and Lake Mead. Under the Water Supply Alternative, there may be a minor negative impact on obligate phreatophytes, and marsh and the wildlife that use such habitats because lake elevations tend to be lower than under the No Action Alternative. Under the Basin States, Conservation Before Shortage, and Reservoir Storage alternatives, and the Preferred Alternative, there may be a minor positive impact on obligate phreatophytes, and marsh and associated wildlife because lake elevations tend to be higher than under the No Action Alternative.

Glen Canyon Dam to Lake Mead. All five action alternatives tend to have lower 10th percentile releases from Glen Canyon Dam than the No Action Alternative. These lowered releases may negatively impact obligate phreatophytes, and marsh and associated wildlife downstream of Lake Powell. The impacts are expected to be minor because though lower, they are within the range of historical flows.

Hoover Dam to Davis Dam and Lake Havasu and Parker Dam. There would be no impacts to vegetation or wildlife in these river reaches under all five action alternatives because there may be only small differences in Lake Mead releases and these reaches are dominated by Lake Mohave and its backwater, and Lake Havasu. Vegetated habitats potentially affected by flow changes between Hoover Dam and Lake Mohave are limited. Lake Mohave and Lake Havasu are operated on monthly rule curves so vegetation and wildlife effects at the lakes under the action alternatives are identical to those under the No Action Alternative.

Davis Dam to Parker Dam. There may be higher 10th and 50th percentile monthly releases and a higher annual median release from Davis Dam under the Water Supply Alternative and this may cause a minor positive impact to obligate phreatophytes, and marsh and associated wildlife as compared to the No Action Alternative. Under the Reservoir Storage Alternative, there may be lower 10th and 50th percentile monthly releases and a lower annual median release from Davis Dam; this may cause a minor negative impact to obligate phreatophytes, and marsh and associated wildlife as compared to the No Action Alternative. These differences remain within the range of historical flows. The other action alternatives, including the Preferred Alternative would have little to no effect compared to the No Action Alternative.

Parker Dam to Imperial Dam. Under the Basin States, Conservation Before Shortage, and Reservoir Storage alternatives, and the Preferred Alternative, there are lower 10th and 50th percentile monthly releases and a lower annual median release from Parker Dam; these lower releases may have a minor negative impact on obligate phreatophytes, and marsh and associated wildlife. Under the Water Supply Alternative there is a higher annual median release from Parker Dam, which may provide a minor benefit to obligate phreatophytes, and marsh and associated wildlife.

Imperial Dam to NIB. There are no impacts to vegetation or wildlife under any of the action alternatives in this reach.

NIB to SIB. Mexico diverts its water at Morelos Diversion Dam (at the NIB) and flows downstream of this dam are rare. There is a higher probability of excess flows passing Morelos Diversion Dam under the Conservation Before Shortage and Reservoir Storage alternatives than under the No Action Alternative, which is expected to cause a moderate positive benefit to river flows, obligate phreatophytes, and marsh and associated wildlife downstream of Morelos Diversion Dam[1]. The other action alternatives, including the Preferred Alternative, would provide similar flows as the No Action Alternative.

ES.2.7.2 Special Status Species

In addition to the assessment of effects on general vegetation and wildlife, the analysis also considered potential effects on special status fish, bird, and plant species. These effects were evaluated for species occurring at Lake Powell and Lake Mead, the reaches of the Colorado River between Glen Canyon Dam and Lake Mead, and downstream of Lake Mead.

Lake Powell. Lower Lake Powell elevations under the Basin States, Conservation Before Shortage, and Water Supply alternatives, and the Preferred Alternative, at the 10th and 50th percentile of reservoir elevations may increase the amount of riverine habitat available at the inflow areas to Lake Powell. This may provide a minor positive impact to razorback sucker, bonytail, Colorado pikeminnow, and flannelmouth sucker found in the riverine areas at the inflows. The higher lake elevations under the Reservoir Storage Alternative may decrease the amount of riverine habitat at the inflow areas, which may result in a minor negative impact.

Clark's grebe that may inhabit Lake Powell could be impacted by elevation changes in Lake Powell that affect marsh habitat at the inflow areas. Under the Reservoir Storage and Water Supply alternatives, there may be higher and lower lake elevations, respectively, which would mean a minor positive and a minor negative impact, respectively, to Clark's grebe.

Glen Canyon Dam to Lake Mead. The action alternatives, except for the Reservoir Storage Alternative, may result in higher river temperatures downstream of Glen Canyon Dam at the 10th percentile elevations and higher to lower temperatures at the 50th percentile elevations relative to the No Action Alternative. The Reservoir Storage Alternative may result in higher to lower river temperatures at the 10th and 50th percentiles elevations, respectively. Higher temperatures may provide a minor positive impact to humpback

[1] These flows were modeled as part of the storage and delivery mechanism under the Conservation Before Shortage and Reservoir Storage alternatives. These modeling assumptions were utilized in the Final EIS in order to analyze the potential impacts to environmental resources of the storage and delivery mechanism, particularly with regard to reservoir elevations and river flow impacts. The use of these modeling assumptions does not represent any determination by Reclamation as to whether, or how, these releases could be made under current management of the Colorado River.

chub, bluehead sucker and flannelmouth sucker spawning and growth. However, these warmer temperatures also benefit non-native fish species which compete with native fish, and parasites that affect native fish, resulting in a minor negative impact. The lower average temperatures in the summer and winter at the 10th percentile of elevations under the Reservoir Storage Alternative could reduce the growing season for humpback chub, bluehead sucker, and flannelmouth sucker but would not affect spawning, resulting in a minor negative impact. The short duration of warmer average temperatures in the spring followed by cooler temperatures are unlikely to provide any benefit to non-native fish and native fish parasites. Lower annual releases in some years could reduce sediment loss from the Colorado River while higher releases in some years could increase sediment losses. How these changes in sediment transport could affect native fish habitat is unknown. The range in hourly flows could be reduced during lower annual releases and increased during higher annual releases. Lower temperatures may provide a minor negative impact to these native fish species. Under the Reservoir Storage Alternative, average water temperatures above 15ºC (59°F) may occur one month later than under the No Action Alternative and may have a minor negative impact on leopard frogs due to increased potential for thermal shock in July. Under the other action alternatives impacts to the leopard frog are not expected relative to the No Action Alternative.

Higher 90th percentile releases under the Reservoir Storage Alternative have a potential for increased impact to beach habitat in the lower Grand Canyon, which could adversely impact vegetation and Grand Canyon evening primrose on those beaches. Under the five action alternatives, flows may exceed those under the No Action Alternative and 17,000 cfs in some months, which may cause additional impact to Kanab ambersnail habitat at Vasey's Paradise. Under the Reservoir Storage Alternative, flows in June could exceed those under the No Action Alternative and exceed 20,000 cfs, thus causing greater impact to Niobrara ambersnail habitat. Under the Basin States, Conservation Before Shortage, and Water Supply alternatives, and the Preferred Alternative at the 90th percentile there may be flows that when above 20,000 cfs are equal to or less than those under No Action Alternative, which would provide a minor positive benefit to the Niobrara ambersnail. Under the five action alternatives there may be a minor negative impact on the southwestern willow flycatcher because of the 10th percentile release flows trend lower than those under the No Action Alternative. These lower potential flows could adversely impact southwestern willow flycatcher habitat in the Grand Canyon.

Lake Mead. The lower and higher Lake Mead elevations that may occur under the Water Supply and Reservoir Storage alternatives, respectively, could cause minor negative and minor positive impacts, respectively, to special status bird species. Impacts on bird species may be caused by increased or decreased potential for dewatering of riparian habitats and headcutting at the Lake Mead inflow areas. Higher lake elevations under the Reservoir Storage Alternative may inundate additional shoreline habitat for the sticky buckwheat, Geyer's milkvetch and Las Vegas Bearpoppy and be a minor negative impact. Lower Lake Mead elevations under the Water Supply Alternative may expose additional shoreline habitat for these plants and be a minor positive impact. These impacts were deemed minor because all habitats below the full pool elevation of Lake Mead are subject to periodic inundation and exposure as the lake elevation fluctuates in the future. Under the Preferred Alternative, there could be minor positive impacts to special status fish when elevations are above the current razorback spawning areas at the 50th percentile of elevations and when lower elevations would extend riverine habitat in the inflow area for special status fish. Elevations higher than under the No Action Alternative at the 10th percentile would have no impacts on razorback sucker spawning. Lake elevations under both the Basin States and Conservation Before Shortage alternatives could be both above and below those under the No Action Alternative and would have no impact to razorback suckers. The increased amount of riverine habitat at the 10th percentile of elevations could provide a minor positive impact to special status fish in the Colorado River inflow. Under the Water Supply Alternative there may be both minor positive and negative impacts to special status fish species due to providing more riverine habitat and lower elevations relative to razorback spawning areas, respectively, at the 50th percentile. Under the Reservoir Storage Alternative, elevations could be above current razorback sucker spawning areas over 50 percent of the time in about half the modeled years, a moderate positive impact. Higher reservoir elevations would provide less riverine habitat for special status fish in the Colorado River inflow at the10th and 50th percentile elevations for a minor negative impact.

Hoover Dam to Davis Dam and Lake Havasu to Parker Dam. There is no substantial difference between the No Action Alternative and any of the action alternatives in this reach.

Davis Dam to Lake Havasu. Lower monthly and annual median releases from Davis Dam under the Reservoir Storage Alternative may have a minor negative impact on obligate phreatophytes, and marsh and associated special status bird species, and Colorado River cotton rat. Impacts to these species may occur through adverse effects to their habitats from reduced dam releases. Razorback sucker, flannelmouth sucker, and bonytail may experience a minor negative impact because lower potential releases could have adverse impacts to riverine spawning habitat and backwater rearing habitats that these species utilize. Higher monthly and annual median releases from Davis Dam under the Water Supply Alternative may have a minor positive impact on obligate phreatophytes, and marsh and associated special status bird species, and Colorado river cotton rat. Razorback sucker, flannelmouth sucker, and bonytail may also benefit from these higher flows because they could maintain more of the spawning and rearing habitats present in this reach.

Parker Dam to Imperial Dam. Lower monthly and annual median flows under the Basin States, Conservation Before Shortage, and Reservoir Storage alternatives, and the Preferred Alternative, may have minor negative impacts to the habitats of the special status bird species and Colorado River cotton rat. Obligate phreatophytes, and marsh and associated special status species would be negatively impacted by lower releases. Razorback sucker and bonytail chub may be negatively impacted by lower flows under the Basin States, Conservation Before Shortage, and Reservoir Storage alternatives, and the Preferred Alternative. Lower flows may negatively impact spawning and rearing habitats for these species. Higher annual median flows under the Water Supply Alternative would benefit the habitats of special status birds, mammals and fish and may have a minor positive impact.

Imperial Dam to NIB. Under the No Action Alternative and the action alternatives there would be no impact to special status species in this reach.

NIB to SIB. Flows past Morelos Diversion Dam[2] are more probable under the Reservoir Storage and Conservation Before Shortage alternatives. The increased probability of flows may have a moderate positive impact on the special status bird species through positive impacts to riparian and marsh habitats these species utilize. These higher probabilities of flows may also positively impact the special status bat species listed in this section, Yuma hispid cotton rat, and Colorado river cotton rat through positive impacts to their riparian and marsh habitats. Though these flows are an overall benefit to the riparian corridor downstream of the NIB, the increased probability of high flows could increase the likelihood of scouring *Atriplex* vegetation in this reach, which would be a minor negative impact to MacNeill's sooty-winged skipper.

ES.2.8 Cultural Resources

For Lake Powell, under the Water Supply Alternative at the 10th percentile, there are at least 227 unexcavated sites subject to effect, as compared to about 193 sites under the other alternatives. Consultation is underway regarding eligibility and effect.

For the reach from Glen Canyon to Lake Mead, the alternatives pose no additional threat to cultural resources because of the programs already underway.

For Lake Mead, there are at least 32 cultural resources located below elevation 1,080 feet msl. The probability of exposing sites below this elevation vary by alternative, with the Reservoir Storage Alternative having the lowest probability (up to 13 percent lower compared to the No Action Alternative) and the Water Supply Alternative having the highest probability (up to nine percent higher compared to the No Action Alternative). The Basin States and Conservation Before Shortage alternatives and the Preferred Alternative have probabilities similar to those of the No Action Alternative.

For reaches downstream of Lake Mead, no adverse effects are anticipated from any of the alternatives. However, consultation regarding eligibility and effect is under way.

For Indian sacred sites and other issues of Tribal concern (not including ITAs), none of the alternatives are expected to restrict access or result in loss of physical integrity to sacred sites. Consultations with Indian tribes are ongoing with respect to these issues and other issues and concerns.

[2] These flows were modeled as part of the storage and delivery mechanism under the Conservation Before Shortage and Reservoir Storage Alternatives. These modeling assumptions were utilized in the Final EIS in order to analyze the potential impacts to environmental resources of the storage and delivery mechanism, particularly with regard to reservoir elevations and river flow impacts. The use of these modeling assumptions does not represent any determination by Reclamation as to whether, or how, these releases could be made under current administration of the Colorado River.

ES.2.9 Indian Trust Assets

After analyzing each resource, it is concluded that Tribal trust assets identified in the study area would not be adversely affected by any of the anticipated environmental impacts stemming from the proposed federal action.

ES.2.10 Electrical Power Resources

The Basin States, Conservation Before Shortage, and Water Supply alternatives could potentially have minor impacts in generation, capacity, and economic value of electrical power at Glen Canyon and Hoover Powerplants due to slightly lower average reservoir elevations that could occur under these alternatives. The Water Supply Alternative could potentially have the highest effect on electrical power production and value because this alternative provides the lowest average reservoir elevations of the action alternatives. The Preferred Alternative and the Reservoir Storage Alternative could potentially provide a benefit to electrical power production and value at Glen Canyon and Hoover Powerplants because these alternatives would provide higher average reservoir elevations than the No Action Alternative. However, most of these changes are less than one percent and as such, these impacts are considered minor.

For the Parker-Davis Project and Headgate Rock powerplants, the Preferred Alternative and the Basin States, Conservation Before Shortage, and Reservoir Storage alternatives could potentially decrease electrical power production at these facilities as compared to the No Action Alternative because of the lower release volumes from the associated dams/powerplants. The Reservoir Storage Alternative generally provides lower water releases compared to the No Action Alternative and other action alternatives and therefore this alternative could have the greatest effect on power production at these facilities. The Water Supply Alternative results in greater release volumes downstream and therefore slight increases in electrical power production and value as compared to the No Action Alternative. Again, these changes are relatively minor (most less than one percent) compared to overall electrical power production at these facilities.

All of the action alternatives, with the exception of the Reservoir Storage Alternative, could potentially increase pumping costs for entities that pump water from Lake Powell due to the lower reservoir elevations, as compared to the No Action Alternative. At Lake Mead, all of the action alternatives, with the exception of the Water Supply Alternative, provide higher reservoir elevations as compared to the No Action Alternative and therefore could potentially result in lower pumping costs for the entities that pump water from Lake Mead.

Reductions in power revenues could reduce the amount of money available to meet the intended uses of the basin power funds, possibly leading to reductions in allocations to power contractors or power rate adjustments. The action alternatives generally have a minor impact on the economic value of electrical power generation at the Glen Canyon and Hoover Powerplants. However, total loss of electrical power generation capabilities would have a substantial effect on the basin power funds. At the Glen Canyon Powerplant, the probability of this type of loss in electrical power generation capability is very small (less than five percent) except under the Water Supply Alternative, which would result in as much as a nine percent probability. At Hoover Powerplant, the probability of total loss of generation is higher, increasing from zero in 2008 to about 30 percent in 2026. However, the Reservoir Storage Alternative is the exception to this, while the remaining alternatives are very similar to the No Action Alternative.

ES.2.11 Recreation

ES.2.11.1 Shoreline Facilities

The Reservoir Storage Alternative would result in higher reservoir elevations and a lower probability of closure of shoreline facilities than the other action alternatives and the No Action Alternative. Conversely, the Water Supply Alternative would result in the highest probability of such closures. The Basin States and Conservation Before Shortage alternatives, and the Preferred Alternative are similar to the No Action Alternative.

At Lake Mead, all of the alternatives have similar probabilities of facility closures except for the Reservoir Storage Alternative, which has a slightly to moderately lower probability. At Lake Mead, under all of the alternatives there is a 74 to 78 percent probability that the Pearce Bay launch ramp would be closed to boaters, except under the Reservoir Storage Alternative this probability is 66 percent. Similarly, there is a 21 to 30 percent probability of closure of the Echo Bay public launch ramp (in the north end of the reservoir) under all of the alternatives, except under the Reservoir Storage Alternative this probability is nine percent.

ES.2.11.2 Boating and Navigation

For safe boating at Lake Powell, probabilities range from 24 to 28 percent that NPS would have to prohibit boating around Castle Rock and Gregory Butte under the No Action Alternative and the Reservoir Storage Alternative. Under the Basin States Alternative there is a 36 percent probability and under the Conservation Before Shortage Alternative there is a 35 percent probability that boating prohibitions would need to be put in place. Under the Water Supply Alternative, the probability of this occurrence is 52 percent. Under the Preferred Alternative there is a 32 percent probability that prohibitions would be put in place.

For Lake Mead, all the alternatives except the Reservoir Storage Alternative in July 2026 provide a 72 to 76 percent probability that boaters may encounter navigational hazards at the upstream end of Lake Mead due to reservoir elevations being drawn down to below 1,170 feet msl. Under the Reservoir Storage Alternative there is a 69 percent probability of a similar recreational impacts. Similar effects would occur in the Overton Arm of Lake Mead.

For whitewater boating through Grand Canyon, the Glen Canyon Dam ROD flows will be maintained. Even in a 7.0 maf Glen Canyon Dam release year, the minimum daily flow will remain at or above 5,000 cfs, a safe boating threshold.

ES.2.11.3 Sport Fish Populations

Sport fish populations would not be adversely affected at Lake Powell under any of the alternatives. Although surface water temperatures may approach lethal levels in the upper 10 feet of the reservoir under any alternative, lethal levels for striped bass and threadfin shad are not expected to be exceeded by any alternative. Moreover, cooler temperatures below the lake surface would serve as a refuge for the fish. The situation for striped bass and threadfin shad in Lake Mead is similar to Lake Powell. Higher water temperatures could impair the Lake Mead Fish Hatchery, particularly under the Water Supply Alternative.

Under the No Action Alternative, 10^{th} percentile temperatures are suitable for growth, spawning and incubation in most months. Higher water temperatures under the Basin States, Conservation Before Shortage, and Water Supply alternatives, and the Preferred Alternative, could affect various life history stages of rainbow trout downstream of Glen Canyon Dam. Under the action alternatives, 10^{th} percentile modeling results indicate that there could be minor impacts to rainbow trout due to warmer temperatures. The Water Supply Alternative shows the most warming and potential to negatively impact trout. The Reservoir Storage Alternative shows the least warming and will often result in colder temperatures than the No Action Alternative. Conditions for trout under the Basin States, Conservation Before Shortage, and Water Supply alternatives, and the Preferred Alternative, will be similar to slightly worse than under the No Action Alternative.

ES.2.12 Transportation

For the Lake Powell ferry, the Basin States and Conservation Before Shortage alternatives, and the Preferred Alternative would have minor effects on ferry service; the Water Supply Alternative could result in potential moderate adverse effects; and the Reservoir Storage Alternative could have beneficial effects. The probability varies from year to year, but there is up to a 17 percent probability that the Lake Powell ferry may become inoperable under the Water Supply Alternative for some period of time. Conversely, the ferry would remain operable with the highest probabilities and greatest durations of time under the Reservoir Storage Alternative.

For the Colorado River ferry service downstream of Davis Dam, only under the Reservoir Storage Alternative are there any measurable effects and these potential effects would be minor. The other action alternatives show no difference from the No Action Alternative.

The Lake Havasu ferry service would be unaffected under all of the action alternatives.

ES.2.13 Socioeconomics

ES.2.13.1 Employment, Income, and Tax Revenue

Although a loss in employment and income could potentially occur under any of the action alternatives, the probability of any shortage occurring would be greater under the No Action Alternative. This suggests that the potential loss in employment, income, and tax revenues estimated for the No Action Alternative would be reduced under each of the action alternatives. The probabilities of any shortage amount occurring would be similar under all the action alternatives during the interim period with the exception of the Water Supply Alternative. When compared to the other action alternatives, the probabilities of any shortage amount occurring would be lower under the Water Supply Alternative. This indicates that, with the exception of the Water Supply Alternative, the potential losses in employment, income, and tax revenues would be similar among the action alternatives during the interim period. However, none of the changes in employment and income are considered substantial when compared to total employment and income generated within the study area.

For the period 2027 through 2060, the change in employment and income would be similar between the No Action Alternative and the action alternatives. The greatest difference would be in 2027 in which the probabilities would be slightly higher when compared to those under the No Action Alternative. However, by 2040, the probabilities of shortages occurring under all of the alternatives are very similar.

ES.2.13.2 Municipal and Industrial Water Uses

Adverse effects on employment and income in Arizona and Nevada during shortages would be minimized as a result of drought plans being in place. No adverse effects are expected in California because of priority of apportionment and the availability of alternative water supplies.

ES.2.13.3 Recreation Economics

Recreation opportunities and associated economic activity at Lake Powell are not expected to be substantially different under the No Action Alternative, the Basin States and Conservation Before Shortage alternatives, and the Preferred Alternative. Recreation opportunities and associated economic activity could potentially be adversely affected under the Water Supply Alternative due to the potentially lower Lake Powell elevations that may occur under this alternative. Conversely, recreation opportunities and associated economic activity would benefit under the Reservoir Storage Alternative as a result of potentially higher Lake Powell elevations under this alternative.

Recreation opportunities and associated economic activity at Lake Mead are not expected to be substantially different under the No Action Alternative, the Basin States, Conservation Before Shortage, and Water Supply alternatives, and the Preferred Alternative. Recreation opportunities and associated economic activity could potentially benefit under the Reservoir Storage Alternative due to the potentially higher Lake Mead elevations that may occur under this alternative.

Because daily and hourly flows in the Lake Powell to Lake Mead reach and in the Colorado River reaches downstream of Lake Mead would likely remain within ranges suitable for boating, there would be no change in river-related economic activity.

ES.2.14 Environmental Justice

After evaluating each resource, it is concluded that the environmental justice communities identified in the study area would not be disproportionately affected by any of the anticipated environmental impacts stemming from the proposed federal action. Nor would the proposed federal action result in adverse disproportionate impacts on human health within these environmental justice communities.

ES.2.15 Indirect Effects of ICS Mechanism

SNWA proposes three ICS projects which were specifically formulated to utilize the ICS mechanism: Virgin River and Muddy River Tributary Conservation, Coyote Spring Well and Moapa Transmission System Project, and lower Colorado River Drop 2 Storage Reservoir Project. It is anticipated that creation of ICS and subsequent delivery of water from Lake Mead for the proposed SNWA projects will be approved as part of the ROD for the proposed federal action. While the proposed SNWA water conservation projects are not federal projects, they will rely on Reclamation's approval for creation and delivery of ICS from Lake Mead. The effects of these projects within the geographic scope of the proposed federal action have been included in the modeling assumptions and are therefore included in the various resource analyses in this Final EIS. The localized impacts of these water conservation projects (outside the geographic scope of the proposed federal action) are described as indirect effects of Reclamation's establishment of the ICS mechanism.

The Coyote Spring Well and Moapa Transmission System Project would increase flow in the Muddy River, although the effect on flows would be minor and may provide minor positive impacts.

The Drop 2 Storage Reservoir Project would result in a reduction in non-storable flows that are delivered to Mexico. The Environmental Assessment for the Drop 2 Storage Reservoir Project included a specific analysis of the hydrologic impacts of the project on smaller (non-flood release) flows in the limitrophe division of the Colorado River and concluded decreases in surface water flows passing Morelos Diversion Dam would not conflict with 1944 Treaty delivery obligations, or substantially alter the existing drainage pattern or flows of the limitrophe reach. The Final EA did not identify significant impacts from the project.

No significant impacts on water quality, visual resources, cultural resources, ITAs, electrical power, recreation, transportation, or environmental justice are anticipated from the SNWA Tributary Conservation projects. The changes in river flow would be minimal and may provide minor positive impacts.

ES.2.16 Climate Change Considerations

Based on the current inability to precisely project future impacts of climate change to runoff throughout the Colorado River Basin at the spatial scale needed for CRSS, Reclamation based its hydrologic analysis for this EIS primarily on the resampled historical record. However, in order to understand the potential effects of future inflow sequences outside the range of historical flows (i.e., future sequences with increased variability including the severity, frequency, and duration of droughts), particularly during the 19-year period of the application of the proposed federal action, Reclamation analyzed the sensitivity of the hydrologic resources (including reservoir storage, reservoir releases, and river flows) to hydrologic scenarios derived from alternative methodologies (including stochastic hydrology methods and paleo-reconstruction methods) in the Draft EIS. An additional analysis has been added to Appendix N in the Final EIS that incorporates a newly published tree-ring reconstruction of hydrologic inflows at Lees Ferry (Meko et al. 2007) that extends the estimate of annual flow at Lees Ferry back to the year 762, a record length of 1,244 years.

Although precise estimates of the future impacts of climate change to runoff throughout the Colorado River Basin at appropriate spatial scales are not currently available, these impacts may include decreased mean annual flow and increased variability, including more frequent and more severe droughts. Furthermore, even without precise knowledge of the effects on runoff, increasing temperatures alone would likely increase losses (e.g., evapotranspiration and sublimation), resulting in reduced runoff.

Acknowledging the potential for impacts due to climate change and increased hydrologic variability, the Secretary proposes that these guidelines be interim in duration and extend through 2026, providing the opportunity to gain valuable operating experience for the management of Lake Powell and Lake Mead, particularly for low reservoir conditions, and improve the basis for making additional future operational decisions, whether during the interim period or thereafter. In addition, the Preferred Alternative has been crafted to include operational elements that would respond if potential impacts of climate change and increased hydrologic variability are realized. In particular, the Preferred Alternative includes a coordinated operation element that allows for the adjustment of Lake Powell's release to respond to low reservoir storage conditions in Lake Powell or Lake Mead as described in Section 2.7 and Section 2.3. In addition, the Preferred Alternative will enhance conservation opportunities in the Lower Basin and the retention of water in Lake Mead through adoption of the ICS mechanism. Finally, the Preferred Alternative includes a shortage strategy at Lake Mead that would result in additional shortages being considered, after appropriate consultation, if Lake Mead elevations drop below 1,025 feet msl.

ES.3 Summary

A summary of potential effects of the No Action Alternative and the action alternatives is provided in Table ES-2.

ES.4 Cumulative Impacts

The proposed federal action would not result in any significant cumulative impacts.

ES-2
Summary of Potential Effects of the Alternatives

Final EIS Section	Environmental Consequences by Resource, Year and Value	Alternatives					
		No Action	Basin States	Conservation Before Shortage	Water Supply	Reservoir Storage	Preferred Alternative
4.3	Hydrologic Resources						
	Probability of Glen Canyon annual release volumes ≥ 7.5 maf, 2009 to 2060	99.96%	96.66%	96.66%	97.9%	100%	96.39%
	Probability of Glen Canyon annual release volumes ≥ 8.23 maf, 2009 to 2060	99%	96.32%	96.38%	96.33%	93.79%	96.64%
	Lake Powell March elevation, probability of water levels ≤ 3,490 feet msl 2026	1.0%	0%	0%	9.0%	0%	0%
	Lake Mead July elevation, probability of water levels ≤ 1,050 feet msl 2026	30%	23%	23%	29%	9%	21%
	Hoover Dam annual release, 2026 50th percentile values	9.04 maf	9.17 maf	9.11 maf	9.39 maf	8.68 maf	9.16 maf
4.4	Water Deliveries						
	Probability of involuntary shortage, 2026	49%	35%	7%	12%	37%	41%
	Probability of voluntary and involuntary shortage, 2026	49%	35%	36%	12%	37%	41%
	Probability of normal deliveries, 2026	34%	26%	25%	47%	45%	19%
	Probability of surplus, 2026	17%	39%	39%	41%	18%	40%
4.5	Water Quality						
	Temperature at Little Colorado River, July 2026, 50th percentile	12 °C	12 °C	12 °C	13 °C	12 °C	12 °C
	Salinity downstream of Parker Dam, 2026,	621 mg/L	625 mg/L	625 mg/L	633 mg/L	615 mg/L	625 mg/L
	Salinity at Imperial Dam, 2026	740 mg/L	747 mg/L	751 mg/L	760 mg/L	735 mg/L	747 mg/L
4.6	Air Quality						
	Lake Powell 2025, 10th percentile exposed shoreline	17,000 acres	17,000 acres	17,000 acres	22,000 acres	14,000 acres	17,000 acres
	Lake Mead 2025, 10th percentile exposed shoreline	89,000 acres	82,000 acres	83,000 acres	90,000 acres	73,000 acres	82,000 acres

Table ES-2
Summary of Potential Effects of the Alternatives

Final EIS Section	Environmental Consequences by Resource, Year and Value	Alternatives					
		No Action	Basin States	Conservation Before Shortage	Water Supply	Reservoir Storage	Preferred Alternative
4.7	Visual Resources						
	Lake Powell maximum height of calcium carbonate ring, 10th percentile, 2025	148 feet	148 feet	148 feet	192 feet	128 feet	148 feet

Chapter One

1.1 Introduction

During the period from 2000 to 2007, the Colorado River has experienced the worst drought conditions in approximately one hundred years of recorded history. During this period, storage in Colorado River reservoirs has dropped from nearly full to less than 55 percent of capacity as of September 30, 2007. Currently, the Department of the Interior (Department) does not have specific operational guidelines in place to address the operations of Lake Powell and Lake Mead during drought and low reservoir conditions.

Accordingly, the Secretary of the Department of the Interior (Secretary), acting through the Bureau of Reclamation (Reclamation), proposes adoption of specific Colorado River Lower Basin (Lower Basin) shortage guidelines and coordinated reservoir management strategies to address operations of Lake Powell and Lake Mead, particularly under drought and low reservoir conditions. This action is proposed in order to provide a greater degree of certainty to United States Colorado River water users and managers of the Colorado River Basin by providing detailed, and objective guidelines for the operations of Lake Powell and Lake Mead, thereby allowing water users in the Lower Basin to know when, and by how much, water deliveries will be reduced in drought and other low reservoir conditions. The environmental impact statement (EIS) process provides the opportunity to develop the information needed to analyze and consider trade-offs between the frequency and magnitude of shortages, and to describe potential effects on water storage in Lake Powell and Lake Mead, and on water supplies, power production, recreation, and other environmental resources.

The Secretary proposes that these guidelines be interim in duration and extend through 2026. Adoption of these new guidelines, along with modification of existing operational guidelines for a consistent interim period through 2026, will provide the opportunity to gain valuable operating experience for the management of Lake Powell and Lake Mead under modified operations and improve the basis for making additional future operational decisions, whether during the interim period or thereafter.

The Secretary intends to consider, adopt and implement the proposed federal action[1] consistent with applicable federal law and judicial decisions, and, further, in a manner that will not require any additional statutory authorization. In addition, the proposed federal action would be implemented consistent with the Colorado River Compact of 1922 (Compact), the Consolidated Decree entered by the United States Supreme Court in the case of *Arizona v. California*, 547 U.S. 150 (2006) (Consolidated Decree), and other provisions of applicable federal law. The proposed federal action will be implemented through the adoption of interim guidelines that would be used each year by the Department in implementing the Criteria for Coordinated Long-Range Operation of Colorado River Reservoirs Pursuant to the Colorado River Basin Project Act of September 30, 1968 (Long-Range Operating Criteria or LROC) through issuance of the Annual Operating Plan for Colorado River Reservoirs (AOP).

[1] The phrase "proposed federal action" is used herein to refer to the action that the Secretary may take to meet the purpose and need. A range of alternatives, including the Preferred Alternative, are considered and analyzed in this Final EIS.

This Final Environmental Impact Statement (Final EIS) has been prepared pursuant to the National Environmental Policy Act of 1969 (NEPA), as amended, and the Council on Environmental Quality's (CEQ) Regulations for Implementing the Procedural Provisions of NEPA (40 Code of Federal Regulations (C.F.R.) part (pt.) 1500 through 1508). This Final EIS has been prepared to address the formulation and evaluation of the proposed federal action and to identify the potential environmental effects of implementing the proposed federal action.

This Final EIS identifies the potentially relevant environmental issues associated with, and analyzes the environmental consequences of, alternatives for implementing the proposed federal action. The alternatives addressed in this Final EIS are those Reclamation has determined would meet the purpose and need for the proposed federal action and represent a broad range of reasonable alternatives.

1.2 Proposed Federal Action

The proposed federal action includes the adoption of specific interim guidelines for Lower Basin shortages and coordinated operations of Lake Powell and Lake Mead. These interim guidelines would remain in effect for determinations to be made through 2025 regarding water supply and reservoir operating decisions through 2026 and would provide guidance each year in development of the AOP. This proposed federal action considers four operational elements that collectively are designed to address the purpose and need for the proposed federal action; these elements are addressed in each of the alternatives described in Chapter 2.

The interim guidelines would be used by the Secretary to:

1) determine those circumstances under which the Secretary would reduce the annual amount of water available for consumptive use from Lake Mead to the Colorado River Lower Division states (Arizona, California, and Nevada) below 7.5 million acre-feet (maf) (a ''Shortage'') pursuant to Article II(B)(3) of the Consolidated Decree;

2) define the coordinated operations of Lake Powell and Lake Mead to provide improved operation of these two reservoirs, particularly under low reservoir conditions;

3) allow for the storage and delivery, pursuant to applicable federal law, of conserved Colorado River system and non-system water in Lake Mead to increase the flexibility of meeting water use needs from Lake Mead, particularly under drought and low reservoir conditions; and

4) determine those conditions under which the Secretary may declare the availability of surplus water for use within the Lower Division states. The proposed federal action would modify the substance of the existing Interim Surplus Guidelines (ISG), published in the *Federal Register* (Fed. Reg.) on January 25, 2001 (66 Fed. Reg. 7772), and the term of the ISG from 2016 through 2026.

1.3 Purpose of and Need for Action

The purpose of the proposed federal action is to: 1) improve Reclamation's management of the Colorado River by considering the trade-offs between the frequency and magnitude of reductions of water deliveries, and considering the effects on water storage in Lake Powell and Lake Mead, water supply, power production, recreation, and other environmental resources; 2) provide mainstream United States users of Colorado River water, particularly those in the Lower Division states, a greater degree of predictability with respect to the amount of annual water deliveries in future years, particularly under drought and low reservoir conditions; and, 3) provide additional mechanisms for the storage and delivery of water supplies in Lake Mead.

The proposed federal action is needed for the following reasons:

- the Colorado River is of unique and strategic importance in the southwestern United States for water supply, hydropower production, flood control, recreation, fish and wildlife habitat, and other benefits. In addition, the United States has a delivery obligation to the United Mexican States (Mexico) for certain waters of the Colorado River pursuant to the February 3, 1944 Treaty between the United States and Mexico Relating to the Utilization of the Waters of the Colorado and Tijuana Rivers and of the Rio Grande (1944 Treaty);

- the eight-year period from 2000 through 2007 was the driest eight-year period in the 100-year historical record of the Colorado River; this drought in the Colorado River Basin has reduced Colorado River system storage, while demands for Colorado River water supplies have continued to increase. From October 1, 1999 through September 30, 2007, storage in Colorado River reservoirs fell from 55.8 maf (approximately 94 percent of capacity) to 32.1 maf (approximately 54 percent of capacity), and was as low as 29.7 maf (approximately 52 percent of capacity) in 2004. This drought was the first sustained drought experienced in the Colorado River Basin at a time when all major storage facilities were in place, and when use by the Lower Division states met or exceeded the annual "normal" apportionment of 7.5 maf pursuant to Article II(B)(1) of the Consolidated Decree. These conditions, among other factors, led the Department to conclude that additional management guidelines are necessary and desirable for the efficient management of the major mainstream Colorado River reservoirs;

- in the future, low reservoir conditions may occur more frequently due to drought periods and anticipated future demands on Colorado River water supplies;

- as a result of actual operating experience and through reviews of the LROC and preparation of AOPs, particularly during recent drought years, the Secretary has determined a need for more specific guidelines, consistent with the Consolidated Decree and other applicable provisions of federal law to assist in the Secretary's determination of annual water supply conditions in the Lower Basin under low reservoir conditions. This increased level of predictability is needed by water managers and the entities that receive Colorado River water to better plan for and manage available water supplies, and to better integrate the use of Colorado River water with other water supplies that they rely on;

- to date, storage of water and flows in the Colorado River has been sufficient so that it has not been necessary to reduce Lake Mead annual releases below 7.5 maf; that is, the Secretary has never reduced deliveries by declaring a "shortage" on the lower Colorado River. Without operational guidelines in place, water users in the Lower Division states who rely on Colorado River water are not currently able to identify particular reservoir conditions under which the Secretary would reduce the annual amount of water available for consumptive use from Lake Mead to the Lower Division states below 7.5 maf. Nor are these water users able to identify the frequency or magnitude of any potential future annual reductions in their water deliveries;

- subsequent to the public consultation meetings held in the summer of 2005, the Secretary has also determined the desirability of developing additional operational guidelines that will provide for releases greater than or less than 8.23 maf from Lake Powell; and

- to further enhance this coordinated reservoir approach, the Secretary has also determined a need for guidelines that provide water users in the Lower Division states the opportunity to conserve, store, and take delivery of water in and from Lake Mead for the purposes of enhancing existing water supplies, particularly under low reservoir conditions. The Secretary has determined the need to modify and extend the ISG to coincide with the duration of the proposed new guidelines. This will provide an integrated approach for reservoir management and more predictability for future Lower Division water supplies.

1.4 Lead and Cooperating Agencies

The Secretary is responsible for the operation of Glen Canyon Dam and Hoover Dam pursuant to applicable federal law. The Secretary is also vested with the responsibility of managing the mainstream waters of the lower Colorado River pursuant to federal law. This responsibility is carried out consistent with the Law of the River.[2] Reclamation, as the agency that is designated to act on the Secretary's behalf with respect to these matters, is the lead federal agency for the purposes of NEPA compliance for the development and implementation of the proposed interim guidelines.

---

[2] The treaties, compacts, decrees, statutes, regulations, contracts and other legal documents and agreements applicable to the allocation, appropriation, development, exportation and management of the waters of the Colorado River Basin are often referred to as the Law of the River. There is no single, universally agreed upon definition of the Law of the River, but it is useful as a shorthand reference to describe this longstanding and complex body of legal agreements governing the Colorado River.

Five federal agencies are cooperating for purposes of assisting with environmental analysis and preparation of this Final EIS. These cooperating agencies are the Bureau of Indian Affairs (BIA), the United States Fish and Wildlife Service (FWS), the National Park Service (NPS), Western Area Power Administration (Western), and the United States Section of the International Boundary and Water Commission (USIBWC).

The BIA has responsibility for the administration and management of lands held in trust by the United States for American Indians (Indian) and Indian tribes located within the Colorado River Basin (a list of these Indian tribes is provided in Chapter 6). Developing forestlands, leasing assets on these lands, directing agricultural programs, protecting water and land rights, developing and maintaining infrastructure and economic development are all part of the BIA's responsibility.

The FWS is involved in the conservation, protection and enhancement of fish, wildlife, and plants and their habitats for the continuing benefit of the American people. FWS manages four national wildlife refuges along the Colorado River. Among its many other key functions, the FWS administers and implements federal wildlife laws, protects endangered species, manages migratory birds, restores nationally significant fisheries, conserves and restores wildlife habitat such as wetlands, and assists foreign governments with international conservation efforts. It also oversees the federal aid program that distributes hundreds of millions of dollars in excise taxes on fishing and hunting equipment to state fish and wildlife agencies.

The NPS administers areas of national significance along the Colorado River, including Glen Canyon National Recreation Area (GCNRA), Grand Canyon National Park, and Lake Mead National Recreation Area (LMNRA). The NPS administers visitor use (including recreation) of cultural and natural resources in these areas from offices located at Page, Arizona; Grand Canyon National Park, Arizona; and Boulder City, Nevada, respectively. The NPS also grants and administers concessions for the operation of marinas and other recreation facilities at Lake Powell and Lake Mead, as well as concessions' operations along the Colorado River between Glen Canyon Dam and Lake Mead.

Western markets and distributes hydroelectric power and related services within a 15-state region of the central and western United States and it is one of four power marketing administrations within the Department of Energy. Its role is to market and transmit electricity from multi-use water projects. Western markets and transmits power generated from the various hydropower plants located within the Colorado River Basin and operated by Reclamation. Western customers include municipalities, cooperatives, public utility and irrigation districts, federal and state agencies, investor-owned utilities (only one of which purchases firm power from Western), and Indian tribes located throughout the Colorado River Basin. The wholesale customers, in turn, provide retail electric service to millions of consumers within the seven Colorado River Basin States (Basin States).

The USIBWC is the United States component of a bi-national organization responsible for administration of the provisions of the 1944 Treaty, which includes the Colorado River waters allotted to Mexico, protection of lands along the Colorado River from floods by levee and floodway construction projects, resolution of international boundary water sanitation and other water quality problems, and preservation of the Colorado River as the international boundary.

The International Boundary and Water Commission (IBWC) consists of the United States Section and the Mexican Section, which have their headquarters in the adjoining cities of El Paso, Texas and Ciudad Juarez, Chihuahua, respectively.

1.5 Scope of the EIS

In a May 2, 2005 letter to the Governors of the Basin States, issued to complete the 2005 AOP mid-year review, the Secretary directed Reclamation to develop additional strategies for improving coordinated management of the reservoirs of the Colorado River system. Pursuant to that direction, Reclamation conducted a public consultation workshop on May 26, 2005, in Henderson, Nevada; issued a *Federal Register* notice on June 15, 2005 soliciting public comments; and conducted public meetings on July 26 and July 28, 2005, in Henderson, Nevada, and Salt Lake City, Utah, respectively. Reclamation received a broad range of public comments and suggestions from these discussions. Based in part on comments received from the public, Reclamation determined that the appropriate level of NEPA documentation for the development of Lower Basin shortage guidelines and coordinated management strategies for the operations of Lake Powell and Lake Mead under low reservoir conditions would be in the form of an EIS.

Consequently, on September 30, 2005, Reclamation published a Notice of Intent (NOI) (70 Fed. Reg. 57322) to prepare an EIS. The NOI described the proposed federal action as having two major elements: 1) adoption of specific Lower Basin shortage guidelines; and 2) developing coordinated reservoir management strategies to address operations of Lake Powell and Lake Mead under low reservoir conditions. The NOI also initiated a public process for determining the scope of specific shortage guidelines and coordinated reservoir management strategies and the issues and alternatives to be considered and analyzed in the preparation of the EIS.

Reclamation conducted public scoping meetings on November 1, 2, 3, and 8, 2005, in Salt Lake City, Utah; Denver, Colorado; Phoenix, Arizona; and Henderson, Nevada, respectively. Reclamation also consulted with representatives from the Basin States, Indian tribes, non-governmental organizations (NGO), and other interested parties. Reclamation provided a 62-day comment period consistent with the Public Notice issued on September 30, 2005. The public comment period ended on November 30, 2005.

On March 31, 2006, Reclamation published a Scoping Summary Report on the development of Lower Basin shortage guidelines and coordinated management strategies for the operations of Lake Powell and Lake Mead and issued a Notice of Availability (NOA) (71 Fed. Reg. 16341). The report summarized the comments received and the issues raised through the scoping process and provided an assessment of the proposed scope of the environmental analysis to be included in the EIS.

A total of 1,153 written comment letters were received during the scoping process. The comment letters were submitted by a wide range of interested parties that included federal, state, and local agencies; Indian tribes; businesses; special interest groups; and individuals.

On February 28, 2007, Reclamation published a NOA (72 Fed. Reg. 9026) for the Draft EIS which commenced a 61-day public review period that ended on April 30, 2007. As part of this review process, Reclamation conducted three public hearings on April 3, 4, and 5, 2007. The hearings took place in Henderson, Nevada; Phoenix, Arizona; and Salt Lake City, Utah, respectively, to invite public input on the Draft EIS. Additionally, a Modeling Workshop was held on March 6, 2007 in Henderson, Nevada to provide the public with information on the modeling performed and used in the Draft EIS to analyze the potential impacts of hydrologic resources and water deliveries. A total of 78 written comment letters were received during the scoping process and two individuals provided oral comments during the public hearings. The comment letters were submitted by a wide-range of interested parties that included businesses; federal, state and local agencies; Indian tribes; special interest groups; and individuals. Volume IV contains reproductions of letters received from the public and transcripts of the three public hearings held in connection with the public review of the Draft EIS and Reclamation's responses to the comments received.

1.5.1 Affected Region and Interests

The geographic region that would be affected by the proposed federal action begins with Lake Powell and extends downstream along the Colorado River floodplain to the Southerly International Boundary (SIB) with Mexico. This proposed federal action would also potentially affect interests of organizations and individuals, whose geographic distribution extends beyond the Colorado River floodplain into the service areas of certain water agencies in the Lower Basin states.

1.5.2 Relevant Issues

The results of the scoping process resulted in Reclamation considering the issues listed in Table 1.5-1. Those issues considered to be potentially significant are addressed in this Final EIS. Those that were not considered potentially significant are not analyzed in this Final EIS.

1.6 Summary of Contents of this Final EIS

Following is a brief description of the topics presented in the four volumes that comprise this Final EIS.

Volume I of this Final EIS (this volume) describes the proposed federal action, the alternatives considered, the analysis of the potential effects of these alternatives on Colorado River operations and associated resources, and environmental commitments associated with the alternatives. The contents of the chapters in this volume are as follows:

- **Chapter 1, Purpose and Need,** includes the following: identification of the purpose of and need for Lower Basin shortage guidelines and coordinated reservoir management strategies of Lake Powell and Lake Mead being considered in the proposed federal action; background information concerning the apportionment of Colorado River waters and the physical facilities associated with the Colorado River Basin; and, discussion of the institutional framework within which the Colorado River Basin is managed. Chapter 1 also discusses previous and ongoing actions that have a relationship to the proposed federal action.

Table 1.5-1
Relevant Issues

Resource	Potentially Significant	Issue Areas
Physical		
Geology and soils	No	No potential for effect
Climate	No	No potential for effect
Minerals	No	No potential for effect
Visual	Yes	Calcium carbonate ring in reservoirs, attraction features, sediment deltas
Unique characteristics	Yes	Wilderness, wild and scenic rivers, park units
Water resources	Yes	Hydrology, water deliveries, groundwater, operations, water quality
Air quality	Yes	Fugitive dust and exposure of reservoir shoreline
Noise	No	No potential for effect
Biological Resource		
Aquatic resources	Yes	Foodbase, fish
Vegetation	Yes	Riparian, wetlands, weeds
Wildlife	Yes	Amphibians, reptiles, raptors, mammals, waterfowl
Special-status species	Yes	Threatened and endangered species, state and tribal sensitive
Socioeconomic		
Environmental justice	Yes	Disproportionate effects on minority and low income populations
Land use	Yes	Relationship to local and state planning documents; agriculture, fallowing, prime farmland
Cultural resources	Yes	Historic properties
Indian Trust Assets	Yes	Water rights and trust lands
Energy and hydropower	Yes	Economic analysis and capacity
Population and housing	No	No potential for effect
Recreation	Yes	Marinas, boating, fishing, camping
Transportation, traffic	Yes	Ferries in Lake Powell, Lake Mohave
Water rights	No	The proposed federal action does not affect water rights. The EIS evaluates potential reductions in water deliveries pursuant to the existing framework of water rights and statutes.

- **Chapter 2, Description of Alternatives,** describes the process of formulating alternatives and presents a range of reservoir operation strategies and guidelines considered under each alternative. A summary table of potential environmental consequences of these alternatives is provided at the end of Chapter 2.

- **Chapter 3, Affected Environment,** describes the affected environment for the proposed federal action.

- **Chapter 4, Environmental Consequences,** presents evaluations of potential impacts that could result from implementation of the alternatives under consideration. The discussion also addresses environmental consequences, i.e., potential effects of the action alternatives that could occur as compared to the No Action Alternative.

- **Chapter 5, Other Considerations and Cumulative Impacts,** discusses cumulative impacts, the relationship between short-term uses and long-term productivity, and irreversible and irretrievable commitments of resources affected by the reservoir operation strategies and guidelines under consideration.

- **Chapter 6, Consultation and Coordination,** describes the public involvement process, including public notices, scoping meetings, and hearings. This chapter also describes the coordination with federal and state agencies, Indian tribes, and Mexico (through the IBWC) during the preparation of this document and any permitting or approvals that may be necessary for implementation of the proposed federal action.

In addition to the above, Volume I includes a list of acronyms used throughout this document, a glossary of commonly used terms, a list of references cited in the Final EIS, a list of persons contributing to the preparation of the Final EIS, a distribution list of agencies, organizations and persons receiving copies of the document, and an index.

Volumes II and III contain appendices which are comprised of documents and other supporting material that provide detailed historical background and/or technical information concerning the proposed federal action.

Volume IV contains reproductions of letters received from the public review of the Draft EIS and Reclamation's responses to the comments received. Volume IV also contains copies of the transcripts of three public hearings.

1.7 Water Supply Management and Allocation

This section summarizes the water supply available in the Colorado River Basin from natural runoff, distribution of this water under the Law of the River, and the reservoirs and diversion facilities through which the water supply is administered from mainstream Colorado River reservoirs and associated facilities.

1.7.1 Colorado River System Water Supply

The Colorado River Basin is located in the southwestern United States, as shown on Figure 1.7-1, and occupies an area of approximately 250,000 square miles. The Colorado River is approximately 1,400 miles in length and originates along the Continental Divide in Rocky Mountain National Park in Colorado. Elevations in the Colorado River Basin range from sea level to over 14,000 feet above mean sea level (msl) in the mountainous headwaters.

Climate varies significantly throughout the Colorado River Basin. Most of the Colorado River Basin is arid and semi-arid, and generally receives less than ten inches of precipitation per year. In contrast, many of the mountainous areas that rim the northern portion of the Colorado River Basin receive, on average, over 40 inches of precipitation per year.

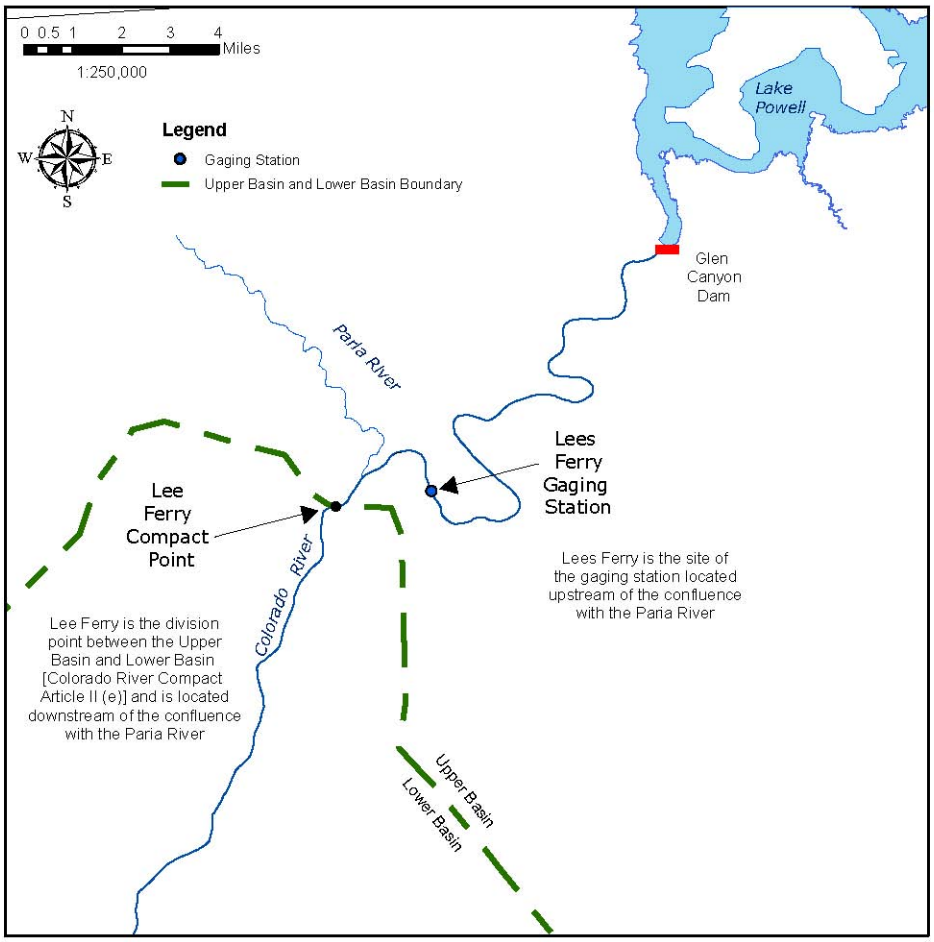
Most of the total annual flow in the Colorado River Basin is a result of natural runoff from mountain snowmelt. Because of this, natural flow is very high in the late spring and early summer, diminishing rapidly by mid-summer. While flows in late summer through autumn sometimes increase following rain events, natural flow in the late summer through winter is generally low. Major tributaries to the Colorado River include the Green River, San Juan River, Yampa River, Gunnison River, and Gila River.

Figure 1.7-1
The Colorado River Basin

The annual flow of the Colorado River and its tributaries varies considerably from year to year. The natural flow at the Lees Ferry Gaging Station in Arizona (Figure 1.7-2) located 15.9 river miles (RMs) downstream of Glen Canyon Dam, has varied annually from 5 maf to 23 maf. Natural flow represents an estimate of flows that would exist without human intervention.

The average annual natural flow at Lees Ferry Gaging Station is approximately 15.1 maf. In the Lower Basin, the average annual natural flow from the Little Colorado River, Virgin River, and Bill Williams River is approximately 1.4 maf.

Figure 1.7-2
Lees Ferry Gaging Station and Lee Ferry Compact Point



1.7.2 Apportionment of Water Supply

This section summarizes the Law of the River, Colorado River apportionments of the Basin States, and the allotment to Mexico pursuant to the 1944 Treaty.

1.7.2.1 The Law of the River

The Secretary is vested with the responsibility to manage the mainstream waters of the Lower Basin pursuant to applicable federal law. This responsibility is carried out consistent with a body of documents referred to as the Law of the River. The Law of the River comprises numerous operating criteria, regulations, and administrative decisions included in federal and state statutes, interstate compacts, court decisions and decrees, an international treaty, and contracts with the Secretary.

Particularly notable among these documents are:

1) the Colorado River Compact of 1922, which apportioned beneficial consumptive use of water between the Colorado River Upper Basin and Lower Basin;

2) the Boulder Canyon Project Act of 1928 (BCPA), which authorized construction of Hoover Dam and the All-American Canal (AAC), required that water users in the Lower Basin have a contract with the Secretary, and established the responsibilities of the Secretary to direct, manage, and coordinate the operation of Colorado River dams and related works in the Lower Basin;

3) the California Seven Party Agreement of 1931, which, through regulations adopted by the Secretary, established the relative priorities of rights among major users of Colorado River water in California;

4) the 1944 Treaty (and subsequent minutes of the IBWC) related to the quantity and quality of Colorado River water delivered to Mexico;

5) the Upper Colorado River Basin Compact of 1948, which apportioned the Upper Basin water supply among the Upper Basin states;

6) the Colorado River Storage Project Act of 1956 (CRSPA), which authorized a comprehensive water development plan for the Upper Basin that included the construction of Glen Canyon Dam and other facilities;

7) the 1963 United States Supreme Court Decision in *Arizona v. California* which confirmed that the apportionment of the Lower Basin tributaries was reserved for the exclusive use of the states in which the tributaries are located; confirmed the Lower Basin mainstream apportionments of 2.8 maf for use in Arizona, 4.4 maf for use in California, and 0.3 maf for use in Nevada; provided water for Indian reservations and other federal reservations in Arizona, California, and Nevada; and confirmed the significant role of the Secretary in managing the mainstream Colorado River within the Lower Basin;

8) the 1964 United States Supreme Court Decree (Decree) in *Arizona v. California* which implemented the Supreme Court's 1963 decision; the Decree was supplemented over time after its adoption and the Supreme Court entered a Consolidated Decree in 2006 which incorporates all applicable provisions of the earlier-issued Decrees;

9) the Colorado River Basin Project Act of 1968 (CRBPA), which authorized construction of a number of water development projects including the Central

Arizona Project (CAP) and required the Secretary to develop the LROC and issue an AOP for mainstream reservoirs;

10) the Colorado River Basin Salinity Control Act of 1974, which authorized a number of salinity control projects and provided a framework to improve and meet salinity standards for the Colorado River in the United States and Mexico; and

11) the Grand Canyon Protection Act of 1992, which addressed the protection of resources in Grand Canyon National Park and in GCNRA, consistent with applicable federal law.

Documents which are generally considered as part of the Law of the River include, but are not limited to, those listed in Table 1.7-1. Among other provisions of applicable federal law, NEPA and the Endangered Species Act of 1973 (ESA), as amended, provide a statutory overlay on certain actions taken by the Secretary. For example, as noted in Section 1.1, preparation of this Final EIS has been undertaken pursuant to NEPA.

1.7.2.2 Apportionment to the Basin States

The initial apportionment of water from the Colorado River was determined as part of the Compact, which divided the Colorado River system into two sub-basins, the Upper Basin and the Lower Basin (Figure 1.7-1). The Upper Basin includes those parts of the states of Arizona, Colorado, New Mexico, Utah, and Wyoming within and from which waters drain naturally into the Colorado River above the Lee Ferry Compact Point in Arizona. The Lower Basin includes those parts of the states of Arizona, California, Nevada, New Mexico, and Utah within and from which waters drain naturally into the Colorado River below the Lee Ferry Compact Point. The Compact also divided the seven Basin States into the Upper Division and the Lower Division states (Figure 1.7-3). The Upper Division states are Colorado, New Mexico, Utah and Wyoming. The Lower Division states are Arizona, California, and Nevada.

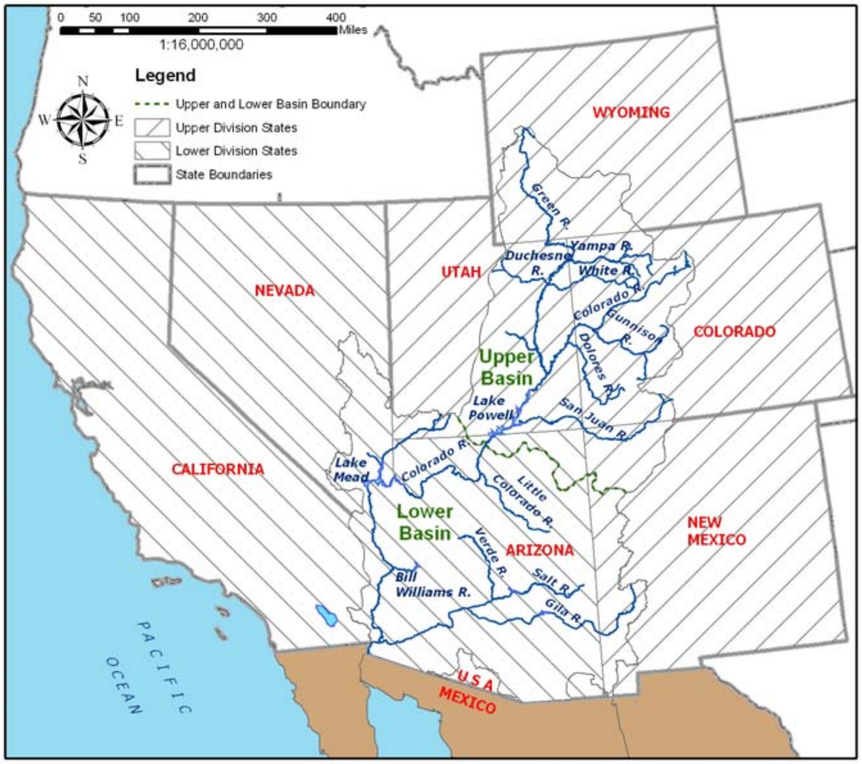
The Compact apportioned to the Lower Basin states and the Upper Basin states, in perpetuity, the exclusive beneficial consumptive use of 7.5 maf of water per year (mafy). In addition to this apportionment, Article III(b) of the Compact gives the Lower Basin states the right to increase their beneficial consumptive use by 1.0 mafy. The Compact also stipulates in Article III(d) that the Upper Division states will not cause the flow of the river at the Lee Ferry Compact Point to be depleted below an aggregate of 75 maf for any period of ten consecutive years.

The Compact, in Article VII, states that nothing in the Compact shall be construed as affecting the obligations of the United States to Indian tribes. While the rights of most Indian tribes to Colorado River water were subsequently adjudicated, some Tribal rights remain unadjudicated. To the extent that Indian tribes consumptively use water from the Colorado River, such uses are included in the apportionment of the appropriate Basin State.

Table 1.7-1
Selected Documents Included in the Law of the River

- The River and Harbor Act of March 3, 1899
- The Reclamation Act of June 17, 1902
- Reclamation of Indian Lands in Yuma, Colorado River and Pyramid Lake Indian Reservations Act of April 21, 1904
- Yuma Project authorized by the Secretary of the Interior on May 10, 1904, pursuant to Section 4 of the Reclamation Act of June 17, 1902
- Warren Act of February 21, 1910
- Protection of Property Along the Colorado River Act of June 25, 1910
- Patents and Water-Right Certificates Acts of August 9, 1912 and August 26, 1912
- Yuma Auxiliary Project Act of January 25, 1917
- Availability of Money for Yuma Auxiliary Project Act of February 11, 1918
- Sale of Water for Miscellaneous Purposes Act of February 25, 1920
- Federal Power Act of June 10, 1920
- The Colorado River Compact of November 24, 1922
- The Colorado River Front Work and Levee System Acts of March 3, 1925 and January 21,1927-June 28, 1946
- The Boulder Canyon Project Act of December 21, 1928
- The California Limitation Act of March 4, 1929
- The California Seven Party Agreement of August 18, 1931
- The Parker and Grand Coulee Dams Authorization of August 30, 1935
- The Parker Dam Power Project Appropriation Act of May 2, 1939
- The Reclamation Project Act of August 4, 1939
- The Boulder Canyon Project Adjustment Act of July 19, 1940
- The Flood Control Act of December 22, 1944
- Treaty between the United States and Mexico Relating to the Utilization of the Waters of the Colorado and Tijuana Rivers and of the Rio Grande of February 3, 1944
- Gila Project Act of July 30, 1947
- The Upper Colorado River Basin Compact of October 11, 1948
- Consolidated Parker Dam Power Project and Davis Dam Project Act of May 28, 1954
- Palo Verde Diversion Dam Act of August 31, 1954
- Change Boundaries, Yuma Auxiliary Project Act of February 15, 1956
- The Colorado River Storage Project Act of April 11, 1956
- Water Supply Act of July 3, 1958
- Boulder City Act of September 2, 1958
- Report of the Special Master, Simon H. Rifkind, *Arizona v. California*, et al., December 5, 1960
- The Consolidated Decree entered by the United States Supreme Court in the case of *Arizona v. California*, 547 U.S. 150 (2006) (Consolidated Decree)
- International Flood Control Measures, Lower Colorado River Act of August 10, 1964
- Southern Nevada (Robert B. Griffith) Water Project Act of October 22, 1965
- The Colorado River Basin Project Act of September 30, 1968
- Criteria for the Coordinated Long Range Operation of Colorado River Reservoirs, June 8, 1970, Amended March 21, 2005
- Supplemental Irrigation Facilities, Yuma Division Act of September 25, 1970
- 43 C.F.R. pt. 417 Lower Basin Water Conservation Measures, September 7, 1972
- Minute 218, March 22, 1965; Minute 241, July 14, 1972, (replaced 218); and Minute 242, August 30, 1973, (replaced 241); Minute 306, December 12, 2000 of the IBWC
- The Colorado River Basin Salinity Control Act of June 24, 1974
- Hoover Power Plant Act of August 17, 1984
- The Numerous Colorado River Water Delivery and Project Repayment Contracts with the States of Arizona and Nevada, cities, water districts and individuals
- Hoover and Parker-Davis Power Marketing Contracts
- Reclamation States Emergency Drought Relief Act of 1991
- Grand Canyon Protection Act of October 30, 1992
- Operation of Glen Canyon Dam, Record of Decision (1996)
- Interim Surplus Guidelines Record of Decision, January 17, 2001 (66 Fed. Reg. 7772).
- Interim 602(a) Storage Guideline, May 19, 2004 (69 Fed. Reg. 28945)
- Colorado River Water Delivery Agreement of October 10, 2003 (69 Fed. Reg. 12202)

Figure 1.7-3
Upper and Lower Division States of the Colorado River



Upper Division State Apportionments. Upper Division state apportionments were established by the Upper Colorado River Basin Compact of 1948. These apportionments allocate the Upper Basin states consumptive use after deduction of up to 50,000 acre-feet per year (afy) for Arizona as follows: Colorado, 51.75 percent; New Mexico, 11.25 percent; Utah, 23.00 percent; and Wyoming, 14.00 percent. The Upper Basin state apportionments have not yet been fully developed.

Lower Division State Apportionments. Lower Division state apportionments were established by Congress in the BCPA and by the Secretary's water delivery contracts under the BCPA. These apportionments are: Arizona, 2.8 maf; California, 4.4 maf; and Nevada, 0.3 maf; totaling 7.5 maf, subject to annual increases or reductions pursuant to Secretarial determinations of a Surplus or a Shortage condition. Under Article II(B)(2) of the Consolidated Decree, when the Secretary determines that there is a Surplus Condition, 46 percent of the available water supply in excess of 7.5 maf may be apportioned for use in Arizona; 50 percent for use in California; and four percent for use in Nevada.

Figure 1.7-4 presents a schematic of the operation of the Colorado River, primarily in the Lower Basin. The Consolidated Decree confirms the apportionments to the Lower Division states established by the BCPA and guides the Secretary's operation of facilities, including Hoover Dam, on the lower Colorado River. If water apportioned for use in a Lower Division state is not consumed by that state in any year, the Secretary may release the unused water for use in another Lower Division state. Water that is stored off-stream by a Lower Division state (for future use by that state or by another Lower Division state) is accounted as consumptive use to the state that stored the water in the year it was stored.

All mainstream Colorado River waters apportioned to the Lower Basin, except for a few thousand acre-feet (af) apportioned for use in Arizona, have been fully allocated to specific entities and, except for certain federal establishments, placed under permanent water delivery contracts with the Secretary for irrigation or domestic use. These entities include irrigation districts, water districts, municipalities, Indian tribes, public institutions, private water companies, and individuals. Federal establishments with federal reserved rights established pursuant to Article II(D) of the Consolidated Decree are not required to have a contract with the Secretary, but the water allocated to a federal establishment is included within the apportionment of the Lower Division state in which the federal establishment is located; e.g., Fort Mojave Indian Reservation in California and the Havasu National Wildlife Refuge in Arizona.

The highest priority lower Colorado River water rights are present perfected rights (PPRs), which the Consolidated Decree defines as those perfected rights existing on June 25, 1929, the effective date of the BCPA. The Consolidated Decree also recognizes federal Indian reserved rights for the quantity of water necessary to irrigate all the practicably irrigable acreage (lands considered suitable for irrigation) on five Indian reservations along the lower Colorado River. The Consolidated Decree defines the rights of Indian and other federal reservations to be federal establishment PPRs. PPRs are important because in any year in which less than 7.5 maf of Colorado River water is available for consumptive use in the Lower Division states, PPRs will be satisfied first, in the order of their priority without regard to state lines.

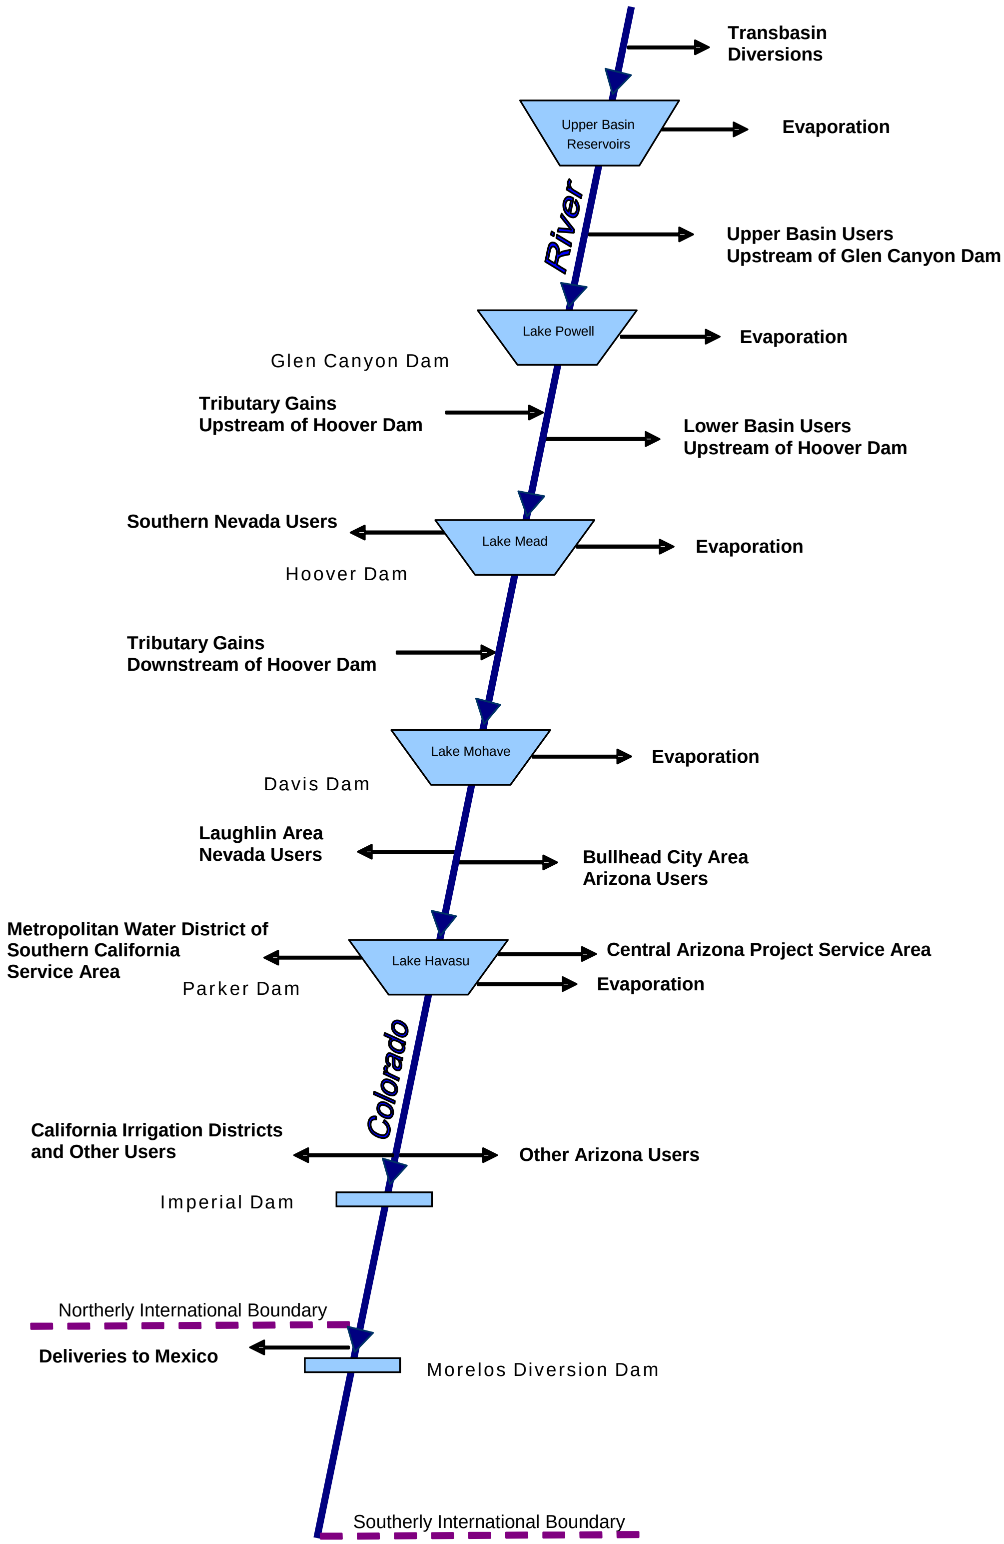
Waters available to a Lower Division state within its apportionment, but having a priority date later than June 25, 1929, have been allocated by the Secretary through execution of water delivery contracts to water users within that state as required by Section 5 of the BCPA.

1.7.2.3 Allotment to Mexico (Pursuant to the 1944 Treaty)

Allocation of Colorado River water to Mexico is governed by the 1944 Treaty. Article 10(a) of the 1944 Treaty states:

> "(a) A guaranteed annual quantity of 1,500,000 acre-feet (1,850,234,000 cubic meters) to be delivered in accordance with the provisions of Article 15 of this Treaty"

Figure 1.7-4
Colorado River Reservoirs and Diversions



Further, Article 10(b) of the 1944 Treaty provides:

> "(b) Any other quantities arriving at the Mexican points of diversion, with the understanding that in any year in which, as determined by the United States Section, there exists a surplus of waters of the Colorado River in excess of the amount necessary to supply uses in the United States and the guaranteed quantity of 1,500,000 acre-feet (1,850,234,000 cubic meters) annually to Mexico, the United States undertakes to deliver to Mexico, in the manner set out in Article 15 of this Treaty, additional waters of the Colorado River system to provide a total quantity not to exceed 1,700,000 acre-feet (2,096,931,000 cubic meters) a year. Mexico shall acquire no right beyond that provided by this subparagraph by the use of waters of the Colorado River system, for any purpose whatsoever, in excess of 1,500,000 acre-feet (1,850,234,000 cubic meters) annually."

Additionally, Article 10 of the 1944 Treaty provides:

> "In the event of extraordinary drought or serious accident to the irrigation system in the United States, thereby making it difficult for the United States to deliver the guaranteed quantity of 1,500,000 acre-feet (1,850,234,000 cubic meters) a year, the water allotted to Mexico under subparagraph (a) of this Article will be reduced in the same proportion as consumptive uses in the United States are reduced."

The proposed federal action is for the purpose of adopting additional operational guidelines to improve the Department's annual management and operation of key Colorado River reservoirs for an interim period through 2026. However, in order to assess the potential effects of the proposed federal action in this Final EIS, certain modeling assumptions (discussed in Chapter 2) are used that display projected water deliveries to Mexico. Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 Treaty or to represent current United States policy or a determination of future United States policy regarding deliveries to Mexico.

The United States will conduct all necessary and appropriate discussions regarding the proposed federal action and implementation of the 1944 Treaty with Mexico through the IBWC in consultation with the Department of State.

1.7.3 System Reservoirs and Diversion Facilities

The Colorado River system contains numerous reservoirs that provide an aggregate of approximately 60 maf of storage (or roughly the same amount of four years' of average flow of the Colorado River). Of these reservoirs, Lake Powell and Lake Mead provide approximately 85 percent of this storage. Lake Powell provides 24.3 maf of this storage.

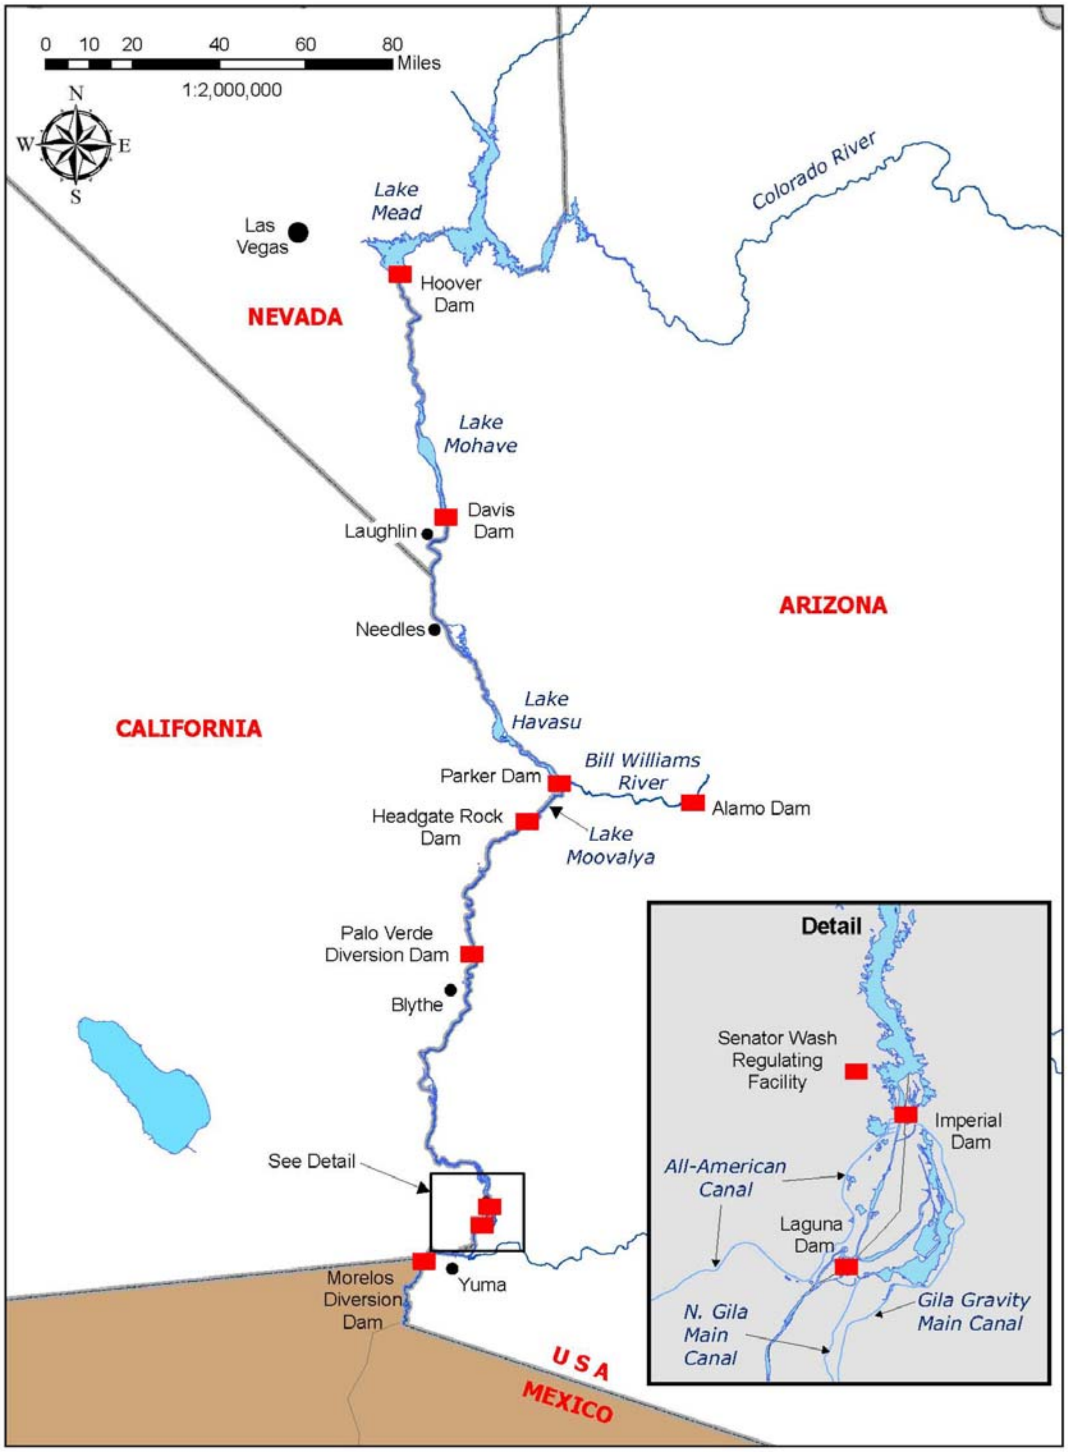
The Lower Basin dams and reservoirs include Hoover Dam, Davis Dam, and Parker Dam (Figure 1.7-5). Hoover Dam created Lake Mead and can store up to 26.2 maf. Davis Dam was constructed by Reclamation to re-regulate Hoover Dam's releases and to aid in the annual delivery of 1.5 maf to Mexico. Davis Dam created Lake Mohave and provides 1.8 maf of storage. Parker Dam forms Lake Havasu (0.65 maf of storage) from which water is pumped by both Metropolitan Water District of Southern California (MWD) and the CAP. Parker Dam re-regulates releases from Davis Dam and from the United States Army Corps of Engineers' (USACE) Alamo Dam on the Bill Williams River, and in turn releases water for downstream use in the United States and Mexico. Other Lower Basin mainstream reservoirs, shown on Figure 1.7-5, are operated primarily for the purpose of river flow regulation to facilitate diversion of water to Arizona, California and Mexico. Diversion facilities of the Lower Division states typically serve multiple entities.

There are several points of diversion in Arizona. Arizona can use up to 50,000 afy of water under its Upper Basin apportionment. In the Lower Basin, the largest diversion for Arizona is the CAP pumping plant on Lake Havasu downstream of the confluence of the Bill Williams River. Irrigation water for the Fort Mojave Indian Reservation, near Needles, California, is pumped from wells. There are also several other municipal, industrial and agricultural water users located along the Colorado River that pump their water from wells. Irrigation water for the Colorado River Indian Reservation near Parker, Arizona, is diverted at Headgate Rock Dam, which was constructed for that purpose. A river pumping plant in the Cibola area provides water to irrigate lands adjacent to the Colorado River. The last major diversion for Arizona occurs at Imperial Dam, where water is diverted into the Gila Gravity Main Canal for irrigation for the Gila and Wellton-Mohawk projects and into the AAC for subsequent release into the Yuma Main Canal for the Yuma Project and the City of Yuma.

California receives most of its Colorado River water at three diversion points: MWD's pumping plant on Lake Havasu; the Palo Verde Irrigation District's diversion at the Palo Verde Diversion Dam near Blythe, California; and the AAC diversion at Imperial Dam (Figure 1.7-5).

In Nevada, the state's consumptive use apportionment of Colorado River water is used almost exclusively for municipal and industrial (M&I) purposes. About 90 percent of this water is diverted from Lake Mead at a point approximately five miles northwest of Hoover Dam at Saddle Island by the Southern Nevada Water Authority (SNWA) facilities. The remainder of Nevada's diversion occurs downstream of Davis Dam in the Laughlin, Nevada area and on the Fort Mojave Indian Reservation.

Figure 1.7-5
Lower Basin Dams and Reservoirs



1.7.4 Flood Control Operation

Under the BCPA, flood control is specified as the project purpose having first priority for the operation of Hoover Dam. Subsequently, Section 7 of the Flood Control Act of 1944 established that the Secretary of War (now the United States Army Corps of Engineers) will prescribe regulations for flood control for projects authorized wholly or partially for such purposes.

The Los Angeles District of the USACE published the current flood control regulations in its Water Control Manual for Flood Control, Hoover Dam and Lake Mead, Colorado River, Nevada and Arizona (Water Control Manual) dated December 1982. The Field Working Agreement between the USACE and Reclamation for the flood control operation of Hoover Dam and Lake Mead, as prescribed by the Water Control Manual, was signed on February 8, 1984. The flood control plan is the result of a coordinated effort between the USACE and Reclamation; however, the USACE is responsible for providing the flood control regulations and has authority for final approval. The Secretary is responsible for operating Hoover Dam in accordance with these regulations. Deviation from the flood control operating criteria must be authorized by the USACE.

1.7.5 Hydropower Generation

Reclamation is authorized by legislation to produce electric power at Glen Canyon Dam, Hoover Dam, Davis Dam, Parker Dam, and other smaller facilities. While Reclamation is the federal agency authorized to produce power at the major Colorado River system dams, Western is the federal agency authorized to market and deliver this power. Western enters into electric service contracts on behalf of the United States with public and private utility systems for distribution of hydroelectric power produced at Reclamation facilities in excess of project demand.

1.7.6 Annual Operating Plan and Long Range Operating Criteria

The CRBPA required the Secretary to adopt operating criteria for the Colorado River by January 1, 1970. The LROC, adopted in 1970 address operation of the Colorado River reservoirs in compliance with requirements set forth in the Compact, the CRSPA, the BCPA, the 1944 Treaty, and other applicable federal laws. Section 602 of the CRBPA, as amended, provides that the LROC can only be modified after correspondence with the governors of the Basin States and appropriate consultation with such state representatives as each governor may designate. The LROC calls for formal reviews at least every five years. The reviews are conducted as a public involvement process and are attended by representatives of federal agencies, the seven Basin States, Indian tribes, the general public including representatives of the academic and scientific communities, environmental organizations, the recreation industry, and contractors for the purchase of federal power produced at federal hydropower plants in the Colorado River Basin.

Under the applicable provisions of the CRBPA, the Secretary makes annual determinations in the AOP regarding the availability of Colorado River water for deliveries to the Lower Division states. A requirement to equalize storage between Lake Powell and Lake Mead when there is sufficient storage in the Upper Basin is also included in the LROC, as required by the CRBPA. Equalization releases are made if: 1) the end of the water year storage forecast for Lake Powell is greater than that of Lake Mead; and 2) the storage forecast for the end of the water year in the Upper Basin reservoirs is greater than the quantity of storage required by Section 602(a) of the CRBPA (602(a) storage) for that same date.

The 602(a) storage quantity is the storage in the Upper Basin necessary to assure Lower Basin delivery obligations without impairing consumptive use requirements in the Upper Basin. The LROC offers factors to be considered to determine 602(a) storage, but does not present a set formula. The factors to be considered include the historic stream flows, the most critical period of record, probability of available waters, and estimated future depletions in the Upper Basin.

In 2004, Reclamation adopted an interim 602(a) storage guideline, in effect through 2016, which establishes that Lake Powell’s elevation must be above 3,630 feet msl (which corresponds to storage of approximately 14.85 maf) for equalization releases to occur (Reclamation 2004f). In the event that the elevation of Lake Powell is below the 602(a) storage guideline, and equalization is not required, the LROC provide that “the objective shall be to maintain a minimum release of water from Lake Powell of 8.23 million acre-feet for that year.”

In the AOP, the Secretary is required to determine when Normal, Surplus, or Shortage conditions occur in the lower Colorado River, based on various factors including storage and hydrologic conditions in the Colorado River Basin.

1.7.6.1 Normal Water Supply Condition

A Normal Condition exists when the Secretary determines that sufficient mainstream water is available to satisfy 7.5 maf of annual consumptive use in the Lower Division states. If a state will not use all of its apportioned water for the year, the Secretary may allow other states of the Lower Division to use the unused apportionment, provided that the use is authorized by a water delivery contract with the Secretary.

1.7.6.2 Surplus Water Supply Condition

A Surplus Condition exists when the Secretary determines that sufficient mainstream water is available for release to satisfy consumptive use in the Lower Division states in excess of 7.5 maf annually. This excess consumptive use is surplus and is distributed for use in Arizona, California, and Nevada pursuant to the terms and conditions provided in the ISG, adopted in 2001. The current provisions of the ISG are scheduled to terminate in 2016.

In general terms, the ISG link the availability of surplus water to the elevation of Lake Mead. When Lake Mead is full and Reclamation is making flood control releases, surplus supplies are unlimited. As Lake Mead’s elevation drops, surplus water amounts are reduced, and ultimately eliminated. The ISG also link surplus availability to continued progress by California in reducing its agricultural use of water to benchmarks established in the ISG.

If a state does not use all of its apportioned water for the year, the Secretary may allow other Lower Division states to use the unused apportionment, provided that the use is authorized by a water delivery contract with the Secretary.

1.7.6.3 Shortage Water Supply Condition

A Shortage Condition exists when the Secretary determines that insufficient mainstream water is available to satisfy 7.5 maf of annual consumptive use in the Lower Division states. To date, the Secretary has never made such a determination. When making a shortage determination, the Secretary must consult with various parties as set forth in the Consolidated Decree and consider all relevant factors as specified in the LROC, including 1944 Treaty obligations, the priorities set forth in the Consolidated Decree, and the reasonable consumptive use requirements of mainstream water users in the Lower Division states.

Pursuant to the Consolidated Decree, the Secretary is required to first provide for the satisfaction of the PPRs in the order of their priorities without regard to state lines. Pursuant to the CRBPA, water contract holders in Arizona with contracts dated September 30, 1968 (when the CAP was authorized) or later, have a lower priority than California's 4.4 maf apportionment. Beyond these two requirements, the Department does not have detailed guidelines in place that define the circumstances under which the Secretary would reduce the annual amount of water available for consumptive use from Lake Mead, i.e., when water supplies would be reduced, by how much, or who would experience specified reductions.

In the absence of specific shortage criteria, a shortage determination would most likely be made on an annual basis through the AOP process. This is a process by which the interests of the different stakeholders are addressed through consultation. Water users who rely on the Colorado River in the Lower Division states are not currently able to identify particular reservoir conditions under which the Secretary would reduce the annual amount of water available for consumptive use from Lake Mead, nor are these water users able to identify the frequency or magnitude of any potential future annual reductions in their water deliveries.

1.8 Related Actions

The alternatives considered in this Final EIS address operation and storage of water in Lake Powell and Lake Mead. While there are many actions related to the operation of the Colorado River with respect to the proposed federal action analyzed in this Final EIS, Reclamation has identified five primary documents that are related to, or would assist the reader in understanding the issues analyzed in this process:

- Operation of Glen Canyon Dam - Final EIS (1995) and Record of Decision (ROD) (1996) (Reclamation 1995, 1996a);
- Off-stream Storage of Colorado River Water and Development and Release of Intentionally Created Unused Apportionment in the Lower Division States - 43 C.F.R. pt. 414 (1999);
- Interim Surplus Criteria - Final EIS (2000) and ROD - Colorado River Interim Surplus Guidelines (2001) (Reclamation 2000, 2001);

- ♦ Implementation Agreement, Inadvertent Overrun and Payback Policy, and Related Federal Actions - Final EIS (2002) and ROD - Colorado River Water Delivery Agreement (2003) (Reclamation 2002a, 2003); and

- ♦ Lower Colorado River Multi-Species Conservation Program (LCR MSCP) - Final Programmatic EIS/Environmental Impact Report (EIR) and ROD - Lower Colorado River Multi-Species Conservation Plan (2005) (Reclamation 2005b).

Chapter 5 of this Final EIS provides an extensive review of these and other related actions that may have a cumulative impact on the resources affected by the alternatives presented herein.

The efforts documented in the references listed above are summarized below.

1.8.1 Operation of Glen Canyon Dam - Final EIS and ROD

The 1995 Operation of Glen Canyon Dam Final EIS was prepared in response to the 1992 Grand Canyon Protection Act, and analyzed alternative operation scenarios that met statutory responsibilities for protecting downstream resources and achieving other authorized purposes. The 1996 Glen Canyon Dam ROD describes detailed criteria and operating plans for dam operations and includes other management actions to accomplish this objective; among these are the Glen Canyon Dam Adaptive Management Program (AMP) of scientific monitoring and experimentation, beach/habitat-building flows (BHBF), and further study of temperature control.

The AMP provides a process for assessing the effects of Glen Canyon Dam operations on downstream resources and project benefits. The results of that assessment are used to develop recommendations for modifying Glen Canyon Dam operations and other resource management actions. This is accomplished through the Adaptive Management Work Group (AMWG), a federal advisory committee. The AMWG consists of stakeholders that include federal and state agencies, representatives of the seven Basin States, Indian tribes, hydroelectric power customers, environmental and conservation organizations, and recreational and other interest groups.

The BHBF releases are scheduled high releases of short duration that are in excess of power plant capacity in accordance with hydrologic triggering criteria. These BHBFs are designed to rebuild high elevation sandbars, deposit nutrients, restore backwater channels, and provide some of the dynamics of a natural system. The first test of a BHBF was conducted in spring of 1996, and a subsequent test of a BHBF was conducted in November 2004.

Evaluating the feasibility of increasing the temperature of water released from Glen Canyon Dam was a common element in the Glen Canyon Dam EIS and one of the elements of the reasonable and prudent alternative in the Biological Opinion (BO) of that document. In 1999, Reclamation issued an environmental assessment regarding potential modification of Glen Canyon Dam to construct a selective withdrawal structure, and has subsequently continued to investigate various structural designs. Reclamation has initiated a NEPA process that, among other elements, will consider construction of a selective withdrawal structure as part of a long-term experimental plan.

1.8.2 Off-stream Storage of Colorado River Water and Development and Release of Intentionally Created Unused Apportionment in the Lower Division States

In 1999, the Department adopted a rule to facilitate off-stream storage of Colorado River water and development and release of “Intentionally Created Unused Apportionment” (ICUA) for the Lower Division states. Reclamation prepared an Environmental Assessment (EA) to assess the environmental impacts of the rule, and a Finding of No Significant Impact (FONSI) was issued on October 1, 1999. The final rule was published in the Federal Register on November 1, 1999 and is codified at 43 C.F.R. pt. 414.

This rule establishes a procedural framework within the Lower Basin states for an authorized entity in one state to enter into storage agreements with authorized entities in another state for the off-stream storage (and future recovery) of Colorado River water. Under the agreements, the storing state will use water it stores under an interstate agreement and, in return, at a future date, decrease its consumptive use of Colorado River water, thereby developing the ICUA that the Secretary will release for consumptive use in the consuming state. Under this rule, two Storage and Interstate Release Agreements (SIRA) have been executed to date.

1.8.3 Interim Surplus Criteria - Final EIS and ROD - Colorado River Interim Surplus Guidelines

On January 17, 2001, the Secretary, through a ROD, adopted specific ISG that identify the conditions under which the Secretary will authorize the release of water from Lake Mead, for use in the Lower Basin, in excess of 7.5 maf. As adopted, the term of the ISG is through 2016. The ISG are applied by the Secretary each year through the AOP.

The ISG provide mainstream users of Colorado River water, particularly those in California, a greater degree of predictability with respect to the likely existence, or lack thereof, of a surplus determination in a given year for the interim period (i.e., through 2016). Prior to adoption of the ISG, availability of surplus was limited to periods when Lake Mead was nearly full and expected to make additional releases to avoid future spills. Conversely, under the ISG, as Lake Mead’s elevation drops, surplus water amounts are reduced, and ultimately eliminated. Surplus determinations under the AOP are further discussed in Section 1.7 of this Final EIS.

The ISG, as adopted in the 2001 ROD, provide for certain benchmarks for reduction of California’s agricultural use of Colorado River water and other actions; as long as the benchmarks are met, the more permissive determinations of surplus under the ISG are permitted. In the event that the benchmarks are not met, surplus determinations revert to a more conservative water management approach (i.e., surplus water is only made available when reservoirs are nearly full).

1.8.4 Implementation Agreement, Inadvertent Overrun and Payback Policy, and Related Federal Actions - Final EIS and ROD - Colorado River Water Delivery Agreement

California’s Colorado River Water Use Plan (CA Plan) calls for conservation measures to be put in place that will reduce California’s historic dependency on Colorado River water in excess of the state's 4.4 maf apportionment. The Colorado River Water Delivery Agreement, signed by the Secretary on October 10, 2003, provides for implementation of major components of the CA Plan and incorporates contractual agreements that facilitate California's sharing and distribution of Colorado River water within its 4.4 mafy entitlement.

The Colorado River Water Delivery Agreement is the Secretary's agreement to make those Colorado River water deliveries specified in the agreements with the relevant California entities. These agreements provide for the conservation and transfer of about 400 kaf of water annually among the Imperial Irrigation District, Coachella Valley Water District, MWD, and San Diego County Water Authority.

1.8.5 Lower Colorado River Multi-Species Conservation Program - Final Programmatic EIS/EIR and ROD - Lower Colorado River Multi-Species Conservation Plan

The LCR MSCP is a 50-year cooperative effort between federal and non-federal entities, approved by the Secretary in April 2005, that:

- conserves habitat and works towards the recovery of threatened and endangered species, as well as reducing the likelihood of additional species being listed;
- accommodates present water diversions and power production and optimizing opportunities for future water and power development, to the extent consistent with the law; and
- provides the basis for incidental take authorizations.

The LCR MSCP provides ESA compliance for specific covered federal actions and non-federal activities under ESA Sections 7 and 10. The LCR MSCP provides ESA coverage for non-federal actions that are related to the use and management of the lower Colorado River (from Lake Mead to the SIB).

In addition to the covered activities of the non-federal LCR MSCP entities, specific present and potential future actions of six federal agencies on the lower Colorado River are also included in the LCR MSCP. Those federal agencies are Reclamation, BIA, NPS, Bureau of Land Management (BLM), Western, and the FWS. These federal agencies and non-federal entities are collectively referred to as the LCR MSCP participants. The covered actions and activities for the LCR MSCP participants occur along the lower Colorado River in Imperial, Riverside, and San Bernardino counties, California; La Paz, Mohave, and Yuma counties, Arizona; and Clark County, Nevada. The duration of the Section 10 permit and the associated formal ESA Section 7 consultation for the federal agencies is 50 years (2005 to 2055).

The Conservation Plan was designed to fully mitigate adverse effects to species included within the LCR MSCP resulting from federal covered actions and non-federal covered activities, and to meet the ESA Section 10 standard to minimize and mitigate the impacts of the covered activities on covered species to the maximum extent practicable. While the LCR MSCP is geared toward special status species, it is important to understand that all species that use the habitats impacted by LCR MSCP-covered activities benefit from the conservation actions currently being carried out under the LCR MSCP.

Federal covered actions included in the LCR MSCP and covered under the LCR MSCP BO (FWS 2005) include the adoption and application of specific surplus and shortage guidelines that would allow for the release of water (excluding 1944 Treaty water) in excess of the 7.5 maf of entitlement waters in surplus years or less than the 7.5 maf in shortage years and approval and implementation of various administrative actions that could result in changes in the storage and delivery of Lower Division state entitlement waters at different points on the Colorado River. The LCR MSCP BO covered the effects of covered actions for a reduction of Lake Mead reservoir elevations to 950 feet msl and Colorado River flow reductions of up to 0.845 maf from Hoover Dam to Davis Dam, 0.860 maf from Davis Dam to Parker Dam, and 1.574 maf from Parker Dam to Imperial Dam. The LCR MSCP identified, and is mitigating impacts to, the covered species and their habitats from the river flow reductions described above.

Reclamation has reviewed the effects of the Preferred Alternative in this Final EIS and has determined that all potential effects to listed species and their habitats along the Colorado River from the full pool elevation of Lake Mead to the SIB are covered by the LCR MSCP. The LCR MSCP coverage also includes the conveyance of conserved Virgin River and Muddy River (tributary) flows through Lake Mead and the Overton Arm. This determination is documented in the Biological Assessment (BA) for the proposed federal action which is the subject of this EIS (Appendix R). Accordingly, the BA for the proposed federal action analyzes potential effects to listed species for areas outside the geographic coverage of the LCR MSCP – from Lake Powell to the inflow to Lake Mead, and for the interrelated/interdependent effects of the Lake Mead storage and delivery mechanism on the Virgin River and the Muddy River.

This page intentionally left blank.

Chapter Two

2.1 Development of Alternatives

This chapter discusses the processes used to define, develop, and analyze the No Action Alternative, as well as a range of reasonable action alternatives and the Preferred Alternative, for implementing the proposed federal action. Based on the information and comments received during the scoping process, the proposed federal action has been designed to reflect, among others, three important considerations:

1) **Encouraging Conservation of Water:** Many comments submitted to Reclamation focused on the importance of encouraging and utilizing water conservation as an important tool to better manage limited water supplies and therefore minimize the likelihood and severity of potential future shortages. Water conservation could occur through a number of approaches such as fallowing of land, lining of canals, financial incentives to maximize conservation, dry-year options, and associated storage and recovery methodologies and procedures to address conservation actions by particular parties.

2) **Consideration of Reservoir Operations at all Operational Levels:** Many comments submitted to Reclamation urged Reclamation to consider and analyze management and operational guidelines for the full range of operational elevations of Lake Powell and Lake Mead. It was suggested that this approach is integral to the prudent development of new operational guidelines for low reservoir conditions, as the approach and management of these reservoirs at higher elevations has a direct impact on available storage, thereby affecting the likelihood and severity of potential future shortages.

3) **Term of Operational Guidelines:** Many comments urged Reclamation to consider interim, rather than permanent, additional operational guidelines. In this manner, Reclamation would have the ability to use actual operating experience for a period of years, thereby facilitating a better understanding of the operational effects of the new guidelines. Modifications could then be made, if necessary, based on this operating experience.

As a result of the analyses of the comments and input received by Reclamation, the following four operational elements of the proposed federal action were developed:

1) **Shortage Guidelines:** Adoption of guidelines that would identify those circumstances under which the Secretary would reduce the annual amount of water available for consumptive use from Lake Mead to the Lower Division states to below 7.5 maf, pursuant to the Consolidated Decree.

   The primary purpose of this element is the distribution of water supplies during drought and low reservoir conditions. While Lake Powell and Lake Mead have large storage capacities, water supply demands are increasing and careful management of existing water supplies will help ensure sufficient supplies are available to meet these demands. The proposed shortage guidelines in the alternatives analyzed in the Final EIS range from aggressive shortages to no reduction of water supplies until the reservoirs are empty. Most of the alternatives have discrete levels of shortage associated with specific Lake Mead reservoir elevations.

2) **Coordinated Reservoir Operations:** Adoption of guidelines for the coordinated operations of Lake Powell and Lake Mead to provide improved operation of these two reservoirs, particularly under low reservoir conditions.

   Lake Powell and Lake Mead operations are currently coordinated only under high reservoir elevations through storage equalization. The action alternatives consider various options designed to better utilize existing reservoir storage throughout the full range of reservoir operations to enhance both water supply and other benefits of the reservoir system for both the Upper Basin and Lower Basin.

3) **Storage and Delivery of Conserved Water:** Adoption of guidelines for the storage and delivery of conserved Colorado River system and non-system water in Lake Mead, pursuant to applicable federal law, to increase the flexibility of meeting water use needs from Lake Mead, particularly under drought and low reservoir conditions.

   One way to increase water deliveries during drought is through the augmentation and conservation of existing water supplies. The alternatives consider options for the creation of a system of storage credits in Lake Mead whereby system and non-system water may be conserved and stored in Lake Mead, with various limits on the maximum size, storage and delivery of the credit water. The alternatives range from an operational scenario that considers no new mechanism (status quo) to a maximum Lake Mead storage credit volume of 4.2 maf.

4) **Interim Surplus Guidelines:** Adoption of guidelines that would identify the conditions under which the Secretary may declare the availability of surplus water for use within the Lower Division states. The proposed federal action would modify the substance of the existing ISG and extend the term of the ISG from 2016 to 2026.

   The ISG are due to expire in 2016. The alternatives range from termination of the permissive provisions of the existing ISG in 2007 to extension of the current provisions of the ISG through 2026. This element of the proposed federal action helps establish an operational strategy for the full range of reservoir operations through 2026.

Reclamation developed five action alternatives for analysis in this EIS. These alternatives include some formulation of each of these four operational elements and reflect input from Reclamation staff, the cooperating agencies, stakeholders, and other interested parties. Reclamation received two written proposals for alternatives that met the purpose and need of the proposed federal action; one proposal was received from the Basin States as revised on April 30, 2007 and another proposal was received from a consortium of environmental NGOs. These proposals were used by Reclamation to formulate two of the alternatives considered and analyzed in this EIS (Basin States Alternative and Conservation Before Storage Alternative, respectively). A third alternative (Water Supply Alternative) was developed by Reclamation and a fourth alternative (Reservoir Storage Alternative) was developed in coordination with NPS and Western. The No Action Alternative and these four action alternatives, analyzed in the Draft EIS (February 2007), were posted on Reclamation's website (http://www.usbr.gov/lc/region/programs/strategies.html) on June 30, 2006.

A fifth action alternative (Preferred Alternative) was developed after consideration of the comments received on the Draft EIS and further analysis. The Preferred Alternative was posted on Reclamation's website (same as above) on June 15, 2007. The preferred alternative is composed of operational elements identified and analyzed in the Draft EIS.

A description of each of the alternatives follows.

2.2 No Action Alternative

The No Action Alternative represents a projection of current conditions to the most reasonable future responses or conditions that could occur during the life of the proposed federal action without any action alternative being implemented. Thus, the No Action Alternative provides a baseline against which action alternatives can be compared.

Pursuant to the LROC, the Secretary makes a number of determinations at the beginning of each operating year through the development and execution of the AOP, including the water supply available to users in the Lower Basin and the annual release from Lake Powell. The LROC do not include specific guidelines for such determinations. Furthermore, there is no actual operating experience under very low reservoir conditions, e.g., there has never been a shortage determination in the Lower Basin. Therefore, in the absence of specific guidelines, the outcome of the annual determination in any particular year in the future cannot be precisely known. However, a reasonable representation of future conditions under the No Action Alternative is needed for comparison to each action alternative. The modeling assumptions used for this representation are consistent with assumptions used in previous environmental compliance documents for the ISG, the Colorado River Water Delivery Agreement, and the LCR MSCP (Section 1.8). The assumptions used in the No Action Alternative are not intended to limit or predetermine the decision in any future AOP determination.

The formulation of the four operational elements of the proposed federal action for the No Action Alternative follows.

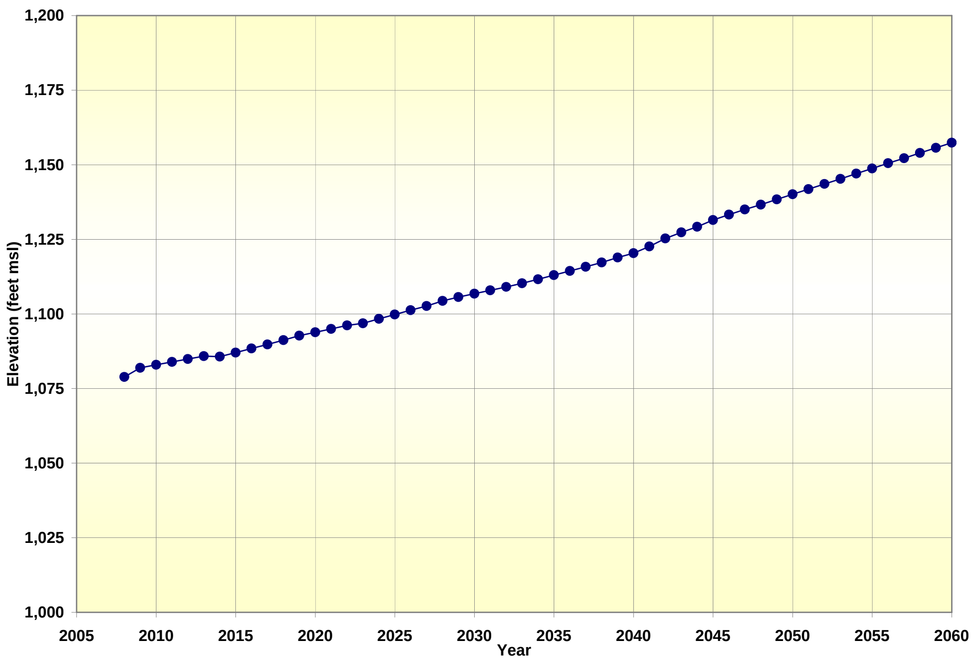
2.2.1 Shortage Guidelines

Each year, the Secretary makes a determination as to whether the consumptive use requirements of mainstream users in the Lower Division states will be met under a Normal, Surplus, or Shortage Condition, in accordance with the Consolidated Decree and the LROC as implemented through the AOP process. The LROC specify that the Secretary will consider all relevant factors in making a shortage determination and list some of the factors to be considered. However, there is no specific guidance as to exactly when, how, or to whom reductions in deliveries would be made. Therefore, it is impossible to know exactly how the Secretary might make a shortage determination in the future. Furthermore, conditions in the Colorado River Basin have been such that there has not been a need to declare a Shortage Condition and there is no actual operating experience with regard to shortage determinations.

To obtain a reasonable representation of future conditions under the No Action Alternative (while not representing official policy of the Department with regard to future determinations), the following assumptions were made:

- as in the modeling assumptions for previous Colorado River Basin environmental compliance documents, shortage trigger elevations (Figure 2.2-1) were used to prevent Lake Mead's elevation from declining below 1,050 feet msl with approximately an 80 percent probability (known as a "Level 1 Shortage", Appendix A). In a given year, a shortage (or reduction in deliveries) that ranges from approximately 350 to 500 thousand acre-feet (kaf) would be imposed when the projected January 1 Lake Mead elevation is below the shortage trigger elevation for that year; and
- if Lake Mead's elevation continues to decline, additional reductions would be imposed to keep Lake Mead elevation above 1,000 feet msl. This approach essentially provides absolute protection of SNWA's lower intake (elevation 1,000 feet msl) at Lake Mead and would reduce deliveries to water users (including SNWA) by amounts required to maintain Lake Mead elevation at or above 1,000 feet msl.

Figure 2.2-1
Lake Mead Level 1 Shortage Trigger Lake Mead Elevations Under the No Action Alternative



In accordance with the Consolidated Decree, the CRBPA, and other key provisions of the Law of the River, the Secretary has the authority to determine and allocate shortages to the Lower Division states. Although some guidance exists with regard to how shortages would be allocated (e.g., PPR deliveries must be met without regard to state lines, California does not incur shortages until Arizona post-1968 contracts are reduced completely), there are no specific guidelines in place to further inform the Secretary's decision with respect to how shortages might be shared by the water users in Arizona, California and Nevada.

Furthermore, the determination of deliveries to Mexico is not a part of the proposed federal action. Any such determination would be made in accordance with the 1944 Treaty (Section 1.7.3).

Nevertheless, modeling assumptions with respect to the distribution of shortages to Lower Division states and water delivery reductions to Mexico are necessary in order to analyze the potential impacts to hydrologic and other environmental resources.[1] These modeling assumptions were applied to the No Action Alternative as well as the action alternatives, i.e., the modeling assumptions with regard to the distribution of shortages are identical under all alternatives.

It was assumed that shortages would be allocated to each Lower Division state and Mexico based on percentages of the total shortage being applied. The modeling assumptions for distribution of shortages used in this Final EIS are presented in Table 2.2-1. More detailed descriptions of these modeling assumptions are provided in Appendix A.

Table 2.2-1
Modeling Assumptions for Distribution of Shortages[1]

Entity	Percentage of Total Shortage, Stage 1	Percentage of Additional Shortage, Stage 2[2]
Arizona	80.00	15 to 20
California	0.00	60 to 65
Nevada	3.33	3.33
Mexico	16.67	16.67
Total	100.00	100.00

1. *These modeling assumptions do not reflect policy decisions and are not intended to constitute an interpretation or application of the 1944 Treaty.*
2. *Shortage amounts presented in the Stage 2 column are incremental over the amount of shortages that would have already been allocated under Stage 1.*

[1] Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 Treaty or to represent current United States policy or a determination of future United States policy regarding deliveries to Mexico. The United States will conduct all necessary and appropriate discussions regarding the proposed federal action and implementation of the 1944 Treaty with Mexico through the IBWC in consultation with the Department of State.

Shortages are first imposed under Stage 1 and would be applied to the most junior users within Arizona (those with post-1968 water rights, i.e., 4th and 5th priority rights within Arizona) and Nevada (primarily the SNWA). Stage 1 shortages would continue until deliveries to the post-1968 water rights holders in Arizona (including the CAP) are reduced to zero. The maximum amount of Stage 1 shortages during the period of analysis is dependent on the scheduled depletions for the post-1968 water rights holders and decreases over time from approximately 1.8 maf in 2008 to 1.7 maf in 2060.

After deliveries to the 4th and 5th priority rights within Arizona are reduced to zero, additional reductions are applied to Arizona, California, and Nevada. These shortages, referred to as Stage 2 shortages, continue to the maximum necessary to keep Lake Mead elevation above 1,000 feet msl.

2.2.2 Coordinated Reservoir Operations

The No Action Alternative assumes Lake Powell's operation would follow the current operating criteria as specified by the LROC and as implemented through the AOP process. Three factors affecting the annual releases from Lake Powell are: 1) the minimum objective release; 2) storage equalization; and 3) spill avoidance.

Pursuant to the LROC, the objective under current operational conditions is to maintain a minimum release of water from Lake Powell of 8.23 maf for the water year. Under the No Action Alternative, a minimum release of 8.23 maf is assumed to be made each water year unless storage equalization or spill avoidance are in effect.

Annual releases from Lake Powell greater than the minimum objective release occur when Upper Basin storage is greater than that required by 602(a) storage, and the storage in Lake Powell is forecast to be greater than the storage in Lake Mead at the end of that water year. Under these conditions, additional releases are made from Lake Powell to equalize the storage in Lake Mead with the storage in Lake Powell by the end of the water year.

The 602(a) storage requirement specifies the amount of storage in Upper Basin reservoirs necessary to assure deliveries to the Lower Basin in compliance with the Compact without impairment to the annual consumptive use in the Upper Basin. If the 602(a) storage requirement is not met, equalization does not occur. The LROC specifies that all relevant factors including historic stream flows, the most critical period of record, the probabilities of water supply, and estimated future depletions be considered when determining the 602(a) storage amount.

In 2004, an Interim 602(a) Storage Guideline was adopted that specifies that through 2016, the 602(a) storage requirement shall utilize a storage amount of not less than 14.85 maf which corresponds to an elevation of 3,630 feet msl for Lake Powell. Under the No Action Alternative, the determination of 602(a) storage is consistent with the storage criterion and the provisions of the Interim 602(a) Storage Guideline. The algorithm used to calculate the 602(a) storage requirement is presented in Appendix A.

Annual release volumes from Lake Powell greater than the minimum objective of 8.23 maf may also be made to avoid anticipated spills. An objective in the operation of Glen Canyon Dam is to attempt to safely fill Lake Powell each summer. When carryover storage from the previous year in combination with the current inflow forecast is projected to exceed Lake Powell's storage capacity, Reclamation schedules the release of the volumes of water needed to avoid spills. Subject to actual inflows, Lake Powell is operated to reach storage of about 23.8 maf in July (0.5 maf from full pool). In years when Lake Powell fills or nearly fills during the summer, additional releases in late summer and early winter are made to draw the reservoir down, so that there is at least 2.4 maf of vacant space in Lake Powell on September 30 for flood protection. Under the No Action Alternative, it is assumed that spill avoidance releases are made when necessary.

2.2.3 Storage and Delivery of Conserved Water

There is currently no mechanism in place for the storage and delivery of conserved system and non-system water in Lake Mead; therefore, the No Action Alternative assumes that none will exist during the interim period.

2.2.4 Interim Surplus Guidelines

The ISG specify ranges of Lake Mead elevations and operational conditions that are used to determine the availability of surplus water for each year during their effective term (through 2016). The elevation ranges are coupled with specific uses of surplus water so that if Lake Mead's elevation declines, the amount of surplus water is reduced. The Surplus, Normal, and Shortage conditions are described below:

2.2.4.1 Flood Control Surplus

If flood control releases are anticipated to be required given the current inflow forecast, the Secretary declares a Flood Control Surplus Condition for that year. The estimated annual amount of surplus water available for pumping and release from Lake Mead (in addition to 7.5 maf) varies over time (2002 to 2016) and ranges between 1.20 to 1.58 mafy. Under current practice, Mexico is allowed to schedule up to an additional 200 kaf pursuant to the 1944 Treaty during flood control years when water supplies exceed those required for use in the United States.

2.2.4.2 Quantified Surplus (70R Strategy)

If flood control releases are anticipated to be required assuming the 70th percentile inflow (the inflow value from the historical record that has not been exceeded more than 30 percent of the time), the Secretary declares a Quantified Surplus Condition for that year. The estimated annual amount of surplus water available for pumping and release from Lake Mead (in addition to 7.5 maf) varies over time (2002 to 2016) and ranges between 1.02 to 1.45 mafy.

2.2.4.3 Full Domestic Surplus (Lake Mead at or above Elevation 1,145 feet msl)

If the projected January 1 Lake Mead elevation is at or above 1,145 feet msl but below the elevation calculated by the 70R Strategy, the Secretary declares a Full Domestic Surplus Condition for that year. The projected annual amount of surplus water available for pumping and release from Lake Mead (in addition to 7.5 maf) varies over time (2002 to 2016) and ranges between 340 to 535 thousand acre-feet per year (kafy).

2.2.4.4 Partial Domestic Surplus (Lake Mead at or above Elevation 1,125 feet msl)

If the projected January 1 Lake Mead elevation is at or above 1,125 feet msl and below 1,145 feet msl, the Secretary declares a Partial Domestic Surplus Condition for that year. The estimated annual amount of surplus water available for pumping and release from Lake Mead (in addition to 7.5 maf) varies over time (2002 to 2016) and ranges between 90 to 375 kafy.

2.2.4.5 Normal and Shortage Conditions (Lake Mead below Elevation 1,125 feet msl)

If the projected January 1 Lake Mead elevation is at or below 1,125 feet msl, the Secretary declares a Normal Condition or a Shortage Condition for that year.

Under the No Action Alternative, surplus determinations through 2016 would be as described above. After 2016, it is assumed that surplus determinations would only be based on the more conservative Quantified Surplus (70R Strategy) and Flood Control Surplus conditions. Further details of these modeling assumptions to represent the ISG are presented in Appendix A.

2.3 Basin States Alternative

The Basin States Alternative proposes a coordinated operation of Lake Powell and Lake Mead that would minimize shortages in the Lower Basin and avoid risk of curtailments of use in the Upper Basin. This alternative also provides a mechanism for promoting water conservation in the Lower Basin. The formulation of the four operational elements of the proposed federal action for the Basin States Alternative follows.

2.3.1 Shortage Guidelines

The Basin States Alternative provides discrete levels of shortage associated with specific Lake Mead elevations as presented below. This alternative provides criteria for shortages up to a maximum of 500 kaf at Lake Mead elevation of 1,025 feet msl.

The shortages modeled under the Basin States Alternative are as follows:

- when Lake Mead is projected to be below elevation 1,075 feet msl and at or above elevation 1,050 feet msl on January 1, a shortage of 333 kaf shall be imposed for that year;

- when Lake Mead is projected to be below elevation 1,050 feet msl and at or above elevation 1,025 feet msl on January 1, a shortage of 417 kaf shall be imposed for that year;

- when Lake Mead is projected to be below elevation 1,025 feet msl on January 1, a shortage of 500 kaf shall be imposed for that year; and

- when Lake Mead is below elevation 1,025 feet msl, the Secretary shall consult with the Basin States to discuss further measures that may be undertaken consistent with the Law of the River.[2]

The shortage amounts are expressed as reductions to water users in the Lower Division states. However, modeling of this and the other alternatives includes the assumption that deliveries to Mexico are also reduced.[3] As such, the total shortage amounts modeled under this alternative are 400; 500; and 600 kaf, at elevations 1,075; 1,050; and 1,000 feet msl, respectively.

2.3.2 Coordinated Reservoir Operations

Under the Basin States Alternative, the annual Lake Powell release is based the volume of water in storage or corresponding elevation of Lake Powell and Lake Mead as described below.

2.3.2.1 Equalization

The Basin States Alternative provides an elevation schedule (Table 2.3-1) that would be used in determining when equalization releases would be made from Lake Powell.

---

[2] This alternative proposes that consultations between the Basin States and Reclamation be undertaken to define additional shortages needed when Lake Mead falls below elevation 1,025 feet msl and is projected to fall below 1,000 feet msl. The possible outcomes of such a consultation process are unknown; therefore, for modeling purposes it was assumed that shortages of 500 kaf would continue to be applied at Lake Mead elevations below 1,025 feet msl.

[3] Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 Treaty or to represent current United States policy or a determination of future United States policy regarding deliveries to Mexico. The United States will conduct all necessary and appropriate discussions regarding the proposed federal action and implementation of the 1944 Treaty with Mexico through the IBWC in consultation with the Department of State.

Table 2.3-1
Basin States Alternative
Lake Powell Equalization Elevations

Year	Reservoir Elevation (feet msl)
2008	3,636
2009	3,639
2010	3,642
2011	3,643
2012	3,645
2013	3,646
2014	3,648
2015	3,649
2016	3,651
2017	3,652
2018	3,654
2019	3,655
2020	3,657
2021	3,659
2022	3,660
2023	3,662
2024	3,663
2025	3,664
2026	3,666

When Lake Powell is at or above these specified elevations and when the volume of Lake Powell is projected to be greater than the volume of Lake Mead at the end of the water year, Lake Powell would release greater than 8.23 mafy to equalize its volume with Lake Mead. Otherwise, 8.23 maf is released from Lake Powell.

2.3.2.2 Upper Elevation Balancing

When Lake Powell is below the elevations stated in Table 2.3-1 and is projected to be at or above 3,575 feet msl at the end of the water year, a release in the amount of 8.23 maf from Lake Powell would be made if the projected elevation of Lake Mead is at or above 1,075 feet msl at the end of the water year. If the projected end of water year elevation of Lake Mead is below 1,075 feet msl, the volumes of Lake Mead and Lake Powell would be balanced if possible, within the constraint that the release from Lake Powell would not be more than 9.0 maf and no less than 7.0 maf.

2.3.2.3 Mid-Elevation Releases
When Lake Powell elevation is projected to be below 3,575 feet msl and at or above 3,525 feet msl at the end of the water year, a release in the amount of 7.48 maf would be made if the projected end of water year elevation of Lake Mead is at or above 1,025 feet msl. If the projected end of water year elevation of Lake Mead is below 1,025 feet msl, a release of 8.23 maf from Lake Powell would be made.

2.3.2.4 Lower Elevation Balancing
When the projected end of water year elevation of Lake Powell is below 3,525 feet msl, Lake Mead and Lake Powell would be balanced if possible, within the constraint that the release from Lake Powell would not be more than 9.5 maf and no less than 7.0 maf.

2.3.3 Creation and Delivery of Intentionally Created Surplus
The Basin States Alternative includes the adoption of a mechanism to encourage and account for augmentation and conservation of water supplies, e.g., fallowing of land, lining of canals and other system efficiency improvements, and introduction of tributary and non-system water in the Lower Basin. The mechanism provides for the creation, accounting, and delivery of Intentionally Created Surplus (ICS). At the time the ICS is created, five percent of the ICS would be dedicated to the Colorado River system on a one-time basis. Additionally, ICS accounted for in Lake Mead longer than one year would be subject to annual evaporation losses of three percent per year. If flood control releases occur, ICS would be reduced on a pro-rata basis until no ICS remains, i.e., ICS would be released first.

The maximum amount of ICS that can be created during any year, the maximum cumulative amount of ICS that can be available at any one time, and the maximum amount of ICS that may be delivered in any one year under this alternative are presented in Table 2.3-2.

Table 2.3-2
Basin States Alternative
Volume Limitations of ICS

Entity	Maximum Annual ICS Creation (kaf)	Maximum Cumulative ICS (kaf)	Maximum Annual ICS Delivery (kaf)
Arizona	100	300	300
California	400	1,500	400
Nevada	125	300	300
Total	625	2,100	1,000

2.3.4 Interim Surplus Guidelines
The Basin States Alternative includes both a modification and an extension of the ISG. The ISG would be extended through 2026 and be modified by eliminating the Partial Domestic Surplus Condition, beginning in 2008, and limiting the amount of water available under the

Full Domestic Surplus Condition during the period 2017 through 2026.[4] The elimination of the Partial Domestic Surplus Condition reduces the amount of surplus water that could be made available and leaves more water in storage to reduce the severity of future shortages.

2.4 Conservation Before Shortage Alternative

The Conservation Before Shortage Alternative was developed by a consortium of environmental NGOs, including Defenders of Wildlife, Environmental Defense, National Wildlife Federation, Pacific Institute, Sierra Club, Sonoran Institute, The Nature Conservancy, and the Rivers Foundation of the Americas. The Conservation Before Shortage Alternative includes voluntary, compensated reductions in water use to minimize involuntary shortages in the Lower Basin and avoid risk of curtailments of use in the Upper Basin. This alternative also provides a mechanism for promoting water conservation in the Lower Basin by expanding the ICS mechanism.

The formulation of the four operational elements of the proposed federal action for the Conservation Before Shortage Alternative follows.

2.4.1 Shortage Guidelines

Although the Conservation Before Shortage Alternative does not include stepped, involuntary shortages, it does include voluntary conservation levels similar to the Basin States Alternative shortage levels described in Section 2.3. These voluntary conservation levels are described below.

This alternative provides a shortage strategy that would absolutely protect Lake Mead elevation of 1,000 feet msl whereby water deliveries would be reduced by the amount required to maintain Lake Mead elevations at or above 1,000 feet msl.

2.4.2 Coordinated Reservoir Operations

The Conservation Before Shortage Alternative assumes the same coordinated reservoir operations as the Basin States Alternative described in Section 2.3.

---

[4] During 2017 through 2026, the distribution of Domestic Surplus water would be limited as follows: 1) for use by MWD, 250 kafy in addition to the amount of California's basic apportionment available to MWD; 2) for use by SNWA, 100 kafy in addition to the amount of Nevada's basic apportionment available to SNWA; and 3) for use in Arizona, 100 kafy in addition to the amount of Arizona's basic apportionment available to Arizona contractors.

2.4.3 Storage and Delivery of Conserved Water

The conservation triggers proposed under this alternative are as follows:

- when Lake Mead is projected to be below elevation 1,075 feet msl and at or above elevation 1,050 feet msl on January 1, the Secretary will seek the conservation of 400 kaf of water;

- when Lake Mead is projected to be below elevation 1,050 feet msl and at or above elevation 1,025 feet msl on January 1, the Secretary will seek the conservation of 500 kaf of water; and

- when Lake Mead is projected to be below elevation 1,025 feet msl on January 1, the Secretary will seek the conservation of 600 kaf of water.

Under the Conservation Before Shortage Alternative, ICS would be generated by activities similar to those described for the Basin States Alternative (Section 2.3). In addition, participation in the ICS mechanism would be expanded to include other entities.

The maximum amount of ICS that can be created during any year, the maximum cumulative amount of ICS that can be available at any one time, and the maximum amount of ICS that may be delivered in any one year under this alternative are presented in Table 2.4-1. ICS that is assumed to be created by other entities is shown in Table 2.4-1 as “Unassigned.”

Table 2.4-1
Conservation Before Shortage Alternative
Volume Limitations of ICS

Entity	Maximum Annual ICS Creation (kaf)	Maximum Cumulative ICS (kaf)	Maximum Annual ICS Delivery (kaf)
Arizona	100	300	300
California	400	1,500	400
Nevada	125	300	300
Unassigned	825	2,100	600
Total	1,450	4,200	1,600

2.4.4 Interim Surplus Guidelines

The Conservation Before Shortage Alternative assumes the same modifications to and extension of the term of the ISG as described under the Basin States Alternative (Section 2.3).

2.4.5 Funding Mechanisms

There are two other aspects of the Conservation Before Shortage proposal that are unique to the Conservation Before Shortage Alternative: a funding mechanism for the voluntary conservation program, and a recommendation that a portion of the conserved water be used to benefit the environment. The details of the modeling assumptions used to simulate the ICS mechanism, including water for environmental purposes, are presented in Appendix M.

The Conservation Before Shortage proposal describes potential funding sources that include a Federal government contribution for the cost of all conservation agreements up to the volume of the bypass flow that the Secretary has not otherwise replaced in the year that a conservation trigger becomes effective, and responsibility for half of the cost of any additional agreements required to generate the proposed voluntary, conserved water. A second component of the funding mechanism would be a "Power Pool Protection Fund" which proposes that a percentage of the funding for the proposed voluntary conservation program be derived from a conditional surcharge on power rates under existing or renewed contracts for hydropower produced at Hoover Dam, depending upon the storage in Lake Mead. A third component of the funding mechanism would be "Temporary Cost Recovery/Delivery Surcharges", requiring that the cost of some portion of the conservation agreements, including those with Colorado River users in Mexico, be funded through a conservation surcharge imposed on a per-acre-foot basis on water deliveries to all Lower Basin contractors.

The viability of the Conservation Before Shortage program funding proposal is not known at this time. The Department currently does not have the authority to implement all facets of this proposal and additional legislation would be necessary to gain such authority.

2.5 Water Supply Alternative

The Water Supply Alternative is intended to maximize water deliveries at the expense of retaining water in storage in the reservoirs for future use. This alternative would implement shortages only when sufficient water to meet entitlements is not available in Lake Mead.

The formulation of the four operational elements of the proposed federal action for the Water Supply Alternative follows.

2.5.1 Shortage Guidelines

Under the Water Supply Alternative, shortages would not be imposed until Lake Mead nears elevation 895 feet msl (top of the dead pool). Near that elevation, releases would be limited to the amount of water available. However, when Lake Mead elevation drops below 1,000 feet msl, SNWA would be unable to take water through its lower intake.

2.5.2 Coordinated Reservoir Operations

When Lake Powell is projected to be above elevation 3,575 feet msl at the end of the water year, the operation of Lake Powell would be the same as under the No Action Alternative unless Lake Mead elevation is below 1,075 feet msl. When Lake Powell elevation is projected to be below elevation 3,575 feet msl at the end of the water year or Lake Mead elevation is projected to be below elevation 1,075 feet msl at the end of the water year, the volumes of Lake Powell and Lake Mead would be balanced if possible, within the constraint that the release from Lake Powell would not be more than 9.5 maf and no less than 7.0 maf.

2.5.3 Storage and Delivery of Conserved Water

The Water Supply Alternative does not include a mechanism for the storage and delivery of conserved system and non-system water in Lake Mead.

2.5.4 Interim Surplus Guidelines

Under this alternative, the existing ISG would be extended through 2026.

2.6 Reservoir Storage Alternative

The Reservoir Storage Alternative was developed in coordination with the cooperating agencies and other stakeholders, primarily Western and NPS. This alternative would keep more water in storage in Lake Powell and Lake Mead to benefit power and recreation interests by reducing water deliveries and by increasing shortages. This alternative also provides a mechanism for promoting water conservation in the Lower Basin.

The formulation of the four operational elements of the proposed federal action for the Reservoir Storage Alternative follows.

2.6.1 Shortage Guidelines

The Reservoir Storage Alternative is similar to the Basin States Alternative in that it provides discrete levels of shortage associated with specific Lake Mead reservoir elevations (Section 2.3). However, shortages in this alternative begin at a higher Lake Mead elevation and the shortages amounts are larger so that more water would be retained in storage and higher Lake Powell and Lake Mead elevations would be maintained. The Reservoir Storage Alternative does not contain provisions that would protect the Lake Mead elevation of 1,000 feet msl.

The shortages modeled under this alternative are as follows:

- when Lake Mead is projected to be below elevation 1,100 feet msl and at or above elevation 1,075 feet msl on January 1, a shortage of 500 kaf shall be imposed for that year;
- when Lake Mead is projected to be below elevation 1,075 feet msl and at or above elevation 1,050 feet msl on January 1, a shortage of 667 kaf shall be imposed for that year;
- when Lake Mead is projected to be below elevation 1,050 feet msl and at or above elevation 1,025 feet msl on January 1, a shortage of 883 kaf shall be imposed for that year; and
- when Lake Mead is projected to be below elevation 1,025 feet msl on January 1, a shortage of 1,000 kaf would be imposed for that year.

The volumes of shortages are expressed as reductions to water users in the Lower Division states. However, modeling of the Reservoir Storage Alternative and the other alternatives includes the assumption that deliveries to Mexico are also reduced.[5] As such, the total shortage amounts modeled under this alternative are 600; 800; 1,000; and 1,200 kaf at elevations 1,100; 1,075; 1,050; and 1,025 feet msl, respectively.

2.6.2 Coordinated Reservoir Operations

When Lake Powell is projected to be above elevation 3,595 feet msl at the end of the water year, the operation of Lake Powell would be the same as under the No Action Alternative. Elevations of Lake Powell that trigger releases that are less than the minimum objective release of 8.23 maf are tied to critical recreation elevations at Lake Powell as follows:

- when Lake Powell is projected to be below elevation 3,595 feet msl and above elevation 3,560 feet msl at the end of the water year, a release in the amount of 7.80 maf from Lake Powell would be made; and
- when Lake Powell is projected to be below elevation 3,560 feet msl at the end of the water year, the volumes of Lake Powell and Lake Mead would be balanced if possible, within the constraint that the release from Lake Powell would not be more than 9.5 maf and no less than 7.8 maf.

[5] Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 Treaty or to represent current United States policy or a determination of future United States policy regarding deliveries to Mexico.

2.6.3 Storage and Delivery of Conserved Water

Under the Reservoir Storage Alternative, storage credits would be generated by activities similar to those described under the Basin States Alternative (Section 2.3). In addition, participation in the storage and delivery mechanism would be expanded to include other entities. At the time the storage credits are created, ten percent of the conserved water would be dedicated to the Colorado River system on a one-time basis.

The maximum amount of storage credits that can be created during any year, the maximum cumulative amount of storage credits that can be available at any one time, and the maximum amount of storage credits that may be delivered by each entity in any one year under this alternative are presented in Table 2.6-1. Storage credits that are assumed to be generated by other entities are shown in Table 2.6-1 as "Unassigned."

Table 2.6-1
Reservoir Storage Alternative
Volume Limitations of Storage and Delivery Mechanism

Entity	Maximum Annual Storage of Conserved System or Non-system Water (kaf)	Maximum Total Storage of Conserved System or Non-system Water (kaf)	Maximum Annual Delivery of Conserved System or Non-system Water (kaf)
Arizona	100	300	300
California	400	1,500	400
Nevada	125	300	300
Unassigned	475	950	950
Total	1,100	3,050	1,950

2.6.4 Interim Surplus Guidelines

Under the Reservoir Storage Alternative, the permissive provisions of the existing ISG are terminated in 2007 and surplus determinations revert to the Quantified Surplus and Flood Control Surplus conditions from 2008 through 2026.

2.7 Preferred Alternative

The Preferred Alternative incorporates operational elements identified in the Basin States and Conservation Before Shortage alternatives. It proposes a coordinated operation of Lake Powell and Lake Mead that would minimize shortages in the Lower Basin and avoid risk of curtailments of use in the Upper Basin and adopts the ICS mechanism for promoting water conservation in the Lower Basin.

The formulation of the four operational elements of the proposed federal action for the Preferred Alternative follows.

2.7.1 Shortage Guidelines

The Preferred Alternative, similar to the Basin States Alternative, assumes discrete levels of shortage associated with specific Lake Mead elevations as described below. This alternative provides criteria for shortages up to a maximum of 500 kaf at Lake Mead elevation of 1,025 feet msl.

The shortages modeled under the Preferred Alternative are as follows:

- ♦ when Lake Mead is projected to be below elevation 1,075 feet msl and at or above elevation 1,050 feet msl on January 1, a shortage of 333 kaf shall be imposed for that year;
- ♦ when Lake Mead is projected to be below elevation 1,050 feet msl and at or above elevation 1,025 feet msl on January 1, a shortage of 417 kaf shall be imposed for that year;
- ♦ when Lake Mead is projected to be below elevation 1,025 feet msl on January 1, a shortage of 500 kaf shall be imposed for that year; and
- ♦ when Lake Mead is below elevation 1,025 feet msl, the Secretary shall undertake appropriate consultation, including with the Basin States, to discuss further measures that may be undertaken consistent with the Law of the River.[6]

The volumes of shortages are expressed as reductions to water users in the Lower Division states. However, modeling of this and the other alternatives includes the assumption that deliveries to Mexico are also reduced.[7] As such, the total shortage amounts modeled under this alternative are 400; 500; and 600 kaf at elevations 1,075; 1,050; and 1,025 feet msl, respectively.

2.7.2 Coordinated Reservoir Operations

The Preferred Alternative assumes the same coordinated reservoir operations as the Basin States and Conservation Before Shortage alternatives described in Sections 2.3 and 2.4, respectively.

---

[6] This alternative proposes that appropriate consultations be undertaken to define additional shortages needed when Lake Mead falls below elevation 1,025 feet msl. The possible outcomes of such a consultation process are unknown; therefore, for modeling purposes it was assumed that shortages of 500 kaf would continue to be applied at Lake Mead elevations below 1,025 feet msl.

[7] Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 Treaty or to represent current United States policy or a determination of future United States policy regarding deliveries to Mexico. The United States will conduct all necessary and appropriate discussions regarding the proposed federal action and implementation of the 1944 Treaty with Mexico through the IBWC in consultation with the Department of State.

2.7.3 Creation and Delivery of ICS

The Preferred Alternative is similar to the Basin States and Conservation Before Shortage alternatives. It includes the adoption of a mechanism to encourage and account for augmentation and conservation of water supplies. The mechanism provides for the creation, accounting, and delivery of ICS. At the time the ICS is created, five percent of the ICS would be dedicated to the Colorado River system on a one-time basis. Additionally, ICS accounted for in Lake Mead longer than one year would be subject to annual evaporation losses of three percent per year. If flood control releases occur, ICS would be reduced on a pro-rata basis until no ICS remains, i.e., ICS would be released first.

The maximum amount of ICS that can be created during any year, the maximum cumulative amount of ICS that can be available at any one time, and the maximum amount of ICS that may be delivered in any one year under the Preferred Alternative are presented in Table 2.7-1. ICS that is assumed to be created by other entities is shown in Table 2.7-1 as "Additional Amounts."

Table 2.7-1
Preferred Alternative
Volume Limitations of ICS

Entity	Maximum Annual ICS Creation (kaf)	Maximum Cumulative ICS (kaf)	Maximum Annual ICS Delivery (kaf)
Arizona	100	300	300
California	400	1,500	400
Nevada	125	300	300
Total[1]	625	2,100	1,000
Additional Amounts	625	2,100	1,000
Total[2]	1,250	4,200	2,000

1 *It is anticipated that the ICS mechanism will be implemented to allow a maximum cumulative amount of ICS that would be available at any one time of up to 2.1 maf.*

2 *The analysis of potential effects in this Final EIS includes a maximum cumulative amount of ICS that would be available at any one time of up to 4.2 maf.*

2.7.4 Interim Surplus Guidelines

The Preferred Alternative assumes the same modifications to and extension of the term of the ISG as described under the Basin States and Conservation Before Shortage alternatives (Sections 2.3 and 2.4, respectively).

2.7.5 Preferred Alternative Summary and Conclusions

The Preferred Alternative is the most reasonable and feasible alternative among those considered and analyzed in the Final EIS. The potential environmental effects of this action alternative, as well as the No Action Alternative and the four other action alternatives have been fully analyzed in the Final EIS. The environmental effects of the Preferred Alternative are well within the range of anticipated effects of the alternatives presented in the Draft EIS and do not affect the environment in a manner not already considered in the Draft EIS.

Reclamation has determined that the four key operational elements described and evaluated in the Draft EIS and selected to formulate the Preferred Alternative best meet all aspects of the purpose and need for the proposed federal action as discussed below. Additionally, Reclamation has developed draft operational guidelines (Appendix S) for how the Preferred Alternative may be implemented during the interim period. These guidelines may be revised and refined prior to adoption in the ROD.

1) **Shortage Guidelines:** The Preferred Alternative defines discrete levels of shortage volumes associated with Lake Mead reservoir elevations. This will provide water users and managers in the Lower Basin with greater certainty with regard to when, and by how much, water deliveries will be reduced in drought and other low reservoir conditions.

2) **Coordinated Reservoir Operations:** The Preferred Alternative proposes coordinated operations of Lake Powell and Lake Mead throughout the full range of operational elevations. Better management of these reservoirs at higher elevations has a direct impact on available storage, thereby affecting the likelihood and severity of potential future shortages.

3) **Creation and Delivery of ICS:** The Preferred Alternative proposes a mechanism to encourage and account for augmentation and conservation of water supplies and thereby minimize the likelihood and severity of potential future shortages. This mechanism provides for the creation, accounting, and delivery of ICS.

   Under the Preferred Alternative, the maximum cumulative amount of ICS that could be available at any one time is 2.1 maf. This amount could be increased up to 4.2 maf in future years. Depending on the severity of drought and low reservoir conditions, it may be desirable to facilitate greater conservation. As appropriate, the Secretary will enter into agreements to deliver ICS.

   At the time the ICS is created, five percent of the ICS would be dedicated to the Colorado River system on a one-time basis. This system assessment will benefit the system and enhance the water in storage in Lake Mead and would be available to meet future needs.

   The draft interim operational guidelines (Appendix S) set forth Reclamation’s concepts for the creation of ICS, verification, water accounting procedures, and any necessary forbearance agreements required to deliver ICS as contemplated under the Preferred Alternative. Although the guidelines for this element are interim and will expire in 2026, some of the conservation projects established under the guidelines could be permanent in duration.

4) **Interim Surplus Guidelines:** The draft interim operational guidelines (Appendix S) would extend the ISG, providing for an operational strategy for the full range of reservoir operations through 2026. The ISG would also be modified by eliminating the Partial Domestic Surplus Condition, beginning in 2008, and by limiting the amount of water available under the Full Domestic Surplus Condition during the

period 2017 through 2026. The elimination of the Partial Domestic Surplus Condition reduces the amount of surplus water that could be made available and leaves more water in storage to reduce the severity of future shortages.

2.8 Summary Comparison of Alternatives

Summary comparisons of the alternatives identified and analyzed in the Final EIS are provided in Table 2.8-1 as a matrix of alternatives and their formulation for each of the four operational elements of the proposed federal action. Table 2.8-2 provides a comparison of the alternatives under the Coordinated Reservoir Operations element of the proposed federal action for Lake Powell. Table 2.8-3 provides a comparison of the alternatives under the Shortage Guidelines element of the proposed federal action for Lake Mead.

Table 2.8-1
Matrix of Alternatives

Alternatives	Shortage Guidelines to Reduce Deliveries from Lake Mead (elevation in feet msl)	Coordinated Reservoir Operations (Lake Mead & Lake Powell) (elevation in feet msl)	Lake Mead Storage and Delivery of Conserved System and Non-system Water	Interim Surplus Guidelines (ISG) for Deliveries/Releases from Lake Mead
No Action	▪ Determination made through the AOP process, absent shortage guidelines ▪ Reasonably represented by a two-level shortage strategy - probabilistic protection of Lake Mead elevation 1,050 and absolute protection of Lake Mead elevation 1,000	▪ Minimum objective release of 8.23 maf from Lake Powell unless storage equalization releases are required ▪ Operation at low reservoir levels reasonably represented by a 8.23 maf release from Lake Powell down to Lake Powell dead pool	▪ No water management mechanism for storage and delivery of conserved system and non-system water	▪ No modification or extension of the ISG which end in 2016 ▪ After 2016, determination made through the AOP process, absent surplus guidelines; reasonably represented by the spill avoidance (referred to as the 70R) strategy
Basin States	▪ Shortages (i.e., reduced deliveries in the United States) of 333, 417, and 500 kaf from Lake Mead at elevations 1,075, 1,050, and 1,025 respectively [1] ▪ Initiate efforts to develop additional guidelines for shortages if Lake Mead falls below elevation 1,025 (Note: includes consultation with Basin States)	▪ Under high reservoir conditions, minimum objective release of 8.23 maf from Lake Powell unless storage equalization releases are required ▪ Under lower reservoir conditions, either reduce Lake Powell release or balance volumes depending upon elevations at Lake Powell and Lake Mead	▪ Creation, accounting, and delivery of ICS ▪ Maximum total ICS of 2.1 maf ▪ System assessment of 5% when ICS is created	▪ Modification of ISG to eliminate Partial Domestic Surplus condition ▪ Extension of the modified guidelines through 2026
Conservation Before Shortage	▪ Shortages are implemented in any given year when necessary to keep Lake Mead above SNWA's lower intake at elevation of 1,000 (absolute protection of elevation 1,000)	▪ Under high reservoir conditions, minimum objective release of 8.23 maf from Lake Powell unless storage equalization releases are required ▪ Under lower reservoir conditions, either reduce Lake Powell release or balance volumes depending upon elevations at Lake Powell and Lake Mead	▪ Prior to shortage, conservation of different volumes of water tied to Lake Mead elevation ▪ Creation, accounting, and delivery of ICS ▪ Water for environmental uses ▪ Maximum total ICS of up to 4.2 maf ▪ System assessment of 5% when ICS is created	▪ Modification of ISG to eliminate Partial Domestic Surplus condition ▪ Extension of the modified guidelines through 2026
Water Supply	▪ Release full annual entitlement amounts until Lake Mead is drawn down to dead pool (elevation 895)	▪ Minimum objective release of 8.23 maf from Lake Powell unless storage equalization releases are required ▪ Balancing if Lake Powell is below elevation 3,575 or Lake Mead is below elevation 1,075	▪ No water management mechanism for storage and delivery of conserved system and non-system water	▪ Extension of the existing ISG through 2026
Reservoir Storage	▪ Shortages (i.e., reduced deliveries in the United States) of 500, 667, 833, and 1,000 kaf from Lake Mead at elevations 1,100, 1,075, 1,050, and 1,025 respectively[1]	▪ Minimum objective release of 8.23 maf from Lake Powell if Lake Powell is above elevation 3,595 unless storage equalization releases are required ▪ 7.8 maf release from Lake Powell between Lake Powell elevations of 3,560 and 3,595 ▪ Balancing below Lake Powell elevation 3,560	▪ Storage and delivery of conserved system and non-system water ▪ Maximum total storage of conserved system and non-system water of 3.05 maf ▪ System assessment of 10% of stored conserved system and non-system water	▪ Provisions of existing ISG terminate after 2007, and during period from 2008-2026, surplus determinations are limited to 70R and Flood Control conditions
Preferred Alternative	▪ Shortages (i.e., reduced deliveries in the United States) of 333, 417, and 500 kaf from Lake Mead at elevations 1,075, 1,050, and 1,025 respectively[1] ▪ Initiate efforts to develop additional guidelines for shortages if Lake Mead falls below elevation 1,025 (Note: Includes consultation)	▪ Under high reservoir conditions, minimum objective release of 8.23 maf from Lake Powell unless storage equalization releases are required ▪ Under lower reservoir conditions, either reduce Lake Powell release or balance volumes depending upon elevations at Lake Powell and Lake Mead	▪ Creation, accounting, and delivery of ICS ▪ Maximum total ICS in Lake Mead of up to 4.2 maf ▪ System assessment of 5% when ICS is created	▪ Modification of ISG to eliminate Partial Domestic Surplus condition ▪ Extension of the modified guidelines through 2026

[1] These are amounts of shortage (i.e., reduced deliveries in the United States). As in the Draft EIS, the Final EIS includes modeling assumptions that identify water deliveries to Mexico pursuant to the 1944 Treaty.

[1] These are amounts of shortage (i.e., reduced deliveries in the United States). As in the Draft EIS, the Final EIS includes modeling assumptions that identify water deliveries to Mexico pursuant to the 1944 Treaty.
[2] If Lake Mead falls below elevation 1,025, the Department will initiate efforts to develop additional guidelines for shortages at lower Lake Mead elevations.

2.9 Summary of Potential Effects

Table 2.9-1 presents a summary of the potential effects of the alternatives. Chapter 4 contains detailed descriptions of these effects.

Table 2.9-1
Summary of Potential Effects of the Alternatives

Final EIS Section	Environmental Consequences by Resource, Year and Value	Alternatives					
		No Action	Basin States	Conservation Before Shortage	Water Supply	Reservoir Storage	Preferred Alternative
4.3	Hydrologic Resources						
	Probability of Glen Canyon annual release volumes ≥ 7.5 maf, 2009 to 2060	99.96%	96.66%	96.66%	97.9%	100%	96.39%
	Probability of Glen Canyon annual release volumes ≥ 8.23 maf, 2009 to 2060	99%	96.32%	96.38%	96.33%	93.79%	96.64%
	Lake Powell March elevation, probability of water levels ≤ 3,490 feet msl 2026	1.0%	0%	0%	9.0%	0%	0%
	Lake Mead July elevation, probability of water levels ≤ 1,050 feet msl 2026	30%	23%	23%	29%	9%	21%
	Hoover Dam annual release, 2026 50th percentile values	9.04 maf	9.17 maf	9.11 maf	9.39 maf	8.68 maf	9.16 maf
4.4	Water Deliveries						
	Probability of involuntary shortage, 2026	49%	35%	7%	12%	37%	41%
	Probability of voluntary and involuntary shortage, 2026	49%	35%	36%	12%	37%	41%
	Probability of normal deliveries, 2026	34%	26%	25%	47%	45%	19%
	Probability of surplus, 2026	17%	39%	39%	41%	18%	40%
4.5	Water Quality

Chapter Three

3.1 Introduction

Chapter 3 describes environmental resources (e.g., hydrologic, biologic, and socioeconomic) of the Colorado River Basin that could be affected by the proposed federal action and the range of alternatives for implementing the proposed federal action described in Chapter 1 and Chapter 2, respectively. The extent to which each specific resource may be impacted is discussed in Chapter 4.

Section 3.2 presents a general discussion of the geographic scope within which potential effects of the alternatives are analyzed, and describes each of the potentially affected Colorado River reaches and water service areas. Subsequent sections in this chapter describe specific resources that may be potentially affected, such as water deliveries, recreation and biologic resources. Each resource section contains a discussion of one or more specific issues identified for consideration through scoping, public review and comment, and internal review (Chapter 1, Table 1.5-1).

This page intentionally left blank.

3.2 Geographic Scope

The proposed federal action considers modified operations of Lake Powell and Lake Mead over a wide range of reservoir elevations as addressed by the four operational elements discussed in Section 1.2, i.e., shortage conditions, coordinated operations of Lake Powell and Lake Mead, storage and delivery of Colorado River system and non-system water, and the modified ISG. Such operational changes may affect reservoir storage levels of, and releases from, Lake Powell and Lake Mead, which in turn may subsequently affect river flows, available water supplies, and other resources.

This section describes the geographic scope of specific issues and potential effects associated with changes in the operations of Lake Powell and Lake Mead, as discussed and analyzed under the alternatives considered in this Final EIS (Chapter 2). Reservoirs located upstream of Lake Powell and operated independently of Lake Powell would not be affected by the proposed federal action. However, the releases from Lake Powell and Lake Mead and downstream river flows could be affected by these changes. As such, the upstream limit of the potentially affected environment for the purposes of this Final EIS is the full pool elevation of Lake Powell, and the downstream limit is the SIB (Figure 3.2-1).

In addition to the potential impacts that may occur within the Colorado river corridor, the alternatives may also affect the water supply that is available to specific Colorado River water users in the Lower Basin due to the shortage guidelines element of the proposed federal action. The following water agency service areas are included in the affected environment discussions:

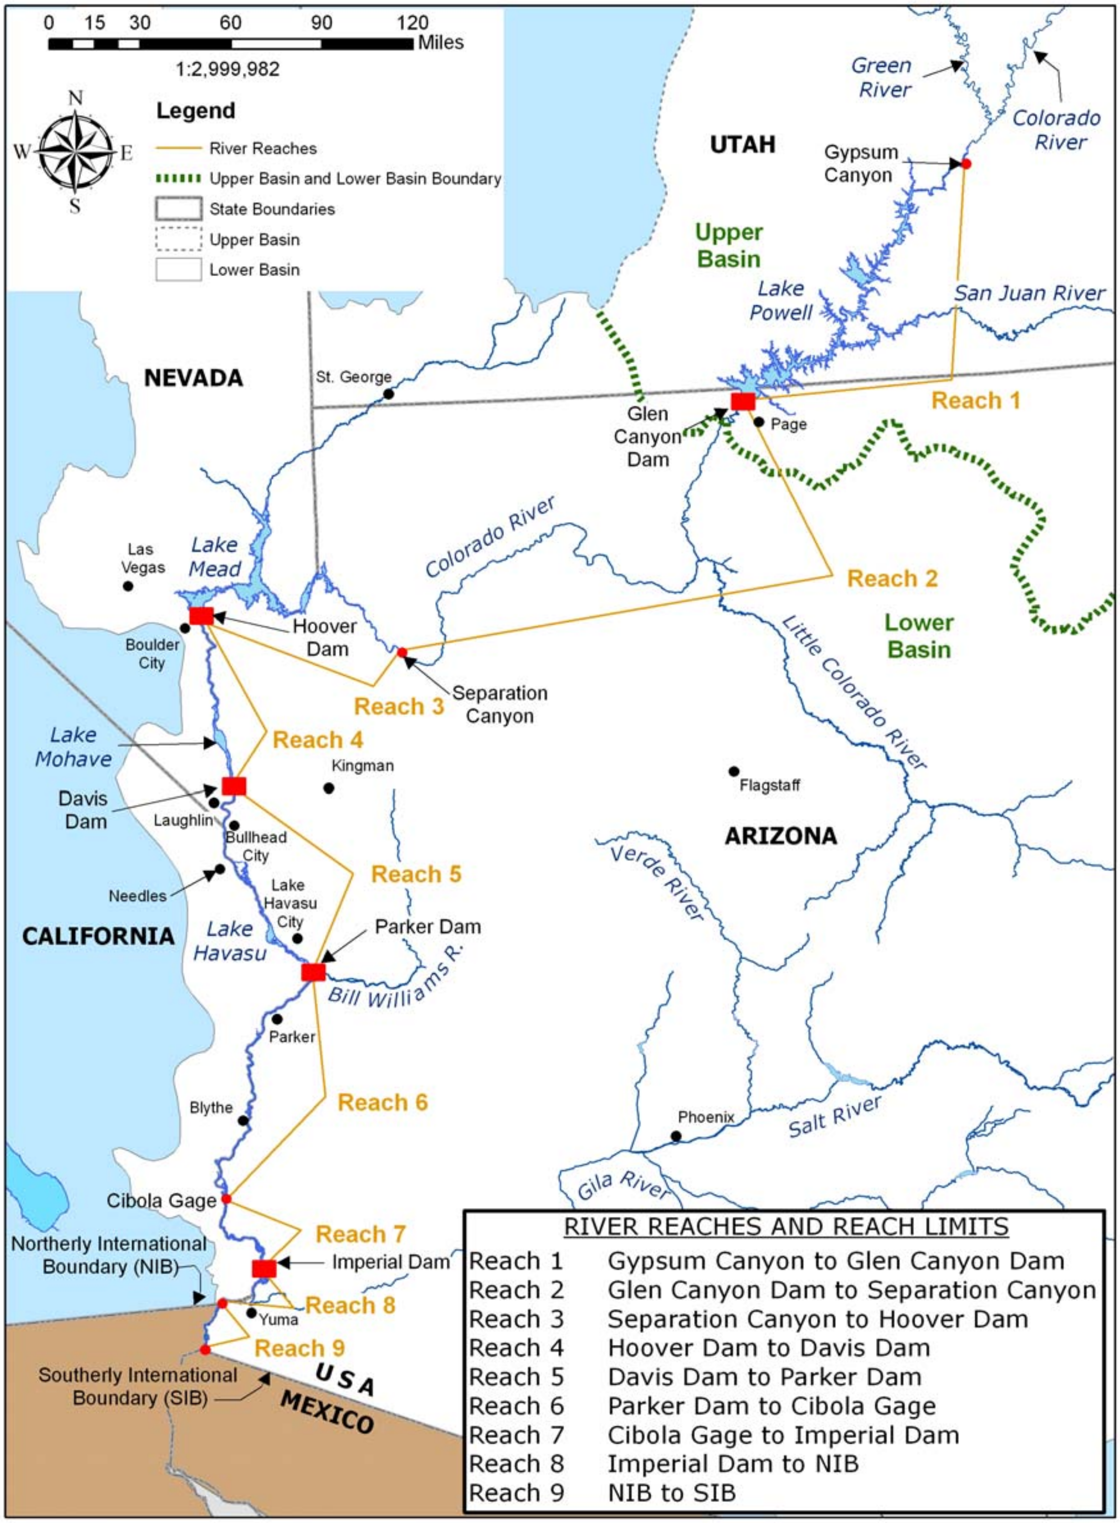
- Arizona water users, particularly the lower priority water users located in the CAP service area;
- The SNWA service area; and
- The MWD service area.

3.2.1 Definition of Colorado River Reaches

The section of the Colorado River extending from Lake Powell to the SIB consists of river reaches, two large reservoirs (Lake Powell and Lake Mead) and two smaller reservoirs located downstream of Lake Mead (Lake Mohave and Lake Havasu, Figure 3.2-2). The Colorado River and adjacent areas (i.e., backwaters and marshes) comprise heterogeneous geographic and hydrologic regimes, which differ in their resource composition and resource management administration.

Figure 3.2-1
Geographic Scope

Figure 3.2-2
Colorado River Reaches



For ease of discussion with respect to affected areas and potential effects, the Colorado River has been divided into the following reaches (Table 3.2-1).

Table 3.2-1
Colorado River Reaches and Reach Limits

Reach	Reach Limits[2]
Lake Powell and Glen Canyon Dam	Gypsum Canyon to Glen Canyon Dam (RM 712.9)
Glen Canyon Dam to Lake Mead	Glen Canyon Dam to Separation Canyon (RM 450.6), *including Grand Canyon National Park*
Lake Mead and Hoover Dam[1]	Separation Canyon (RM 450.6) to Hoover Dam (RM 342.2), *including Lake Mead*
Hoover Dam to Davis Dam[1]	Hoover Dam (RM 342.2) to Davis Dam (RM 276), *including Lake Mohave*
Davis Dam to Parker Dam[1]	Davis Dam (RM 276) to Parker Dam (RM 192.3), *including Lake Havasu*
Parker Dam to Cibola Gage (Adobe Ruin) [1]	Parker Dam (RM 192.3) to Adobe Ruin and Reclamation's Cibola Gage (RM 87.3)
Cibola Gage to Imperial Dam[1]	Reclamation's Cibola Gage (RM 87.3) to Imperial Dam (RM 49.2)
Imperial Dam to Northerly International Boundary (NIB) [1]	Imperial Dam (RM 49.2) to the NIB (RM 23.1)
NIB to SIB[1]	NIB (RM 23.1) to SIB (RM 0.0)

1 These reaches are identical to those described in the LCR MSCP (Reclamation 2004a-e).

2 For purposes of this Final EIS, river miles are numbered along the length of the Colorado River channel south to north starting with RM 0.0 at the SIB with Mexico. Dam locations, other features and reach limits are identified and noted at their respective river miles.

These reaches and their associated issues are discussed briefly below and in more detail in Section 3.3, Hydrologic Resources. Each of the resource discussions is generally organized by river reaches and in some instances the river reaches are combined to better focus the discussion of issues.

3.2.1.1 Lake Powell and Glen Canyon Dam

Lake Powell is the second largest reservoir on the Colorado River and has a total storage capacity of 24.32 maf. It is formed by waters of the Colorado River impounded by Glen Canyon Dam. The reservoir is narrow, over 180 miles in length, and has a shoreline that is over 1,900 miles long. Lake Powell primarily provides water storage for use in meeting the delivery requirements to the Lower Basin consistent with the Law of the River. At the full pool elevation of Lake Powell, this reach includes approximately 25 miles of Cataract Canyon, 50 miles of the San Juan River, and approximately 170 miles of Glen Canyon.

Lake Powell is located within the GCNRA which is administered by NPS. Reclamation retains authority and discretion for the operation of Glen Canyon Dam and Lake Powell. The Navajo Indian Reservation also borders a segment of this river reach. The City of Page, Arizona is also located within this reach and diverts water from Lake Powell.

3.2.1.2 Glen Canyon Dam to Lake Mead

This reach of the Colorado River extends from Glen Canyon Dam to the upper limits of Lake Mead. It is comprised of a narrow river corridor through the last 15 miles of Glen Canyon, Marble Canyon, and Grand Canyon. These canyons are in the GCNRA and Grand Canyon National Park which are administered by NPS. Navajo Indian Reservation and Hualapai Indian Reservation also border segments of this river reach.

3.2.1.3 Lake Mead and Hoover Dam

Lake Mead, formed by Hoover Dam, is the largest reservoir on the Colorado River and has a total storage capacity of 27.38 maf. The reservoir is approximately 115 miles in length and has a shoreline that is over 550 miles long. The reservoir provides water storage to regulate the water supply and meet the delivery requirements of the Lower Division states and Mexico. The reservoir is located within the LMNRA which is administered by NPS. Reclamation retains authority and discretion for the operation of Hoover Dam and Lake Mead.

3.2.1.4 Hoover Dam to SIB

The Colorado River reach from Hoover Dam to the SIB is contained within the shallow Colorado River Valley in which Lake Mohave, Lake Havasu and other smaller diversion reservoirs are located. Under the BCPA and the Consolidated Decree (Chapter 1), releases from Hoover Dam are generally made to meet the downstream water delivery requirements for Arizona, California, Nevada, and Mexico. The northern segment of this river reach, which includes Lake Mohave, lies within the LMNRA, which is administered by NPS. The lower reach is bordered by a combination of federal, Tribal and private land. Lake Havasu State Park is administered by the State of Arizona. Picacho State Recreation Area is administered by the State of California. Refuges managed by FWS include Havasu National Wildlife Refuge (NWR), Bill Williams River NWR, Cibola NWR, and Imperial NWR. Fort Mojave, Chemehuevi, Colorado River Indian, Fort Yuma Indian, and Cocopah Indian Reservations are located along this river reach. The 23.7 mile long reach that extends between the NIB to the SIB also forms part of the international boundary with Mexico.

The individual reaches included between Hoover Dam and the SIB are:

- **Hoover Dam to Davis Dam.** This reach extends from Hoover Dam to Davis Dam and includes Lake Mohave up to its full pool elevation. The approximately 67-mile length of this reach generally comprises Lake Mohave. The reach is bound for most of its length by the steep walls of Pyramid Canyon, El Dorado Canyon, and Black Canyon. Lake Mohave is relatively narrow, not more than four miles across at its widest point. A major feature located within this reach is the Willow Beach National Fish Hatchery which is located on the Colorado River approximately five miles downstream of Hoover Dam. The Willow Beach National Fish Hatchery is managed by FWS and is used as a hatchery and for rearing razorback suckers and bonytail chub which are used for stocking nearby Lake Mohave and Lake Mead.

- **Davis Dam to Parker Dam.** This reach extends from Davis Dam to Parker Dam and includes Lake Havasu up to its full pool elevation. Parker Dam is located approximately 155 miles downstream from Hoover Dam. The upper 39 miles of this reach comprises an open river reach. Lake Havasu, formed by Parker Dam, comprises the lower 45 miles of this reach and can store approximately 0.648 maf of water. At its maximum elevation of 450.5 feet msl, Lake Havasu has a surface area of approximately 20,390 acres.

  Several communities are located adjacent to this reach and include Laughlin, Needles, Bullhead City, and Lake Havasu City. The Fort Mojave and Chemehuevi Indian Reservations are also located within this reach. Other important features located within this reach include Topock Marsh and the Havasu NWR, both managed by FWS. Topock Marsh is located on the Arizona side of the Colorado River midway between Davis Dam and Parker Dam and it is almost entirely within the Havasu NWR. Topock Marsh was created by backwaters resulting from the construction of Parker Dam. The Bill Williams River, a major tributary to the Colorado River, discharges to this reach at a point located just upstream of Parker Dam.

  Lake Havasu provides a forebay and desilting basin from which water is pumped into the Colorado River Aqueduct (California) and the CAP Aqueduct System (Arizona). The pumping plant that pumps water into the Colorado River Aqueduct is located on the west side of the river and operated by the MWD. The pumping plant that pumps water into the CAP Aqueduct System is located on the east side of the river and operated by the Central Arizona Water Conservation District (CAWCD).

- **Parker Dam to Cibola Gage.** This reach is approximately 105 miles long and extends from Parker Dam to Adobe Ruin and Reclamation's Cibola Gage located at RM 87.3. The reach is generally channelized with the greater portion bound by levees. Several features located downstream of Parker Dam are also used to manage the flows in the river and make deliveries to the Colorado River water users that divert water downstream of Parker Dam. These features include Palo Verde Diversion Dam and Headgate Rock Dam. Lake Moovalya, the reservoir impounded by Headgate Rock Dam, is located between Parker Dam and Headgate Rock Dam. Several communities are located adjacent to this reach and include the cities of Parker, Arizona and Blythe, California. The Colorado River Indian Reservation is also located within this reach, as is the Cibola NWR.

- **Cibola Gage to Imperial Dam.** This reach is approximately 38 miles long and extends from Cibola Gage to Imperial Dam. The major features located within this reach include Senator Wash Dam, Martinez Lake, Imperial NWR, and Imperial Dam. Senator Wash Dam and Regulating Reservoir are located approximately two miles upstream of Imperial Dam on the California side of the Colorado River. This is an off-stream water storage reservoir that is used by Reclamation to facilitate water scheduling and to help in balancing the river flows and supply with demands. Imperial Dam and the impoundment that it forms upstream of the dam raises the water surface of the river flows by approximately 25 feet to provide controlled gravity flow of water into the AAC and the Gila Gravity Main Canal. The AAC system diverts water from the California side of Imperial Dam and serves the Imperial Irrigation District (IID), the Coachella Valley Water District (CVWD), the Yuma Project in Arizona and California, and the City of Yuma. The Gila Gravity Main Canal system diverts water from the Arizona side of Imperial Dam and serves the north and south Gila Valley, Yuma Mesa, and Wellton-Mohawk area. Imperial Dam is also used to regulate deliveries to Mexico. The AAC Desilting Works, which is located adjacent to the AAC diversion structure, is used to remove most of the sediment carried by the Colorado River prior to the water entering the AAC. The Imperial NWR is located mostly on the Arizona side of the Colorado River. Martinez Lake is a small water cove formed by the impoundment and backwater located upstream of Imperial Dam.

- **Imperial Dam to NIB.** This reach extends from Imperial Dam to the NIB between the United States and Mexico. The entire extent of the channel within this reach is bound by a system of levees. Several features located downstream of Imperial Dam are also used to manage river flows and make deliveries to the Colorado River water users that divert water downstream of Imperial Dam. These features include Laguna Dam, Laguna Desilting Basin, Morelos Diversion Dam, California Wasteway, and Pilot Knob Wasteway. Other features include water conveyance system components (levees, bypass channels, wasteways, etc.), access roads, farmlands, and vegetation. Mittry Lake is also located on the Arizona side of the Colorado River. The Gila River, a major tributary of the Colorado River, also discharges to the river at a point located approximately nine miles downstream of Laguna Dam.

  Laguna Dam is located on the Colorado River some five miles downstream of Imperial Dam. The original purpose of this dam was to divert Colorado River water to the Yuma Project area. Laguna Dam now serves as a regulating structure for Colorado River water, for regulating sluicing flows from Imperial Dam, and for downstream toe protection for Imperial Dam. The reservoir created by Laguna Dam is commonly referred to as Laguna Reservoir.

Mittry Lake is located on the east side of the Colorado River between Laguna Dam and Imperial Dam. The Mittry Lake Wildlife Area generally surrounds and includes Mittry Lake and includes approximately 600 acres of water surface and 2,400 acres of marsh or upland habitat. Numerous serpentine waterways connect to the main lake body. The Mittry Lake Wildlife Area is jointly managed by BLM, Reclamation, and the Arizona Game and Fish Department.

The California Wasteway of the Yuma Main Canal is located approximately four miles downstream of the mouth of the Gila River. This wasteway returns to the river the water which is used to fulfill the 1944 Treaty obligation to Mexico. The Rockwood Heading, an old intake structure on the Alamo Canal, is located approximately two miles upstream of Morelos Diversion Dam. It is no longer used for an intake structure but it is used as a point of return for the Pilot Knob Powerplant and Wasteway from the AAC. Under normal operating procedures, a portion of the water scheduled to be delivered to Mexico is diverted at Imperial Dam, conveyed via the AAC, and then returned to the Colorado River through the California and Pilot Knob waterways.

- **NIB to SIB.** This reach extends from the NIB to the SIB and it is 23.7 miles long. This section of the Colorado River, referred to as the limitrophe section, serves as the international boundary between the United States and Mexico, and has levees on both sides.

  Located approximately 1.1 miles downstream of the NIB is Morelos Diversion Dam. This dam functions as a diversion control structure for the Alamo Canal, which conveys water to Mexico. The Morelos Diversion Dam and the limitrophe section of the Colorado River channel, including the floodplain, are designed to handle a maximum flow of 140,000 cubic feet per second (cfs). Other major features located within this reach include water conveyance system components (levee, bypass channel, wasteways, etc.) and access roads.

3.2.2 Colorado River Water User Service Areas

In addition to the mainstream river reaches and potentially affected service areas of mainstream water users, certain off stream service areas of Colorado River water users may be affected as a result of water management programs associated with the proposed federal action. These potential effects correspond to the following agency water service areas.

3.2.2.1 Arizona Water Users, Central Arizona Project Service Area

The largest Arizona diversion of water is the CAP, which delivers water to contractors in the central part of the state. CAP's diversion is located at Lake Havasu. The CAWCD administers the CAP water diversions. The CAP has more than 80 customers that generally fall within three classifications of CAP users: municipal (e.g., cities such as Phoenix, Mesa, and Scottsdale), agricultural (irrigation districts such as the Maricopa-Stanfield Irrigation District), and Indian communities (12 tribes with Colorado River water allocations within Arizona). Figure 3.2-3 presents the general service area of the CAP, and Table 3.2-2 provides a listing of the CAP water users.

Figure 3.2-3
CAP Service Area

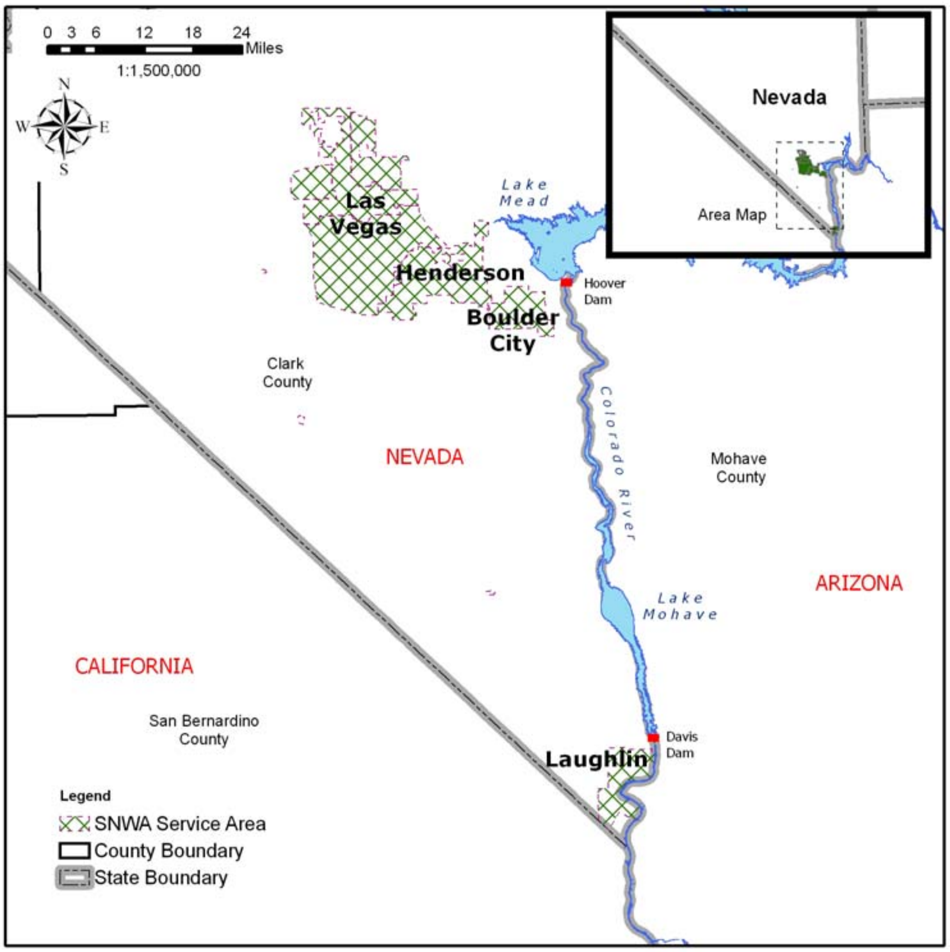
ID; Irrigation District

3.2.2.2 Southern Nevada Water Authority Service Area

Most of the Colorado River water use in Nevada occurs in the southern portion of Nevada, primarily within the Las Vegas Valley and the Laughlin area approximately 60 miles south. The largest diversion is associated with the Las Vegas Valley water users who pump water from Lake Mead at Saddle Island (on the west shore of the lake's Boulder Basin) through facilities of SNWA. SNWA is a wholesale water purveyor whose member agencies are: Big Bend Water District, Boulder City, Clark County Water Reclamation District, Henderson, Las Vegas, Las Vegas Valley Water District, and North Las Vegas (Figure 3.2-4).

Figure 3.2-4
SNWA Service Area

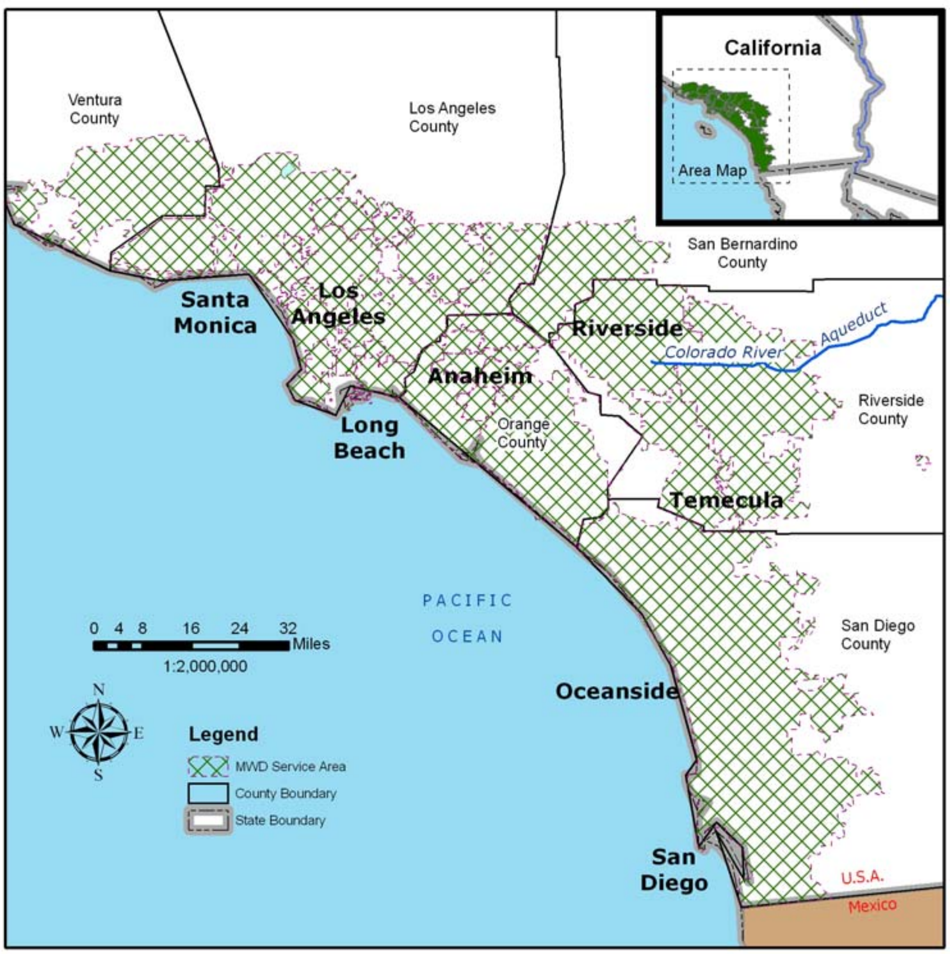


3.2.2.3 Metropolitan Water District of Southern California Service Area

MWD is a wholesale water agency that develops, stores, and distributes water to its member agencies. MWD owns and operates the Colorado River Aqueduct, which it uses to convey water from the Colorado River to its service area. MWD's Colorado River Aqueduct diversion is located at Lake Havasu.

MWD's service area covers the Southern California coastal plain. The total area served is nearly 5,200 square miles, and it includes portions of Los Angeles, Orange, Riverside, San Bernardino, San Diego, and Ventura counties. MWD is currently composed of 26 member agencies, including 14 cities, 11 municipal water districts, and one county water authority. Figure 3.2-5 shows the member agencies of MWD and the cities and communities served by those member agencies.

Figure 3.2-5
MWD Service Area



3.3 Hydrologic Resources

Hydrologic resources within the study area that could potentially be affected by implementation of the proposed federal action include:

- reservoir storage, reservoir releases, and corresponding changes in Colorado River flows downstream of the reservoirs; and
- groundwater located within the Colorado River corridor and/or off-stream.

This section presents an overview of the hydrology of the Colorado River Basin, followed by descriptions of potentially affected hydrologic resources by river reach, from Lake Powell to the SIB.

A detailed description of the system facilities and current operations is provided in Appendix B. Water supply and water quality resources are discussed in Section 3.4 and Section 3.5, respectively.

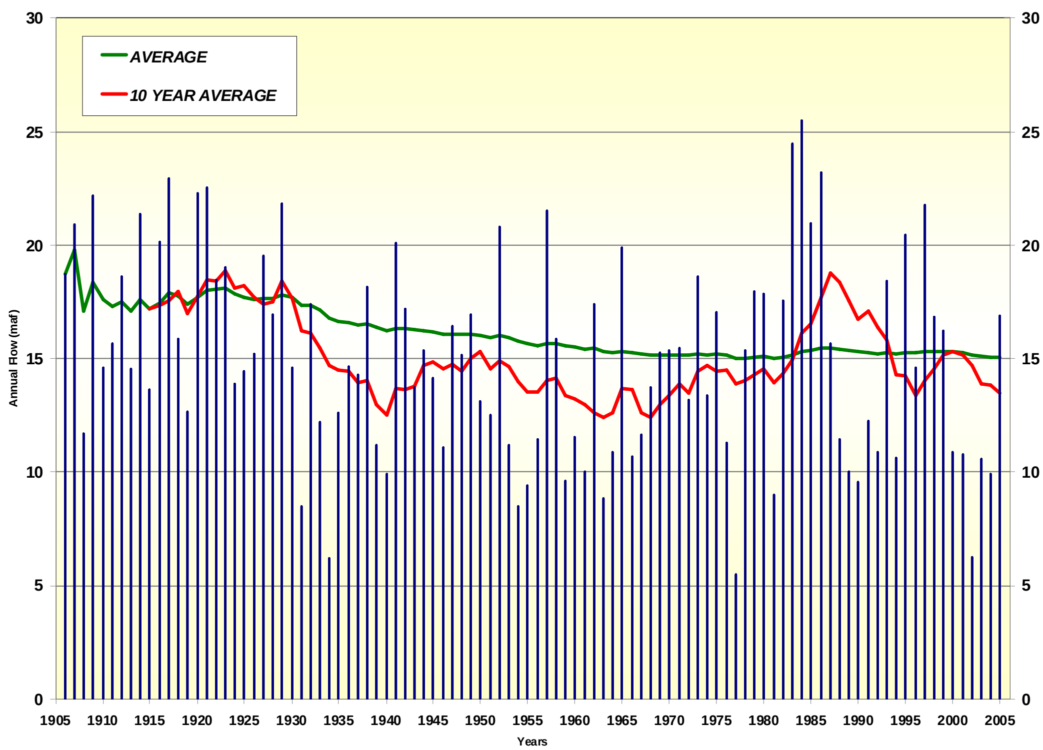
3.3.1 Hydrologic Overview

Inflows into Lake Powell originate from the mainstream of the Colorado River, Green River, and San Juan River. Although most of the Colorado River Basin is comprised of desert or semi-arid rangelands, which generally receive less than ten inches of precipitation per year, many of the mountainous areas that rim the Upper Basin receive, on average, over 40 inches of precipitation per year. Most of the total annual flow in the Colorado River Basin is the result of runoff from mountain snowmelt. As such, river flows are typically very high in the late spring and early summer and diminish rapidly by mid-summer. While flows in late summer through autumn sometimes increase following rain events, flow in the late summer through winter is generally low.

Due to variability in climatic conditions, natural flow in the Colorado River Basin is highly variable from year to year. Natural flow is an estimate of the flow that would exist at a specific point in a natural setting, without upstream storage, alteration or depletion by humans. About 92 percent of the total natural flow in the lower Colorado River originates in only 15 percent of the watershed in the mountains of Colorado, New Mexico, Utah, and Wyoming. While the average annual natural flow from 1906 through 2005 at Lees Ferry Gaging Station in Arizona is currently calculated as approximately 15.072 maf, annual flows have ranged between 5.399 maf and 25.432 maf.

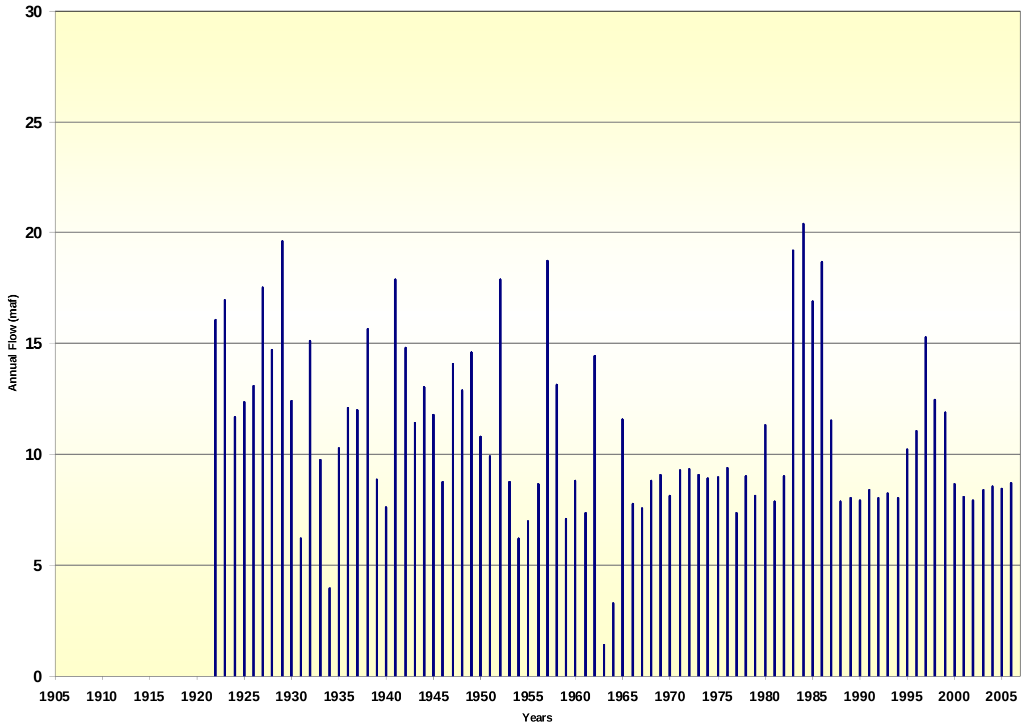
The natural flow calculated at Lees Ferry Gaging Station from 1906 through 2005 is shown in Figure 3.3-1. By comparison, the observed flows recorded at Lees Ferry Gaging Station for the period 1922 through 2005 are shown in Figure 3.3-2. The natural flow has been calculated from the observed flow by correcting for upstream reservoir changes in storage and release, losses including evaporation, as well as depletions due to agriculture and domestic uses (Reclamation 2005b). The natural flow record at Lees Ferry Gaging Station has also been extended from 1922 back to 1906 by using other observed records (Lee et al. 2006).

Figure 3.3-1
Natural Flow of the Colorado River at Lees Ferry Gaging Station, Arizona
1906 through 2005



Provisional data, subject to change.

Figure 3.3-2
Historic Annual Flow of the Colorado River at Lees Ferry Gaging Station, Arizona
1922 through 2005



Data from Upper Colorado Hydrologic Database

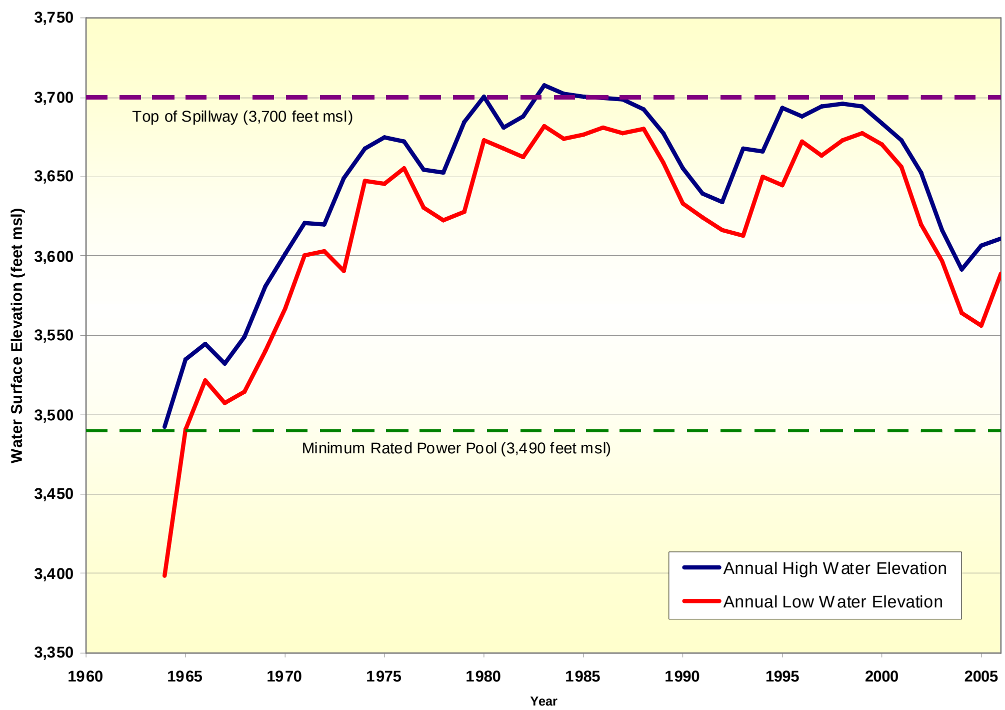
3.3.2 Lake Powell and Glen Canyon Dam

Lake Powell is the reservoir impounded by Glen Canyon Dam. Glen Canyon Dam and Lake Powell are operated consistent with the Colorado River Storage Project Act, the authorizing legislation, which states that the purpose of the project is … "to initiate the comprehensive development of the water resources of the Upper Colorado River Basin, for the purposes, among others, of regulating the flow of the Colorado River, storing water for beneficial consumptive use, making it possible for the States of the Upper Basin to utilize, consistently with the provisions of the Colorado River Compact, the apportionments made to and among them in the Colorado River Compact and the Upper Colorado River Basin Compact, respectively, providing for the reclamation of arid and semiarid land, for the control of floods, and for the generation of hydroelectric power, as an incident of the foregoing purposes … "Additionally, some water deliveries are made directly from Lake Powell (e.g., for the City of Page, Arizona and for the Navajo Generating Station's cooling water).

The operating range of Lake Powell is between elevations 3,490 feet msl and 3,700 feet msl. Elevation 3,490 feet msl corresponds to the minimum power pool. Releases from Glen Canyon Dam can be made below elevation 3,490 feet msl down to elevation 3,370 feet msl through the river bypass tubes. Elevation 3,700 feet msl corresponds to the top of the spillway radial gates, with the crest of each spillway at elevation 3,648 feet msl. The crest of Glen Canyon Dam itself is at elevation 3,715 feet msl.

Lake Powell began filling in 1963 and reached a high elevation of 3,708.34 feet msl in 1983. The elevation of the reservoir has ranged from approximately 3,400 feet msl in 1964 to the 1983 maximum high of 3,708.34 feet msl, as illustrated in Figure 3.3-3. The fluctuations in Lake Powell elevations are primarily the result of the highly variable hydrologic inflows into Upper Basin as discussed in Section 1.7.

Figure 3.3-3
Historic Annual Lake Powell Elevations
(Annual Highs and Lows)



Under the proposed federal action, future elevations of Lake Powell are expected to be within the range of historic reservoir elevations. However, the length of time that the reservoir may be at any given elevation in the future may be affected by the proposed federal action. These potential effects are analyzed and discussed in Section 4.3.

Releases from Glen Canyon Dam are scheduled on an annual, monthly and hourly basis. The annual volume of water released from Glen Canyon Dam is made according to the provisions of the LROC that includes a minimum objective release of 8.23 maf, storage equalization between Lake Powell and Lake Mead under prescribed conditions, and the avoidance of spills. Annual releases from Lake Powell greater than the minimum objective release occur if Upper Basin storage is greater than the storage required by Section 602(a) of the CRBPA, if storage in Lake Powell is greater than the storage in Lake Mead, and to avoid anticipated spills (Appendix A).

Monthly release decisions are generally made to meet intermediate targets needed to systematically achieve the annual operating requirements, comply with the coordinated operation requirements of the CRBPA, and provide other authorized project benefits. The actual volume of water released from Lake Powell each month depends on the inflow forecast, storage targets, and annual release requirements described above. Demand for energy is also considered and accommodated within the constraints described above.

Glen Canyon Dam is operated consistent with the 1996 Glen Canyon Dam ROD (62 Fed. Reg. 9447-9448) developed as directed under the Grand Canyon Protection Act of 1992. The 1996 Glen Canyon Dam ROD describes criteria to ensure that Glen Canyon Dam is operated in a manner consistent with the Grand Canyon Protection Act of 1992. The daily and hourly release constraints of Glen Canyon Dam are as presented in Table 3.3-1.

Table 3.3-1
Glen Canyon Dam Release Constraints

Parameter	Release Volume (cfs)	Conditions
Maximum Flow[1]	25,000	
Minimum Flow	5,000	Nighttime
	8,000	7:00 a.m. to 7:00 p.m.
Ramp Rates		
Ascending	4,000	Per hour
Descending	1,500	Per hour
Daily Fluctuations[2]	5,000 to 8,000	

1 May be exceeded for emergency and during extreme hydrological conditions.

2 Daily fluctuation limit is 5,000 cfs for months with release volumes less than 0.6 maf; 6,000 cfs for monthly release volumes of 0.6 maf to 0.8 maf; and 8,000 cfs for monthly volumes over 0.8 maf.

Pending the outcome of the Long-Term Experimental Plan (Section 5.2), future daily and hourly releases are expected to continue to be made according to the parameters of the 1996 Glen Canyon Dam ROD and will not be affected by the proposed federal action. However, the annual release as well as the monthly distribution of releases may be affected; these potential effects are analyzed and discussed in Section 4.3.

In addition to the daily and hourly release constraints discussed above, the 1996 Glen Canyon Dam ROD implemented an Adaptive Management Program that provides a process for assessing the effects of Glen Canyon Dam operations on downstream resources, and by using the results to develop recommendations to the Secretary with regard to Glen Canyon Dam operations and other resource management actions. These recommendations have included releases for sediment conservation (i.e., BHBF), modification of powerplant fluctuations, non-native fish removal, and native fish translocation. Recommendations are developed by the AMWG, a federal advisory committee. Long-term monitoring and research activities provide a continuous record of resource conditions for use in evaluating the effectiveness of any experimental and management actions.

3.3.3 Glen Canyon Dam to Lake Mead

The Colorado River reach between Glen Canyon Dam and Lake Mead is a narrow river corridor through Marble Canyon, Glen Canyon, and Grand Canyon. The flows in this river reach are primarily from controlled Glen Canyon Dam releases (Lake Powell) with contributions from tributaries between Glen Canyon Dam and Lake Mead. Releases from Glen Canyon Dam are managed as discussed in the previous section.

The Paria River and Little Colorado River are the major tributaries that discharge to the Colorado River within this reach. The Paria River is a perennial stream which also provides the principal drainage for the Painted Desert. The Little Colorado River is also a perennial stream and it drains the rugged and arid region southeast of the Colorado River.

Inflows from these two tributaries are variable and on average provide less than 3 percent of the total flow in this reach. For the 100-year period from 1906 through 2005, annual inflow from the Little Colorado River ranged from 17 kaf to 643 kaf and averaged 180 kafy. During this same period, annual inflow from the Paria River ranged from 9 kaf to 48 kaf and averaged 21 kafy. By contrast, the annual Glen Canyon Dam releases from 1996 through 2005 ranged from 7,795 kaf to 15,289 kaf and averaged 9,975 kafy. The daily and hourly releases from Glen Canyon Dam and therefore the daily and hourly flows in this reach will not be affected by the proposed federal action. However, the monthly and annual flows in this reach may be affected; these potential effects are analyzed and discussed in Section 4.3.

Groundwater in hydraulic connection with the Colorado River in Grand Canyon is limited to sandbars. Due to the incised nature of this river corridor, there are no anticipated groundwater related issues that need to be considered.

3.3.4 Lake Mead and Hoover Dam

Lake Mead is the reservoir impounded by Hoover Dam and in accordance with the BCPA, is operated to meet the following priorities:

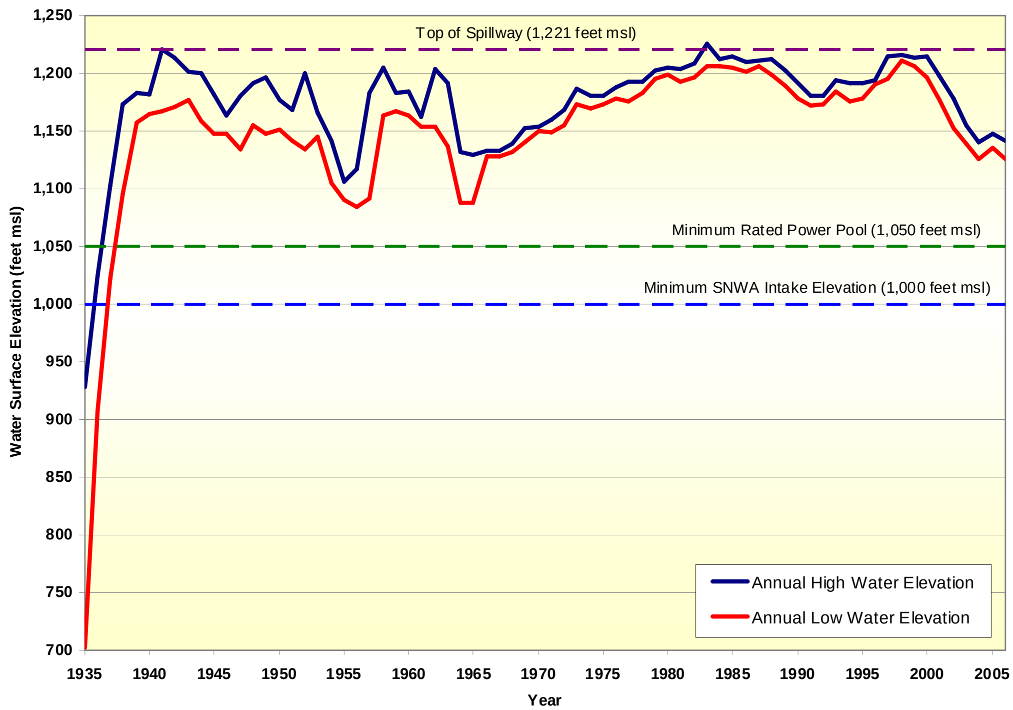
1) to provide river regulation, improvement of navigation, and flood control;

2) to provide water to meet irrigation and domestic uses, including the satisfaction of PPRs; and

3) to generate hydroelectric power.

The typical operating range of Lake Mead is between elevations 1,219.6 feet msl and 1,050 feet msl. Elevation 1,050 feet msl corresponds to the minimum power pool. Releases through the turbines can be made from Hoover Dam below elevation 1,050 feet msl down to elevation 895 feet msl through the intake towers, although the turbines currently in place would require modification or replacement to consistently generate hydroelectric power below elevation 1,050 feet msl. The crest of the spillways is at elevation 1,205.4 feet msl and the top of the raised spillway gates is at elevation 1,221.0 feet msl. The storage space above elevation 1,219.6 feet msl is reserved exclusively for flood control purposes. Since its initial filling in the late 1930s, Lake Mead elevations have fluctuated from a high of 1,225.8 feet msl in July 1983 to a low of 1,083.2 feet msl in April 1956, as illustrated in Figure 3.3-4.

Figure 3.3-4
Historic Annual Lake Mead Elevations
(Annual Highs and Lows)



Future Lake Mead elevations may be affected by the proposed federal action. These potential effects are analyzed and discussed in Section 4.3.

Lake Mead's annual release is determined either by strict flood control regulations or to meet water use apportionments to the Lower Division states and allotment to Mexico.

The USACE is responsible for developing the flood control operation plan for Hoover Dam and Lake Mead (33 C.F.R. pt. 208.11) and the Secretary is responsible for operating Hoover Dam in accordance with these regulations. The current regulations were implemented under the Field Working Agreement[1] which set forth criteria to meet system space requirements from August through December and to determine reservoir releases from January through July. During all months of the year, the top 1.5 maf of space (the space above elevation 1,219.6 feet msl) is reserved exclusively for flood control purposes. Lake Mead is considered to be under flood control operations when the regulations determine that releases need to be made in excess of those necessary to meet water use demands in order to make available this flood control space.

Water use demands are determined by the apportionments to each Lower Division state and Mexico. For the Lower Division states, the Secretary determines the water supply condition for each year (Surplus, Normal, or Shortage), as specified by the Consolidated Decree and the LROC. Under a Normal Condition, water is delivered to meet a total of 7.5 maf of use by the Lower Division states. Under a Surplus Condition, additional water can be made available for consumptive use in the Lower Division states. Adopted in 2001 and extending through 2016, the ISG provide additional guidance on the amount and use of surplus water depending upon Lake Mead's elevation and other factors. Under a Shortage Condition, an amount of water less than 7.5 maf would be made available for use by the Lower Division states. However, there are currently no guidelines with regard to when and by how much water supplies would be reduced (Section 1.3).

In addition to the releases made to meet the Lower Division states' consumptive use, releases are made from Hoover Dam to meet Mexico's water delivery schedule. In accordance with the 1944 Treaty, Mexico can schedule a total delivery of 1.5 maf each year and under current practice, up to an additional 200 kaf during flood control years when water supply exceeds the needs of Colorado River water users in the United States.

During non-flood control operations, the end-of-month Lake Mead elevations are driven by water needs pumped from and delivered downstream of Hoover Dam, releases from Glen Canyon Dam, and tributary inflows. Lake Mead end-of-month target elevations are not fixed as are the end-of-month target elevations for Lake Mohave and Lake Havasu. Normally, Lake Mead elevations decline with increasing irrigation deliveries through June and July and then rise slightly by November and December.

Hoover Dam releases are managed on an hourly basis to maximize the value of generated power by providing peaking during high-demand periods. The monthly release is determined

[1] Field Working Agreement between Reclamation and USACE for Flood Control Operation of Hoover Dam and Lake Mead, Colorado River, Nevada and Arizona, dated February 8, 1984 as prescribed by the Water Control Manual of December 1982.

based on water demands and is converted to a monthly energy target. Hoover Powerplant is run on a real-time basis to meet fluctuating energy and capacity demands while meeting the end-of-month energy target. This results in fluctuating hourly flows below Hoover Dam that can typically vary from 1,000 cfs to 49,000 cfs. However, these flows are regulated by Lake Mohave immediately downstream. For the 10-year period from 1996 through 2005, annual Hoover Dam releases ranged from 8.275 maf to 12.776 maf and averaged 10.380 mafy.

Hourly and daily releases from Hoover Dam will not be affected by the proposed federal action. However, the proposed federal action may alter the annual release as well as the monthly distribution of those releases. These potential effects are analyzed and discussed in Section 4.3.

3.3.5 Hoover Dam to Davis Dam

The 67-mile reach from Hoover Dam to Davis Dam is dominated by Lake Mohave, the reservoir formed by Davis Dam. The upper part of this reach is bounded by the steep walls of Pyramid Canyon, El Dorado Canyon, and Black Canyon. Lake Mohave is relatively narrow, not more than four miles across at its widest point. At the high reservoir elevations (635 feet msl), the backwater from Lake Mohave affects the river stage (known as the tailbay) just downstream of Hoover Dam. Although there are some minor side washes in this river reach, the flows in this reach are comprised almost entirely of releases from Hoover Dam.

The hourly and daily operation of Hoover Dam will not be affected by the proposed federal action. As such, the hourly and daily flows through this river reach will also not be affected.

Although the annual and monthly releases from Hoover Dam may be affected by the proposed federal action, Lake Mohave will continue to be operated to meet monthly target elevations as explained in Appendix B. Lake Mohave generally reaches its maximum elevation in the spring and its minimum elevation in the fall. Reclamation generally lowers the lake elevation in the fall to provide flood control storage space for runoff that results from large hurricane-type storms coming up-river from Baja California, Mexico. The minimum elevation of Lake Mohave under future conditions will continue to be about 630 feet msl. The maximum target elevation will continue to be 646.5 feet msl. Therefore, the proposed federal action will not change the range of elevations that have been historically observed in Lake Mohave. Combined with the extent of this reach occupied by Lake Mohave, the potential changes in Hoover Dam monthly and annual releases will have no effect on this reach.

The upper section of this reach is the narrow Black Canyon immediately below Hoover Dam. Groundwater connected to the river in this bedrock canyon is limited to a few small sandbars. The rest of this reach is dominated by Lake Mohave. The proposed federal action will have no effect on the operation of Lake Mohave or the elevations in this reservoir. Therefore, there are no anticipated effects of the proposed federal action to these groundwater basins.

3.3.6 Davis Dam to Parker Dam

This reach is approximately 84 miles long and it is bounded downstream by Parker Dam which forms Lake Havasu. Lake Havasu provides a forebay and desilting basin from which water is pumped into aqueducts for delivery to the MWD and CAP service areas. Above Lake Havasu, there are some minor tributaries. However, the flows in this reach are comprised almost entirely of releases from Davis Dam.

The largest tributary in this reach is the Bill Williams River, which flows directly into Lake Havasu. Inflows from the Bill Williams River are regulated by USACE operations of Alamo Dam upstream and are typically small (on the order of 50 cfs). Larger flows from Bill Williams River are concentrated over short periods of time and are due to flood control operations at Alamo Dam. For the 100-year period from 1906 through 2005, the annual inflow to the Colorado River mainstream from the Bill Williams River ranged from 1.3 kaf to 702 kaf and averaged 102 kafy. By contrast, during the 10-year period from 1996 through 2005, annual releases from Davis Dam ranged from 8,000 kaf to 12,587 kaf and averaged approximately 10,092 kafy.

Releases from Davis Dam are scheduled on a daily and hourly basis, primarily to meet downstream water needs, although the hourly release pattern is typically shaped to meet demand for power. Releases can range from a maximum of 28,000 cfs to a minimum of about 1,000 cfs, the minimum flow needed to run one turbine at about one-half capacity. Such low flows are usually associated with downstream flooding, construction, search and rescue, or other emergency conditions.

The range of hourly releases from Davis Dam and the corresponding range of flows in this river reach will not be affected by the proposed federal action. However, the shape and duration of hourly flows and the corresponding daily, monthly, and annual flows may be affected; these potential effects are analyzed and discussed in Section 4.3.

Although releases from Davis Dam may be affected by the proposed federal action, Lake Havasu will continue to be operated to meet monthly target elevations as explained in Appendix B.

Lake Havasu generally reaches its maximum elevation in the spring and its minimum elevation in the winter. Similar to Lake Mohave, Reclamation generally lowers the lake elevation during the winter months to provide flood control storage space for runoff that results from large storms coming up-river from Baja California, Mexico. The minimum elevation of Lake Havasu under future conditions will continue to be about 445.8 feet msl. Reclamation attempts to accommodate this minimum target elevation when other higher priority uses are not compromised. The maximum target elevation will continue to be 450.5 feet msl. Therefore, the proposed federal action will not affect the range of historically observed Lake Havasu elevations.

The Davis Dam to Parker Dam reach of the Colorado River flows through two separate groundwater basins. The bedrock Topock Narrows separates the Mohave Valley to the north of the narrows from the Chemehuevi Valley to the south. On the Arizona side, the valley south of Topock Narrows is called the Lake Havasu basin.

The aquifer in Mohave Valley is mostly alluvial fill deposited by both the Colorado River and the washes draining to the river from the mountains bounding the valley, and may be affected by the proposed federal action. The potential effects due to the potential change in river flows in this segment of this river reach are analyzed and discussed in Section 4.3.

The portion of the Colorado River reach that is located within the Chemehuevi Valley and the Lake Havasu basin is dominated by Lake Havasu. As noted above, the proposed federal action will have no effect on the operation of Lake Havasu or the elevations in this reservoir. Therefore, there are no anticipated effects of the proposed federal action to the groundwater basins underlying the Chemehuevi Valley and the Lake Havasu basin.

3.3.7 Parker Dam to Cibola Gage

This reach is approximately 105 miles long and it is bounded by Reclamation's Cibola Gage at RM 87.3 downstream. Although there are some minor drainages, flows in this reach are almost entirely comprised of releases from Parker Dam to meet water delivery requirements in the United States and Mexico.

Similar to Davis Dam, releases from Parker Dam are scheduled on a daily and hourly basis, primarily to meet downstream water needs, although the hourly release pattern is typically shaped to meet demand for power. Releases can range from a maximum of 16,800 cfs to a minimum of about 1,000 cfs, the minimum flow needed to run one turbine at about one-half capacity. Such low flows are usually associated with downstream flooding, construction, search and rescue, or other emergency conditions. For the 10-year period from 1996 through 2005, annual Parker Dam releases have ranged from 6.185 maf to 10.344 maf and averaged 7.578 mafy.

The ranges of hourly releases from Parker Dam and the corresponding ranges of flows in this river reach will not be affected by the proposed federal action. However, the shape and duration of hourly flows and the corresponding daily, monthly, and annual flows may be affected; these potential effects are analyzed and discussed in Section 4.3.

Impoundments associated with the two major diversion dams located in this reach (Headgate Rock Dam, used to divert water for use by the Colorado River Indian tribes, and Palo Verde Diversion Dam, used to divert water for use by the Palo Verde Irrigation District) are operated at nearly constant elevations in order to facilitate the diversion of water. These facilities will continue to be operated in this same manner and, therefore, the elevations of these impoundments will not be affected by the proposed federal action. However, releases from the diversion dams may be affected. These potential effects are analyzed and discussed in Section 4.3.

The Colorado River reach from Parker Dam to Cibola Gage flows through one very large groundwater basin but it is typically referred to by separate valley names (Parker Valley, Cibola Valley, and Palo Verde Valley). The aquifer underlying these valleys is mostly alluvial fill deposited by the Colorado River and secondarily by the washes draining to the Colorado River from the mountains bounding the valleys. The potential effects due to the potential change in river flows are analyzed and discussed in Section 4.3.

3.3.8 Cibola Gage to Imperial Dam

This reach is approximately 38 miles long and it is bounded by Imperial Dam downstream. Although there are some minor drainages, flows in this reach are almost entirely comprised of releases from Parker Dam reduced by upstream depletions, including diversions of water for the Colorado River Indian tribes and the Palo Verde Irrigation District.

The ranges of hourly releases from Parker Dam and the corresponding ranges of flows in this river reach will not be affected by the proposed federal action. However, the shape and duration of hourly flows and the corresponding daily, monthly, and annual flows may be affected; these potential effects are analyzed and discussed in Section 4.3.

The impoundment associated with Imperial Dam is operated at a nearly constant elevation in order to facilitate the diversion of water. The AAC diverts water from the California side of Imperial Dam and serves IID, CVWD, the Yuma Project in Arizona and California, the City of Yuma, and Mexico. The Gila Gravity Main Canal system diverts water from the Arizona side of Imperial Dam and serves the north and south Gila Valley, Yuma Mesa, and Wellton-Mohawk area. This facility will continue to be operated in this same manner and, therefore, the elevations of this impoundment will not be affected by the proposed federal action.

Senator Wash, an off-stream reservoir just upstream of Imperial Dam is used to store and release mainstream Colorado River water to meet demands at Imperial Dam. It will continue to be operated in the same manner to manage water deliveries and will not be affected by the proposed federal action.

The Colorado River reach from Cibola Gage to Imperial Dam is located in a relatively narrow alluvial fill valley. There is no irrigated agriculture along this reach and there are many backwaters, especially in the southern half of the reach. The potential effects due to the potential change in river flows are analyzed and discussed in Section 4.3.

3.3.9 Imperial Dam to NIB

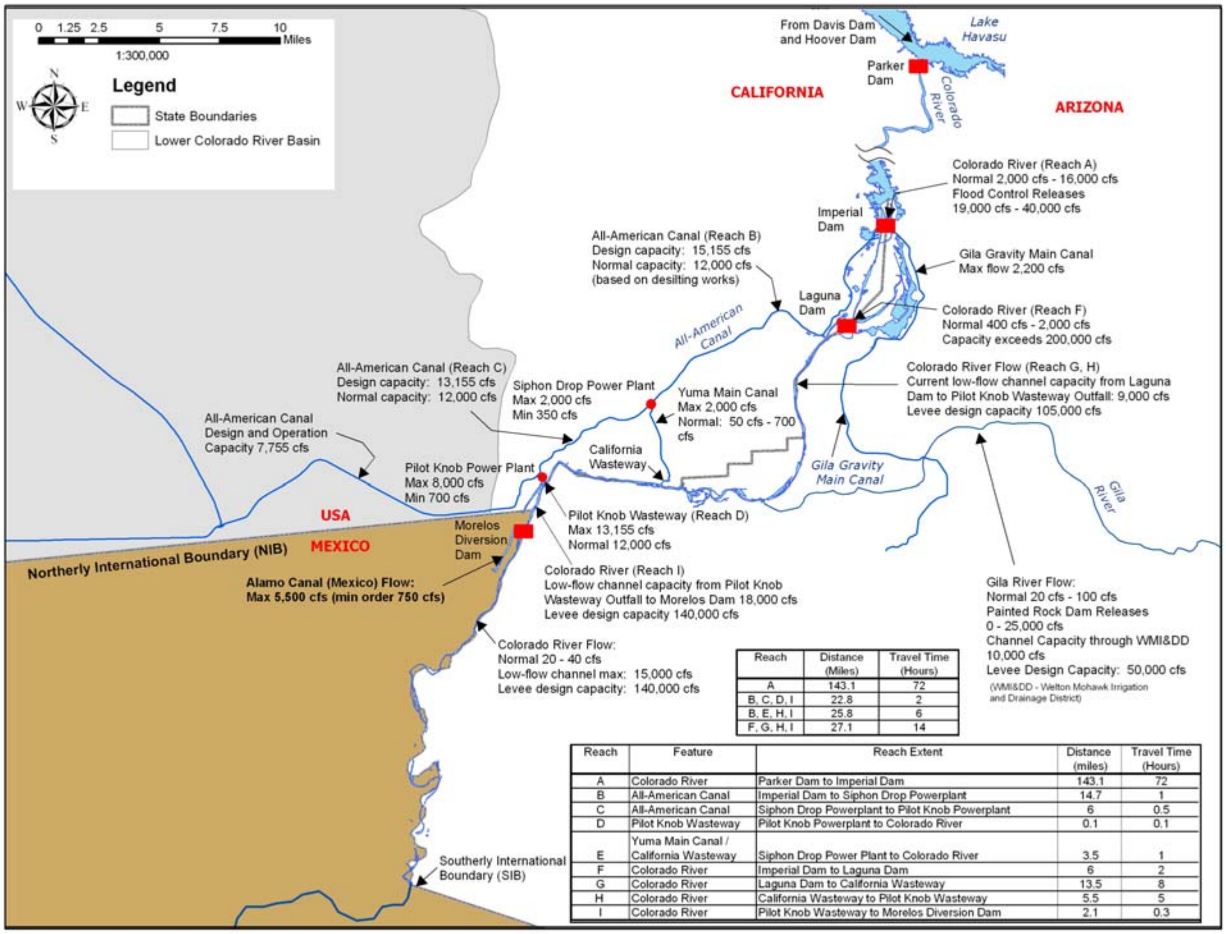
This reach is approximately 26 miles long and is bounded by the NIB downstream. Excluding inflows from the confluence of Gila River, flows in this reach are comprised primarily of water that has leaked from or has been released from Imperial Dam, and return flows from water diverted at Imperial Dam.

The flows in the upper portion of this reach (just downstream of Imperial Dam) typically range from about 250 cfs to 350 cfs and are comprised principally of return flows from the AAC desilting basins, gate leakage from the California sluiceway gates at Imperial Dam, and occasional small releases to meet Mexico’s scheduled water deliveries at the NIB. In addition, water may be released to remove accumulated sediment from the desilting basins in the sluiceway channel (known as “sluicing flows”). These flows occur two to three times per month, may range from 8,000 cfs to 12,000 cfs, and the duration may be up to 20 minutes. Laguna Dam, just downstream of Imperial Dam, is used to capture these sluicing flows for subsequent delivery downstream. These operations and the flows in the upper portion of the reach will not be affected by the proposed federal action.

The drainage return flows discussed above originate from the irrigated lands located in the Yuma area and are nearly constant throughout the year and from year to year. These drainage return flows comprise both gravity and pumped drainage flows and are not expected to be affected by the proposed federal action.

Most of Mexico's scheduled delivery at the NIB is diverted at Imperial Dam into the AAC and returned to the Colorado River through Pilot Knob and Siphon Drop Powerplants and their respective wasteway channels, 2.1 miles and 7.6 miles upstream of the NIB, respectively. Mexico diverts that water at Morelos Diversion Dam which it owns, operates, and maintains. Figure 3.3-5 shows how water deliveries to Mexico pursuant to the 1944 Treaty are routed from Imperial Dam to the NIB, as well as the source and routing of other flows that occur between Imperial Dam and the NIB. The proposed federal action will not alter the operation of these diversions and wasteways.

Figure 3.3-5
Water Routing from Imperial Dam to NIB
Deliveries to Mexico Pursuant to the 1944 Treaty



Reach	Distance (Miles)	Travel Time (Hours)
A	143.1	72
B, C, D, I	22.8	2
B, E, H, I	25.8	6
F, G, H, I	27.1	14

Reach	Feature	Reach Extent	Distance (miles)	Travel Time (Hours)
A	Colorado River	Parker Dam to Imperial Dam	143.1	72
B	All-American Canal	Imperial Dam to Siphon Drop Powerplant	14.7	1
C	All-American Canal	Siphon Drop Powerplant to Pilot Knob Powerplant	6	0.5
D	Pilot Knob Wasteway	Pilot Knob Powerplant to Colorado River	0.1	0.1
E	Yuma Main Canal / California Wasteway	Siphon Drop Power Plant to Colorado River	3.5	1
F	Colorado River	Imperial Dam to Laguna Dam	6	2
G	Colorado River	Laguna Dam to California Wasteway	13.5	8
H	Colorado River	California Wasteway to Pilot Knob Wasteway	5.5	5
I	Colorado River	Pilot Knob Wasteway to Morelos Diversion Dam	2.1	0.3

The Gila River is highly regulated and although inflows from the Gila River to the mainstream Colorado River have averaged approximately 250 kafy over the past 75 years, these inflows occur very sporadically and they are of very high magnitudes. These inflows are not expected to be affected by the proposed federal action.

Groundwater basins proximal to the Colorado River within this reach include portions of the Yuma Valley and the South Gila Valley. With the exception of the Yuma Valley, these basins are generally small in size and are bounded by zones of non-water-bearing rock. The method used to route water from Imperial Dam to the NIB bypasses most of the river channel and the proposed federal action will not affect these operations. Therefore, the portions of the groundwater basins adjacent to this reach are not anticipated to be affected by the proposed federal action.

3.3.10 NIB to SIB

Mexico diverts the majority of its Colorado River water supply at Morelos Diversion Dam, and only limited flows occur in the river reach that extends between Morelos Diversion Dam and the SIB. These flows may occur as a result of:

1) seepage from Morelos Diversion Dam;
2) water in excess of Mexico's scheduled delivery (e.g. flood flows, cancelled orders in the United States) not diverted by Mexico and released from Morelos Diversion Dam;
3) irrigation return flows from Mexico and the United States; and
4) groundwater accumulation from both the United States and Mexico.

Water released from Parker Dam for irrigation districts in Imperial Valley, Coachella Valley, and the lower Colorado River Valley, normally takes up to three days to reach its point of diversion. Occasionally, unforeseen events such as localized precipitation force the irrigation districts to cancel these water delivery orders after the water has been released at Parker Dam. Usually, the water is diverted at Morelos Diversion Dam for use in Mexico. However, some of this water may flow past Morelos Diversion Dam. The proposed federal action will not affect water that flows past the NIB as a result of canceled water orders.

Morelos Diversion Dam forms an impoundment that facilitates Mexico's diversion of water from the Colorado River. The elevation of this impoundment is maintained nearly constant in order to facilitate the diversion of water by Mexico. It is anticipated that Mexico will continue to operate Morelos Diversion Dam and this impoundment in this same manner, and therefore, elevations of this impoundment will not be affected by the proposed federal action. Accordingly, the rate of seepage that occurs at Morelos Diversion Dam will not be affected by the proposed federal action.

Gila River flood events reaching the mainstream of the Colorado River are rare. Only once has flow been recorded over 4,000 cfs at Dome Gaging Station, Arizona, since 1941. In 1993, up to 27,500 cfs flowed past Dome Gaging Station as a result of the 1993 Gila River flood (USGS 1999). The 1993 flood created much of the habitat presently found along the Colorado River below its confluence with the Gila River (Hernandez et al. 2000). The proposed federal action will not affect water that flows past the NIB as a result of Gila River flood events.

Flows in excess of Mexico's scheduled diversion at the Morelos Diversion Dam resulting from flood control releases from Lake Mead may be affected by the proposed federal action. These flood control releases are dictated by the flood control criteria established for Lake Mead and Hoover Dam and are largely dependent upon hydrologic conditions. The proposed federal action may affect the frequency and magnitude of flood control operations that originate at Hoover Dam due to potential changes in reservoir storage that occurs under the different action alternatives. These potential effects are analyzed and discussed in Section 4.3.

The Colorado River reach from the NIB to the SIB flows through the large and deep Colorado River delta groundwater basin. The upstream portion of this reach is a gaining reach, which means that groundwater enters the channel and provides a portion of the river's surface flow. This occurs because the high groundwater level in the adjacent lands has a sloping gradient that intercepts the Colorado River channel. The proposed federal action is not expected to affect this gaining reach because the high groundwater levels occur due to application of water on the adjacent irrigated lands, a condition that will remain unchanged.

The downstream portion of this reach is a losing reach, which means that a portion of the surface flows from the Colorado River channel provides recharge to the groundwater basin. However, the proposed federal action will not affect the flows that normally occur in this part of the river reach and that contribute to groundwater recharge. Therefore, the portions of groundwater basins adjacent to this reach are not anticipated to be affected by the proposed federal action.

This page intentionally left blank.

3.4 Water Deliveries

Colorado River water is delivered to entities in the seven Basin States and Mexico, consistent with a body of documents often referred to as the Law of the River, as discussed in Section 1.7. Water is diverted from the Colorado River at various points and used for irrigation and domestic purposes. A portion of the diverted water may be returned to the river for subsequent use downstream, which is referred to as return flow. The net amount of water used (termed consumptive use, or depletion) is equal to the diversion less the return flow.[1]

This section describes the water deliveries to entities within the study area that could potentially be affected by implementation of the proposed federal action, including shortage determinations, the storage and delivery of conserved water in Lake Mead, and modification and/or extension of the ISG.

3.4.1 Apportionments to the Upper Division States

The Compact apportioned 7.5 maf of water per year for consumptive use in the Upper Basin and stipulated that the flow in the Colorado River at the Lee Ferry Compact Point not be depleted below 75 maf for any consecutive 10-year period (Section 1.7). The Upper Colorado River Basin Compact of 1948 allocated the Upper Basin apportionment among the four Upper Division states. The apportionments are based on percentages of the total quantity of consumptive use available each year within the Upper Basin remaining after deduction of the use, not to exceed 50,000 af made in the State of Arizona. These apportionment percentages are provided in Table 3.4-1.

Table 3.4-1
Upper Division States Apportionment

State	Annual Apportionment (%)
Colorado	51.75
New Mexico	11.25
Utah	23.00
Wyoming	14.00

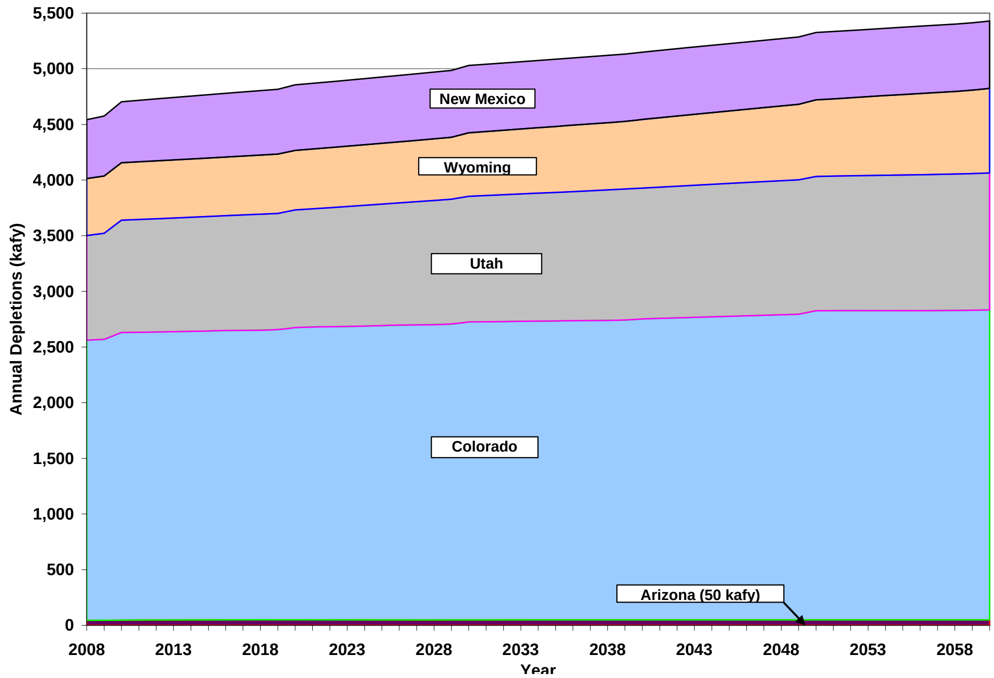
The Upper Colorado River Basin Compact of 1948 also established the Upper Colorado River Commission (Commission). The Commission is an interstate administrative agency, that among other duties, makes findings with regard to the annual quantities of Colorado River water that are available for use and are used by each Upper Basin state, and the annual quantity of water delivered at Lee Ferry. Reclamation operates the mainstream reservoirs to meet the project purposes including the delivery of water downstream. Each Upper Division state regulates and controls the use of Colorado River water within its boundaries.

[1] Alternatively, consumptive use in the Upper Basin is defined in the Upper Colorado River Compact as man-made depletions of natural flow at Lees Ferry. In this EIS for purposes of analyzing the potential impacts of the proposed federal action within the geographic scope, consumptive use is defined as diversions less return flow.

Depletion schedules for the Upper Basin states were developed by each Upper Basin state and approved for transmittal by the Commission. The schedules were submitted by the Commission to Reclamation in December 1999. These depletion schedules were subsequently updated by Reclamation in coordination with the Commission to include updated Indian tribe depletions (Appendix C).

Figure 3.4-1 shows that the total scheduled depletions of the Upper Division states increases from approximately 4,500 kaf in 2008 to approximately 5,400 kaf by 2060. The schedules shown in Figure 3.4-1 and detailed in Appendix C do not include the evaporation losses from the CRSPA reservoirs (Lake Powell and Flaming Gorge, Blue Mesa, Morrow Point, and Crystal reservoirs) and the Navajo Reservoir, estimated to average approximately 574,000 afy.

Figure 3.4-1
Upper Basin Scheduled Depletions
2008 through 2060



The proposed federal action would not affect the apportionments to the Upper Division states nor their ability to use those apportionments.

3.4.2 Apportionments to the Lower Division States and Water Entitlements within Each State

The apportionments to the Lower Division states which were established by the BCPA and confirmed by the Consolidated Decree are provided in Table 3.4-2.

Table 3.4-2
Lower Division States Apportionment

State	Annual Apportionment (maf)
Arizona	2.8
California	4.4
Nevada	0.3
Total	7.5

The apportionments to the Lower Division states would not be affected by the proposed federal action.

3.4.2.1 Water Delivery Entitlements to Entities in the Lower Division States

With the exception of approximately 10,000 af in the state of Arizona, all of the water apportioned to each Lower Division state by the BCPA is allocated to specific entities within each state. These allocations, known as entitlements, are established in accordance with the BCPA and the Consolidated Decree.

Section 5 of the BCPA authorizes the Secretary to operate as the contracting authority for the delivery of water from the lower Colorado River and requires any user of Colorado River water in the Lower Basin to have a water delivery contract with Reclamation. This requirement, which was confirmed by the Consolidated Decree, applies to all diversions made from the Colorado River except for federal establishments and PPRs.

For Colorado River water users in the Lower Division states, an entitlement to use Colorado River water can exist in one of three forms: (i) a decreed right, (ii) a Section 5 water delivery contract with the Secretary, or (iii) a Secretarial Reservation.

A decreed right is a right to use water defined by the Consolidated Decree. The right, which must have existed prior to June 15, 1929 (the effective date of the BCPA), is also referred to as a PPR. The Consolidated Decree lists and quantifies these PPRs. A summary of the total amounts of water apportioned to the PPRs in the Lower Division state is provided in Table 3.4-3. These entitlements are summarized based on the diversion and consumptive-use entitlements. The return flow credits used to compute consumptive use have been estimated from historical data.

Table 3.4-3
Colorado River Water Apportioned to PPRs in the Lower Division States

State	Estimated Diversion Entitlement (afy)	Estimated Consumptive-use Entitlement (afy)
Arizona	1,077,971	618,172
California	3,019,573	2,723,325
Nevada	13,034	8,898
Total Lower Division States	4,110,578	3,350,395

A Section 5 water delivery contract is a written agreement between the United States, through the Secretary or his/her duly authorized representative, and another person or entity. All Colorado River water delivery contracts in the Lower Basin are for permanent service, as provided in the BCPA. The form and content of these contracts have evolved since 1929 to reflect advancements in flow measurement, water scheduling, and water accounting technology. Water delivery contracts describe the entitlement in terms of an annual diversion right, an annual consumptive use right, or in some cases both.

A Secretarial Reservation is an entitlement established by the Secretary. Secretarial Reservations have been used to reserve Colorado River water for use at federal facilities or lands. Secretarial Reservations have been exercised for Colorado River water use at the Cibola NWR, for use on BLM lands, and for uses at Hoover Dam and Davis Dam.

The proposed federal action will not affect the entitlements to Colorado River water for water users in the Lower Division states. However, water deliveries to each Lower Division state and to users within each Lower Division state may potentially be affected; these potential effects are analyzed and discussed in Section 4.4.

3.4.3 Lower Division States Water Supply Determination

In accordance with the Consolidated Decree and Article III of the LROC, the Secretary determines yearly the water supply condition for the Lower Division states. The conditions are as follows:

- Normal Condition: when sufficient mainstream water is available to satisfy 7.5 maf of consumptive use in the Lower Division states;
- Surplus Condition: when sufficient mainstream water is available to satisfy in excess of 7.5 maf of consumptive use in the Lower Division states; and
- Shortage Condition: when insufficient mainstream water is available to satisfy 7.5 maf of consumptive use in the Lower Division states.

Under a Surplus Condition, the Consolidated Decree apportioned 46 percent of the surplus in excess of 7.5 maf for use in Arizona, 50 percent for use in California, and four percent for use in Nevada. The ISG established further guidelines for the Secretary's decision with regard to when a surplus would be declared, and the amounts and types of use (e.g., agricultural use, domestic use) of that surplus water, including the recognition of any agreements between the states that might modify how the surplus waters would be divided amongst the states (known as "forbearance" agreements).

Under a Shortage Condition, the Consolidated Decree directs the Secretary to first satisfy all PPR's in order of their priority dates without regard to state lines, and then to apportion any remaining shortage amount consistent with the BCPA and other applicable federal statutes. The CRBPA states that satisfaction of all PPRs and California's 4.4 maf apportionment would have priority over CAP and other post-1968 water delivery contracts (contracts with approval dates after September 30, 1968). It also states that Nevada shall not be required to bear shortages in any proportion greater than would have been imposed in the absence of the CRBPA. The proposed federal action will provide guidance to the Secretary's annual determination of the water supply condition for the Lower Division states.

3.4.4 Depletion Schedules for Lower Division States (Normal and Surplus)

The following sections describe the projected depletions of the three Lower Division states, Arizona, California, and Nevada, for Normal and Surplus conditions, under the No Action Alternative. Surplus schedules for each action alternative are presented in Appendix D.

3.4.4.1 State of Arizona

Arizona's depletion schedule for a Normal Condition is shown on Figure 3.4-2. These depletions are projected to be 2.8 maf throughout the period of analysis (2008 through 2060). The CAP is the largest single Arizona diverter and its consumptive use is projected to be approximately 1.382 maf in 2008 and gradually decrease to 1.271 maf by 2060. Concurrently, the demands of Arizona's non-CAP users increase towards their full apportionment during this period, making up the balance of Arizona's normal 2.8 maf apportionment.

Figure 3.4-2
Arizona's Projected Colorado River Water Depletion Schedules Under the No Action Alternative

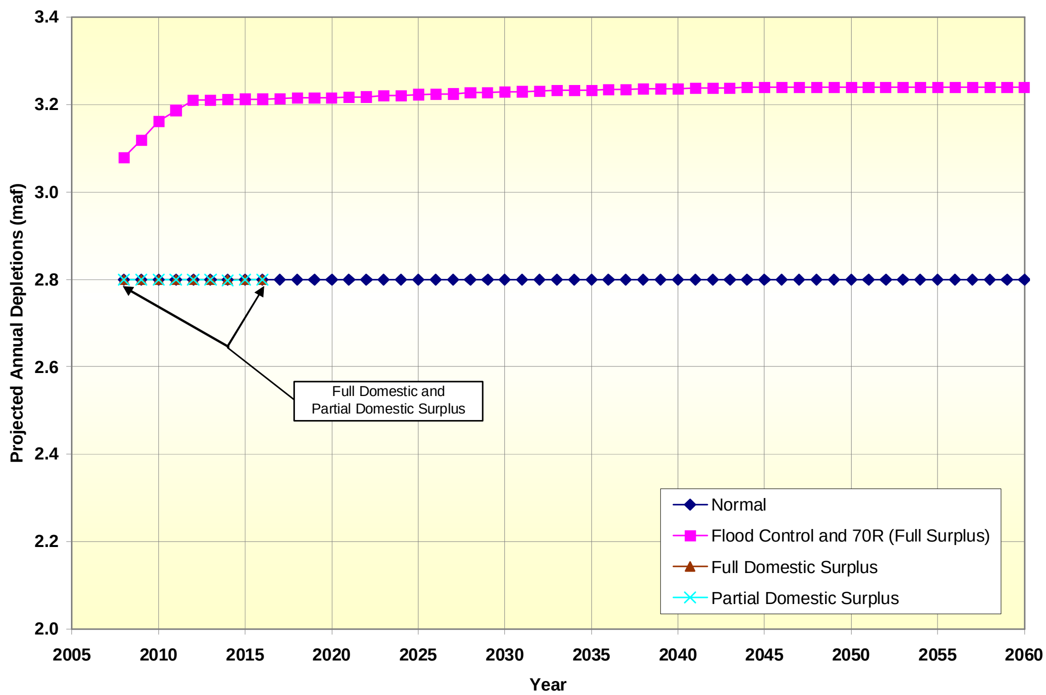


Figure 3.4-2 also shows Arizona's scheduled depletions for the Flood Control Surplus, 70R Surplus, Full Domestic Surplus, and Partial Domestic Surplus conditions for the No Action Alternative. Arizona's projected Full Surplus depletions increase from 3.08 maf in 2008 to approximately 3.24 maf in 2060. Arizona's Full Domestic Surplus and Partial Domestic Surplus schedules are 2.8 maf thought the modeling period.

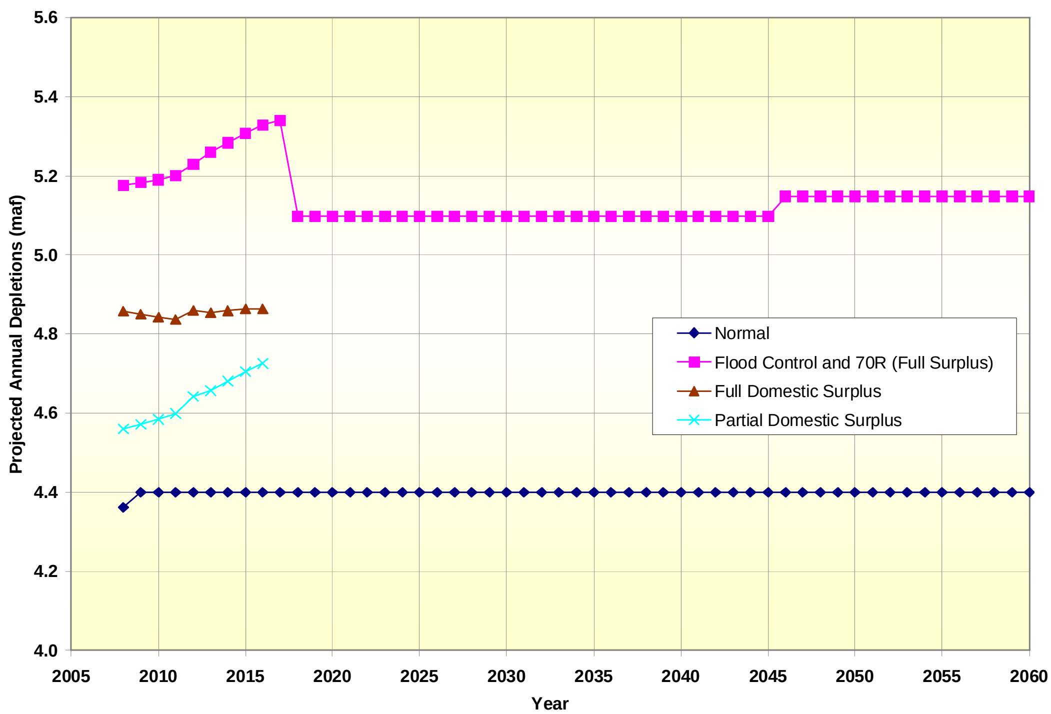
3.4.4.2 State of California

California's depletion schedule for a Normal Condition is shown on Figure 3.4-3. These depletions are projected to be 4.4 maf throughout the period of analysis (2008 through 2060). The exception to this is the first year (2008) wherein the depletion schedule reflects a delivery reduction of 23,315 af which coincides with scheduled repayment of inadvertent overruns by IID (14,763 af) and CVWD (8,552 af). As such, California's scheduled depletion for 2008 is modeled as 4.377 maf.

The surplus schedules for California consider its continued need for surplus water, when available, in order to help the state implement the provisions of the Quantification Settlement Agreement. California's surplus schedule considers the potential availability of more surplus water during the effective period of the ISG, which are scheduled to expire in 2016. Figure 3.4-3 also shows California's surplus depletion schedules under the Flood Control Surplus, 70R Surplus, Full Domestic Surplus, and Partial Domestic Surplus conditions for the No Action Alternative.

Figure 3.4-3
California's Projected Colorado River Water Depletion Schedules Under the No Action Alternative

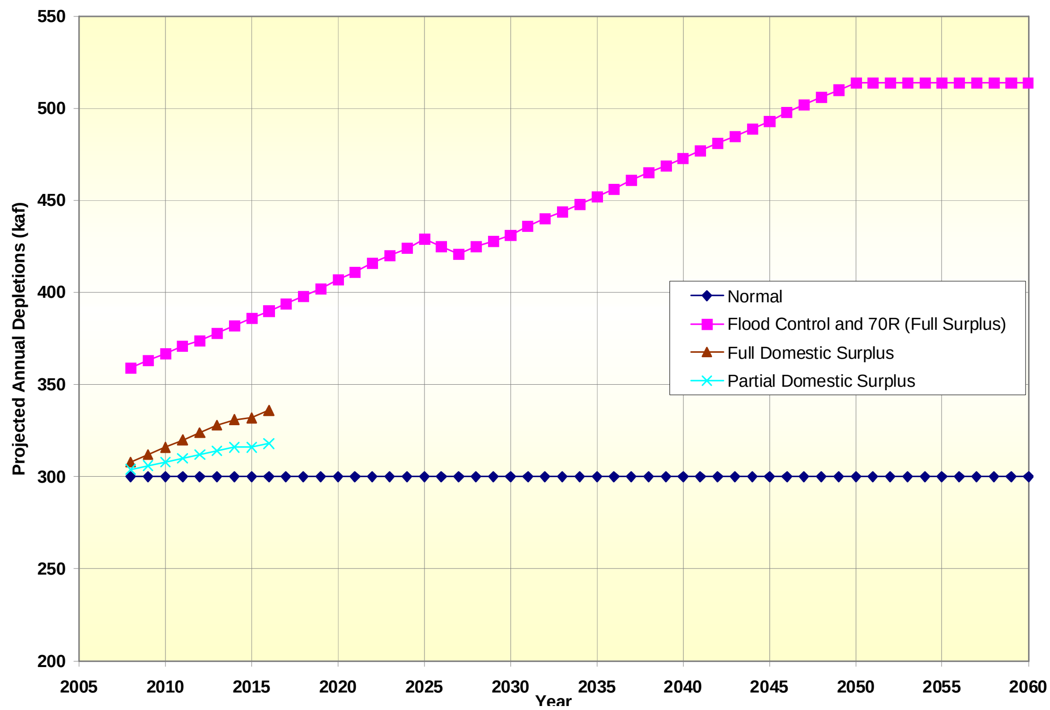


3.4.4.3 State of Nevada

Nevada's depletion schedule for a Normal Condition is shown on Figure 3.4-4. These depletions are projected to be 300 kaf throughout the period of analysis (2008 through 2060). The SNWA is the largest single Nevada diverter and its depletions are projected to be approximately 271 kaf for the period 2008 through 2025, increasing to 279 kaf in 2026, increasing to 287 kaf in 2027 and remains at that level through 2060. Figure 3.4-4 also shows Nevada's surplus depletion schedule under the Flood Control Surplus, 70R

Surplus, Full Domestic Surplus, and Partial Domestic Surplus conditions for the No Action Alternative. Nevada's projected Full Surplus depletions increase from 330 kaf in 2008 to approximately 514 kaf in 2060.

Figure 3.4-4
Nevada's Projected Colorado River Water Depletion Schedules Under the No Action Alternative



3.4.5 Mexico's Allotment

Mexico has an allotment to Colorado River water under Article 10 of the 1944 Treaty (Section 1.7) that states the following:

> "Of the waters of the Colorado River, from any and all sources, there are allotted to Mexico:
>
> (a) A guaranteed annual quantity of 1,500,000 acre-feet (1,850,234,000 cubic meters) to be delivered in accordance with the provisions of Article 15 of this Treaty.
>
> (b) Any other quantities arriving at the Mexican points of diversion, with the understanding that in any year in which, as determined by the United States Section, there exists a surplus of waters of the Colorado River in excess of the amount necessary to supply uses in the United States and the guaranteed quantity of 1,500,000 acre-feet (1,850,234,000 cubic meters) annually to Mexico, the United States undertakes to deliver to Mexico, in the manner set out in Article 15 of

> this Treaty, additional waters of the Colorado River system to provide a total quantity not to exceed 1,700,000 acre-feet (2,096,931,000 cubic meters) a year. Mexico shall acquire no right beyond that provided by this subparagraph by the use of waters of the Colorado River system, for any purpose whatsoever, in excess of 1,500,000 acre-feet (1,850,234,000 cubic meters) annually.
>
> In the event of extraordinary drought or serious accident to the irrigation system in the United States, thereby making it difficult for the United States to deliver the guaranteed quantity of 1,500,000 acre-feet (1,850,234,000 cubic meters) a year, the water allotted to Mexico under subparagraph (a) of this Article will be reduced in the same proportion as consumptive uses in the United States are reduced."

Additionally, Minute 242 provides, in part, that the United States will deliver to Mexico approximately 1,360,000 af annually upstream of Morelos Diversion Dam and approximately 140,000 af annually on the land boundary at San Luis and in the limitrophe section of the Colorado River downstream from Morelos Diversion Dam. While a portion of Mexico's 1.5 maf annual allotment is actually delivered downstream of Morelos Diversion Dam, the entire delivery to Mexico was modeled at Morelos Diversion Dam. This basic assumption, while different than actual practice, served to simplify and facilitate the analysis of water deliveries to Mexico under the No Action Alternative, the action alternatives, and the Preferred Alternative.

Allocation of Colorado River water to Mexico is governed by the 1944 Treaty. The proposed federal action will improve the Department's annual management and operation of key Colorado River reservoirs for an interim period through 2026. However, in order to assess the potential effects of the proposed federal action, certain modeling assumptions (Chapter 2) are used in this Final EIS that display projected water deliveries to Mexico. Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 Treaty or to represent current United States policy or a determination of future United States policy regarding deliveries to Mexico. The United States will conduct all necessary and appropriate discussions regarding the proposed federal action and implementation of the 1944 Treaty with Mexico through the IBWC in consultation with the Department of State.

3.4.6 Distribution of Shortages To and Within the Lower Division States

The assumptions with respect to the distribution of shortages between the three Lower Division states are discussed in Section 4.2 and Appendix A. The following sections describe the priority systems and agreements that direct how shortages would be distributed within each state. The modeling assumptions regarding shortage distribution within each state are detailed in Appendix G.

3.4.6.1 Distribution of Shortages Within Arizona

Of Arizona's 2.8 maf apportionment, the largest use is the CAP which has historically diverted up to 1.7 mafy from Lake Havasu for delivery to water users in the central part of the state. Other noteworthy diversions are those of the Colorado River Indian Reservation at Headgate Rock Dam and the Gila and Yuma Projects at Imperial Dam. Other diversions serve irrigated areas and communities along the Colorado River corridor, including lands of the Fort Mojave Reservation, water used by federal agencies in Arizona, the cities of Bullhead, Lake Havasu and Parker, the Mohave Valley Irrigation and Drainage District, and the Cibola Valley Irrigation and Drainage District. A portion of the water from the Colorado River corridor is also diverted by wells located along the Colorado River.

Arizona established the Arizona Water Banking Authority (AWBA) in 1996 to store unused apportionment from Arizona and other states in groundwater basins in Arizona for future use. These banked water supplies help ensure an adequate water supply to municipal users of Colorado River water in times of shortages or disruptions of the CAP system, in meeting water management plan objectives of the Arizona state groundwater code, and in Indian water rights claims settlements.

Within Arizona, a priority system for the delivery of Colorado River water to water users within the state has been included in the water delivery contracts executed after 1992. Prior to 1992, the contracts defined priorities as existing in three time bands: entitlements existing before June 25, 1929, entitlements existing between June 26, 1929 and September 30,1968, and entitlements existing after September 30, 1968. For water delivery contracts in Arizona executed after 1992, Reclamation assigned a numerical rating to these priorities (priorities 1 through 4) and also defined priorities for unused apportionment (priority 5) and surplus water (priority 6) (Table 3.4-4).

Table 3.4-4
Arizona Priority System for Mainstream Colorado River

Priority	Rights to be Satisfied
First	Present Perfected Rights established prior to June 25, 1929
Second [1]	Federal reservations and perfected rights established or effective prior to September 30, 1968
Third [1]	Entitlements pursuant to contracts executed on or before September 30, 1968
Fourth	(1) Entitlements pursuant to contracts, Secretarial Reservations, and other arrangements between the United States and water users established subsequent to September 30, 1968 (2) Contract for CAP
Fifth	Any unused Arizona entitlement
Sixth	Entitlements to surplus water

1. The Arizona 2nd and 3rd priority entitlement holders are co-equal in their priority.

All Arizona water users in each priority are listed in Appendix E.

Under shortage conditions, any use of water occurring under contracts for unused entitlement would be the first eliminated. In the absence of shortage-sharing agreements, any remaining reduction in Arizona would most likely be shared proportionately among the CAP and the non-CAP holders with fourth priority entitlements. More severe shortages would result in holders of higher priority entitlements having to incur reductions in their water use.

Arizona's framework for responding to shortages is presented in the Arizona Drought Preparedness Plan and the Operational Drought Plan that was released in October 2004. Elements of this framework are discussed in Section 4.14. The framework includes an assortment of actions that collectively are designed to manage the impacts of reduced water supplies.

These actions in part rely on the water management actions and responses of the regional water agencies, irrigation districts, municipalities, and other local water purveyors. These actions include both supply and demand side management responses. A major component of Arizona's shortage management strategy is Arizona's Water Bank which is managed by AWBA. To date, the AWBA has stored some 2.6 maf in various groundwater basins throughout central and southern Arizona to meet future needs including providing a dry year supply.

Through the Arizona Department of Water Resources (ADWR) Director's Shortage Sharing Workgroup (Workgroup), a general agreement and recommendations were developed regarding how shortages should be allocated between the CAP and equivalent priority mainstream Colorado River water users. These recommendations were included in the modeling assumptions used in the Final EIS (Section 4.4 and Appendix G).

3.4.6.2 Distribution of Shortages Within California

Of California's 4.4 maf apportionment, the largest use is the IID which diverts approximately 3.1 mafy from Imperial Dam for delivery and use primarily for irrigated agriculture in the Imperial Valley. Other major water users include the Palo Verde Irrigation District (PVID), the CVWD, the Chemehuevi Reservation, the Fort Yuma Indian Reservation, the Colorado River Indian Reservation, the Fort Mojave Reservation, and the MWD. Other diversions serve irrigated areas and communities along the Colorado River corridor. A portion of the water from the Colorado River corridor is also diverted by wells located along the Colorado River.

Within California, a priority system for the delivery of mainstream Colorado River water to users within the state was established by Secretarial regulations that incorporated provisions of the California Seven-Party Agreement of 1931 (Table 3.4-5).

Table 3.4-5
California's Seven-Party Agreement for Mainstream Colorado River

Priority	Rights to be Satisfied
First	PVID for beneficial use upon 104,500 acres
Second	Reclamation's Yuma Project for beneficial use on up to 25,000 acres
Third[1,2]	(a) Imperial Irrigation District and Coachella Valley Water District (b) Palo Verde Irrigation District for use on 16,000 acres on the Lower Palo Verde Mesa
Fourth[3]	MWD and/or City of Los Angeles and/or others on the coastal plain of Southern California for 550,000 afy
Fifth	(a) MWD and/or City of Los Angeles and/or others on the coastal plain of Southern California for 550,000 afy (b) City and/or County of San Diego for 112,000 afy
Sixth[4]	(a) IID and CVWD (b) PVID for use on Lower Palo Verde Mesa
Seventh	All remaining water available within California for agricultural use

1. *The total beneficial use of priorities 1, 2, and 3 shall not exceed 3.85 mafy*
2. *Article 4.7 of the Quantification Settlement Agreement and the Agreement For Acquisition Of Conserved Water by and between Imperial Irrigation District and Coachella Valley Water District, dated October 10, 2003, contain provisions for shortage sharing between these two agencies.*
3. *The sum of priorities 1 through 4 totals 4.4 mafy.*
4. *The sum of priority 6 is 300 kafy*

The Consolidated Decree, however, also identified a number of PPRs in California as listed in Appendix E. Although some of the California PPRs were included in the Seven-Party Agreement, the Colorado River Water Delivery Agreement, and the Quantification Settlement Agreement (QSA) addressed how the rights of other PPRs would be met relative to the priority scheme set forth in the Seven-Party Agreement during the applicable term of these agreements as embodied in the QSA and related agreements.

Due to the provision in the CRBPA that CAP and other fourth priority rights in Arizona are junior to 4.4 maf of water use in California, reductions to California water users would occur only during severe shortages. If that were to occur, MWD would most likely incur the shortage owing to its lower priority within the 4.4 maf apportionment.

MWD's short-term and long-term strategies for managing and building its portfolio of water supplies are presented in its 2006 Integrated Water Resources Plan. Elements of this plan are discussed in Section 4.14.

MWD's 2006 Integrated Water Resources Plan integrates the following sources of dry-year water supply:

- ♦ Colorado River Aqueduct;
- ♦ conservation;
- ♦ recycling groundwater recovery, desalination;

- State Water Project;
- Central Valley storage and transfers;
- in-basin groundwater storage;
- in-basin surface water storage; and
- local groundwater, surface water and Los Angeles Aqueduct deliveries.

Together these resources represent MWD's tools for managing shortages that may occur due to a variety of factors including potential reductions in water deliveries from the Colorado River.

3.4.6.3 Distribution of Shortages within Nevada

Of Nevada's 0.3 maf apportionment, SNWA is the single largest diverter, with consumptive use of approximately 280 kafy. Established in 1991, SNWA delivers M&I water from Lake Mead to the service areas of Las Vegas, North Las Vegas, Henderson, Boulder City and Nellis Air Force Base. Water is pumped from two intakes at elevations 1,050 feet msl and 1,000 feet msl.

Existing water delivery contracts that authorize the use of Colorado River water by entities within Nevada are listed in Table 3.4-6. This priority system was developed and implemented in 1992 when Reclamation contracted with SNWA for the balance of Nevada's apportionment.

Under Shortage Conditions, Nevada would likely share in shortages due to the recent dates of the majority of its water delivery contracts. Within Nevada, reductions would most likely be borne by the lower priority use of SNWA. More severe shortages would result in holders of higher priority entitlements having to incur reductions in their water use. In accordance with the Consolidated Decree, the PPRs would not be affected.

SNWA and the State of Nevada's Colorado River Commission have developed a water resources management plan for southern Nevada to manage and develop water supplies to meet the current and future water demands of the region. This plan is summarized in SNWA's 2006 Water Resource Plan. Elements of this plan are discussed in Sections 4.4 and 4.16.

The SNWA Water Resource Plan identifies resources that are available to meet future water demands. The demands and resources considered in the Water Resource Plan are discussed in terms of two planning horizons:

- near-term (2006 through 2016); and
- long-term (2017 through 2055).

SNWA has taken a portfolio approach to water resource development and demand management. The portfolio approach emphasizes acquisition and development of a diverse set of resources (Colorado River and Nevada in-state resources), both surface water and groundwater, in an effort to offset the risks typically associated with any single resource option (e.g., availability, volume, timing of use).

Table 3.4-6
Nevada's Priority System for Mainstream Colorado River

Priority	Rights to be Satisfied
First	Fort Mojave Reservation (12,534 afy) Lake Mead National Recreation Area (Diversion = 500 afy or CU= 300 afy)
Second	Lake Mead National Recreation Area (1,500 afy, estimated)
Third	Boulder City (5,876 afy)
Fourth	City of Henderson (15,878 afy) Basic Management, Inc. (8,608 afy)
Fifth	Lakeview Co. (0 afy) Pacific Coast Building Products (PABCO) (928 afy)
Sixth	Las Vegas Valley Water District (15,407 afy)
Seventh	U.S. Air Force (Delivery from SNWA) (4,000 afy) Boy Scouts (Annexed by SNWA) (10 afy) Reclamation (300 afy) Nevada Department of Wildlife (formerly Nevada Department of Fish and Game) (25 afy)
Eighth	Robert B. Griffith Project (304,000 afy) Big Bend (10,000 afy) SNWA (balance of state apportionment, unused and surplus)

This page intentionally left blank.

3.5 Water Quality

This section describes the historic and existing water quality constituents that could potentially be affected by the proposed federal action. These water quality constituents of concern include:

- salinity;
- temperature;
- sediment;
- nutrients and algae;
- dissolved oxygen;
- metals; and
- perchlorate.

While other water quality-related issues and parameters were also considered, they were determined unlikely to be affected by the proposed federal action, or there was insufficient data to provide an assessment and are therefore not discussed here.

3.5.1 Salinity

Increased salinity levels are a primary water quality concern in the Colorado River because of its effects on agricultural, municipal and industrial users. As a result of increased salinity levels, agricultural water users may suffer economic damage due to reduced crop yields, added labor costs for irrigation management, and added drainage requirements. Urban or municipal users must replace plumbing and appliances more often, or spend increased money on water softeners or bottled water. Industrial users and water and wastewater treatment facilities incur reductions in the useful life of infrastructure (Colorado River Basin Salinity Control Forum 2005). Water treatment plants face increased costs when salinity is elevated, and high salinity source water may result in increased disinfection by-product (DBP) formation that exceeds drinking water regulations (Reclamation 1999).

Salinity occurs naturally in the Colorado River Basin due to the erosion of saline sediments and rocks; however, human activities such as agriculture, irrigation, and energy production may increase the rate of natural salt movement to the system (Colorado River Basin Salinity Control Forum 2005; USEPA 1971). Consumptive use of system water also reduces the dilution capacity of the watershed, increasing the salinity concentrations.

In 1972, the United States Environmental Protection Agency (USEPA) suggested the development of water quality criteria for salinity in the Colorado River following passage of the Federal Water Pollution Control Act (Clean Water Act [CWA]) of 1972, as amended. In 1973, the seven Basin States formed the Colorado River Basin Salinity Control Forum (Forum) to develop salinity criteria and an implementation plan to provide compliance while allowing the Basin States to continue to develop their Compact-allocated water. The Forum specifies flow-weighted average annual salinity criteria for three locations on the lower Colorado River (Table 3.5-1). The criteria, first established in 1975, are reviewed every three years; the latest review was completed in 2005.

Table 3.5-1
Numeric Salinity Criteria for the Colorado River[1]

Station	Flow-weighted average annual salinity (mg/L)[2]
Below Hoover Dam	723
Below Parker Dam	747
At Imperial Dam	879

[1] Developed by the Colorado River Basin Salinity Control Forum (2005)

[2] mg/L – milligram per liter

Historic salinity concentrations and Colorado River flows, and the criteria specified by the Forum by location for the lower reaches of the Colorado River downstream of Hoover Dam are shown in Figures 3.5-1 through 3.5-3. Since the adoption of the salinity criteria in 1975, salinity downstream of Glen Canyon Dam has varied between 390 to 660 mg/L. Prior to the adoption of the salinity criteria, episodes of higher salinity concentrations had been observed. As shown in Figures 3.5-1 through 3.5-3, increases in salinity typically correspond to decreases in river flow. Diluting effects of record high flows in the Colorado River during the 1980s have resulted in lower salinity levels. Conversely, low flows from 1988 through 1992 and 2000 through 2004 have caused relatively higher salinity levels. While the salinity concentrations vary from year to year, concentrations have not exceeded the criteria at any of the locations, even during the recent drought.

To address Mexico's concerns with regard to salinity, Minute 242 (Section 3.4) was developed in 1973 pursuant to the 1944 Treaty. Minute 242 limits the differential in annual salinity between Imperial Dam and the NIB to 115 parts per million (ppm) $\pm$ 30 ppm. The United States will continue to undertake activities to comply with the provisions of Minute 242 and these activities will not be affected by the proposed federal action. In addition, the Colorado River Basin Salinity Control Act of 1974 was authorized to implement desalting and salinity control projects to improve river water quality. Salinity control projects that have been implemented include projects to control irrigation seepage and reduce transport of groundwater salt loads to the Colorado River.

1941 through 2005

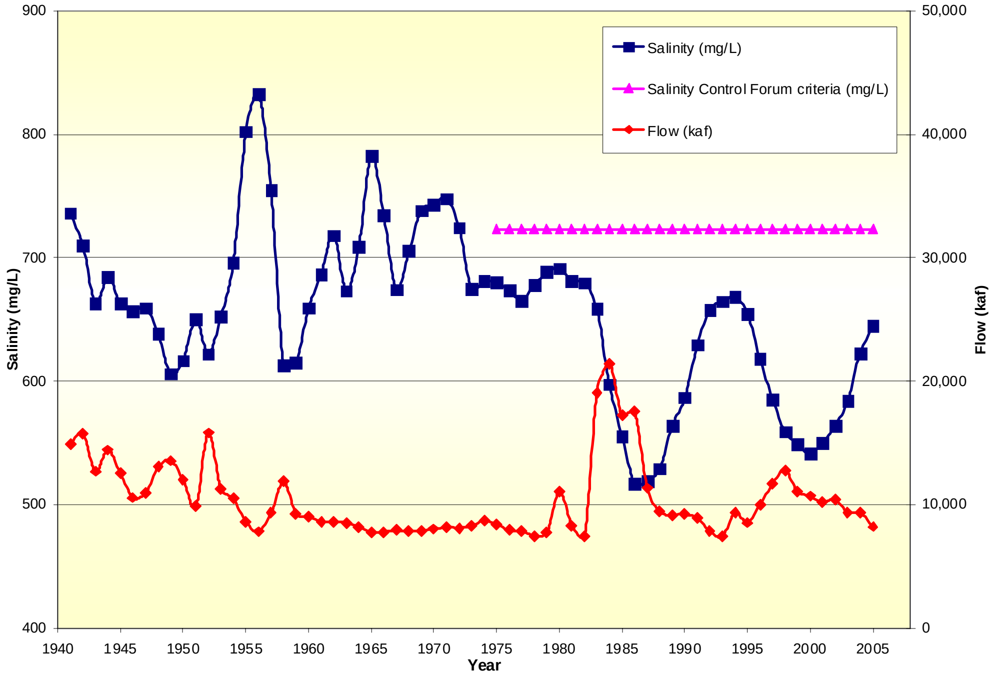

Figure 3.5-2
Historic Colorado River Salinity Concentrations and Flows Downstream of Parker Dam
1941 through 2005

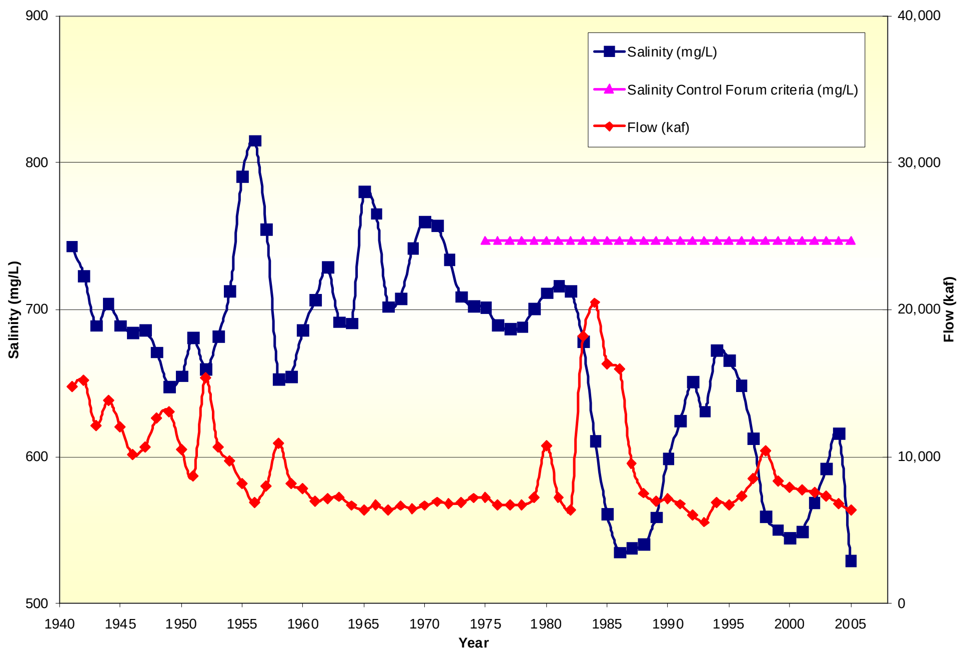

Figure 3.5-3
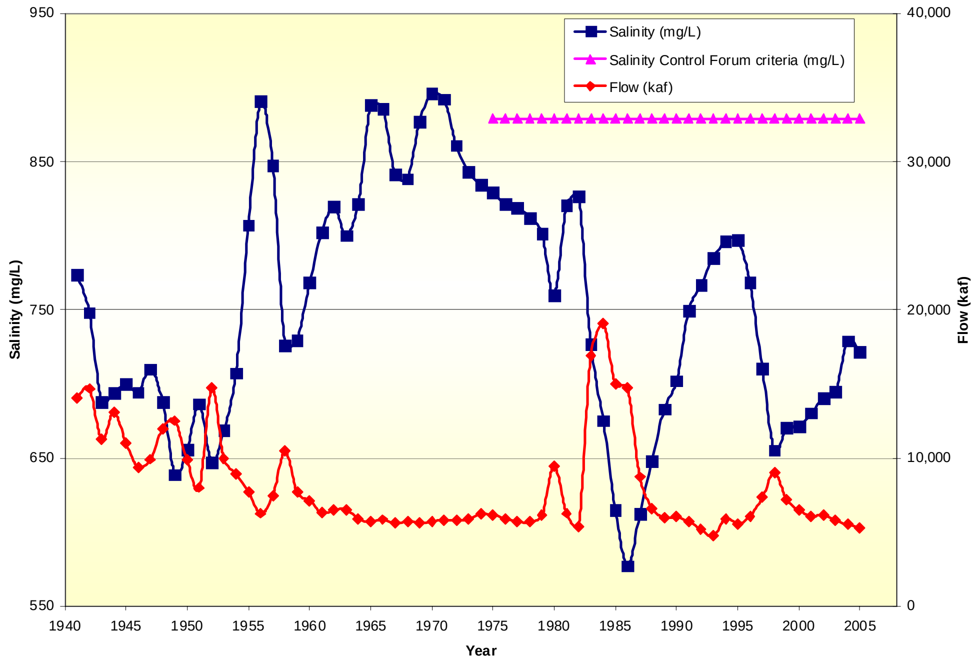
Historic Colorado River Salinity Concentrations and Flows at Imperial Dam
1941 through 2005

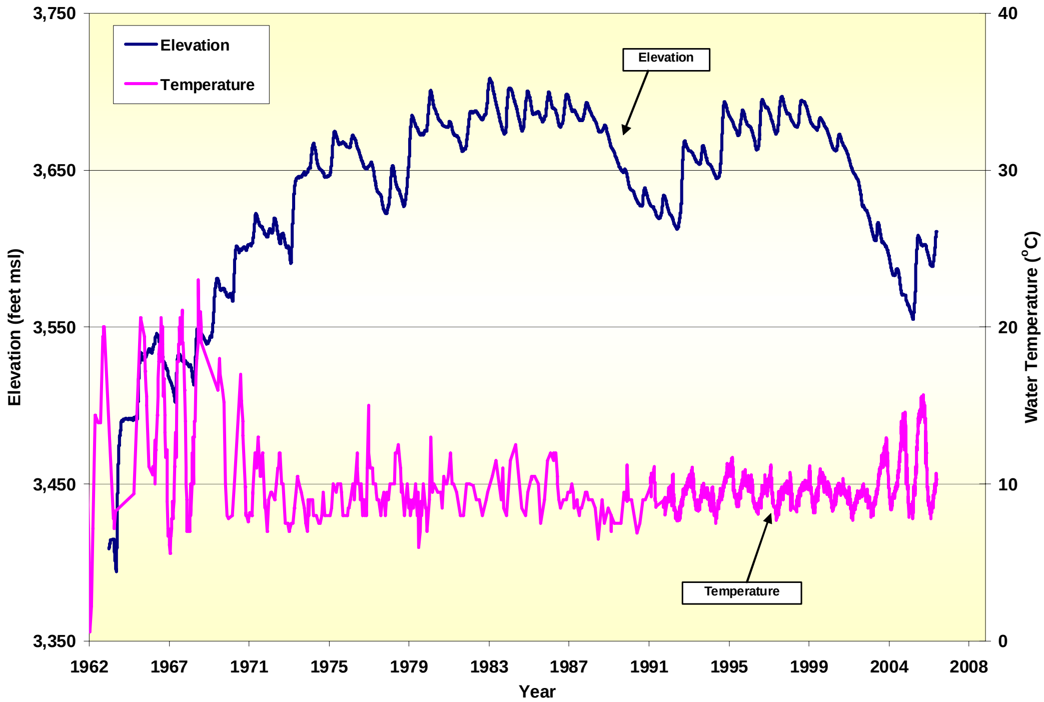


3.5.2 Temperature

Impounding water in reservoirs affects the water temperatures of dam releases due to stratification. The surface layers (epilimnion) of Lake Powell and Lake Mead warm as a result of inflows, ambient air temperature, and solar radiation. For example, during the summer, both Lake Powell and Lake Mead epilimnions reach temperatures as high as 30 degrees Celsius (30°C) or 86° Fahrenheit (F) (LaBounty and Horn 1997). Lake Mead's deeper layer (hypolimnion) remains around 12°C (54°F) year-round and Lake Powell's ranges from 6° to 9°C (43° to 48°F) (LaBounty and Horn 1997), typically resulting in cold dam release temperatures.

Water temperatures downstream of Lake Powell are influenced by Lake Powell elevations and release volumes. Figure 3.5-4 illustrates that Lake Powell release temperatures varied from 7° to 11°C (45° to 52°F) until 2002. Between 1999 and 2005, Lake Powell elevations dropped more than 140 feet as a result of a basin-wide drought. While winter release temperatures remained cold, Lake Powell release temperatures increased to 16°C (61°F) in the summer of 2005. The drop in Lake Powell elevation resulted in the warmer epilimnion being closer to the penstock withdrawal zone and the warmer water being released downstream. Release temperatures from Glen Canyon Dam during 2004 and 2005 were the highest since August 1971 when the reservoir was filling.

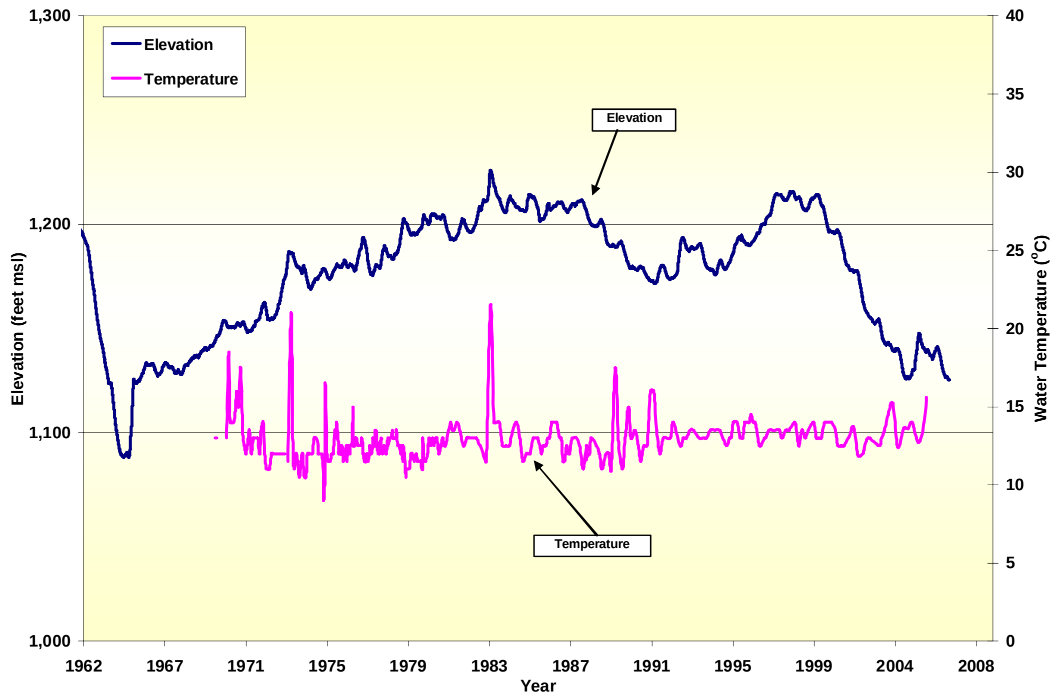
Figure 3.5-4
Historic Elevation and Dam Release Temperatures at Lake Powell



As water travels between Glen Canyon Dam and Lake Mead, water temperatures in the Colorado River can increase by 7°C (13°F) (Vernieu et al. 2005). The amount of warming is affected by season and release volume, with highest warming rates occurring in mid-summer and at low release volumes. Generally, during late fall and winter, as air temperatures decrease, water released from Glen Canyon Dam cools as it moves downstream towards Lake Mead.

Figure 3.5-5 illustrates that historic water release temperatures at Lake Mead have typically been approximately 13°C (55°F).

Figure 3.5-5
Historic Elevation and Dam Release Temperatures at Lake Mead



3.5.3 Sediment

After Glen Canyon Dam and Hoover Dam were constructed, the reservoirs behind these dams retained the vast majority of the inflowing sediment. Following dam closure, large sediment deltas formed near the inflow areas. When the reservoirs are drawn down during droughts, the Colorado River must cut new channels through the sediment deltas to reach the reservoirs. Generally the greater the reservoir drawdown, the greater the sediment delta headcut and the finer the sediment exposed. The resuspended sediments have a significant oxygen demand and also temporarily release nutrients which can result in greater algal growth.

Riverine sediment transport is an important concern in the Glen Canyon Dam to Lake Mead reach due to recreation and biological resource impacts, and is addressed in the AMP. Beach sediment volumes have declined since closure of Glen Canyon Dam eliminated annual replenishment by sediment-laden spring runoff. Recent efforts by the AMP have focused on making BHBF releases from Glen Canyon Dam timed with downstream tributary inputs from the Paria River and the Little Colorado River to rebuild these sandbar deposits.

Downstream of Hoover Dam, the only significant sediment inputs are produced by large, infrequent events on the Bill Williams River and the Gila River, affecting the reaches from Parker Dam to Imperial Dam and from Imperial Dam to the NIB. On-going Reclamation dredging operations remove this sediment at and upstream of Imperial Dam as well as upstream of Morelos Diversion Dam to improve diversion capability and to efficiently convey water to downstream users (Figure 3.3-5). These operations will continue and therefore the proposed federal action would have no impact.

3.5.4 Nutrients and Algae

Nutrients are organic and inorganic chemical elements or compounds that are essential for animal and plant growth. Carbon, hydrogen, and oxygen are consumed in the greatest quantities. In addition, nitrogen, phosphorous and potassium are also needed by animals and plants in large quantities. Elevated nitrogen and phosphorous are nutrients of concern because they foster algal growth which in excess can negatively impact water quality. Excess algal growth can affect drinking water treatment operations, and can contribute to taste and odor problems and potentially to DBP formation. Noxious and toxic blue-green algae blooms may also be a concern.

Large, long reservoirs like Lake Powell are very efficient at retaining nutrients through biological processes and settling. Paulson and Baker (1983) found phosphorus to be the limiting nutrient for primary biological activity in both reservoirs. More than 95 percent of the phosphorous reaching Lake Powell is in particulate form or associated with suspended sediment particles, and a large percentage of the particulate phosphorous load settles out of the water column in the upstream portion of the reservoir. Therefore, primary biological activity is phosphorous-limited by the time the water reaches Glen Canyon Dam. A similar storage effect is repeated at Lake Mead. This settling process can be reversed when the reservoirs are drawn down and deltaic sediments are re-suspended by the inflows. Nutrient concentrations remain elevated in the hypolimnion where the lack of light limits primary biological activity. Consequently, hypolimnetic releases from Glen Canyon Dam are relatively nutrient rich whereas periods of epilimnetic releases may cause a reduction in the amount of nutrients available to the downstream ecosystem.

Tributary inflows (Paria River and Little Colorado River) are important sources of phosphorus in the Colorado River between Glen Canyon Dam and Lake Mead (Maddux et al. 1987). However, most phosphorus arrives in particulate form adsorbed to fine sediment. This fine sediment causes high turbidity and restricts primary biological activity due to limited light penetration.

Lake Mead receives nutrient loads primarily from Las Vegas Wash and the Colorado River. A Total Maximum Daily Load (TMDL) has been developed by the Nevada Division of Environmental Protection (NDEP) and USEPA to reduce ammonia and phosphorous concentrations in Las Vegas Wash. Boulder Basin, the receiving body of Las Vegas Wash, has the highest nutrient concentrations in the Lake Mead system (Paulson and Baker 1981; Prentki and Paulson 1983). Except for the algae growth in the Boulder Basin substantial algae growth along the rest of the system is not common.

3.5.5 Dissolved Oxygen

Dissolved oxygen concentrations in reservoirs are affected by variations in inflow volume and temperature, seasonal reservoir circulation, and biological production and decomposition. In years of high inflows and when the reservoir elevations are low, flows cut through deltaic sediments, resuspending organic matter and nutrients that contribute to both chemical and biological oxygen demand as the inflow water passes down through the reservoir water column. The resulting plumes of low oxygen-water cause the release of oxygen-poor water. When deltaic sediments and organic matter are not resuspended, oxygen demand is lower and dissolved oxygen concentrations remain higher. Downstream of dams, turbulence, exposure to the atmosphere, and primary productivity reaerate the water column.

To date, low dissolved oxygen has only been an issue at Lake Powell with Glen Canyon Dam releases. The dissolved oxygen concentration reaches saturation downstream of Glen Canyon Dam before the confluence with the Little Colorado River (Gloss et al. 2005) after passing through several major rapids.

In Lake Mead, dissolved oxygen concentrations decrease in Boulder Basin as a result of nutrient contributions from Las Vegas Wash and algae growth. However, dissolved oxygen has not been documented to have dropped below acceptable minimum levels. Further, dissolved oxygen has not been documented as an issue in downstream reaches.

3.5.6 Metals

Metals of concern in the study area are selenium, chromium, and mercury. Selenium is an essential trace element, but can be bioconcentrated in a complex aquatic food chain to potentially hazardous levels to wildlife. A chronic standard to protect wildlife has been adopted by the Lower Basin states of 2 micrograms per liter (µg/L). This is a more stringent standard than the USEPA drinking water maximum contaminant level (MCL) for selenium of 50 µg/L. Selenium concentrations are currently not a drinking water public health concern.

The Forum established a selenium sub-committee in 2004 (Reclamation 2005). The long term average selenium concentration is 2.4 µg/L downstream of Glen Canyon Dam, greater than the Lower Basin states selenium standard of 2 µg/L (Reclamation 2005).

Selenium present in marine sedimentary rocks dissolves in runoff and groundwater flows to the Colorado River and its tributaries. Concentrations along the Colorado River in the Lower Basin indicate that selenium loads to the Colorado River are from the Upper Basin and Lower Basin tributaries only (Reclamation 2004a). The Colorado River from Hoover Dam to Lake Mohave inlet and from Parashant Canyon to Diamond Creek, as well as the reaches of the Gila River, Las Vegas Wash, and the Virgin River have all been designated as impaired waterbodies due to selenium. To date, TMDLs have not been drafted or approved for selenium in these waterbodies.

The USEPA drinking water MCL for the soluble hexavalent form of chromium (Cr(VI)) is 100 µg/L; at this concentration, it is considered potentially harmful to human health. Hexavalent chromium has been detected in groundwater in two known locations in the Lower Basin, at the former McCulloch Manufacturing Plant in Lake Havasu City, Arizona, and at the Pacific Gas & Electric (PG&E) Compressor Station near Needles, California. The Cr(VI) plume in Lake Havasu City has been delineated and is being monitored by the current land owner. Concentrations of Cr(VI) have been detected as high as 240,000 µg/L Cr(VI) and the plume is approximately 3,800 feet from the Colorado River.

The plume of contaminated groundwater from the PG&E facility has concentrations of Cr(VI) as high as 700 µg/L and has traveled several hundred feet from its source to within 60 feet of the Colorado River. Investigation and mitigation efforts are ongoing under the direction of the California Environmental Protection Agency (Cal EPA) Department of Toxic Substances Control (DTSC).

Mercury is naturally occurring in the Colorado River Basin and has been mobilized as a result of historic mining activities. Mercury can be toxic to both humans and wildlife and has been shown to bioaccumulate and biomagnify up the food chain. High levels of methylmercury have been detected in fish tissue at Alamo Lake in the Bill Williams Watershed, a tributary to Lake Havasu. Mercury is present in the discharge from Alamo Lake and may also be entering the Colorado River from the Little Colorado River and between Lake Mead and Lake Havasu. The USEPA drinking water MCL for mercury is 2.0 µg/L.

3.5.7 Perchlorate

Perchlorate in the form of ammonium perchlorate is a concern when found in drinking water because of its potential adverse effect on human thyroid function. No final USEPA drinking water regulations have been promulgated for perchlorate. Perchlorate contamination in water supplies in the lower Colorado River was traced to Lake Mead and Las Vegas Wash from a groundwater plume from the Kerr McGee Chemical Company in Henderson, Nevada. Containment control and mitigation activities are ongoing and have been reducing perchlorate concentrations in Lake Mead and downstream.

This page left intentionally blank.

3.6 Air Quality

The air quality issue related to the proposed federal action would be fugitive emissions (dust) generated from shorelines exposed by changes in Lake Powell and Lake Mead elevations.

3.6.1 Federal Air Quality Requirements

The Clean Air Act, as amended (42 United States Code [U.S.C.] Section (§) 7401) established Prevention of Significant Deterioration (PSD) provisions for use in protecting the nation's air quality and visibility. The PSD provisions apply to new or modified major stationary sources and are designed to keep an attainment area in continued compliance with the National Ambient Air Quality Standards (NAAQS). Major stationary sources are industrial-type facilities and include powerplants and manufacturing facilities that emit over 100 tons per year of a regulated pollutant. The USEPA promulgated NAAQS for six criteria pollutants to protect public health and welfare. One of the national air quality standards addresses particulate matter (PM), or dust.

No major stationary sources are being proposed for construction or modification by the proposed federal action; therefore the statutory provisions are not applicable. However, the standards do provide thresholds from which to evaluate potential effects to ambient air quality.

The PSD standards are most stringent in Class I Areas and are progressively less stringent in the Class II and Class III Areas (Table 3.6-1). Lake Powell and Lake Mead are designated as Class II Areas while the Grand Canyon National Park is designated as a Class I Area.

Table 3.6-1
Clean Air Act Prevention of Significant Deterioration Designations

Designation	Definition
Class I Area	Visibility is protected more stringently than under the NAAQS; includes national parks, wilderness areas, monuments, and other areas of special national and cultural significance.
Class II Area	Moderate change is allowed but stringent air quality constraints are nevertheless desired.
Class III Area	Substantial industrial or other growth is allowed and increases in concentrations up to the national standards would be considered insignificant.

The allowable PM concentrations increase over the baseline concentrations for the Class I, II and III Area designations are provided in Table 3.6-2.

Table 3.6-2
Clean Air Act Allowable Particulate Matter Concentration Increases over the Baseline Concentrations

Pollutant	Averaging Times	Class I Area [1,2]	Class II Area [1,2]	Class III Area [1,2]
Particulate Matter	Annual Geometric Mean	5	19	37
	24-Hour Maximum	10	37	75

1 *Unit of measure for standards is in micrograms per cubic meters of air (µg/m3)*

2 *Maximum allowable increases over baseline concentrations*

3.6.2 State and Local Air Quality Requirements

In 2006, USEPA established new PM10 (dust particles of 10 micrometers or less in diameter) and PM2.5 (dust particles less than 2.5 micrometers in diameter) standards for future implementation. These revised PM standards were promulgated to better protect the public from particulate exposures.

Additionally, each state must develop an implementation plan describing how it will attain and maintain the NAAQS. Some states have developed more stringent ambient air quality standards for PM10 and PM2.5, as listed in Table 3.6-3. California continues to have a more stringent PM10 standard than the other states and the federal standard. Arizona, Nevada, and Utah have adopted PM standards to meet the previous NAAQS (CalEPA 2006; Clark County AQEM 2006; MDAQMD 2006; Utah 2006; UDAQ 2006). These state standards were adopted prior to the new 2006 NAAQS.

Table 3.6-3
National and State Ambient Air Quality Standards for Particulate Matter

Jurisdiction	PM10 (µg/m^3)	PM2.5 (µg/m^3)	Averaging Times
2006 NAAQS	150	35	24-hours
	None [1]	15	Annual Arithmetic Mean
Arizona	150	65	24-hours
	50	15	Annual Arithmetic Mean
California	50	65	24-hours
	20	12	Annual Arithmetic Mean
Nevada	150	65	24-hours
	50	15	Annual Arithmetic Mean
Utah	150	65	24-hours
	50	15	Annual Arithmetic Mean

1 *Revoked in 2006 due to a lack of evidence linking health problems (effective December 17, 2006).*

Three state and local air quality agencies are responsible for attaining the state and federal standards within the study area, as listed in Table 3.6-4.

Table 3.6-4
State and Local Air Pollution Control Agencies Having Jurisdiction within the Lake Powell and Lake Mead Areas

Agency	Location	Colorado River Reaches
Arizona Department of Environmental Quality	Arizona	Lake Powell and Glen Canyon Dam Glen Canyon Dam to Lake Mead
Utah Department of Environmental Quality, Division of Air Quality	Utah	Lake Powell and Glen Canyon Dam
Clark County Air and Environmental Management	Nevada	Lake Mead and Hoover Dam Hoover Dam to Davis Dam

3.6.3 Ambient Air Quality by River Reach

A description of the PSD classification and the air quality standards within the reaches provides a means of characterizing the standards applied to the affected environment. Reaches meeting regulatory standards are classified as attaining a pollutant standard. The attainment status provides a qualitative characterization of a reach as compliant with the standards; attainment characterizes the specific pollutant as not a significant concern within the reach. Consequently, characterizing the PM attainment status in the reaches provides a qualitative assessment of the significance of fugitive emissions within the reach. The Glen Canyon to Lake Mead reach is included because particulate matter generated at the Lake Mead delta may be dispersed into this reach.

3.6.3.1 Lake Powell and Glen Canyon Dam

The Lake Powell and Glen Canyon Dam reach is a PSD Class II Area. North central Arizona and southern Utah, including Lake Powell, is in attainment of the PM10 and PM2.5 standards (USEPA 2006a; 2006b). This attainment status corresponds with windrose information for both areas (i.e., relatively low average wind speeds implying low wind-blown fugitive emissions on average) and the relatively low levels of fugitive emissions generated from human activities.

3.6.3.2 Glen Canyon to Lake Mead

This reach is located in northern portions of Mohave County and Coconino County and encompasses the Grand Canyon National Park. Consistent with the federal air quality designations for national parks, the Grand Canyon National Park is designated as a PSD Class I Area. Mohave County and Coconino County, including the Glen Canyon Dam to Lake Mead reach, is in attainment of the PM10 and PM2.5 standards (EPA 2006a). Within the Grand Canyon National Park, wind velocities with the greatest potential for particulate transport from the Lake Mead delta occur during the April and May windy season.

3.6.3.3 Lake Mead and Hoover Dam

Lake Mead is located in the LMNRA on the Nevada and Arizona boundary in Clark County and Mohave County, respectively, and is a PSD Class II Area. The Lake Mead and Hoover Dam reach is in attainment of the PM10 and PM2.5 standards (EPA 2006a; 2006c). While some urban areas (including Las Vegas, North Las Vegas, and Henderson) within Clark County are in non-attainment of the NAAQS for PM10, the remaining county, including Lake Mead, is in attainment of the standard. That portion of Mohave County, Arizona adjacent to Lake Mead is also in attainment of the PM10 standard (Reclamation 2000).

3.7 Visual Resources

This section discusses the visual resources within the study area that may be affected by the proposed federal action. The visual resources issues addressed include:

- attraction features;
- extent (height) of visible calcium carbonate ring; and
- exposure of sediment deltas at reservoir in-flow areas.

3.7.1 Lake Powell and Glen Canyon Dam Reach

3.7.1.1 Attraction Features

The general visual/scenic resources of the Glen Canyon/Lake Powell area are dominated by the presence of Navajo Sandstone and desert varnish. Resources include sweeping vistas of red rock towers, buttes, and mesa framed by Lake Powell. One geologic attraction feature within this reach is Rainbow Bridge. It is contained within the Rainbow Bridge National Monument that was established in 1910. At that time, it was accessible only by the rugged Wetherill Trail from Navajo Mountain. Today, it is estimated that more than 82,000 visitors see this attraction on an annual basis, most of them arriving by boat. With today's lower reservoir elevations, visitors must walk further from the boat docks to see the bridge and they do not see water under or near the bridge, whether looking to the bridge from the west along the Wetherill Trail or looking east along the trail from the boat docks. Therefore, while Rainbow Bridge is an important visual resource, also important are the potential effects of the alternatives on this visual resource with respect to how reservoir elevations impact water access. These potential effects are analyzed in Section 4.3.

This visual impact analysis includes another geologic attraction, Cathedral in the Desert. This feature was inundated by the waters of Lake Powell as the reservoir filled. This geologic feature is now only exposed at low Lake Powell elevations; it is completely visible and accessible when reservoir elevations are below 3,550 feet msl.

Glen Canyon Dam is also an attraction feature. The American Society of Civil Engineers considers it one of the finest examples of concrete thin arch dams in the United States.

3.7.1.2 Calcium Carbonate Rings

Lake Powell has deposits of calcium carbonate surrounding the reservoir that become visible as the reservoir is drawn down. At lower reservoir elevations the colorful sandstone canyon walls show a white band of calcium carbonate deposit between the full reservoir elevation and the lower reservoir elevation, which change the visual contrast of rock and water.

3.7.1.3 Sediment Deltas

Sediment deltas appear as expansive, deep and eroding mud flats, cut by river channels. Sediment exposed for more than a few months is soon colonized by tamarisk. Sediments carried by the Colorado River and the San Juan, Dirty Devil, and Escalante rivers are deposited near the inflow areas of Lake Powell, forming downstream-progressing deltas. These sediment deltas are considered a visual detraction, particularly as the reservoir elevation decreases and the deltas become more visible.

3.7.2 Glen Canyon Dam to Lake Mead

River trips down the Colorado River through Marble Canyon and the Grand Canyon are renowned for their visual character. The proposed federal action will not have any visual effects on this reach.

3.7.3 Lake Mead and Hoover Dam

3.7.3.1 Attraction Features

Hoover Dam is a major destination and a national landmark. In 1955, it was selected as one of the seven engineering wonders in the United States by the American Society of Civil Engineers. The dam is located in a narrow, steep-walled canyon. Only a small portion of Lake Mead within Black Canyon can be viewed from Hoover Dam and the adjacent visitor facilities.

3.7.3.2 Calcium Carbonate Rings

Lake Mead also has deposits of calcium carbonate on the surrounding reservoir walls that become visible as the reservoir is drawn down. At lower reservoir elevations the steep rock slopes, canyon walls, and islands show a white band of calcium carbonate deposit between the full reservoir elevation and the lower reservoir elevation, which changes the visual contrast of rock and water. The ring is primarily noticeable to travelers on U.S. Highway 93 between Boulder City, Nevada and Hoover Dam, and to boaters and hikers. The main viewshed affected is the 56 square mile Boulder Basin.

3.7.3.3 Sediment Deltas

Sediment deltas have built up at the confluence of the Virgin River and Muddy River at the upper Overton Arm and at upper Lake Mead (Iceberg Canyon, Pearce Basin, and lower Granite Gorge). Sediment deltas are visible primarily to water-based recreationists, though they can also be viewed by visitors of the Lake Mead National Recreation Area (NRA) at Overton Beach and Pearce Ferry.

3.8 Biological Resources

This section describes the existing conditions related to biological resources within the study area that could be affected by implementation of the proposed federal action, including vegetation, wildlife and special status species associated with the Colorado River, its mainstream reservoirs, and historic floodplain.

Water deliveries are made to the service areas of the CAP, SNWA, and MWD through a series of pumps, pipelines, diversions, and lined canals. Accordingly, the vegetation and wildlife habitat potential of this infrastructure is essentially absent. Therefore, no impacts to biological resources within these facilities are expected, and they are not analyzed in the Final EIS.

Furthermore, Reclamation does not have the authority to decide how these agencies will operate under a Shortage Condition. For example, Reclamation does not control, and cannot anticipate which specific agricultural acreages may be planted or fallowed as a result of changes in water deliveries due to the proposed federal action, nor are individual farm operator's response to various water delivery conditions predictable over the long-term given access to alternative sources of water, economic conditions, and other factors. While the Final EIS has identified the potential for fallowing agricultural lands, it cannot identify specific acreage which would be fallowed as a result of the proposed federal action. Therefore, the effect on any specific acreage is not reasonably certain to occur and it would be speculative to attempt to identify potential biological effects within the service areas. Thus these potential biological effects are not analyzed in this Final EIS.

Reclamation is involved with numerous ongoing activities aimed at reducing the impact its operations have on biological resources, particularly on endangered species. For example, Reclamation is implementing the Glen Canyon Dam Adaptive Management Program aimed at protecting and improving the environment downstream of Glen Canyon Dam, and the LCR MSCP aimed at enhancing habitat for several endangered species and providing comprehensive mitigation to offset impacts from a range of conditions downstream of Hoover Dam.

3.8.1 Vegetation

Plant communities in the study area can be broadly categorized as riparian. The riparian vegetation along the Colorado River is among the most important wildlife habitat in the region. Riparian habitats, or vegetated areas along streams and rivers, in the Western United States typically support a disproportionately large number of wildlife species.

Much of the information in this section comes from the Final Environmental Impact Statement on the Colorado River Interim Surplus Criteria (Reclamation 2000) and various LCR MSCP documents (Reclamation 2005b).

3.8.1.1 Lake Powell and Glen Canyon Dam

Riparian vegetation around Lake Powell is extremely restricted because of the desert terrain that extends directly to the water's edge, and the continuously fluctuating lake elevations. Salt cedar, also known as tamarisk (*Tamarix ramosissima*), a nonnative invasive shrub along the Lake Powell shoreline is still becoming established and has not yet formed stable communities. These communities may attain some level of importance as insect and wildlife (particularly bird) habitat in the future, and provide habitat for fish during high lake elevations when the plants are inundated.

Fluctuations in lake elevations may result in standing water in the side canyons of Lake Powell where riparian vegetation has become established. Dominant plants found in these canyons include Fremont cottonwood (*Populus fremontii*), salt cedar, and cattail (*Typha sp.*). The GCNRA has many springs, seeps that are common in alcoves along Glen Canyon walls, and waterpockets located in canyons and uplands. These areas are recognized for their significance as wetland habitats and as unique ecosystems within the desert. These seeps support hanging gardens which are a specialized vegetation community (Welsh et al. 1987). The water sources that support hanging gardens originate from natural springs and seeps within the Navajo Sandstone formation and are independent of Lake Powell. This plant community will not be affected by the proposed federal action and as such it is not considered further in the Final EIS.

3.8.1.2 Glen Canyon Dam to Lake Mead

There is a change in the composition of the riparian community in this reach from Intermountian flora to that of the southern Basin and Range. Total area associated with the riparian community measures at least 10 square miles (6,400 acres).

Today, salt cedar, arrowweed (*Pluchea sericea*), black willow or Gooding willow (*Salix goodingii*), coyote willow (*Salix exigua*), and Emory seepwillow (*Baccharis emeroyi*) are the primary phreatophytes in the riparian zone (taxonomy is after Welsh et al. 1987). Those species that are more adapted to dry conditions may also be found further upslope on the terraces. Terrace dominants including four-wing saltbush (*Atriplex canescens*), arrowweed (*Pluchea sericea*), rubber rabbitbrush (*Chrysothamnus nauseosus*), and netleaf hackberry (*Celtis reticulata*), may also be located closer to the riverbank.

Marshes composed of emergent aquatics such as common cattail (*Typha domingensis*), broad-leaved cattail (*Typha latifolia*), and bulrushes (*Scirpus spp.*) have become established in return-current channels (backwaters), channel margins, and mouths of tributary streams from Glen Canyon Dam downstream to Lake Mead. Stands of emergent marsh vegetation in the riparian zone tend to be dominated by a few species, depending on soil texture and drainage. A cattail (*Typha domingensis*) and common reed (*Phragmities australis*) association grows on fine-grained silty loams while a horseweed (*Conyza canadensis*), knotweed (*Polygonum aviculare*), and Bermuda grass (*Cynodon dactylon*) association grows on loamy sands.

Since 1995, there has been a modest increase in woody vegetation and an increase in marsh communities under modified Glen Canyon Dam operations (Gloss et al. 2005). However, the increase in woody vegetation is partially due to expansion of the non-native salt cedar and arrowweed into the riparian zone. The United States Geological Survey (USGS) has indicated that there has been a decrease in wet marsh and an increase in dry marsh (Gloss et al. 2005).

3.8.1.3 Lake Mead to SIB

The highest concentration of vegetated habitat associated with Lake Mead is found in the Lake Mead and Virgin River deltas. Fluctuating lake elevations limit the shoreline vegetation. Riparian vegetation that does develop within the range of Lake Mead elevation fluctuations is temporary as fluctuating lake elevations either dewater or inundate these areas through time. Linear riparian woodlands may be present along the shoreline of the Lake Mead delta following high water flows, and associated sediment deposition and exposure. The sediment deposition and the associated growth of riparian vegetation at the Lake Mead delta has occurred for decades. As lake elevations decline, vegetation in the Lake Mead and Virgin River deltas begins to establish on clay/silt deposits. The dynamic nature of fluctuating lake elevations and deposition of sediment in the Lake Mead delta is expressed as a change in plant species composition and relative abundance over time. An increase in sediment deposition in the deltas followed by lower lake elevations allows establishment of native riparian habitat if the lowering of the lake elevations is timed to match native seed dispersal.

Vegetation for this reach is categorized using the methodology outlined in the LCR MSCP. Detailed descriptions of the vegetation resources can be found in the LCR MSCP documents. A summary of the vegetation cover types, and their characteristics, found from Lake Mead to the SIB is provided in Table 3.8-1.

Table 3.8-1
Summary of Vegetation Cover Types from Lake Mead to the SIB

Vegetation Cover Type	Characteristics
Woody Riparian	
Cottonwood-willow (6 structural types)	Gooding willow and cottonwood at least 10 percent of total trees
Saltcedar (6 structural types)	Saltcedar species constituting 80 to 90 percent of total trees
Honey Mesquite (4 structural types)	Honey mesquite constituting 90 to 100 percent of trees
Saltcedar-honey mesquite (4 structural types)	Honey mesquite at least 10 percent of total trees (usually <40 percent)
Saltcedar-screwbean mesquite (5 structural types)	Screwbean mesquite at least 20 percent of total trees
Arrowweed	Arrowweed at least 90 to 100 percent of total vegetation
Atriplex	Saltbush species constituting 90 to 100 percent of total vegetation
Marsh (7 compositional types)	Cattail/bulrush, little common reed, trees and grasses, and open water
Aquatic	
River	Mainstream plus tributaries and natural/artificial channels
Reservoir	Lakes formed by dams with variable water levels
Backwater	Open water plus marsh, temporary to permanent
Desert Scrub	Adjacent to riparian and aquatic land cover types
Agriculture	Active or fallow, adjacent to riparian and aquatic land cover types
Developed	Buildings, roads, campgrounds, landscaped areas

Table 3.8-2 provides a summary of the vegetation cover type acreage by river sub-reach that was determined to be present for the LCR MSCP analysis. A detailed breakdown of the sub-categories of cover types is provided in Table 4-8 of the LCR MSCP BA.

Table 3.8-2
Summary of Vegetation Cover Types from Lake Mead to the NIB (acres)[a]

Type	Lake Mead and Hoover Dam	Hoover Dam to Davis Dam	Davis Dam to Parker Dam	Parker Dam to Cibola Gage	Cibola Gage to Imperial Dam	Imperial Dam to NIB
Cottonwood-willow	1,721	1	1,541	889	616	1,325
Saltcedar	2,254	838	13,647	26,923	5,581	6,257
Honey Mesquite	0	4	627	6,443	175	5
Saltcedar-Honey Mesquite	58	359	3,463	13,398	778	234
Saltcedar-Screwbean Mesquite	0	32	5,058	4,654	579	786
Marsh	137	22	4,358	2,091	3,762	1,414
Atriplex	0	0	19	582	0	177
Arrow weed	0	0	496	6,541	48	1,069
Desert Scrub	353	31	7,676	11,710	397	3,151
Agriculture	0	0	19,166	169,664	260	36,799
Undetermined Riparian	0	0	6,634	6,268	0	2,337

[a] *From LCR MSCP BA Table 4-8 (Reclamation 2004c).*

For reference, further description of the LCR MSCP vegetation types present in this reach are provided below. The vegetation is classified according to the Anderson and Ohmart system, which is further described in the LCR MSCP documents (Reclamation 2005b).

3.8.1.4 NIB to SIB

Riparian communities comprise approximately 6,974 acres of the land cover present below Morelos Diversion Dam; 3,638 acres of which is in the United States. Approximately 77 percent of these communities are dominated by non-native saltcedar. The types of riparian communities present in this reach are described in Table 3.8-1. Table 3.8-3 summarizes the extent of riparian communities in the United States below Morelos Diversion Dam, from the NIB to the SIB.

The Borderlands Task Force consisting of the BLM, the Border Patrol (Department of Homeland Security), the USACE, FWS, Reclamation, and the Cocopah Tribe of Arizona is planning a vegetation clearing project along this reach aimed at improving security along this section of the United States and Mexico border. BLM is the lead federal agency responsible for compliance on this proposed effort.

Table 3.8-3
Summary of Vegetation Cover Types in the United States from NIB to SIB[a]

Type	Acreage
Arrow weed	33
Atriplex	38
Cottonwood-Willow-I	14
Cottonwood-Willow-II	38
Cottonwood-Willow-III	212
Cottonwood-Willow-IV	165
Cottonwood-Willow-V	27
Subtotal	*527*
Marsh	50
Saltcedar	2,996
Saltcedar-screwbean mesquite	65
TOTAL	3,638

[a] *Reclamation, July-September 2005 surveys.*

3.8.2 Wildlife

The Colorado River and its associated riparian vegetation provide important habitat for a variety of wildlife. Table 3.8-4 lists the native and non-native fish species that occur in the study area. The study area extends from the northern tip of Lake Powell in Utah south to the SIB (RM 0.0).

3.8.2.1 Lake Powell and Glen Canyon Dam

Fifteen fish species reside in Lake Powell and include 14 non-native fish species and one native fish species (flannelmouth sucker).

Common fish species in Lake Powell include walleye, bluegill, green sunfish, carp and channel catfish. Species that occur in the reservoir, but that are mainly associated with tributaries and inflow areas, include fathead minnow, mosquitofish, red shiner and plains killifish (NPS 1996). Mueller and Horn (1999) reported large numbers of fish in the reservoir upstream of the dam, but Budy et al. (2005) found large seasonal variances in fish abundances with low numbers of striped bass, threadfin shad and gizzard shad present at Wahweap Bay in May and July.

Table 3.8-4
Native and Non-Native Fish Species Present in the Study Area by Reach

Species	Reach	Native/ Non-native
Black bullhead *(Ictalurus melas)*	All	Non-native
Black crappie *(Pomoxis nigromaculatus)*	All	Non-native
Bluegill *(Lepomis macrochirus)*	All	Non-native
*Bluehead sucker *(Catastomus discobolus)*	Glen Canyon Dam to Lake Mead	Native
*Bonytail *(Gila elegans)*	Lake Powell (rare), Hoover Dam to Imperial Dam	Native
Carp *(Cyprinus carpio)*	All	Non-native
Channel catfish*(Ictalurus punctatus)*	All	Non-native
*Colorado pikeminnow *(Ptychocheilus lucius)*	Lake Powell to Glen Canyon Dam (rare)	Native
Fathead minnow *(Pimephales promelas)*	All	Non-native
*Flannelmouth sucker *(Catostomus latipinnis)*	Lake Powell, Separation Canyon, Lake Mead, immediately downstream of Davis Dam	Native
Flathead catfish *(Pylodictis olivaris)*	Davis Dam to the NIB	Non-native
Green sunfish *(Lepomis cyanellus)*	Lake Powell to Glen Canyon Dam, Lake Mead to the SIB	Non-native
*Humpback chub *(Gila cypha)*	Lake Powell (rare) Glen Canyon Dam to Separation Canyon	Native
Largemouth bass *(Micropterus salmoides)*	Lake Powell to the NIB	Non-native
Mosquitofish *(Gambusia affinis)*	Glen Canyon Dam to the SIB	Non-native
Plains killifish *(Fundulus zebrinus)*	Glen Canyon Dam to Hoover Dam	Non-native
Rainbow trout *(Oncorhynchus mykiss)*	Glen Canyon Dam to Below Davis Dam	Non-native
*Razorback sucker *(Xyrauchen texanus)*	Lake Powell to Imperial Dam (rare upstream of Lake Mead)	Native
Red shiner *(Notropis lutrensis)*	All	Non-native
Shortfin mollies *(Poecilia mexicana)*	Lake Mead, Laguna Dam to the SIB	Non-native
Smallmouth bass *(Micropterus dolomieui)*	Lake Powell, Separation Canyon (rare), Lake Mead to Imperial Dam	Non-native
Speckled dace *(Rhinichthys osculus)*	Glen Canyon Dam to Lake Mead	Native
Striped bass *(Morone saxatilis)*	Lake Powell to the NIB	Non-native
Threadfin shad *(Dorosoma petenense)*	Lake Powell to the SIB	Non-native
Tilapia *(Oreochromis aureus)*	Lake Mead to the SIB	Non-native
Walleye *(Stizostedion vitreum)*	Lake Powell to Glen Canyon Dam	Non-native
Redear Sunfish *(Lepomis Microlophus)*	Davis Dam to the NIB	Non-Native
Warmouth *(Chaenobryttus gulosus)*	Parker Dam to the NIB	Non-Native
Sailfin Molly *(Poecillia latipinna)*	Palo Verde Diversion Dam to the SIB	Non-native
Striped Mullet *(Mugil cephalus)*	Laguna Dam to the SIB	Native
Goldfish *(Carassius auratus)*	Lake Mead to the SIB	Non-native
Yellow bullhead *(Ameiurus natalis)*	Lake Powell to the SIB	Non-native

Distribution Information from: CDFG 2000; Colorado Division of Wildlife no date; Fuller 2006; New Mexico Game and Fish 2004; NatureServe 2006; Pima County no date; Ptacek et al. 2005; Rees et al. 2005a; Rees et al. 2005b; FWSa no date; FWSb no date; FWSc no date; Valdez 2006.

**Note: These fish species are discussed further below under Special Status Species.*

Non-native fish species became established by intentional and unintentional introductions. Lake Powell was stocked with non-native sport and forage fish and movement of stocked non-native fish into the lake has also taken place. Largemouth bass and crappie populations were stocked initially and proliferated to provide the bulk of the sport fisheries. Both species have declined in recent years due to lack of habitat structure for young fish. Filling and fluctuation of the reservoir resulted in changing habitat that eliminated most of the vegetation favored by many species. The habitat change led to the introduction of smallmouth bass and striped bass, presently the two dominant predator species in the reservoir, with striped bass being the most dominant. Threadfin shad were introduced to provide an additional forage base and quickly became the predominant prey species (NPS 1996).

The sport fishery in Lake Powell is primarily based on striped bass. Other sport fish found in Lake Powell include largemouth bass, catfish and trout. Threadfin shad in Lake Powell exist in the northernmost portion of their range, and are the primary food source for striped bass.

July 2007 sampling in Lake Powell found three individual quagga and/or zebra mussel larvae near Wawheap Marina and near Glen Canyon Dam. The testing method is not able to determine whether these larvae are zebra or quagga mussels. Uncertainty remains as to whether there is an established population of zebra and/or quagga mussels in Lake Powell (Utah Division of Wildlife Resources 2007).

At least six species of amphibians are currently known to live in Glen Canyon National Recreation Area. The Canyon tree frog (*Hyla arenicolor*) is common along the shores of Lake Powell (Spence 1996). All other herpetofauna, including the declining northern leopard frog (*Rana pipiens*), are associated with side canyons off Lake Powell and are therefore outside the area of influence of the proposed federal action.

Common waterfowl of the Lake Powell area include American widgeon (*Anas americana*), northern pintail (*Anas acuta*), bufflehead (*Bucephala albeola*) common goldeneye (*Bucephala clangula*), common merganser (*Mergus merganser*), green-winged teal (*Anas crecca*), lesser scaup (*Aythya affini*), eared grebe (*Podiceps nigricollis*), and mallard (*Anas platyrhynchos*). The majority of these are winter residents or spring and fall migrants. Most shorebirds are summer residents. Common shorebird species include western sandpiper (*Calidris mauri*), least sandpiper (*Calidris minutilla*), American avocet (*Recurvirostra americana*), long-billed dowitcher (*Limnodromus scolopaceus*), snowy egret (*Egretta thula*), and great blue heron (*Ardrea herodias*). Ring-billed gulls (*Larus delarwarensis*) are common year-round residents.

Larger mammals inhabiting the study area include beavers, desert bighorn sheep, mule deer, coyotes, mountain lions, and bobcats (Reclamation 2004b). Mountain lions and bobcats are rare. Smaller mammals include ringtail and western spotted skunks and six bat species (Carothers and Brown 1991). Two skunk species are some of the most common mammals in the area.

3.8.2.2 Glen Canyon Dam to Lake Mead

A total of 18 non-native fish species have been reported between Glen Canyon Dam and Lake Mead during the period of 1957 through 2006 (Lauretta and Johnstone 2005; Lauretta and Seratto 2006; Trammell and Valdez 2003; Valdez and Ryel 1995). Non-native fish infrequently occurring in this reach include the golden shiner, redside shiner, striped bass, and threadfin shad.

The Glen Canyon Dam to Lake Mead reach supports six native fish species which include small numbers of the three non-ESA listed species: flannelmouth sucker, bluehead sucker, and speckled dace. The flannelmouth sucker spawns in the Colorado River (McIvor and Thieme 1999; Thieme 1998), although the water generally is too cold for survival of eggs and larvae. Populations of bluehead and flannelmouth suckers are protected under a multi-state cooperative agreement between Arizona, Colorado, Nevada, New Mexico, Utah and Wyoming (Utah Department of Natural Resources 2004). Their populations appear to have remained relatively stable under the Modified Low Fluctuating Flows (MLFF) operating policy of Glen Canyon Dam.

The primary sport fish in the Colorado River between Glen Canyon Dam and Lake Mead inflow is rainbow trout. Natural reproduction of rainbow trout in the Grand Canyon is dependent on cool water temperatures, access to tributaries for spawning and continued availability of suitable mainstream habitat. These variables are directly related to patterns of flow releases from Lake Powell. McKinney and Speas (2001) conducted a study analyzing 658 rainbow trout around Lees Ferry to determine the predominant food sources. It was found that *Gammarus*, chironomids, and *Cladophora* constituted about 90 percent of the food by volume.

Humpback chub have also been reported to rely on *Gammarus* and chironomids, but also rely on larval simuliids, which become more common downstream of the Paria River (Gloss et al. 2005). *Cladophora, Oscillatoria spp* and terrestrial organic matter serve as key energy sources for aquatic invertebrates between Glen Canyon Dam and Lake Mead. *Cladophora and Oscillatoria* are also consumed by fish (Gloss et al. 2005).

Zebra and/or quagga mussels prefer slow moving water and are currently not known to exist in the Colorado River between Glen Canyon Dam and Lake Mead (Britton 2007, personal communication).

Over 27 species of herpetofauna have been documented in the riparian zone of Grand Canyon. Within this reach, herpetofauna densities are generally highest in the new high water zone of riparian vegetation that has developed since construction of Glen Canyon Dam. The old high water zone is situated higher in elevation, a result of pre-dam flooding. However, Carpenter (2006) found that, other than the resident frog species, all herpetofuana observed in the canyon utilized all three hydrologic zones - shoreline, the new high water zone and the old high water zone. Toads and tree lizards used the shoreline proportionally more than any of the other species and were observed more in the new, than in the old high water zone.

The most common lizards in the riparian zone are the side-blotched lizard (*Uta stansburiana*), the Western whiptail (*Cnemidophorus tigris*), the desert spiny lizard (*Sceloporus magister*), and the tree lizard (*Urosaurus ornatus*). The collared lizard (*Crotaphylus insularis*) and the chuckwalla (*Sauromalus obesus*) are less common in the riparian zone than in the old high water zone. Warren and Schwalbe (1986) reported lizard densities during June averaged 858 per hectare in the riparian zone versus 300 per hectare in the old high water zone. Kearsley et al. (2006) suggested that the high density of lizards in the riparian zone may be attributed to increased abundance of food resources (insects) and to some degree to organic debris left on popular camping beaches.

Snakes are common in the higher and drier elevations of the riparian zone and in the more xeric terraces and hillsides. Eight snake species have been documented within the riparian zone; the most common of these are the Grand Canyon rattlesnake (*Crotalus viridis abyssus*), the southwestern speckled rattlesnake (*C. mitchellii pyrrhus*) and the desert striped whipsnake (*Masticophis taeniatus*).

Recent surveys have found healthy populations of the Woodhouse's toad (*Bufo woodhousii*), the red-spotted toad, (*B. punctatus*), the canyon treefrog, and the tiger salamander (*Ambystoma tigrinum*) (Gloss et al. 2005).

The canyon tree frog is confined mostly to relatively steep side canyons while the two toad species are generally found in the active riparian zone in spring and fall but appear to favor the shore zone in summer (Kearsley et al. 2003). For riverside dwellers, egg deposition and larval development generally occurs in the backwaters or along the shallow waters at the boundary of the aquatic and riparian ecosystems.

Listed as a species of special concern in Arizona, the northern leopard frog is declining throughout its range. Leopard frogs have disappeared from 70 percent of the known sites upstream and downstream of Glen Canyon Dam and there appear to be declines among some of the remaining populations (Gloss et al. 2005). The only known remaining population downstream of Glen Canyon Dam is located between Glen Canyon Dam and the Paria River in a series of off-channel pools. Inundation at this site occurs at approximately 21,000 cfs. This population has experienced wide year-to-year fluctuations in numbers, but recent survey efforts indicate a sharp decline in population size with only two adult individuals found in 2004 (Drost 2004).

In 2004, a previously unknown small population of a second leopard frog species was found in Surprise Canyon. Although genetic studies are still in progress, the frogs appear to be an ever rarer species, the lowland leopard frog (*Rana yavapaiensis*). This small population is located well up the canyon and outside the influence of flows in the Colorado River (Drost 2005).

More than 30 bird species have been recorded breeding in the riparian zone along the Colorado River in Grand Canyon. Most of these bird species nest and forage for insects within the riparian zone and the adjacent upland area. Of the 15 most common riparian breeding bird species, 10 are neotropical migrants that breed in the study area but winter primarily south of the United States-Mexico border. The rest of the breeding birds that use the canyon are year-round residents or short-distance migrants that primarily winter in the region or in nearby southern Arizona (Brown et al. 1987).

Eleven of these nesting bird species are referred to as obligate riparian birds due to their complete dependence on the riparian zone. Obligate riparian birds nesting within the riparian zone include the neotropical migrants Lucy's warbler (*Vermivora luciae*) and Bell's vireo (*Vireo bellii*), two species identified as "high priority" under regional Partners-in-Flight bird plans and area state bird plans, Common yellowthroat (*Geothlypis trichas*), yellow warbler (*Dendroica petechia*), yellow-breasted chat (*Icteria virens*), black-chinned hummingbirds (*Archilochus alexandri*), the endangered Southwestern willow flycatcher (*Empidonax trailii extimus*), and Bewick's wren (*Thryomanes bewickii*), a sometimes permanent resident of Grand Canyon. Black Phoebe (*Sayornis nigricans*) is a common permanent resident of the canyon having a close association with water.

The riparian breeding bird community appears little changed since the riparian plant community stabilized in the 1970s and bird studies were initiated in the 1980s. Exceptions are Bell's vireo and song sparrow (*Melospiza melodia*), which appear to have expanded their breeding ranges, and Bullock's oriole (*Icterus bullockii*) and yellow warbler which have increased in number. The blue-gray gnatcatcher (*Polioptila caerulea*) has shown a steady decline in numbers (Brown et al. 1987; Spence 2004; Yard and Blake 2004).

Winter songbirds include ruby-crowned kinglet, white-crowned sparrow, dark-eyed junco, and song sparrow (Spence 2004). Spence (2004) found that winter species diversity increased below RM 205.

The aquatic bird community is almost exclusively made up of winter residents. Thirty-four species of wintering waterfowl along with loons, cormorants, grebes, herons, rails, and sandpipers utilize the Colorado River corridor. Increases in abundance and species richness have been attributed to the increased river clarity and productivity associated with the presence of Glen Canyon Dam (Spence 2004; Stevens et al. 1997a). The majority of waterfowl tends to concentrate above the Little Colorado River due to the greater primary productivity that benefits dabbling ducks and greater clarity for diving, piscivorous ducks. Common waterfowl species include American coot (*Fulica americana*), American widgeon, bufflehead, common goldeneye, common merganser, gadwall (*Anas strepera*), green-winged teal, lesser scaup (*Aythya affinis*), mallard, and ring-necked duck (*Aythya collaris*). Shorebirds other than great blue heron and spotted sandpiper (*Actitis macularia*) are rare in the action area. These species are fairly common winter and summer residents along the Colorado River.

The American peregrine falcon (*Falco peregrinus*) are uncommon year-round residents in the study area. In recent years, as many as twelve active eyries have been found in Glen Canyon. Nest sites are usually associated with water. In Grand Canyon, common prey items in summer include white-throated swift (*Aeronautes saxatalis*), swallows, other song birds, and bats (Brown 1991), many of which feed on invertebrate species (especially Diptera) that emerge out of the Colorado River (Stevens et al. 1997b). In winter, a common prey item is waterfowl.

The common bird species found in this reach (Gloss et al. 2005) are summarized in Table 3.8-5 and Table 3.8-6.

Table 3.8-5
The Fifteen Generally Most Common Terrestrial Breeding Bird Species Found in Riparian Habitats Along the Colorado River in Grand Canyon

Common Name	Scientific Name
Ash-throated flycatcher	*Myiarchus cinerascens*
Bell's vireo	*Vireo bellii*
Bewick's wren	*Thryomanes bewickii*
Black-chinned hummingbird	*Archilochus alexandri*
Blue grosbeak	*Passerina caerulea*
Blue-gray gnatcatcher	*Polioptila caerulea*
Bullock's oriole	*Icterus bullockii*
Common yellowthroat	*Geothlypis trichas*
House finch	*Carpodacus mexicanus*
Lesser goldfinch	*Carduelis psaltria*
Lucy's warbler	*Vermivora luciae*
Mourning dove	*Zenaida macroura*
Song sparrow	*Melospiza melodia*
Yellow warbler	*Dendroica petechia*
Yellow-breasted chat	*Icteria virens*

Table 3.8-6
The Ten Generally Most Common Overwintering Aquatic Bird Species Encountered During Surveys Along the Colorado River Downstream of Glen Canyon Dam

Common Name	Scientific Name
American coot	*Fulica Americana*
American wigeon	*Anas Americana*
Bufflehead	*Bucephala albeola*
Common goldeneye	*Bucephala clangula*
Common merganser	*Mergus merganser*
Gadwall	*Anas strepera*
Green-winged teal	*Anas crecca*
Lesser scaup	*Aythya affinis*
Mallard	*Anas platyrhynchos*
Ring-necked duck	*Aythya collaris*

Within the GCNRA and Grand Canyon National Park, 64 and 34 species of mammals, respectively, have been found (Carothers and Aitchison 1976; Warren and Schwable 1986; Frey 2003). Of these mammals only three can be considered obligate aquatic mammals - beaver (*Castor canadensis*), muskrat (*Ondatra canadensis*), and river otter (*Lutra canadensis*). Despite occasional reported sightings of river otters in Grand Canyon, river otters are classified as extirpated and muskrats are considered extremely rare.

An increase in the population size and distribution of beavers in Glen Canyon and Grand Canyon has occurred since the construction of Glen Canyon Dam, likely due to the increase in riparian vegetation and relatively stable flows. Beavers cut willows, cottonwoods, and shrubs for food and can significantly affect the riparian vegetation. Bats in Grand Canyon typically roost in desert uplands, but forage on abundant insects along Lake Powell, the Colorado River and its tributaries. The deer mouse (*Peromyscus maniculatus*) is restricted to the riparian zone. Larger mammals include coyotes (*Canis latrans*), bighorn sheep, mule deer (*Odocoileus rafinesque*), mountain lions (*Puma concolor*), and bobcats (*Lynx rufus*). Mountain lions and bobcats are rarely seen (Gloss et al. 2005).

3.8.2.3 Lake Mead and Hoover Dam

The sport fishery in Lake Mead is primarily for striped bass and largemouth bass. Other sport fish found in the lakes include catfish and hatchery reared rainbow trout (Reclamation 2000).

Native fishes in this reach include the razorback sucker, and the flannelmouth sucker. Non-native fishes inhabiting this reach include red shiner (*Cyprinella lutrensis*), common carp (*Cyprinus carpio*), and mosquitofish, among others (Reclamation 1982).

A large number of non-native fish species are present, predominantly downstream of the Warm Springs area on the Muddy River and continuing into Lake Mead (FWS 1995). Non-native species that co-occur with native fishes in spring-fed pools include shortfin mollies (*Poecilia mexicana*), mosquitofish, and tilapia (*Oreochromis aureus*) (Scoppettone et al. 1998).

The non-native quagga mussel (*Dreissena rostriformis bugensis*) was discovered at Lake Mead in early January 2007 (FWS 2007). Monitoring is ongoing to determine their extent.

The herpetofauna and their habitat use of upper Lake Mead is an extension of the more common species and habitat use described above for the Glen Canyon Dam to Lake Mead reach. The two relict leopard frog (*Rana onca*) populations within LMNRA are associated with isolated springs and are outside the area of influence of the proposed federal action. The spiny soft-shelled turtle (*Trionyx spiniferus*) has also been introduced and it is present in Lake Mead (Allan and Roden 1978).

Avifauna for upper Lake Mead is similar to that discussed for the previous river reaches. Songbird species are similar to those of the canyons upstream with greater diversity than in Glen Canyon and Grand Canyon. Waterfowl species are similar to those described above for Lake Powell. Waterfowl use of Lake Mead is highest in winter months.

Mammalian use of this reach is similar to that discussed for the previous reaches.

3.8.2.4 Hoover Dam to NIB

This section of the lower Colorado River supports several hundred species of wildlife (birds, mammals, fish, reptiles, and amphibians), including both resident species and migratory visitors, that use the land cover types described above. Common mammals include mule deer (*Odocoileus hemionus*), burro (*Equus asinus*) (a non-native mammal), coyote (*Canis latrans*), bobcat (*Felis rufus*), Audubon cottontail (*Sylvilagus audubonii*), several species of rodents and bats, striped skunk (*Mephitis mephitis*), and raccoon (*Procyon lotor*) (Anderson and Ohmart 1984). Reptiles and amphibians are represented by several species of lizards, snakes, toads, and frogs, many of which are native to the area. Most of these use upland and riparian areas, but the amphibians require water for reproduction. The spiny soft-shelled turtle (*Trionyx spiniferus*) has also been introduced in Lake Mohave (Allan and Roden 1978). A variety of aquatic invertebrates inhabit the reservoirs and river. Fourteen species of zooplankton have been reported in Lake Mead and Lake Mohave as well as mollusks, crustaceans, aquatic and terrestrial insects, and a freshwater jellyfish (Allan and Roden 1978).

The non-native quagga mussel was recently discovered in Lake Mohave and Lake Havasu (FWS 2007). Monitoring is ongoing to determine their extent.

The Colorado River corridor provides important habitat for migratory birds, both neotropical songbirds and waterfowl and other wetland dependent species, as well as habitat for resident species. These migratory species include such songbirds as humming birds, cuckoos, flycatchers, vireos, warblers, tanagers, orioles, buntings, waterfowl and wetland birds such as geese, ducks, cranes, rail, killdeer and other plovers, stilts, avocets, yellowlegs, dowitchers, and sandpipers. Woody riparian vegetation and wetlands provide habitat for a variety of raptors that include sharp-shinned hawk (*Accipiter striatus*), Cooper's hawk (*Accipiter cooperii*), northern harrier (*Circus cyaneus*), red-tailed hawk (*Buteo jamaicensis*), rough-legged hawk (*Buteo lagopus johannis*), common black hawk (*Buteogallus anthracinus*), Harris' hawk (*Parabuteo unicinctus*), bald eagle (*Haliaeetus luecocephalus*), golden eagle (*Aquila chrysaetos*), white-tailed kite (*Elanus leucurus*), American kestrel (*Falco sparverius*), peregrine falcon (*Falco peregrinus*), and osprey (Pandion haliaetus). Other common birds include egrets, herons, and woodpeckers. Backwaters and reservoirs provide resting and foraging habitat for waterfowl and shorebirds.

3.8.2.5 NIB to SIB

Aquatic habitats within this reach are supplied by surface water present in the lower Colorado River channel and in backwaters maintained by subsurface lower Colorado River flow. Approximately 205 acres of open water were present in this reach in 2005. These open water areas and associated emergent vegetation provide habitat for a variety of waterfowl, wading birds (e.g., herons), water birds (e.g., grebes), and shorebirds. Huerta et al. (2003) recorded 13 species of water-associated bird species using aquatic habitats of the limitrophe in 2003. Permanent fish habitats are limited to the upstream portions of the limitrophe that maintain surface water throughout the year. Fish present in the limitrophe are primarily introduced species (e.g., catfish and other sport fishes). As identified in Table 3.8-4, sixteen species of fish, primarily non-native, may be found in this reach. Native species historically occurring in this reach included the following marine or brackish water species: spotted sleeper (*Eleotris picta*), machete (*Elops affinis*), longjaw mudsucker (*Gillichthys mirabilis*), and striped mullet (*Mugil cephalus*) (Reclamation 2004d).

Woody riparian vegetation provides habitat for common mammals such as coyote, bobcat (*Felis rufus*), Audubon cottontail, several species of rodents and bats, muskrat (*Ondatra zibheticus*), beaver (*Castor canadensis*), and raccoon (*Procyon lotor*) (Huerta et al. 2003). Common birds associated with riparian habitats include mourning dove, ash-throated flycatcher, Crissal thrasher, Bullock's oriole, brown-headed cowbird, Abert's towhee, and verdin. Reptiles and amphibians known to occur include Woodhouse's toad (*Bufo woodhousii*), bullfrog (*Rana catesbeiana*), the non-native spiny softshell (*Trionyx spiniferus*), tree lizard (*Urosaurus ornatus*), and bullsnake (*Pituophis catenifer sayi*) (Huerta et al. 2003). The lower Colorado River also serves as a migration corridor for numerous neotropical migrant birds and riparian vegetation present in this reach provides stopover habitat for these species during migration.

3.8.3 Special Status Species

Special status species are species that are listed, or those that are proposed for listing as threatened or endangered under the ESA that may be present in the study area, and include species of special concern to states and other entities responsible for management of resources within the study area. This includes special status species and their habitat from Lake Powell to the SIB that may be affected by the proposed federal action. Special status species not associated with the Colorado River, or which otherwise are not likely to be affected, are not described in this EIS.

Reclamation is consulting with the FWS to meet its responsibilities under Section 7 of the ESA on the potential effects of the proposed federal action to ESA-listed species. A considerable amount of information pertinent to this analysis is available from various recent documents prepared by Reclamation and the FWS under NEPA and/or the ESA. These documents were relied upon for much of the information for this section.

Reclamation prepared a BA on the ISG and the Secretarial Implementation Agreement (SIA), which analyzed the potential effects on special status species, including ESA-listed species which may occur in the study area from the full pool elevation of Lake Powell to the SIB (Reclamation 2000).

More recently, Reclamation completed consultation under ESA for various current and projected federal and non-federal activities covered by the LCR MSCP. The purpose of the LCR MSCP was to provide for conservation of several federally listed species and many non-listed species, while allowing the federal and non-federal MSCP partners to continue their ongoing and future operations below Lake Mead. The geographic scope of the LCR MSCP includes the full pool elevation of Lake Mead and the floodplain downstream to the SIB. Among the activities covered by the consultation were future water delivery reductions under shortage conditions.

Reclamation is consulting with the FWS to meet its responsibilities under Section 7 of the ESA on potential effects of the proposed federal action to federally listed species beyond the LCR MSCP coverage (Appendix R). This includes: 1) Lake Powell to Lake Mead (outside LCR MSCP coverage); 2) the full length of the Muddy River in Nevada, and the Virgin River from the Mesquite Diversion near Mesquite, Nevada to Lake Mead; and 3) incremental effects beyond the LCR MSCP coverage, if any, from Lake Mead to the SIB.

Table 3.8-7 lists those special status species potentially affected by the proposed federal action. Further description of special status species is available in several existing documents including the LCR MSCP (Reclamation 2004a-e, 2005b) and the Colorado River Interim Surplus Criteria Final EIS (Reclamation 2000).

Listing Status Legend

FT – Federally threatened under Endangered Species Act (ESA)

FT PDL – Federally threatened under ESA, proposed for de-listing

FE – Federally endangered under ESA

FE CH – Federally endangered under ESA with designated Critical Habitat (CH)

FE EX – Federally endangered under ESA, experimental population

FC – Federal candidate for listing under ESA

FSC – Federal Species of Concern (non-ESA)

BLM S – Bureau of Land Management Sensitive

NV E – Nevada Endangered

NV CE – Nevada Critically Endangered

NV SP – Nevada State Protected

AZ SC – Arizona Wildlife of Special Concern

CA T – California Threatened

CA E – California Endangered

CA SC – California Species of Special Concern

UT CS – Utah special management under Conservation Agreement to preclude the need for Federal listing

UT SC – Utah Species of Concern

UT SP – Utah State Protected

This page intentionally left blank.

3.9 Cultural Resources

This section describes the cultural resources that may be affected by the proposed federal action. The cultural resources include historic and prehistoric buildings, structures, sites, and objects, including Indian sacred sites and traditional cultural properties. Historic properties are the subset of cultural resources that are either listed or determined eligible for listing on the National Register of Historic Places (NRHP). Eligibility to the NRHP is determined by the ability of a property to convey its significance or importance in American history, prehistory, culture, or engineering, and by its integrity, essentially its preservation (36 C.F.R. pt. 60.4).

Section 106 of the National Historic Preservation Act of 1966 (NHPA), as amended, and its implementing regulations (36 C.F.R. pt. 800) require federal agencies to take into account the effects of their actions (undertakings) on historic properties and to allow the Advisory Council on Historic Preservation (ACHP) an opportunity to comment. Executive Order (Exec. Order) No. 13007 requires consultation with Indian tribes regarding Indian sacred sites. Executive Memorandum from the White House of April 29, 1994 requires government-to-government consultation on other issues of Tribal concern. These concerns may also involve cultural resources. Reclamation has initiated consultation with concerned Indian tribes, State Historic Preservation Officers (SHPO), Tribal Historic Preservation Officers (THPO), and other interested parties regarding cultural resources.

3.9.1 Undertaking Determination

Reclamation has determined that the proposed federal action is an undertaking subject to compliance with Section 106 of the NHPA. This is because it adds a new element to the existing program of on-going operations of the Colorado River that could lead to changes in the manner in which Lake Powell and Lake Mead have been operated historically. Specifically, the alternatives address operation of these two reservoirs at low elevations that might result in the emergence of cultural resources that have been submerged since the creation of the reservoirs. A reduction in the amount of water to be delivered downstream of Lake Mead could result in lower river elevations, which could lead to changes in stream dynamics and patterns of deposition and erosion that could potentially affect cultural resources.

3.9.2 Definition of the Area of Potential Effects and Identification Efforts

The area of potential effects (APE) of an undertaking is defined at 36 C.F.R. pt. 800.16(d) as “the geographic area or areas within which an undertaking may directly or indirectly cause changes in the character or use of historic properties, if any such properties exist.” This section goes on to state that “the APE is influenced by the scale of the undertaking and may be different for different kinds of effects caused by the undertaking.” Reclamation defines the APE to be the reaches of the Colorado River from Lake Powell downstream to Imperial Dam. In the reach from Davis Dam to Imperial Dam, the APE is further defined as the Colorado River channel from bank to bank, and the lateral extent of backwaters, lakes, and marshes directly connected to it.

Reclamation has compiled all available information about previously documented cultural resources in the APE. This information will form the basis of consultation with the SHPO and THPO, as required by 36 C.F.R. pt. 800.

3.9.3 Lake Powell and Glen Canyon Dam

The NPS database indicates that 518 historic properties were recorded within the full reservoir pool of Lake Powell (elevation 3,700 feet msl) during the Upper Colorado River Basin Archaeological Salvage Project (more commonly referred to as the Glen Canyon Project [Jennings 1966]) between 1956 and 1963. All were inundated by 1980 when Lake Powell reached full pool elevation. The Glen Canyon Project was completed prior to the enactment of the NHPA; hence none of the sites were evaluated for eligibility to the NRHP. Of the 518 sites, 61 were excavated and 10 tested for significance under the Historic Sites Act of 1935. This left 447 sites for which documentation was the only form of mitigation.

It is not known whether any of the inundated sites would retain integrity should they be exposed through the lowering of Lake Powell elevation. Inundation studies conducted by the NPS and the USACE (Dunn 1996; Lenihan et al. 1981; Ware 1989) concluded that cultural resources located within the deep-water zone of reservoirs are least susceptible to impacts of inundation and reservoir operations, while cultural resources within the operational zones of reservoirs are subject to adverse impacts from wave action and the alternating effects of wetting and drying related to fluctuating reservoir elevations. Cultural resources located immediately above the full pool elevation have generally been disturbed and damaged by recreation and visitation.

Indian sacred sites and other resources of Tribal concern have been documented in this reach.

3.9.4 Glen Canyon Dam to Lake Mead

The first 15 miles of this reach is within the GCNRA. The remainder of the reach is within the Grand Canyon National Park, the Navajo Indian Reservation and the Hualapai Indian Reservation. An intensive archaeological survey of this reach was conducted during 1991 and 1992 by NPS and the Department of Anthropology, Northern Arizona University (NAU) through funding provided by Reclamation. In all, 475 sites were recorded, 336 of which were potentially subject to impacts from dam operations. Of the 336 sites, 313 were determined NRHP-eligible, 14 not eligible, and nine were recommended for testing (Fairley et al. 1994). A programmatic agreement was developed to address the possible impacts to cultural resources resultant from the operation of Glen Canyon Dam (Reclamation 1994b). Currently, Reclamation in conjunction with the NPS, Navajo Nation Archaeological Department (NNAD), Utah State University (USU), the Zuni Cultural Resource Enterprise (ZCRE), and Museum of Northern Arizona is developing a treatment plan for mitigation of adverse effects to 160 historic properties. Additional long term monitoring and resource protection is afforded by the Grand Canyon Protection Act of 1992.

The Navajo Nation, Pueblo of Zuni, Hopi Tribe, Hualapai Indian Tribe, Kaibab Band of Paiute Indians, and Paiute Indian Tribe of Utah have been actively monitoring Grand Canyon natural resources, as well as resources of traditional religious and cultural significance. These tribes are currently developing culturally specific long-term monitoring protocols.

In addition, the Pueblo of Zuni has completed a NRHP eligibility nomination for selected historic properties or Traditional Cultural Properties (TCP) as defined by National Register Bulletin 38. The Navajo Nation, Hopi Tribe, and Hualapai Indian Tribe are currently developing TCP nominations. Indian sacred sites and other resources of Tribal concern have been documented in this reach.

3.9.5 Lake Mead and Hoover Dam

Most of the prehistoric cultural resources in this reach were documented by Harrington and the Civilian Conservation Corps in the 1920s and 1930s (Harrington 1925a, b, 1926, 1927; Harrington et al. 1930), while those of historic and architectural value are compiled in WESTEC Services Inc. (1980). Property types include: mines, ferry and steamboat landings, roads, ranches, farms, buildings, and sites of historical towns of Kaolin, St. Thomas, Rioville, and Callville Bay. Notable ethnographic resources include a Southern Paiute farm observed by Jedediah Smith in 1827, a village site, and the Salt Song Trail, the general location of which is shown in the map that serves as the frontispiece to Laird's work on the Chemehuevi (Laird 1976). Two resources are listed on the NRHP: Lost City/Pueblo Grande de Nevada, and Hoover Dam. Hoover Dam is further distinguished by its status as a National Historic Landmark. Most of these resources have been submerged since 1937 when Lake Mead rose above elevation 1,083 feet msl to an elevation of 1,102 feet msl.

Since its initial filling in the late 1930s, Lake Mead elevations have fluctuated from a high of 1,226 feet msl in 1983 to a low of 1,083 feet msl in 1956. Based on the results of the National Reservoir Inundation Study (Lenihan et al. 1981; Ware 1989) it is anticipated that most cultural resources located within the historical operational zone of Lake Mead (between the 1,225 foot msl and 1,083 foot msl elevation contours) have lost integrity as a result of repeated, periodic exposure at the margin of the reservoir where they would have been subject to mechanical erosion by wave action. Although some sites in the historical operational zone such as St. Thomas (Wyskup 2006) may continue to retain integrity, the National Reservoir Inundation Study and other reservoir specific studies (Labadie 2001) indicate only cultural resources submerged at depth since initial inundation are likely to retain integrity. Recent sidescan sonar and high-resolution seismic-reflection studies performed at Lake Mead (Harper et al. 2005; Twichell et al. 1999, 2003) appear to confirm this finding and suggest that cultural resources submerged in Lake Mead since it reached historic operational elevations in 1937 could retain sufficient integrity for listing on the NRHP.

Though some 156 resources appear in agency records, documentary sources, and inventory reports, this analysis concentrates on 108 sites previously identified in agency and repository records. Of these 108 sites it is likely that as many as 73 sites within the operational zone of Lake Mead, between elevations 1,226 feet msl and 1,083 feet msl, are likely to have been completely destroyed or damaged to the point where they would not qualify for listing on the NRHP. The remaining 35 sites below elevation 1,083 feet msl may retain sufficient integrity to qualify for listing. Examples of submerged resources in excellent condition are the B-29 bomber that went down in Lake Mead in the 1950s, and features associated with the aggregate classification plant located in Boulder Basin, which was used for the construction of Hoover Dam (Harper et al. 2005).

Previously undocumented cultural resources in the operational zone of Lake Mead will likely have been impacted to varying degrees and some will probably retain sufficient integrity to qualify for listing on the NRHP. However, the excellent condition of the B-29 bomber and the features associated with the aggregate classification plant located in Boulder Basin suggest there is a good chance that previously undocumented cultural resources that have been submerged since 1937, at depths below elevation 1,083 feet msl, could retain sufficient integrity to be considered for listing. Examples of the kinds of cultural resources that are likely to retain some information potential include historic sites with structural remains and archaeological sites with subsurface deposits and features. Information from sidescan sonar studies conducted in Boulder Basin and other areas of Lake Mead indicate deposition of sediment has been greatest in the area of the delta, and along the old channels of the Colorado River and Virgin River, and the major washes that feed into them. Undocumented cultural resources in these areas are likely buried beneath considerable thickness of sediment or, as is the case with St. Thomas, cultural resources may be covered by a mantle of silt several to tens of inches thick (Wyskup 2006).

3.9.6 Lake Mohave and Davis Dam

Most of the prehistoric cultural resources in this reach were documented by Baldwin (1943, 1948). WESTEC Services, Inc. (1980) reported on historic and architectural resources. Though 196 previously recorded prehistoric and historic period cultural resources are known or suspected to be located in or immediately adjacent to the Lake Mohave and Davis Dam reach, many of the resources documented by Baldwin prior to the construction of Davis Dam (Baldwin 1943, 1948) are features, rather than sites. When Baldwin's clusters are treated as single sites, the total number of sites suspected to be located in and immediately adjacent to the Lake Mohave and Davis Dam reach is reduced to 89.

Types of historic sites include mines, ranches, buildings and structures, ferry and steamboat landings, roads, trails, campsites, and a railroad (the Quartette Mining Company line). One traditional cultural property of importance to several tribes that is listed on the NRHP is located in this reach. Prehistoric property types documented in this reach include pit houses, rock art, rock shelters, lithic and ceramic scatters, rock circles, rock alignments, and rock piles.

With respect to the probable condition of documented and undocumented sites submerged in Lake Mohave, it can be anticipated that the portions of resources located between the 647-foot msl elevation contour and the 628-foot msl elevation contour will have lost integrity as a result of wave action. The results of a recent sidescan sonar and seismic-reflection study (Foster et al. 2004) suggest portions of sites located below the 628-foot msl elevation contour may retain sufficient integrity to qualify them for consideration for listing on the NRHP.

3.9.7 Davis Dam to Parker Dam

The environment in which cultural resources exist is different in fluvial and lacustrine systems. For this reason, the highly channelized river reach from Davis Dam to Upper Lake Havasu is treated separately from that of the Lake Havasu and Parker Dam reach.

3.9.7.1 Davis Dam to Upper Lake Havasu

The 39-mile reach of the Colorado River from Davis Dam to Upper Lake Havasu is one of its most highly modified and controlled stretches. Within this part of the reach, the Colorado River elevations will likely fall rather than rise from a decrease in water deliveries when shortages are declared. For this reason, the APE for this reach is the Colorado River channel from bank to bank, and the lateral extent of backwaters, lakes, and marshy areas directly connected to it.

Information contained in WESTEC Services, Inc. (1980) indicates that at least 22 historic period cultural resources may be present in or located in the immediate vicinity of the Davis Dam to Upper Lake Havasu reach. Property types located in this reach include river crossings, ferry and steamboat landings, town sites or camps, buildings, structures, trails, roads, highways, railroads, bridges, and the suspected site of the Rose-Brown massacre. This information also indicates that a number of these resources had already been significantly impacted by the 1970s by residential and commercial development, historic flood events, or destroyed during the 1950's when portions of this stretch was confined within levees, channelized, and stabilized with rip-rap. The Arch Bridge/ 1916 Colorado River Highway Bridge, a part of a multiple property listing on the NRHP, is in this reach. Prehistoric sites include caves and rockshelters, lithic and ceramic scatters, rock alignments, and petroglyphs.

3.9.7.2 Lake Havasu and Parker Dam

This part of the APE includes Lake Havasu from RM 237 downstream to Parker Dam. Information contained in WESTEC Services, Inc. (1980) and other sources provide a brief description of eight cultural resources submerged beneath Lake Havasu. These are primarily river landings associated with mills, and commercial and residential structures established to support several local mines active from 1860 to the turn of the century. Historic records indicate that several historic-period Chemehuevi Indian villages were located along both sides of the Colorado River at the upper end of the Chemehuevi Valley. An additional 20 cultural resources appear in repository records as being located at the margin of Lake Havasu or on small islands or peninsulas extending into the reservoir. Prehistoric types include lithic and ceramic scatters, rock alignments, trails, bedrock mortars, petroglyphs, and intaglios. Due to limited information currently available, it is not possible to know the condition of the submerged resources or how much post-impoundment sedimentation has occurred.

Any cultural resources located within the current operational zone of the reservoir (between elevations 450.5 feet msl and 445.8 feet msl), or within the historic operational zone (between elevations 451 feet msl and 444 feet msl), will likely have been impacted. Sites located in these zones will likely not be considered as eligible properties. However, it is possible based on results of recent findings in Lake Mead and Lake Mohave that cultural resources consistently submerged beneath Lake Havasu since its creation may retain sufficient integrity to be eligible for the NRHP.

3.9.8 Parker Dam to Imperial Dam

This reach extends from Parker Dam to Imperial Dam and covers the 143 miles of river channel (from bank to bank) and the lateral extent of backwaters, lakes, and marshy areas having a direct connection to the river.

Minimal cultural resources inventory taking has been conducted in this portion of the APE. Possible cultural resources within the limits of the APE are described in the Implementation Agreement FEIS (Reclamation 2002a). The information provided in this document suggests that numerous historic resources may be present in and around this reach. Twelve sites have been recorded proximate to the boundary of the APE. These consist of a segment of a railway where it crosses the Colorado River, a ceramic scatter, heat altered rock, intaglios, historic mining/milling features, bedrock mortar depressions, a natural cavern used as a jail for the historic gold milling community of Picacho, a lithic scatter, a trail segment, mining cairns, rock art, and cleared circles. Only one of the twelve sites, a prehistoric habitation site, is listed on the National Register and is near the edge of the APE. Only three recorded sites are known to exist within the APE. These are Parker Dam, Imperial Dam, and a portion of the "Old Parker Road" alignment. Parker Dam is a contributing element to the Parker Dam Historic District, which is eligible for listing on the National Register. Imperial Dam is potentially eligible for individual listing on the National Register and is a contributing element to the AAC.

Though cultural inventories of areas within the historic floodplain of this river reach are extremely limited, it appears that historic site distribution along the Colorado River corridor is more random then on the uplands bordering the historic floodplain. Also, prior to construction of Hoover Dam in the 1930s, river flows were extremely dynamic, its course meandering and altering across the floodplain. Trench evaluations reveal that sediments within the floodplain have been laid down under high-energy fluvial conditions, under which it is extremely unlikely to expect *in situ* cultural remains.

3.9.9 Imperial Dam to SIB

There is little to no data relative to the existence of historic properties within the Imperial Dam to the SIB reach. Nevertheless, any known or as yet undiscovered cultural resources within this reach of the Colorado River will not be affected by the proposed federal action because the existing river operations will continue into the future. This also applies to sites listed on the NRHP. One of these sites is the Ocean to Ocean Bridge, constructed in 1915 for U.S. Highway 80 in Yuma, Arizona which is the first highway bridge to be constructed across the Colorado River. Another site is Yuma Crossing and associated sites, which has been designated as a National Historic Landmark. The landmark boundaries straddle the Colorado River from the St. Thomas Yuma Indian Mission on the north and the Quartermaster Depot and Yuma Territorial Prison on the south.

3.10 Indian Trust Assets

This section discusses the Indian Trust Assets (ITAs) that may be affected by the proposed federal action. ITAs are "…'legal interests' in 'assets' held in 'trust' by the federal government for federally recognized Indian tribes or individual Indians" (Reclamation 1994a). The United States, as trustee, is responsible for protecting rights reserved by, or granted to, Indian tribes or individual Indians by treaties, statutes, executive and secretarial orders, and other federal actions. The Department's policy is that when a proposed federal action appears likely to adversely affect an ITA, the action agency should seek ways to minimize or avoid the adverse effect; if adverse effects cannot be avoided, then the action agency should provide appropriate mitigation or compensation. While most ITAs are located on reservation lands, they can also be located off-reservation. Examples of ITAs include, but are not limited to, water rights, land, minerals, and rights to hunt and fish.

Reclamation consulted with potentially affected tribes (Chapter 6) whose reservations are located along the mainstream Colorado River from Lake Powell to the SIB, as well as with those tribes who have a water service contract to identify ITAs and to assess potential effects of the proposed federal action on these ITAs. Reclamation has determined that no tribes or reservations located upstream of Lake Powell will be affected by the proposed federal action.

The trust assets that might potentially be impacted as a result of implementing the proposed federal action are described and discussed below. Impacts to the ITAs are discussed and analyzed in Chapter 4, and cumulative effects are discussed in Chapter 5.

3.10.1 Water Rights and Trust Lands

For this analysis, the Indian water rights and land assets considered include:

- federally reserved Indian rights to Colorado River water including rights established pursuant to *Arizona v. California;*
- Colorado River water Tribal delivery contracts where such contracts are part of a congressionally approved water rights settlement; and
- Indian reservations.

Indian trust lands are areas for which the United States holds title in trust for the benefit of the tribe (Tribal trust land) or for an individual Indian (individual trust land). Trust lands may be located on or off a reservation. While Indian reservations are not technically synonymous with trust lands, the exterior boundaries of Indian reservations are used to define the trust assets for purposes of this NEPA analysis. The BIA and United States Census Bureau identified and provided the data on size and location of reservations analyzed here.

3.10.1.1 Indian Trust Assets Determined under Arizona v. California: Fort Mojave, Chemehuevi, Colorado River Indian, Fort Yuma Indian, and Cocopah Indian Reservations

The March 9, 1964 *Arizona v. California* Decree and several supplemental decrees (consolidated in 2006 into the Consolidated Decree) quantified the Indian reserved water rights of the Fort Mojave, Chemehuevi, Colorado River Indian, Fort Yuma Indian, and Cocopah Indian Reservations. The amounts of water (diversion entitlements), priority dates for these water rights, net acres of irrigated land, and the states where the water rights are perfected for these Indian reservations are listed in Table 3.10-1, and discussed below.

Table 3.10-1
Colorado River Mainstream Diversion Entitlement (Water Rights) in Favor of Indian Reservations

Reservation	State	Diversion Entitlement (Water Right) (afy)[1]	Net Acres[1]	Present Perfected Right Number[1]	Priority Within State	Priority Date[1]
FORT MOJAVE RESERVATION	Arizona	27,969	4,327	3	1	Sept.18,1890
		75,566	11,691			Feb 2, 1911
	California	16,720	2,587	25	1	Sept. 18, 1890

California Total	--	156,522	--	--	--	
Nevada Total	--	12,534	--	--	--	

1 *Source: Consolidated Decree of March 27, 2006. The quantity of water in each instance is measured by (i) diversions or (ii) consumptive use required for irrigation of the respective acreage and for satisfaction of related uses, whichever of (i) or (ii) is less.*

Fort Mojave Reservation (Fort Mojave Indian Tribe of Arizona, California and Nevada). The Fort Mojave Reservation is located in the Lower Basin where Arizona, California, and Nevada meet. The Fort Mojave Reservation possesses present perfected federal reserved water rights from the Colorado River in all three of these states that contain reservation land pursuant to the Consolidated Decree.

As a result of recent changes made to the Fort Mojave Reservation's water rights resulting from a boundary adjustment, the reservation has the right to divert up to 103,535 afy in Arizona (2004 diversion was 69,103 af)[1], up to 16,720 afy in California (2004 diversion was 16,019 af), and up to 12,534 afy in Nevada (2004 diversion was 3,870 af).

Chemehuevi Reservation (Chemehuevi Indian Tribe of the Chemehuevi Reservation, California). The Chemehuevi Reservation is located in southern California, near Lake Havasu. The Chemehuevi Reservation holds present perfected federal reserved water rights from the mainstream Colorado River pursuant to the Consolidated Decree. The lands of the Chemehuevi Reservation are mostly on the plateau above the shoreline of Lake Havasu. Present agricultural water use is limited. The Chemehuevi Reservation has a right to divert up to 11,340 afy in California; the 2004 reported diversion was 1,444 af.

Colorado River Indian Reservation (Colorado River Indian Tribes of the Colorado River Indian Reservation, Arizona and California). The Colorado River Indian Reservation is located in Arizona and California. The Colorado River provides 90 miles of shoreline for the Colorado River Indian Reservation. The reservation economy centers around agriculture, recreation, and light industry. The Colorado River Indian Reservation was established on March 3, 1865. The Colorado River Indian Reservation's diversion right in Arizona is 662,402 afy (2004 diversion was 585,534 af) and the reservation's diversion right in California is 56,846 afy (2004 diversion was 6,231 af).

Fort Yuma Indian Reservation (Quechan Tribe of the Fort Yuma Indian Reservation, California and Arizona). The Fort Yuma Indian Reservation is located in southwestern Arizona and southern California, near Yuma, Arizona. The Consolidated Decree provided additional water rights to the Fort Yuma Indian Reservation in both Arizona and California. The Fort Yuma Indian Reservation has the right to divert up to 6,350 afy in Arizona (2004 diversion was 1,279 af) and up to 71,616 afy in California (2004 diversion was 46,259 af).

Water for the Fort Yuma Indian Reservation is diverted from the Colorado River at Imperial Dam and delivered through the Yuma Project Reservation Division - Indian Unit. The Fort Yuma Indian Reservation has other uses of small amounts of water at homestead sites south of Yuma, Arizona. The current water uses shown in Table 3.10-1 include only uses within the Fort Yuma Indian Reservation.

[1] 2004 diversions are provided in this section to indicate approximate use of the entitlements for each Indian tribe.

Cocopah Indian Reservation (Cocopah Tribe of Arizona). The Cocopah Indian Reservation is located in southwestern Arizona. The western boundary of the reservation is bordered by Mexico and portions of the Colorado River. The Cocopah Indian Reservation was established through Exec. Order No. 2711 on September 27, 1917, but additional acres were added to the reservation through 1974. The Cocopah Indian Reservation economy is centered on agriculture. The Cocopah Indian Reservation's present perfected federal reserved water rights provide for the diversion of up to 10,847 afy in Arizona. The 2004 reported diversion was 3,878 af.

The 1974 decreed right for the Cocopah Indian Reservation is unique because of its more recent priority date (i.e., post-1968). The 1984 Supplemental Decree in *Arizona v. California* recognized the decreed right for the Cocopah Indian Reservation dated June 24, 1974 and amended paragraph 2 of Article II (D) of the 1964 Decree to reflect this 1974 right.

3.10.1.2 Seven Central Arizona Indian Tribes

The CAP makes Colorado River water available to Indian tribes located in central Arizona in addition to the ITA entitlements discussed above. Over the years, there have been several Secretarial decisions allocating water to ten Indian tribes in central Arizona. All of these Indian tribes, with the exception of the Gila River Reservation, signed CAP water delivery contracts in 1980. The Gila River Reservation, with the largest allocation of CAP water, signed its CAP water delivery contract in 1992. Each of the CAP water delivery contracts contained a provision that the Indian tribes' CAP water would be credited against their Winters right (*Winters v. United States*, 207 U.S. 564 [1908]), if and when such rights were finally determined. Over the years, water rights settlements have been implemented for seven of these ten Indian tribes. Under these settlements, the seven Indian tribes generally have a right to lease their CAP water within Arizona; the CAP water does not have to have a history of use in order for the water to be leased. A listing of the major water rights settlement legislation for these seven Indian tribes in chronological order follows:

- ♦ Settlement of Ak-Chin Indian Community Water Rights Claims of July 28, 1978 (92 Stat. 409) and the Ak-Chin Indian Community Water Rights Settlement Act of October 19, 1984 (96 Stat. 2698)
- ♦ Southern Arizona Water Rights Settlement Act of October 12, 1982 (Title III of Public Law 97-293) and Title III of the Arizona Water Settlements Act of December 10, 2004 (118 Stat. 3536)
- ♦ Salt River Pima-Maricopa Indian Community Water Rights Settlement Act of 1988 (102 Stat. 2549)
- ♦ Fort McDowell Indian Community Water Rights Settlement Act of 1990 (104 Stat. 4469)

- San Carlos Apache Tribe Water Rights Settlement Act of 1992 (Title XXVII of the Reclamation Projects Authorization and Adjustment Act of 1992 (106 Stat. 4600)

- Yavapai-Prescott Indian Tribe Water Rights Settlement Act of 1994 (108 Stat. 4526) (Indian tribes' CAP water permanently assigned to Scottsdale)

- Gila River Indian Community Water Rights Settlement Act (Title II of the Arizona Water Settlements Act of December 10, 2004 (118 Stat. 3499)

Table 3.10-2 lists the CAP Tribal water entitlements for the seven Indian tribes discussed above. These entitlements and their priorities are further discussed below.

An understanding of the CAP priority system is necessary to discern how shortages can potentially impact the different priorities of CAP water and CAP water users, including Indian tribes. Within CAP, shortages reduce water deliveries to CAP water users in the following order: CAP 5 Bank; CAP 4 Excess Agricultural Users; CAP 3 NIA Priority Water; equally CAP 2 M&I Priority and Indian Priority Water; and finally CAP 1 Arizona Priority 2 and 3. A detailed explanation of the CAP water priority rights is included in Appendix G. Modeled reductions are based on what would be available to a user under its entitlement in that year based on higher priority use.

Ak-Chin Indian Community of the Maricopa (Ak-Chin) Indian Reservation. In 1912, President Taft created a reservation at Ak-Chin comprised of 21,840 acres. In 1961, the Ak-Chin Tribal Council was formally recognized under the Indian Reorganization Act of 1934. The Ak-Chin Indian Reservation is located in Pinal County 50 miles south of Phoenix. Farming (Ak-Chin Farms) is a major part of the economy of the reservation.

Ak-Chin Reservation's water rights settlement of 1978 was the first of a series of Indian water rights settlements in central Arizona. The 1978 Settlement Act was amended in 1984. Under the 1984 water rights settlement, the Ak-Chin Indian Reservation has the right to receive up to 75,000 afy of water at the southeastern corner of the reservation. When excess water is available in the CAP canal, the United States may deliver up to an additional 10,000 afy of water to the Ak-Chin Indian Reservation (maximum of 85,000 afy). In years of shortage on the Colorado River, the United States must pay damages if less than 72,000 afy is delivered to the Ak-Chin Indian Reservation. The United States acquired 50,000 afy of Colorado River water entitlement from the Yuma Mesa Division of the Gila Project to partially meet the requirement to deliver required quantities to the Ak-Chin Indian Reservation. After losses, 47,500 afy is delivered to the Ak-Chin Indian Community with a priority date that precedes the date of enactment of the CRBPA, and therefore has a higher priority during times of shortage than other CAP water.

The Ak-Chin Indian Reservation was provided with the right to lease some of its CAP water supplies within Arizona, and the Ak-Chin Indian Reservation has leased a portion of its water to the Del Webb Corporation. The Ak-Chin Indian Reservation's water infrastructure is in place, and with the exception of water that the Ak-Chin Indian Reservation leased, the community is using all of its CAP water for farming purposes.

Table 3.10-2
Central Arizona Project Indian Tribal Diversion Entitlements (Water Rights)

Reservation	Diversion Entitlement (Water Right) (afy)	Land Area (square miles)[1]	Arizona Priority	CAP Priority[2]

	120,600[6]	--	4	CAP 3
Gila River Reservation Total	*311,800*	*583.9*		

1 *Source is www.census.gov\geo\wvw\ezstate\airpov.pdf, accessed December 10, 2006*

2 *CAP Priority Definitions:*

CAP 1: Arizona Priority 2 and Arizona Priority 3 Water
CAP 2: M&I Priority and Indian Priority Water
CAP 3: NIA Priority Water
CAP 4: Excess Agricultural Users
CAP 5: Excess Water for Bank

3 *When excess water is available in the CAP canal, Ak-Chin Indian Community is entitled to the excess water up to 10,000 af annually in addition to the 75,000 afy.*

4 *Firmed by the United States to the M&I Priority of CAP 2 for a period of 100 years.*

5 *After the Secretary has met the water delivery obligation to the Ak-Chin Indian Community under the Ak-Chin Water Rights Settlement, any excess water under the Ak-Chin Indian Community's CAP water delivery contract is available for delivery to the San Carlos Apache Tribe. Estimated delivery losses of six percent on the Santa Rosa Canal, incurred in the delivery of water to the Ak-Chin Indian Community, are charged to the Community's CAP water delivery contract.*

6 *15,000 afy are firmed for a period of 100 years by the State of Arizona to CAP 2 M&I Priority Water.*

Tohono O'odham Nation of Arizona. The Tohono O'odham Nation sits in the heart of the Sonoran Desert, sixty miles west of Tucson, Arizona. The Tohono O'odham Nation is divided into multiple districts totaling more than 4,342 square miles. Under the Tohono O'odham Nation's 1982 water rights settlement, as subsequently amended, the nation's water rights are specific to two of Tohono O'odham Nation's districts, the San Xavier District, and the Schuk Toak District.

The San Xavier District has the right to receive a total of 50,000 afy of water, consisting of 27,000 afy of CAP 2 Indian Priority Water, and 23,000 afy of CAP 3 NIA Priority Water (Table 3.10-2). CAP 3 NIA Priority Water is the most vulnerable portion of the CAP water supply, and the United States is required to firm (i.e., provide a backup water supply) the delivery of this water to M&I Priority Water of CAP 2 during the next 100 years.

The Schuk Toak District has the right to receive a total of 16,000 afy of water, consisting of 10,800 afy of CAP 2 Indian Priority Water, and 5,200 afy of CAP 3 NIA Priority Water. The United States is required to firm the delivery of CAP 3 NIA Priority Water to M&I Priority of CAP 2 during the next 100 years as in the case with the San Xavier District.

Yet another Tohono O'odham Nation's district, the Chui-Chu District, has a CAP water delivery contract with the Secretary to receive up to 8,000 afy of CAP 2 Indian Priority Water. As this water is not presently part of a water rights settlement, it is not considered an ITA.

Construction of the works necessary for the Tohono O'odham Nation to take delivery of its water under the 1982 Settlement Act is ongoing. The works necessary to deliver water to the Schuk Toak and San Xavier Districts have been completed. The Schuk Toak District is currently using a portion of the water provided under this settlement. The San Xavier District has initiated water deliveries and will expand these deliveries upon completion of the rehabilitation of its existing cooperative farm, which is ongoing.

Salt River Reservation (Salt River Pima-Maricopa Indian Community). The Salt River Reservation is located in Arizona, aside the boundaries of Mesa, Tempe, Scottsdale, Fountain Hills, and metropolitan Phoenix. The reservation was created in 1879. The Salt River Reservation is occupied by two tribes, the Pima and the Maricopa; and the combined enrolled population exceeds 7,000. The Salt River Reservation consists of 53,600 acres and maintains 19,000 acres as a natural preserve. Approximately 12,000 acres are under cultivation with cotton, melons, onions, broccoli, and carrots being the major crops.

Under its water rights settlement, the United States obtained the rights to 22,000 afy of Colorado River water entitlement from the Wellton-Mohawk Irrigation and Drainage District, near Yuma, Arizona. This right is senior to CAP. Pursuant to the settlement, this water was contracted by the Secretary to several Phoenix area cities and the tribe agreed to accept delivery of an equivalent amount of Salt River Project (SRP) water. The SRP water deliveries to the tribe will not be affected by the proposed federal action.

The Salt River Reservation has the right to receive up to 13,300 afy of CAP 2 Indian Priority Water. The Salt River Reservation has the right to lease its CAP water under the settlement within Arizona and has leased all of its CAP water to the City of Phoenix for a 100-year period. This water supply is considered an ITA.

Fort McDowell Reservation (Fort McDowell Yavapai Nation). The Fort McDowell Reservation is located in Maricopa County, Arizona about 23 miles northeast of Phoenix. The Verde River flows north to south through the reservation. The Fort McDowell Reservation was created by executive order in 1903 for the Yavapai, Mojave, and Apache Indian tribes. The 38.6 square-mile Fort McDowell Reservation is home to 600 community members, while another 300 members live off the reservation.

Under its water rights settlement, the Fort McDowell Reservation received a combination of water resources from both the SRP and the CAP. With respect to the Colorado River supplies, the Fort McDowell Reservation received the rights to delivery of up to 18,233 afy of water. This consisted of 4,300 afy of CAP water that the Fort McDowell Reservation had contracted for in 1980, plus an additional 13,933 afy of CAP water that the United States acquired from the Harquahala Valley Irrigation District (HVID). The acquired HVID water was converted from its CAP 3 NIA Priority Water to CAP 2 Indian Priority Water through this settlement. The Fort McDowell Reservation has leased 4,300 afy of its CAP water to the City of Phoenix for a 100-year period, and the reservation is presently not using the remaining 13,933 afy of CAP water.

San Carlos Reservation (San Carlos Apache Tribe). The San Carlos Reservation is located in southeastern Arizona. The reservation was established by executive order in 1871 and covers 2,910.6 square miles. Approximately one-third of the San Carlos Apache Tribe's land is forested or wooded. San Carlos Lake is a hub of recreational activity, especially for fishing.

Under its water rights settlement, the San Carlos Reservation has the rights to delivery of 12,700 afy of CAP 2 Indian Priority Water, 18,145 afy of CAP 2 M&I Priority Water (previously allocated to Phelps Dodge and the town of Globe), and excess water made available by the Ak-Chin Indian Community Water Rights Settlement Act of 1984. The excess Ak-Chin water is unquantified in the settlement and estimated to be 30,800 afy before losses. The tribe's right to receive the excess Ak-Chin water is subordinate to the Secretary's obligation to deliver water to the southeast corner of the Ak-Chin Indian Reservation under that community's water right settlement. Given that the San Carlos Reservation is not able to physically divert CAP water, the tribe would need to implement a water exchange to benefit from its CAP water supplies. The San Carlos Reservation has the right to lease CAP water under its 1992 settlement, and has leased up to 14,000 afy to Phelps Dodge through an exchange with the SRP. The San Carlos Reservation has also entered into a lease with the City of Scottsdale for 12,500 afy of CAP 2 M&I Priority Water.

Yavapai Reservation (Yavapai-Prescott Tribe of the Yavapai Reservation). Under its 1994 settlement, the Yavapai Reservation permanently assigned and transferred its CAP contractual right of 500 afy to the city of Scottsdale, Arizona, in return for funds to develop alternative water supplies. Since the Yavapai Reservation no longer has a right to CAP water, no trust asset is attributable to the Yavapai Reservation.

Gila River Reservation (Gila River Indian Community). The Gila River Reservation was established by an act of Congress in 1859 for Pima and Maricopa Indians. The 583.9 square mile reservation is located in Maricopa and Pinal Counties, 35 miles south of the Phoenix metropolitan area. The Gila River Reservation is bounded by the San Tan and Sacaton Mountains to the east, the Estrella Mountains to the west, and the South Mountains to the north. The Gila River Indian Community established Gila River Farms during the late 1960s, with approximately 16,000 acres in production. The Gila River Reservation is the homeland for two distinct tribes, the Pima and the Maricopa.

The 2004 Gila River Indian Community Water Rights Settlement Act provides the community with 311,800 afy of CAP water, consisting of 120,600 afy of CAP 3 NIA Priority Water and 191,200 afy of CAP 2 Indian Priority Water. Under the 2004 Settlement Act, the state of Arizona is required to firm 15,000 afy of the CAP 3 NIA Priority Water so that it has a reliability equivalent to CAP 2 Indian Priority and M&I Priority Water over a 100-year period. Construction of the infrastructure to deliver CAP water to the Gila River Reservation for farming purposes is ongoing. Under the 2004 settlement, the Gila River Reservation has the right to lease its CAP water within Arizona for a term of up to 99 years. Approximately 40,000 afy of the Gila River Reservation’s CAP water has already been leased to Phoenix area cities, subject to implementation of the Gila River Indian Community water rights settlement. In addition, the Gila River Reservation has entered into effluent exchange agreements with surrounding municipalities, Chandler and Mesa, whereby the Gila River Reservation exchanges some of its CAP water for a larger quantity of treated effluent.

3.10.2 Hydroelectric Power Generation and Distribution

Headgate Rock Dam and Powerplant are owned and operated by the BIA, which supplies energy generated at the Headgate Rock Powerplant to the Colorado River Indian Tribes of the Colorado River Indian Reservation, Arizona and California (CRIT) and other Indian tribes. Western markets any excess power produced at Headgate Rock Powerplant on the open market. Headgate Rock Powerplant is a run-of-the-river hydroelectric powerplant, which means it is dependent on Colorado River flow to generate power. For this reason Headgate Rock Dam is unable to store water in excess of the amount that can flow through its generator turbines or through CRIT’s diversion facilities. Any water that is not diverted by CRIT or used by the Headgate Rock Powerplant generators is spilled downstream. Chapter 4 of the Final EIS provides a more detailed description of hydroelectric power generation. Reclamation has determined that water appropriated to non-CRIT entities that flows through Headgate Rock Dam and generates power is not an ITA.

3.10.3 Cultural Resources

Cultural resources located on Indian trust lands are often the property of the tribe or individual Indians beneficially owning those lands; these resources may be ITAs (Reclamation 1994a). During consultation, the Hualapai Tribe identified historic and traditional cultural properties, archaeological resources and sacred sites in Grand Canyon and on the Hualapai Reservation as Tribal trust resources that should be addressed in this EIS. None of the tribes identified cultural resources on- or off-reservation lands that should be considered ITAs for the purposes of this analysis.

3.10.4 Biological Resources

During consultation on this proposed federal action, none of the tribes identified fishing or hunting rights. The Hualapai Indian Tribe raised a concern with fish and wildlife, wildlife habitat, and culturally significant vegetation located throughout Grand Canyon and on the Hualapai Reservation.

3.10.5 Other Potentially Affected Tribes Asserting Colorado River Water Rights

Reclamation has determined that no quantified water right trust assets are located within the study area upstream of Lake Mead. However, the following tribes have asserted that they have unquantified water right trust assets and other ITAs that will be affected by the proposed federal action.

3.10.5.1 Navajo Indian Reservation (Navajo Nation, Arizona, New Mexico and Utah)

The Navajo Nation is a federally recognized Indian tribe whose 12.5 million-acre reservation was initially established by treaty in 1868 and expanded by a series of executive orders in 1884, 1900, and 1930. The Navajo Nation economy is historically based on livestock herding, dry farming, and mining. Under the Winters doctrine established by the United States Supreme Court, the United States implicitly reserved water in an amount necessary to fulfill the purposes of an Indian reservation. The existence of a federally reserved right for the Navajo Nation to mainstream Colorado River water has not been judicially determined at this time. Unquantified water rights of the Navajo Nation are considered an ITA.

During consultation on this proposed federal action, the Navajo Nation wrote Reclamation a letter dated August 21, 2006 identifying a water budget of 76,732 afy that the Navajo Nation believes must be satisfied out of the Colorado River mainstream. The water budget of the Navajo Nation is premised on the use of 63,000 afy from the Little Colorado River which would otherwise contribute to the supply available in Lake Mead. In addition, the Navajo Nation asked Reclamation to consider the effects of the proposed federal action on 6,411 afy of CAP 3 NIA Priority Water identified for use by the Navajo Nation in the Arizona Water Settlements Act of 2004. This water is included in the 76,732 afy that the Navajo Nation believes must be satisfied out of the Colorado River mainstream. Overall, the Navajo Nation has asked the Secretary to account for the needs of the Navajo Nation as the Secretary undertakes the difficult task of developing guidelines to deal with Lake Powell and Lake Mead in time of shortage (Navajo Nation letter dated August 21, 2006).

3.10.5.2 Hualapai Indian Reservation (Hualapai Indian Tribe)

The 992,463-acre Hualapai Indian Reservation is located in northwestern Arizona. The reservation was established by executive order on January 4, 1883. Under the Winters doctrine established by the United States Supreme Court, the United States implicitly reserved water in an amount necessary to fulfill the purposes of an Indian reservation. The existence of a federally reserved right for the Hualapai Indian Tribe to mainstream Colorado River water has not been judicially determined at this time. Unquantified water rights of the Hualapai Indian Tribe are considered an ITA.

During consultation on this proposed federal action, the Hualapai Indian Tribe has asserted in a letter to Reclamation dated August 28, 2006 that it has Tribal trust resources and other Tribal assets in Grand Canyon and on the Hualapai Indian Reservation that may be adversely affected by the proposed federal action. The Hualapai Indian Tribe's claimed resources include:

> "…tribal lands, the Tribe's senior, federal reserved water rights to the use and flows of the Colorado River, historic and traditional cultural properties, archaeological resources and sacred sites, fish and wildlife habitat, sensitive beaches, and culturally significant plants located throughout the Grand Canyon and on the Hualapai Reservation" (Hualapai Indian Tribe letter dated August 28, 2006).

This page intentionally left blank.

3.11 Electrical Power Resources

This section provides an overview of electrical power (i.e., hydropower) generation, power marketing, and the Colorado River Basin power funds used to manage electrical power revenues and expenditure requirements for mainstream Colorado River dams. A description of potentially affected electrical power generation facilities and energy dependent infrastructure within the study area is provided below. The electrical power resources that could potentially be affected by implementation of the proposed federal action include:

- amount of electrical power generated;
- available generation capacity;
- economic value of electrical power produced;
- electrical power related revenues and contributions to the different Colorado River Basin power funds and programs supported by these funds; and
- electrical costs for entities that pump water directly from Lake Powell and Lake Mead.

3.11.1 Overview

The primary electrical power resources that could be affected by the proposed federal action include the Glen Canyon Powerplant, Hoover Powerplant, Parker-Davis Project (P-DP) generation systems, and the Headgate Rock Powerplant. Reclamation operates and maintains the Glen Canyon, Hoover, and P-DP power generation facilities. Western is responsible for marketing and transmitting the power. The Headgate Rock Powerplant is operated by the BIA.

3.11.1.1 Hydropower Generation

Hydropower generation is directly related to the net effective head on the generating units and the quantity of water flowing through the turbines. The net effective head is the difference between the elevation of the forebay behind a dam and in the tail water below the dam. The head influences the maximum power output capability of the powerplant, measured in megawatts (MW). In general, the powerplant capability increases as a function of increasing head. However, turbine capacities or other equipment limitations, such as switches or transformer ratings, limit maximum powerplant output levels.

The turbines at a powerplant are designed to produce maximum efficiency at a design head. At design head, the powerplant can produce the maximum capacity and the most energy per acre-foot of water passing through the turbine. As the net effective head on the powerplant is reduced from the design head because of reduced forebay (upstream reservoir) elevation, the power output of the turbine, the electrical capacity of the generator attached to the turbine, and the efficiency of the turbine are all reduced. This reduction continues as net effective head decreases until, below the minimum elevation for power generation, the turbines cannot be operated safely and must be bypassed for downstream water deliveries. Minimum power elevation generally occurs at a point where cavitation within the turbine causes extremely rough operation, air becomes entrained in the water, and/or vortices appear in the forebay. Excessive cavitation can lead to turbine damage and is avoided.

Ramping is the change in water release from the reservoir to meet the electrical load. Both scheduled and unscheduled ramping are crucial in load following, ancillary services, emergency situations, and variations in real time (what actually happens compared to what was scheduled) operations. North American Electric Reliability Council (NERC) and Western Electricity Coordinating Council (WECC) operating criteria require Western and Reclamation to meet scheduled load changes by ramping the generators up or down beginning at ten minutes before the hour and ending at ten minutes after the hour.

Hydropower generation can react instantaneously to the load (or power demand) - a pattern called load following. By comparison, coal- and nuclear-based resources have a relatively slow response time; consequently, they generally are not used for load following in the WECC.

As a control area operator, Western regulates the transmission system within a prescribed geographic area. Western is required to react to moment-by-moment changes in electrical demand within this area, adjusting the electrical power output of hydroelectric generators within the area in response to changes in the generation and transmission system to maintain the scheduled level of generation in accordance with prescribed NERC criteria. Automatic Generation Control (AGC) is a process whereby the control system automates the water releases in a manner that follows the power system’s actual dynamic demands on a moment-to-moment (typically a four-second-interval) basis.

Regulation depends on being able to ramp releases up or down quickly in response to system conditions. In addition, each utility is required to have sufficient generating capacity, in varying forms of readiness, to continue serving its customer load, even if the utility loses all or part of its own largest generating unit or largest capacity transmission line. This reserve capacity ensures electrical service reliability and an uninterrupted power supply.

Generating capacity that is in excess of the load on the system is called spinning reserve. Spinning reserves are used to quickly replace lost electrical generation resulting from a forced outage, such as the sudden loss of a major transmission line or generating unit. Additional off-line generating units are also used to replace generation shortages, but they cannot replace lost generation capacity as quickly as spinning reserves.

3.11.1.2 Power Marketing and Customers

Western markets the power and administers the power contracts for power generated from Reclamation-owned and operated hydropower facilities (i.e., Glen Canyon, Hoover, P-DP, and the smaller generation facilities).

Marketing of electricity is based on two concepts: capacity and energy. In power marketing, capacity is the rate of delivery or demand of electricity and is measured in kilowatts (kW) or megawatts. Electricity must be available the instant consumers need it. Capacity is important for meeting consumers' instantaneous demand as they turn on lights, appliances, and motors. Energy is the amount of electricity delivered over time and is measured in kilowatt-hours (kWh) or megawatt-hours (MWh). One kilowatt-hour of energy delivered over one hour requires one kilowatt of capacity. Energy is important for meeting consumers' continuing need for electricity. With the delivery of electricity, capacity and energy are both present; however, they can be marketed and billed separately. Power rates usually include individual charges for capacity and energy.

Power is marketed in terms of firm and nonfirm power. Firm power is capacity and energy that is guaranteed to be available. A sufficient portion of the generation capacity is held in reserve to enable continued delivery of firm power even if an outage occurs at a powerplant. The amount of power that is held in reserve is established by various power pooling agreements and reliability criteria.

Nonfirm power is sold to power contractors that would rather purchase nonfirm energy that is less expensive than the cost of their own generation or cost of alternative sources of supply. Nonfirm energy is usually sold with the requirement that the sale can be stopped on short notice and the buyer must have the resource available to meet its own load. Rates for nonfirm energy only include a charge for the energy delivered, since the customer has the capacity to meet its loads, if necessary.

Any power surplus or deficit affects all WECC power customers since the WECC region is one large interconnected system. However, customers most affected are those that have an allocation of hydropower resources sold by Western through various contractual arrangements.

The contracts for power from Glen Canyon Dam terminate in 2025, from Hoover Dam in 2017, and from the P-DP in 2008. After these dates, the identity of the recipients of power from these resources is not known. Recognizing that contracts for power will exist in some form in the future, an analysis of the effects of the action alternatives compared with those of the No Action Alternative consider the general effects in the overall areas served by the power facilities.

The states that could be potentially affected by changes in energy production and capacity changes at Glen Canyon and Hoover Powerplants are Arizona, California, Colorado, Nevada, Utah, Wyoming, and New Mexico. These states make up the Rocky Mountain, Arizona-New Mexico-Southern Nevada, and California-Mexico areas of the WECC. Electrical energy produced in each of these areas is derived from a variety of sources including Glen Canyon and Hoover Powerplants. The total generation capability of the areas as of January 1, 1999, is 86,348 MW. The generation capability of each WECC area is listed in Table 3.11-1.

Table 3.11-1
Generation Capability in WECC Areas

WECC Area	Available Capacity (MW)
Rocky Mountain	10,584
Arizona-New Mexico-Southern Nevada	22,272
California-Mexico	53,492

The capacity of Glen Canyon and Hoover powerplants represents approximately 3.6 percent of the total generating capability of these three areas of WECC (WECC 1999).

3.11.2 Lake Powell and Glen Canyon Dam

Glen Canyon Powerplant has eight generators with a maximum combined capacity of 1,320 MW when the reservoir elevation is 3,700 feet msl. The maximum combined discharge capacity of the eight turbines is approximately 31,500 cfs. Due to environmental restrictions, the maximum release is limited to 25,000 cfs except for extreme hydrologic or emergency conditions, limiting Glen Canyon Dam power generation capacity to approximately 1,000 MW, depending on reservoir elevation. The generators require a minimum Lake Powell elevation of 3,490 feet msl to operate. At this elevation, Glen Canyon Powerplant has a maximum capacity of about 630 MW. The annual gross generation has averaged approximately 4,951,918 MWh for the last 25 years and has averaged approximately 3,453,806 MWh over the past 5 years.

Glen Canyon Powerplant is part of the Salt Lake City Area Integrated Projects (SLCA/IP), which is a group of hydroelectric facilities marketed by Western. The SLCA/IP consists of hydroelectric facilities of Colorado River Storage Project (CRSP), Rio Grande Project, and Collbran Project.

Changes to reservoir elevations or releases could affect electrical power generation at Glen Canyon Dam.

3.11.3 Lake Mead and Hoover Dam

Hoover Powerplant is located at the toe of Hoover Dam, and extends downstream 650 feet along each canyon wall of the Colorado River. The turbines are designed to operate at heads ranging from 420 to 590 feet. The minimum reservoir elevation for efficient power generation is currently estimated to be approximately 1,050 feet msl. The final generating unit, N-8, was installed at Hoover Dam in 1961, giving the Hoover Powerplant a total of 17 commercial generating units with a rated capacity of 1,850,000 horsepower. Two station-service units, rated at 3,500 horsepower each, increased the powerplant total rated capacity to 1,344.8 MW.

Between 1982 and 1993, the 17 commercial generating units were uprated with new turbines, and new transformers and breakers were installed, raising the Hoover Powerplant's maximum capacity to 2,074 MW. The annual gross generation has averaged approximately 4,819,524 MWh for the last 25 years and has averaged approximately 4,014,655 MWh over the past 5 years.

Western markets the power to 15 customers in three states (Arizona, California, and Nevada); these are non-firm contracts. Any excess energy generated at the Hoover Powerplant is distributed to Hoover Powerplant contractors in accordance with their contracts.

Changes to reservoir elevations or releases could affect electrical power generation at Hoover Powerplant.

3.11.4 Parker-Davis Projects

The Davis Powerplant has five generators and a 256 MW maximum operating capacity. Between 1987 and 2005, the average annual net energy generated at the Davis Powerplant was 1,166,286 MWh.

Parker Powerplant has four generators and a 108 MW maximum operating capacity. Between 1987 and 2005, the average annual net energy generated at the Parker Powerplant was 487,649 MWh. MWD has a perpetual contract right to 50 percent of the electric power generated at the Parker Powerplant. Reclamation's 50 percent share of power generated at the Parker Powerplant is part of the P-DP.

The P-DP was formed in 1954 by consolidating the Parker Dam power project and the Davis Dam power project. Western markets the power generated by the P-DP. The P-DP supplies power to five Priority Use Projects (PUP) customers and 25 firm electric service contractors. The P-DP has 283 MW of capacity under contract to PUP and to firm electric service customers. The total annual energy committed to the five PUP and 25 firm electric service customers is 1,345,800 MWh (the PUP commitment is 195,266 MWh and the firm commitment is 1,150,534 MWh). The contracted capacity and energy for the P-DP, including system losses and reserves, is based on Davis Powerplant capacity and energy and Reclamation's half of Parker Powerplant's capacity and energy. The current P-DP firm electric service commitments are in effect until September 30, 2008. Western is close to concluding the process of finalizing the contractual commitments through September 30, 2028.

Under the existing P-DP firm electric service contracts, the amount of power per month and per season are guaranteed. This means that if the power is not available, Western would need to purchase the additional power required to fulfill the contracts.

Power generated at the P-DP, over and above what has been guaranteed to PUP and preference customers having firm electric service contracts, is referred to as surplus energy. A portion of the surplus energy, referred to as excess energy, is offered to P-DP customers for purchase at an “at cost” rate or for “banking” of energy up to the limit of the contractor’s contract rate of delivery. Any remaining surplus energy may be sold at market rates to interested parties or may be banked for future use.

Changes to dam releases could affect electrical power generation at the P-DP.

3.11.5 Other Small Hydropower Facilities

Headgate Rock Dam and Powerplant, which is owned and operated by the BIA and located downstream of Parker Dam, is a run-of-the-river powerplant that generates power through three turbines with a total capacity of 19.5 MW. Between 2001 through 2005, the average net energy generated annually at Headgate Rock Powerplant was 76,157 MWh. Changes to downstream water demand could affect electrical power generation at Headgate Rock Powerplant.

There are other small hydropower facilities located below Parker Dam. These facilities include Senator Wash, Siphon Drop, and Pilot Knob. In addition, there are several hydropower facilities owned by IID located at various drop structures along the AAC and on various other canals. These other small hydropower facilities will not be affected by the proposed federal action.

3.11.6 Basin Power Funds

3.11.6.1 Upper Colorado River Basin Fund

The Upper Colorado River Basin Fund (Basin Fund) was established under Section 5 of the CRSP Act. The CRSP Act “authorized a separate fund in the Treasury of the United States to be known as the Upper Colorado River Basin Fund for carrying out provisions of this Act other than Section 8”. Money appropriated for construction of CRSP facilities and Section 8 funding is credited in the Basin Fund. Revenues derived from operation of the CRSP and participating projects are deposited in the Basin Fund. Most of the revenues come from sales of hydroelectric power and transmission services. The Basin Fund also receives revenues from M&I water service sales, rents, salinity control funds from the Colorado River Lower Basin (as a pass-through for the Colorado River Basin Salinity Control Program), and miscellaneous revenues collected in connection with the operation of the CRSP and participating projects.

Basin Fund revenues must first be used to repay costs associated with the operation and maintenance of the CRSP units and used to repay the United States Treasury Department the reimbursable investment costs previously spent on construction of the CRSP units and costs allocated to the irrigation investment above the irrigator’s ability to pay. The Basin Fund is managed by Western. Approximately $175 million is needed each year to fund Reclamation and Western operation and maintenance needs. Of this amount, approximately $20 million is used to support environmental programs. Reclamation’s allocation of its portion of the Basin Fund, approximately $62 million, is shown in parentheses below.

- ♦ Reclamation and Western's costs associated with the operation, maintenance, equipment replacements, and emergency expenditures for all facilities of the CRSP and participating projects, provided that with respect to each participating project, such costs shall be paid from revenues received from each such project (Reclamation - $42.9 million);
- ♦ cost sharing for Colorado River Basin Salinity Control Program (Reclamation - $2 million);
- ♦ the major portion of the cost of the Glen Canyon Adaptive Management Program (Reclamation - $9 million);
- ♦ cost sharing for Upper Colorado River Endangered Fish Recovery Program (Reclamation - $7 million);
- ♦ water quality studies (Reclamation - $0.8 million); and
- ♦ consumptive use studies (Reclamation - $0.3 million).

Basin Fund revenues may not be appropriated and used for construction projects. Also, they may not be used for construction, operation and maintenance of public recreational facilities or facilities to mitigate losses of and improve conditions for the propagation of fish and wildlife (Section 8 of the CRSP Act authorizes Congressional appropriations for these purposes).

Western is responsible for transmission and marketing of CRSP power, collecting payment for the power, and transfer of revenues for repayment to the United States Treasury Department. A change in the amount of available capacity or energy could potentially affect the revenue derived from the sale of energy and the contributions to the Basin Fund, or rates charged to power customers.

3.11.6.2 Lower Colorado River Basin Funds

Currently there are three funds that are used to manage revenue and expenditure requirements of Lower Colorado Region power projects for the CAP, Boulder Canyon Project (Hoover) and the P-DP. Two are legislated funds and one is an account fund. A change in the amount of available capacity or energy could potentially affect the revenue derived from the sale of energy and the contributions to these funds, or rates charged to power customers.

The Lower Colorado River Basin Development Fund (Development Fund) was established by the CRBPA. The Colorado River Dam Fund (Dam Fund) was established by the BCPA. The Parker-Davis Account was established to enable the P-DP to fund in advance capital improvements and other expenses.

Lower Colorado River Basin Development Fund. In a manner similar to the Basin Fund, the Development Fund defrays costs of operation, maintenance and replacements of all project facilities, salinity control programs, repayment of CAP construction, and, as amended by the Arizona Water Settlements Act, of certain Tribal projects. It also reimburses water users in Arizona for losses sustained as a result of diminution of the production of hydroelectric power at Coolidge Dam, Arizona, resulting from exchanges of water between users in Arizona and New Mexico. The Development Fund is composed of revenue deposited from:

- surplus power sales of the United States entitlement of the Navajo Generating Station;
- CAP surcharge revenues from the Boulder Canyon and P-DP; and
- certain other CAP revenue receipts.

Colorado River Dam Fund. The Dam Fund is utilized to fund operation and maintenance (O&M) of Hoover Dam, payments to states, visitor services, up-rating program, replacements, investment repayment, and interest expenses of the Boulder Canyon Project (BCP). The Dam Fund is composed of:

- power revenues collected from the BCP power contractors;
- revenues collected from the BCP Visitor Center; and
- revenues from other BCP revenue receipts.

The BCP annual revenue requirement, base charge and rates, are determined annually to provide sufficient revenue to pay all annual costs, including interest expense and to repay investments, within the allowable period.

Parker-Davis Account. The Parker-Davis Account is utilized to advance-fund the costs of the P-DP, including operation, maintenance, and capital improvements. The funds are drawn from the customers' account into Reclamation on a monthly basis throughout the year. The advances are reconciled to the actual expenditures and the customers get credit for any remaining balance in the following period.

3.11.7 Water Supply System

3.11.7.1 Navajo Generating Station

The Navajo Generating Station (NGS) is a 2,250 MW coal-fired powerplant located on the Navajo Indian Reservation near Page, Arizona, and serves electric customers in Arizona, California and Nevada. The coal-fired powerplant is jointly owned by Reclamation, SRP, Los Angeles Department of Water and Power, Arizona Public Service Company, Nevada Power Company, and the Tucson Electric Power Company. The SRP operates the plant. The station supplies energy to pump water through the CAP. NGS was constructed near Lake Powell to ensure it had a dependable supply of cooling water for its three generators.

When NGS was constructed, it received an annual allotment of 34,100 af of water, and the intakes that pump water from Lake Powell to the powerplant were installed at an approximate elevation of 3,470 feet msl, or 230 feet below the lake's full pool elevation of 3,700 feet msl. A decrease in Lake Powell elevation could result in an increase in pumping costs for the NGS due to the increase in the required pumping lift.

To ensure that cooling water will be available for the continued operation of NGS, a proposal is being advanced to modify the water intake system of NGS by installing new intake structures at an elevation below that of the current intakes. The planning for this proposal is ongoing.

3.11.7.2 City of Page Water Supply Intake

The City of Page provides municipal water to approximately 7,800 residents from Lake Powell. The intake pump station is operated by Reclamation using power produced at the Glen Canyon Powerplant. Municipal water use in the City of Page is dominated by residential use with substantial residential landscape irrigation. The average annual use of water by the City of Page in recent years has been about 2,650 af. Under contract with Reclamation, the City of Page pays energy costs associated with pumping the water plus costs associated with operation and maintenance of the pump station by Reclamation. Annual energy usage has averaged around 3,900,000 kWh per year over the past 10 years. At the current rate of $0.03286 per kWh, the annual cost of energy for pumping the water is approximately $130,000 per year. Changes in CRSP power generation or drops in the elevation of Lake Powell could cause an increase in the cost of power for the City of Page's intake pump station.

3.11.7.3 SNWA Lake Mead Intake

The largest diverter of Colorado River water in Nevada is the SNWA. It diverts most of its allocation of Colorado River water from Lake Mead through the SNWA pumping plant located at Saddle Island within Lake Mead. The power-consuming features of this system are the pumping plants that are used to pump water from Lake Mead to the water treatment facility that is also owned and operated by SNWA.

The minimum required Lake Mead elevations necessary to operate the pumping units for SNWA's upper and lower intakes are 1,050 and 1,000 feet msl, respectively. A decrease in Lake Mead elevation could result in an increase in pumping costs for the SNWA due to an increase in the required pumping lift.

This page intentionally left blank.

3.12 Recreation

Key recreation resources or issues include reservoir or riverine recreational activities or facilities that might be affected by changes in reservoir elevation or river flow. The affected environment for recreation resources includes:

- shoreline public use;
- reservoir boating;
- river and whitewater boating; and
- sport fishing.

Information in this section was compiled after review of published and unpublished sources and through personal communications with Reclamation, NPS, and resource specialists. Key published sources of information used in the preparation of this section include:

- Lake Mead National Recreation Area, General Management Plan Amendment/EA (NPS 2005a);
- Grand Canyon National Park Final EIS, Colorado River Management Plan, Volume I (NPS 2005b);
- Glen Canyon National Recreation Area Final EIS, Personal Watercraft Rulemaking, Volume I (NPS 2003);
- Lower Colorado River Multi-Species Conservation Program, Final PEIS/EIR (Reclamation 2004a);
- Colorado River Interim Surplus Criteria Final EIS (Reclamation 2000); and
- Operation of Glen Canyon Dam Final EIS (Reclamation 1995).

3.12.1 Shoreline Public Use

The following sections describe shoreline public use associated with boating facilities (marinas, boat docks, and boat launch ramps), access to points of interest, and other opportunities within each Colorado River reach. Where available, the number and type of facilities at each marina, boat dock, and boat launch ramp are included for major shoreline access points. Recreational boating in the study area is dependent on these major shoreline access points. Fluctuation in pool elevations is a normal aspect of reservoir operations, and facilities have been designed and operated to accommodate these fluctuations. However, changes in pool elevations or increased variations or rates in pool elevation fluctuation could result in changes in operation costs and temporary closures.

Representative threshold pool elevations and river flows were selected for the boating facilities, at or below which certain facilities may be rendered inoperable or relocation of facilities could be required to maintain their operation. These thresholds were chosen based on either information provided in studies or communications with NPS personnel.

3.12.1.1 Lake Powell and Glen Canyon Dam

Lake Powell is located entirely within the GCNRA, which receives approximately two million visitors each year (NPS 2006d). Table 3.12-1 summarizes visitation to GCNRA for the most recent six years. The data indicate a gradual decrease in the number of visitors.

Table 3.12-1
Glen Canyon National Recreation Area Recreational Visitors

Year	Recreational Visitors
2000	2,568,111
2001	2,340,031
2002	2,106,896
2003	1,876,984
2004	1,841,845
2005	1,908,726

Source: NPS, 2006f.

Table 3.12-2 summarizes the total number of visits to GNCRA by visitor segment for 2003, the most recent year for which data are available.

Table 3.12-2
Glen Canyon National Recreation Area Visits by Visitor Segment for 2003

	Local Day Trips	Non-Local Day Trips	Hotel	Camp	Total
Number of Recreational Visits	187,698	656,944	218,548	750,794	1,876,984
Percent Segment Shares in Recreational Visits	10	35	15	40	100
Party Days[1]	81,608	252,671	196,886	870,804	1,415,939

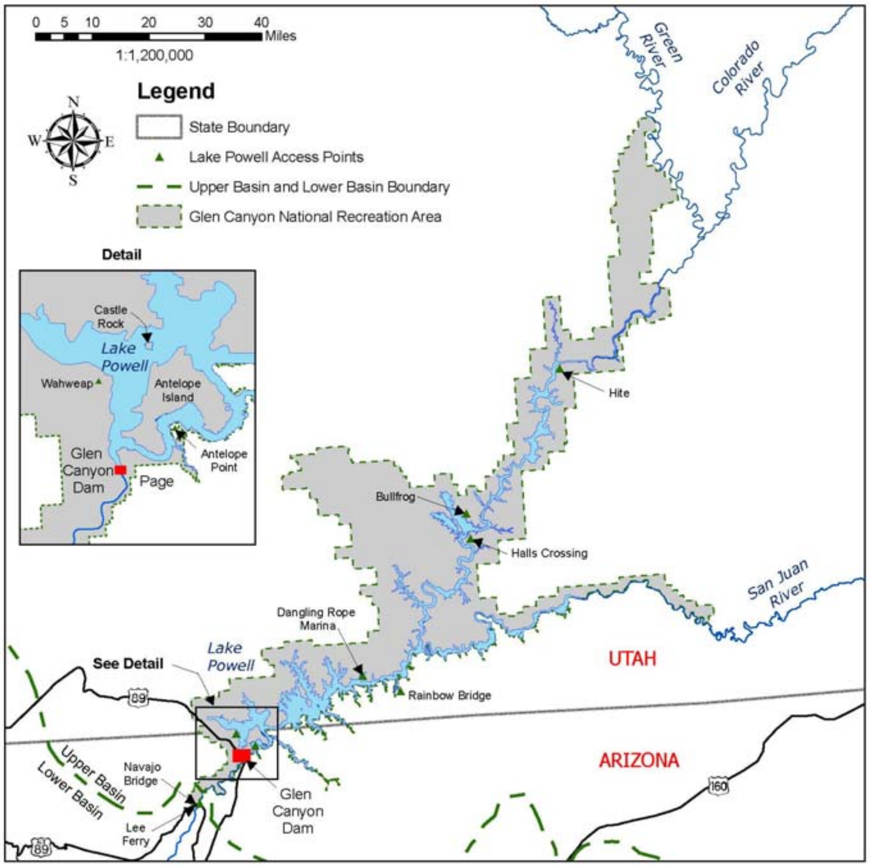
Source: NPS 2006b.

1 *Party days equal the number of days each visitor party spends in the local region. Party days are estimated by converting recreation visits using estimates of the average party size, length of stay in the area, and number of park entries per trip (re-entry rate).*

Lake Powell, its many side canyons, and related natural, cultural, and geologic resources are the primary recreation features of GCNRA. Recreation activities that occur at Lake Powell include swimming and sunbathing, power boating, waterskiing, fishing, off-beach activities associated with boat trips (such as hiking and exploring ruins), house boating, personal water craft use, canoeing, kayaking, sailing, wildlife viewing, photography, sightseeing, and other activities. Visitors can enjoy camping opportunities ranging from remote and undeveloped campsites to fully developed campgrounds. Visitors can also see archeologically and culturally important sites throughout the recreation area.

Boating Facilities. Recreation boating is the most important recreational activity on Lake Powell, with more than 831,000 boater days in 2001 (NPS 2003). Specific boating facilities, and reservoir elevations important to their operation, are discussed in the following sections. Figure 3.12-1 shows Lake Powell and the locations of its shoreline access points.

Figure 3.12-1
Lake Powell Shoreline Access Points



Water-based recreational facilities at Lake Powell are located at Wahweap, Dangling Rope, Halls Crossing, Bullfrog, Hite, and Antelope Point marinas. Table 3.12-3 lists critical lake elevations, identified by the NPS for Lake Powell, below which marinas, boat docks, or boat launch ramps become inoperable. Dangling Rope Marina is only accessible by boat, and it is used primarily for accessing Rainbow Bridge National Monument. There are no known reservoir elevations that would impair operation of Dangling Rope Marina.

Table 3.12-3
Critical Elevations for Lake Powell by Boating Facility

Lake Elevation (feet msl)	Impact and Facility
3,700	Full pool
3,620	Castle Rock Cut closed; Hite Marina and Public Launch Ramp closed
3,588	Antelope Point Public Launch Ramp closed
3,580	Main Bullfrog Launch Ramp closed
3,560	Wahweap and Stateline Public Launch Ramps closed; Bullfrog Low Water Alternative Launch Ramp closed; Halls Crossing Public Launch Ramps closed
3,555	Wahweap Marina closed; Antelope Point Marina closed; Bullfrog Marina closed; Halls Crossing Marina closed

Source: Henderson 2006

Access to Points of Interest. The facilities at Rainbow Bridge National Monument include courtesy docks, restrooms, a floating walkway, and a floating interpretive platform. Trails from the dock lead to viewing areas. One viewing area is used when Lake Powell is at the full pool elevation of 3,700 feet msl, and the other is used when the reservoir is below full pool elevation. The docks and trail system are designed to accommodate Lake Powell elevation fluctuations from 3,490 feet msl to 3,700 feet msl (NPS 1993). Boat tours to the Rainbow Bridge National Monument originate at Dangling Rope Marina.

When Lake Powell elevations fall below 3,650 feet msl, the floating walkway and interpretive platforms would be removed and stored, dock facilities would be moved to a lower elevation, dock facilities would be connected to the trail with a short walkway, and the old land trail through Bridge Canyon (submerged at full pool elevation) would be exposed, hardened, and used for access (NPS 1990).

3.12.1.2 Glen Canyon Dam to Lake Mead

The 15.5-mile river reach downstream of Glen Canyon Dam to Lees Ferry is managed by GCNRA and is used by anglers; campers; and commercial float trip operators, kayakers, and other boaters. Fishing opportunities (with an Arizona state non-native fishing license and a trout stamp) for rainbow and brown trout also occur downstream of this reach.

Grand Canyon National Park begins at Lees Ferry and the NPS manages most of the reach, except where it is bordered on the east by the Navajo Indian Reservation and the south by the Hualapai Indian Reservation. The Grand Canyon National Park regulates visitor use of the Colorado River in accordance with the Colorado River Management Plan (NPS 2005b).

The Lees Ferry to Diamond Creek reach has relatively low use densities and levels of development, providing opportunities for solitude on the Colorado River and at many camps and attraction sites. This section of the Colorado River is where the majority of whitewater boating occurs. Take-outs are located at Diamond Creek and Pearce Ferry, and the reach downstream of Diamond Creek offers different recreation opportunities than the river reach upstream as it transitions to a more populated and developed setting. The Pearce Bay take-out is closed at elevation 1,175 feet msl. Whitewater boating trips become intermingled with very high levels of general boating and recreation use in the Quartermaster Area.

Several helicopter operations transport people into the Grand Canyon and connect with motorized pontoon boats that give 20-minute tours of the immediate area. These same helicopters serve a dual service in flying out boaters who have traveled from Diamond Creek on commercial motor day trips.

Camping also occurs in the Grand Canyon National Park on undeveloped beaches along the river. The important variable is the number and quality of high-water versus low-water campsites.

The Hualapai Indian Reservation offers camping, fishing, hiking, and big game hunting. A Tribal enterprise operates a river rafting company that offers rafting trips on the section of the Colorado River from Diamond Creek to Quartermaster Canyon.

Boating Facilities. There are few boating facilities in Grand Canyon National Park, except for major launch facilities that include Lees Ferry, Phantom Ranch, Whitmore, Diamond Creek, and the Quartermaster Area. Brief descriptions of each facility are provided below.

Lees Ferry. The primary put-in at the start of a Grand Canyon river trip, Lees Ferry has a large ramp, parking, a camping area, and an information kiosk where pre-trip logistics and information sessions are conducted.

Phantom Ranch. Phantom Ranch is a collection of cabins, a small store, an NPS ranger station, and campground. River trips are prohibited from camping at Phantom Ranch, but it is a popular exchange location.

Whitmore. The Whitmore exchange point consists of a helicopter landing pad on Hualapai Indian Reservation and a boat tie-up and camping area. The Whitmore area is used by commercial trips as an exchange point for passengers to begin or end their river trip; nearly all of those passengers arrive at or depart from the area via a helicopter flight.

Diamond Creek. The Diamond Creek take-out and launch is operated by both the NPS and the Hualapai Indian Tribe. The tribe charges fees to use Diamond Creek. The Hualapai River Runners (HRR) manage take-out and launch operations in addition to conducting guided whitewater trips that put-in at Diamond Creek, and floating trips that put-in at Quartermaster Canyon. All of these trips take out at Pearce Ferry. There is a gravel ramp area and a limited parking lot.

Quartermaster Area. There are 15 helipads, 2 docks, and other facilities in the Quartermaster Area. While all of the pads offer access for look-and-leave flights, a few pads are also used to transport HRR and pontoon trip passengers out of the canyon.

Camping. Sandbars form the camping beaches used by river runners. Camping is possible in only a limited number of locations along the Colorado River between Glen Canyon Dam and Lake Mead because most of the shoreline is unsuitable. At a given time, however, campable area depends on the local stage (height) of the river, which is determined by the magnitude of releases and local topography.

There are three general categories for camp sizes: small (one to 12 people); medium (13 to 24 people); and large (25 to 36 people), that are further divided into high-water and low-water camps (Kearsley and Warren 1993). High-water camps are available at flows above 15,000 cfs, generally on terraces. Low-water camps are available only at flows below 15,000 cfs. Thirty-seven favorable sites that become available at discharges of 15,000 cfs or less were identified by Kearsley and Warren (1993). Table 3.12-4 lists the number of small, medium, and large camps, as well as the number of high- and low-water camps.

Table 3.12-4
Number of Camping Beaches by Camp Size for High- and Low-Water Camps

High- and Low-Water Camping Beaches	Small (1 to 12 people)	Medium (13 to 24 people)	Large (25 to 36 people)	Total
Camping beaches at high water (15,000 cfs or greater)	47	102	90	239
Additional camping beaches available at low water only (15,000 cfs or less)	27	10	*	37

*Source: Kearsley and Warren 1992, 1993; * not measured.*

3.12.1.3 Lake Mead and Hoover Dam

LMNRA contains 1.5 million acres and encompasses the 110-mile-long Lake Mead, 67-mile-long Lake Mohave, the surrounding desert, and the isolated Shivwits Plateau in Arizona.

The Virgin River flows into upper Lake Mead from the north. Recreational activities such as camping, boating, fishing, and hiking occur on upper Lake Mead. The Overton Wildlife Management Area provides opportunities for wildlife viewing and photography, waterfowl and upland game bird hunting, hiking, and fishing. The Overton Wildlife Management Area has an average of 5,300 annual visitor use days (Nevada Department of Wildlife 2006).

LMNRA extends along the lower Colorado River from the western border of Grand Canyon National Park (with the dividing line at the Grand Wash Cliff, RM 276.5) to Davis Dam. Primary recreational activities on Lake Mead by percentage of users include cruising/sailing 41.4 percent, personal watercraft usage 17.5 percent, waterskiing

16.9 percent, fishing 14.2 percent, swimming 6.7 percent, and other 3.3 percent (NPS 2002). A number of campgrounds and picnic areas provide additional recreational opportunities and include Boulder Beach, Calville Bay, Echo Beach, Las Vegas Bay, and Temple Bar. The LMNRA has approximately six million visitor use days per year (NPS 2001).

Table 3.12-5 summarizes recreational visits to LMNRA for the last six years.

Table 3.12-5
Lake Mead National Recreation Area Recreational Visitors

Year	Recreational Visitors
2000	8,755,005
2001	8,465,547
2002	7,550,284
2003	7,915,581
2004	7,819,984
2005	7,692,438

Source: NPS 2006c.

Table 3.12-6 summarizes the total number of visits to LMNRA by visitor segment for 2003, the most recent year for which data are available.

Table 3.12-6
Lake Mead National Recreation Area Visits by Visitor Segment for 2003

	Local Day Trips	Non-Local Day Trips	Hotel	Camp	Total
Number of Recreational Visits	2,374,674	2,374,674	791,558	2,374,674	7,915,581
Percent Segment Shares in Recreational Visits	30	30	10	30	100
Party Days[1]	719,598	719,598	263,853	668,482	2,415,452

Source: NPS 2006d.

1 *Party days equal the number of days each visitor party spends in the local region. Party days are estimated by converting recreational visits using estimates of the average party size, length of stay in the area, and number of park entries per trip (re-entry rate).*

Boating Facilities. The LMNRA is considered one of the premier water-based recreation areas in the nation. Most visitors are involved in water-based recreational activities, primarily between May and September. These recreational activities are supported by marina and launch ramp facilities developed along the Lake Mead shoreline. On average, the majority of boats are personal watercraft. There may be as many as 6,000 boats on Lake Mead and Lake Mohave during a peak recreation use weekend. The Boulder Beach developed area, which is one of the most heavily visited portions of the recreation area located near the urbanized area of Las Vegas and surrounding communities, includes special use areas for sailing, recreational diving, and personal watercraft use.

Water-based recreational facilities at Lake Mead are located at Boulder Beach, Las Vegas Bay, Callville Bay, Echo Bay, Overton Beach, and Temple Bar marinas, and Hemenway, Government Wash, South Cove, and Pearce Ferry boat ramps. Pearce Ferry is used as a take-out by Colorado River boaters. Table 3.12-7 shows critical elevations, identified by the NPS for Lake Mead, below which marinas, boat docks, or boat launch ramps become inoperable. The Pearce Bay launch ramp, a take-out point for rafts and whitewater boats, is closed at elevation 1,175 feet msl. This results in rafts and other whitewater boats having to continue downstream to South Cove, an additional 16 miles.

Table 3.12-7
Critical Elevations for Lake Mead by Recreational Facility

Lake Elevation (feet msl)	Impact and Facility
1,221	Full Pool
1,175	Pearce Bay Launch Ramp closed
1,150	Las Vegas Bay and Government Wash Public Launch Ramps closed
1,125	Overton Beach Marina, Callville Ramp and South Cove Ramp closed
1,112	Lake Mead Marina – Relocation of "C Dock" to Hemenway
1,110	Overton Public Launch Ramps closed
1,100	Lake Mead Marina must relocate out of protected harbor
1,080	Lake Mead Marina public launch ramp closed; Hemenway public launch ramp closed; Temple Bar Public Launch Ramp closed
1,050	Echo Bay Public Launch Ramp closed

Source: Henderson 2006.

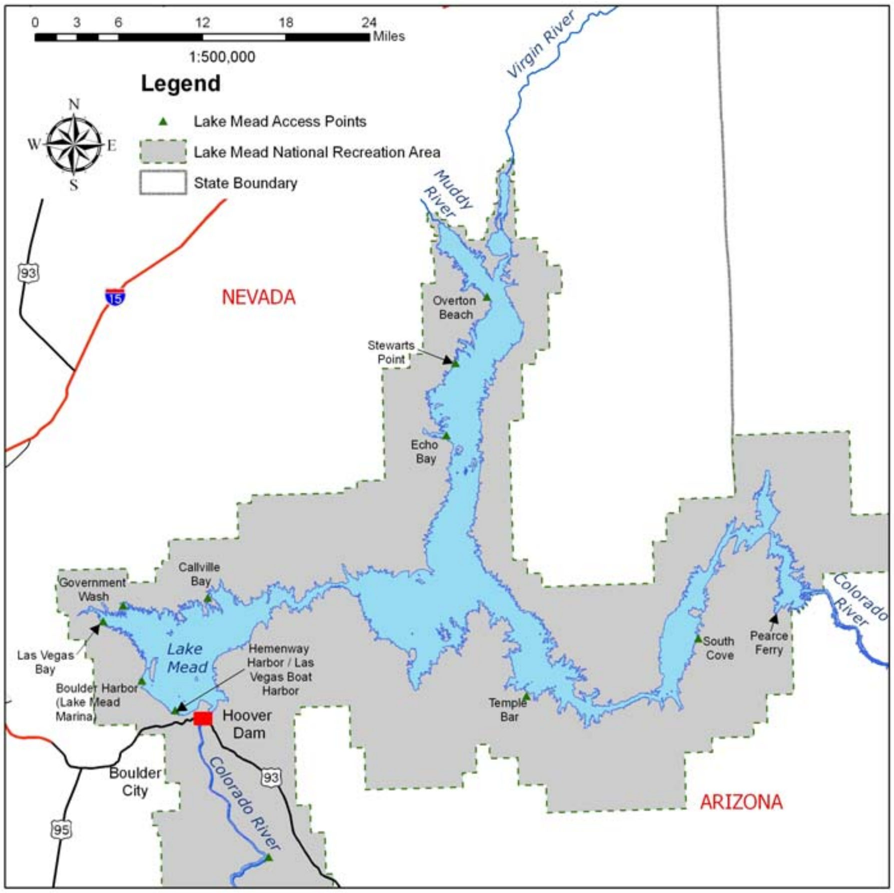
Shoreline public use facilities on Lake Mead are shown on Figure 3.12-2 and described on the following pages.

Pearce Ferry. Pearce Ferry includes a primitive public launch ramp used by Grand Canyon raft tour companies as their take-out. The ramp is located in a cove off of the river and operable when Lake Mead is at an elevation above 1,175 feet msl. Below that elevation, the cove becomes isolated from the river by a large sand bar separating the cove and graded ramp from the main flow of the Colorado River (NPS 2006e).

When Pearce Ferry is inaccessible due to low flows, boaters must continue downstream to South Cove, an additional 16 miles. This costs river runners fuel (for motorized craft), time (one to two more hours on the river), and possible safety problems (due to fatigue).

South Cove. The facilities at South Cove provide access to one of the best sand beach areas. There is one courtesy dock, public launch ramp, picnic facilities, and unpaved parking (Henderson 2000). The public launch ramp is constructed of asphalt and concrete and extends to an elevation of 1,125 feet msl. Other public facilities include a picnic area and restrooms. In addition, there is an airstrip approximately four miles from the facilities at South Cove (Henderson 2000).

Figure 3.12-2
Lake Mead Shoreline Access Points



Temple Bar. Temple Bar Marina includes a public launch ramp, boat, houseboat, and personal watercraft rentals, slip rentals, and fuel. Other facilities and services include a restaurant/lounge, motel, cabin rentals, trailer village, recreational vehicle sites, dry boat storage, store, shower/laundry, boat/motor repairs, and auto/boat gas.

Overton Beach. The facilities at Overton Beach Marina include two public launch ramps. The marina is closed at elevation 1,125 feet msl and the public launch ramps are closed at elevation 1,110 feet msl.

Additional available facilities and services at the Overton Beach Marina include covered rental slips, boat and personal watercraft rentals, small boat repair, fuel dock, and snack bar. Land based facilities include a store, shower/laundry, recreational vehicle campground, a trailer village, and dry boat storage.

Stewart's Point. Stewart's Point has an unpaved launch ramp (River Lakes Host 2006). The shoreline at Stewart's Point is a popular summertime weekend destination. The area is also a vacation cabin site area. The 2003 Lake Management Plan approved the future construction of a public boat launch at this location.

Echo Bay. The Echo Bay Marina includes boat, houseboat, and personal watercraft rentals, slip rentals, and fuel. Other facilities and services include a restaurant, motel, trailer village, recreational vehicle sites, dry boat storage, store, shower/laundry, boat/motor repairs, and auto/boat gas.

Callville Bay. The Callville Bay Marina includes rental slips; boat, houseboat, and personal watercraft rentals; and fuel. Other facilities and services include boat and motor repair, a trailer village, recreational vehicle sites, cafe/lounge, shower/laundry, auto/boat gas, dry boat storage, and a general store.

Government Wash. The facilities at Government Wash include one courtesy dock, public launch ramp, and a parking area. These facilities are closed at elevation 1,150 feet msl.

Las Vegas Bay. The facilities at Las Vegas Bay Marina include two public launch ramps, dry boat storage, and fuel service and maintenance area. The public launch ramps close at elevation 1,150 feet msl.

Las Vegas Boat Harbor. The facilities at Las Vegas Boat Harbor Marina are located next to Hemenway Harbor, and include rental slips, boat and personal watercraft rentals, floating gas dock, boat/motor repairs, store, and restaurant.

Hemenway Harbor. The facilities at Hemenway Harbor include one courtesy dock, public launch ramp, campgrounds, and a parking area. It also serves as the departure point for Lake Mead Cruises that provides sightseeing tour boat service to and from Hoover Dam, breakfast and dinner cruises, and charter boat service.

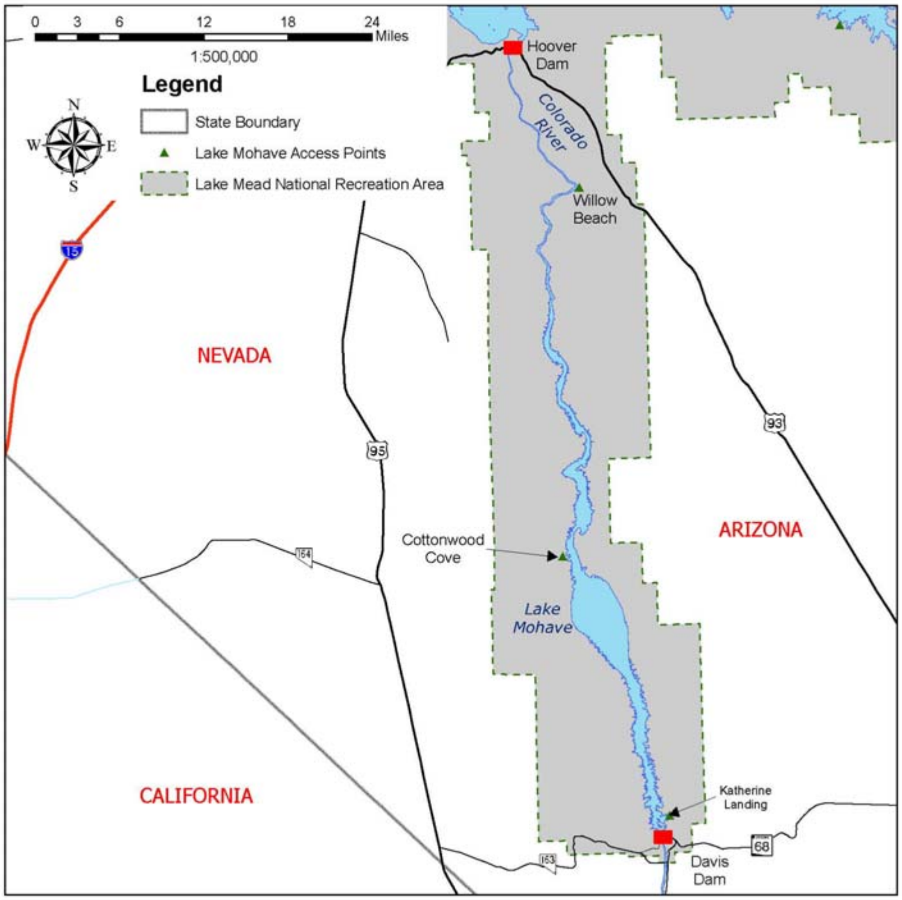
Boulder Harbor. The facilities at Boulder Harbor include two public launch ramps at Boulder Beach.

3.12.1.4 Hoover Dam to Davis Dam

Lake Mohave, formed by Davis Dam, provides a multitude of recreational opportunities. Activities include boating, canoeing on northern parts of the lake, camping, exploring, fishing, photography, picnicking, swimming, parasailing, two locations for cliff diving, and water skiing. There are also hundreds of beaches that can only be accessed by boat.

The main shoreline access points for Lake Mohave are Katherine Landing, Cottonwood Cove, and Willow Beach (Figure 3.12-3). Facilities for public use and boat launching are located at Katherine's Landing in Arizona near Davis Dam, and at Cottonwood Cove, east of Searchlight, Nevada. Boats and jet skis can be rented at both locations. Public campgrounds are available at both locations where concessionaires provide trailer parks, restaurants, lodging, docking facilities, boat and fishing tackle equipment, and fishing licenses. Facilities for public use and boat launching are also located at Willow Beach, 31 miles upstream on the Arizona shore.

Figure 3.12-3
Lake Mohave Shoreline Access Points



3.12.1.5 Davis Dam to Parker Dam

Recreational Areas. The Davis Dam to Parker Dam reach includes several recreational areas along the Colorado River including Laughlin, Bullhead City, Davis Camp, Needles, Havasu NWR, Lake Havasu State Park, and Bill Williams River NWR. Relevant recreational areas are briefly described in the following sections.

Davis Camp. Located near Bullhead City, Davis Camp, a campground and day use area, has boat launching facilities, picnic areas, numerous campsites, and recreational vehicle hookups. Davis Camp offers many river-oriented recreational opportunities, including fishing and water sports.

Havasu National Wildlife Refuge. The Havasu NWR, managed by the FWS, covers 30 river miles (300 miles of shoreline) from Lake Havasu City, Arizona to Needles, California, and includes one of the last remaining natural stretches of the lower Colorado River, which flows through the 20-mile-long Topock Gorge (FWS 2002). Typical activities include canoeing, fishing, boating through the scenic Topock Gorge, and hiking in the Havasu Wilderness Area. Each year, thousands of visitors explore the 4,000-acre Topock Marsh, which offers excellent canoeing, fishing, and water-bird watching. Other activities offered by the Havasu NWR include camping and hunting.

Lake Havasu State Park. Lake Havasu, formed by Parker Dam, contains a number of coves and inlets, and it is a popular spot for fishing. The waters of Lake Havasu also are used for canoeing, house boating, jet-skiing, kayaking, sailing, and speed-boating, swimming, and water-skiing. Camping and hiking also occur along the more than 400 miles of the lake's shoreline. Additional visitor opportunities include viewing the London Bridge. Lake Havasu is a popular spring break and family vacation destination.

Lake Havasu is the premier attraction area within the Davis Dam to Parker Dam reach. Visitation at Arizona's Lake Havasu and Cattail Cove State Parks is listed in Table 3.12-8.

Table 3.12-8
Visitation at Arizona's Lake Havasu and Cattail Cove State Parks

State Park	Visitation (1995-1996)	Visitation (2000-2001)	Percent Change
Lake Havasu	371,700	345,590	-7.0
Cattail Cove	96,459	106,939	10.9
Totals	468,159	451,983	-3.4

Source: Northern Arizona University 2002.

Bill Williams River National Wildlife Refuge. The Bill Williams River NWR, managed by the FWS, is located along the Bill Williams River near its confluence outlet into Lake Havasu. The refuge offers a variety of recreational opportunities, including hiking and bird watching (as well as other wildlife viewing), with opportunities to view Yuma clapper rails and southwestern willow flycatchers, among other species. Hunting is permitted for dove, cottontail, quail, and desert bighorn sheep. Other activities include boating and fishing.

Boating Facilities. The Davis Dam to Parker Dam reach includes shoreline public use facilities at Laughlin, Nevada; Bullhead City, Arizona; Davis Camp, near Bullhead City; Needles, California; Havasu NWR, covering 30 river miles (300 miles of shoreline) from Lake Havasu City, Arizona to Needles, California; Lake Havasu State Park, Arizona; and Bill Williams River NWR, Arizona. Recreational activities within this reach include canoeing, fishing, houseboating, jet-skiing, kayaking, sailing, speed-boating, swimming, and water-skiing.

3.12.1.6 Parker Dam to Cibola Gage

Recreational Areas. The Parker Dam to Cibola Gage reach includes several recreational areas including Parker Strip Recreation Area, Palo Verde Diversion Dam, Blythe, and Cibola NWR. Brief descriptions of relevant recreational areas located on this reach follow.

Parker Strip Recreation Area. The Parker Strip Recreation Area includes an 11-mile road along the Colorado River. Recreational activities include boating, camping, fishing, hiking, rock hounding, swimming, and wildlife viewing.

Palo Verde Diversion Dam. There are approximately 95 miles of navigable waters between Imperial Dam downstream of Yuma and Palo Verde Diversion Dam upstream of Blythe. Activities include canoeing, fishing, hunting, power boating, and other water sports.

Cibola National Wildlife Refuge. The Cibola NWR, including Cibola Lake, managed by the FWS is located about 15 miles south of Blythe. The largest concentration of Canada geese and sandhill cranes on the lower Colorado River winter at this refuge. Visitors to the refuge engage in canoeing, fishing, hiking, hunting, photography, and wildlife observation.

Boating Facilities. The Parker Dam to Cibola Gage reach includes shoreline public use facilities at Parker Strip Recreation Area, Arizona; Palo Verde Diversion Dam, Arizona; Blythe, California; and Cibola NWR, Arizona. Typical water activities within this reach include canoeing, power boating, fishing, swimming, and other water sports.

3.12.1.7 Cibola Gage to Imperial Dam

Recreational Areas. The Cibola Gage to Imperial Dam reach includes a few recreational areas including Picacho State Recreation Area (SRA), Imperial NWR, and Martinez Lake. Brief descriptions of these recreational areas follow.

Picacho State Recreation Area. Picacho SRA is a popular area for camping, desert exploring, river running, and sport fishing. It receives approximately 60,000 visitors annually (Picacho State Recreation Area 2006), and has a group boat-in area, three individual boat-in camp areas, and large group camping areas. Bird watching and small game hunting for doves, ducks, and quail are among other recreational opportunities.

Imperial National Wildlife Refuge. Recreational opportunities at the Imperial NWR include canoeing, fishing, and hunting. The refuge is valued by boaters for its remote scenery.

Martinez Lake. Martinez Lake, which adjoins the Imperial NWR, encompasses 300 to 500 acres and it is an attraction catering to anglers, birdwatchers, boaters, fishers, hunters, nature lovers, rock hounds, sightseers, and water skiers. Martinez Lake has a large variety of birds year around that can be viewed from boats on the Colorado River as well as the many side lakes along the river.

Boating Facilities. Cibola Gage to Imperial Dam reach includes shoreline public use facilities at Picacho SRA, California; Imperial NWR, Arizona; and Martinez Lake, Arizona. Picacho SRA has a group boat-in area and three individual boat-in camp areas. Typical water activities within this reach include river running, boating, canoeing, water-skiing, and sport fishing.

3.12.1.8 Imperial Dam to NIB

Recreational Areas. The Imperial Dam to the NIB reach includes a few recreational areas along the Colorado River, including Betty's Kitchen and Mittry Lake Wildlife Area. Brief descriptions of these recreational areas follow.

Betty's Kitchen. Betty's Kitchen, a 10-acre wildlife interpretive area, provides bird watching and fishing opportunities.

Mittry Lake Wildlife Area. Mittry Lake, within the Mittry Lake Wildlife Area, covers approximately 600 acres and it is an ideal location for small game hunting and sportfishing. There is a three-lane boat launch ramp for motorized boating on the lake. The area is also popular for birdwatching and nature study.

Boating Facilities. The Imperial Dam to the NIB reach includes shoreline public use facilities such as a public fishing pier (National Recreation Trails Program 2006) at Betty's Kitchen, Arizona and a three-lane boat launch ramp for motorized boating and fishing jetties at Mittry Lake Wildlife Area, Arizona (AZBLM 2006). Typical water activities within this reach include boating, swimming, and sport fishing.

3.12.1.9 NIB to SIB

The NIB to the SIB reach includes shoreline public use facilities in the City of Yuma, Arizona. Located on the edge of the historic floodplain to the east of the Colorado River, typical water activities within this reach include boating, swimming, and sport fishing.

3.12.2 Reservoir Boating

Reservoir boating is affected by fluctuating reservoir elevations, specifically causing changes in exposure to boating navigation hazards and changes in safe boating capacities. Hazards such as exposed rocks may become more evident and changes in navigation patterns may be necessary as reservoir elevations decline. At low-pool elevations, special buoys or markers may be placed within reservoirs to warn boaters of navigational hazards. In addition, signs may be placed in areas that are deemed unsuitable for navigation.

3.12.2.1 Lake Powell

Safe Boating Navigation. In 1986, the GCNRA developed an Aids to Navigation Plan for Lake Powell that identified boating safety issues on the reservoir and low-pool elevations that could affect boating (NPS 1986). The navigation system uses regulatory buoys and other marking devices to warn boat operators of hazardous conditions associated with subsurface obstructions or changes in subsurface conditions that could be hazardous for safe passage. Placement of many of these marking devices is dependent on the lake elevation.

At pool elevations below 3,680 feet msl, there are several places that remain passable, although buoys are placed for safe navigation. At elevations 3,626 feet msl and 3,620 feet msl, there are two areas on the reservoir that are closed to commercial tour boats and recreational boats, respectively, because of hazardous obstructions to navigation. One of these areas is around Castle Rock (elevation 3,620 feet msl), just east of the Wahweap Marina, and the other is around Gregory Butte, which is about midway to Dangling Rope Marina from Wahweap (Figure 3.12-1). At elevation 3,626 feet msl commercial tour boats leaving the Wahweap Marina heading up reservoir (east) must detour 8.5 miles around the southern end of Antelope Island. At elevation 3,626 feet msl, commercial tour boats must detour 4.5 miles around Padre and Gregory Buttes (NPS 1986). The added mileage and increased travel time makes the more popular half-day trips to the area infeasible for commercial tour boat operators. In addition, the added mileage may influence recreational boaters to remain in the area of Wahweap Bay, which can result in congestion (Henderson 2000).

In addition to buoys marking obstructions, the Aids to Navigation Plan also established a marked travel corridor to guide boat travel on Lake Powell. This primary travel corridor is the main channel of the Colorado River and it is marked with buoys along the entire length of the reservoir. Except for the reservoir mouth, there are no known pool elevations at which boat passage along this main travel corridor becomes restricted and affects boating.

Near Hite a delta has formed that can affect river boaters coming into Lake Powell at low-pool elevations. River boaters from the Colorado River row or motor through Lake Powell to a location where a boat transports them 20 to 25 miles (depending on the pick-up location) to the Hite Marina. At low elevations, the river boaters must travel further downstream to reach a location accessible to the transport company’s boat. Although this results in more miles to the take-out, there is usually enough current in the river to carry the boats. At lower elevations, additional rapids are exposed in Cataract Canyon (Hyde 2000), benefiting river runners; however, lower Lake Powell elevations result in the possibility of additional navigational hazards due to restricted channel widths, and subsurface conditions.

As listed in Table 3.12-9, watercraft use in the GCNRA peaks in the months of June through August.

Table 3.12-9
Estimates of Watercraft Use in Glen Canyon National Recreation Area by Month and Annually in 2001

Month	Other Watercraft		Personal Watercraft		All Watercraft	
	Boat Days	Monthly Use (percentage)	Boat Days	Monthly Use (percentage)	Boat Days	Annual Use (percentage)
January	747	96	30	4	777	<1
February	1,059	97	33	3	1,092	<1
March	8,995	97	261	3	9,256	1
April	18,686	94	1,122	6	19,808	2
May	68,444	81	15,771	19	84,215	10
June	137,675	74	47,985	26	185,660	22
July	113,984	70	48,600	30	162,584	20
August	126,628	72	49,491	28	176,119	21
September	80,045	62	49,883	38	129,928	16
October	37,658	86	6,336	14	43,994	5
November	11,946	96	445	4	12,391	2
December	5,189	99	67	1	5,256	1
Total	611,056	74	220,023	26	831,079	100

Source: NPS 2003.

Safe Boating Capacity. Recreational boating is the most frequent type of boating activity on Lake Powell, with an estimated 1.5 million boaters per year. One of the most popular activities at Lake Powell is to take houseboats and motorboats for multiple day excursions to explore the reservoir.

At full pool elevation for Lake Powell (3,700 feet msl), its operating surface area is 160,782 acres. Using nine surface acres per boat, Lake Powell’s safe boating capacity at full pool elevation is approximately 17,865 boats at one time. As pool elevation decreases, the surface area available for boats also decreases.

3.12.2.2 Lake Mead

Safe Boating Navigation. Regulatory buoys and other marking devices are used on Lake Mead to warn boat operators of dangers, obstructions, and changes in subsurface conditions in the main channel or side channels.

The main channel of the Colorado River forms the primary travel corridor on Lake Mead and it is marked along its entire length with buoys for boating guidance. In addition, regulatory buoys are placed in areas where there may be a danger for safe passage.

Excursions from Lake Mead into the Grand Canyon are a popular activity. Boats entering the Grand Canyon usually launch at Pearce Ferry, South Cove, or Temple Bar (Figure 3.12-2). In addition to sightseeing being a popular activity, many boaters include overnight camping on these excursions.

The upper arms and inflow areas of Lake Mead may be difficult to navigate due to shifting subsurface sediments. In the main channel of the reservoir, the Grand Wash Cliffs area is the beginning of dangerous navigation conditions and no houseboats are allowed beyond this point (NPS 2005a).

Over the years, sediment has built up in the section of the reservoir between Grand Wash and Pearce Ferry. When Lake Mead elevations drop below 1,170 feet msl, the sediment is exposed as mud flats and there is no well-defined river channel. As a result, the area is too shallow for motor boats to navigate upstream and into the lower reaches of the Grand Canyon. With fluctuating flows, even smaller crafts may have a difficult time accessing the area because of the shifting channel (Reclamation 1995). Based on this information, elevation 1,170 feet msl is considered a threshold elevation for safe boating navigation for the upper end of Lake Mead.

While the area around Pearce Ferry is an issue for navigation at elevation 1,170 feet msl, the Pearce Bay launch ramp is inaccessible as a take-out for boaters at elevation 1,175 feet msl and boaters must paddle an additional 16 miles to South Cove (Henderson 2006).

Safe Boating Capacity. At full pool elevation, Lake Mead’s operating surface area is 153,235 acres. Using the safe boating density of nine surface acres per boat, Lake Mead’s safe boating capacity at full pool elevation is approximately 17,000 boats. As pool elevation decreases, the safe boating capacity also decreases.

3.12.2.3 Lake Mohave and Lake Havasu

Because Lake Mohave and Lake Havasu will continue to be operated to meet monthly target elevations, reservoir boating safe navigation and capacity in these reaches will not be impacted by the proposed federal action.

3.12.3 River and Whitewater Boating

Whitewater boating is the key recreational activity in Grand Canyon from Lees Ferry to the Diamond Creek or Pearce Ferry take-outs. Other reaches are not predominately whitewater localities and so they are not covered here.

3.12.3.1 Glen Canyon Dam to Lake Mead

Most Grand Canyon river trips begin at Lees Ferry and take-out at Diamond Creek or Pearce Ferry when Lake Mead elevations are higher than 1,175 feet msl, or at South Cove when Lake Mead elevations are below 1,175 feet msl (Figure 3.12-2). Boating is regulated by the NPS through its Colorado River Management Plan (NPS 2005b). The number of permits or boaters will not change as a result of this proposed federal action; the key issue is whether the visitor experience could change as a result of potential changes in Glen Canyon Dam releases. The total number of river users is approximately

22,800 per year. Use is expected to increase to 28,000 per year as indicated in the Grand Canyon National Park Colorado River Management Plan. There are seasonal differences in the number of river users, with the winter season having the lowest daily and monthly uses.

Motorized boats travel up and down river from Glen Canyon Dam to Lees Ferry and in the upper end of Lake Mead. Limited camps in the latter area discourages overnight use.

3.12.3.2 Hoover Dam to SIB

Fluctuations in river flows between Hoover Dam and the SIB under each alternative are expected to be within the range of historic operations for the Colorado River and would not deviate from historic highs and lows. Between Hoover Dam and the SIB, river and whitewater boating are not expected to be adversely affected by the proposed federal action.

3.12.4 Sport Fishing

This discussion is based on the GCNRA Fish Management Plan (NPS 1996) for Lake Powell, and the Desert Lake View Newspaper, Fall/Winter 1999 for Lake Mead. In addition, creel information and angler fishing data have been obtained from state agencies in Arizona, Nevada, and Utah responsible for managing the fisheries resources at Lake Mead, Lake Powell, Lake Mohave, and on the Colorado River.

There are no specific reservoir elevation thresholds or river stages related to sport fishing identified from the literature reviewed. Catch rates for reservoir fishing are assumed to be directly related to reservoir habitat. Fishing satisfaction is assumed to be directly related to the general recreation issues of boating access to water via shoreline facilities, and boating navigation potential for hazards or reservoir detours due to low reservoir elevations. Catch rates are not expected to be affected by fluctuations in reservoir elevations.

3.12.4.1 Lake Powell and Glen Canyon Dam

Lake Powell supports a popular warm water sport fishery comprised mainly of striped and smallmouth bass. The striped bass depend on threadfin shad, a mid-water forage species, for a significant portion of their diet. The threadfin shad in Lake Powell are at the northernmost portion of their range and are sensitive to fluctuations of water temperature. Gizzard shad, which were inadvertently released recently and made their way to Lake Powell, may become an important striped bass forage fish. In addition to striped and smallmouth bass, Lake Powell supports largemouth bass, walleye, channel catfish, bluegill, and black crappie. There are two million angler hours per year in pursuit of sport fish. Due to the drought and declining visitation, angler use in 2003 was the lowest it has been since 1985 (Blommer et al. 2004).

3.12.4.2 Glen Canyon Dam to Lake Mead

The rainbow trout in the 15.5-mile river reach downstream of Glen Canyon Dam attract large numbers of local and international anglers. In 2003, angler use was approximately 14,000 user days. The fishery is managed as a blue ribbon rainbow trout fishery by the Arizona Game and Fish Department and GCNRA. The intention of blue ribbon management is to provide a quality fishing opportunity where anglers can catch larger than average trout, at a relatively high catch rate, in a unique recreational setting. Most fishing occurs from boats, but some anglers wade in the area around Lees Ferry. Downstream of this area the native fishery is emphasized. Whirling disease was discovered in Lees Ferry trout in June of 2007, which is the first documented case of the disease in wild fish in public waters in Arizona (Arizona Game and Fish 2007).

3.12.4.3 Lake Mead and Hoover Dam
Lake Mead has an excellent warm water sport fishery comprised of largemouth bass, striped bass, channel catfish, rainbow trout, bullhead catfish, sunfish, crappie, and bluegill. Eighty-six percent of the catch consists of striped bass. Fishing is generally better in the fall months of September, October, and November. Larger fish are caught by deep water trolling in spring from March through May.

3.12.4.4 Hoover Dam to Davis Dam
Lake Mohave's fishery is similar to Lake Mead's fishery. In Lake Mohave there are largemouth bass, striped bass, channel catfish, rainbow trout, bullhead catfish, sunfish, crappie, and bluegill. Largemouth and striped bass are in deep water in the winter and move into shallow water to spawn in the spring. Fishing is open year round, but the best fishing generally occurs in September, October, and November. For deep water trolling, March through May is best.

3.12.4.5 Davis Dam to Parker Dam
Striped bass is the dominant sport fish in Lake Havasu. They can be caught throughout the year, but best fishing locations change with seasons and with water temperature. The largemouth bass population supports tournaments nearly every weekend from September through May. The smallmouth bass population has experienced an increase in numbers over the past couple of years adding a needed resource for tournament anglers. Channel catfish are abundant and average two to four pounds in size. Flathead catfish grow to large sizes in Lake Havasu. Only a limited number of anglers fish specifically for catfish. Black crappie numbers are limited due to over-harvesting and lack of habitat. The lake also contains some very large bluegill and redear sunfish; many weigh well over a pound (Lake Havasu Fishing 2006).

3.12.4.6 Parker Dam to SIB
Fishing in Cibola NWR is limited to certain times of the year. Cibola NWR is managed to protect wintering waterfowl that use Cibola Lake. The lake is closed to fishing from Labor Day to March 15. Sport fishing in Cibola Lake includes largemouth, smallmouth, and striped bass, channel and flathead catfish, crappie, sunfish, tilapia, and common carp (FWS 2006a).

The Imperial NWR is managed as a refuge and breeding area for migratory birds and other wildlife (FWS 2006b). Hunting and fishing are permitted in some areas, according to state regulations, and fishing is allowed in the mainstream Colorado River any time of the year by boat. Fluctuations in flows between Parker Dam and the SIB under the alternatives are expected to be within the historic operating range of the Colorado River.

This page intentionally left blank.

3.13 Transportation

Transportation refers to the movement of people and vehicles on existing road networks and on ferries that cross the Colorado River. While there are other transportation services, only the ferry services have the potential to be impacted by the proposed federal action.

3.13.1 Ferry Service

Three ferry services transport people and vehicles across the Colorado River and its reservoirs. These services are:

- Lake Powell ferry service;
- Laughlin river taxis and tour boats; and
- Lake Havasu ferry service.

3.13.1.1 Lake Powell Ferry Service

The John Atlantic Burr Ferry on Lake Powell is located 95 miles upstream from Glen Canyon Dam and connects Bullfrog and Hall Crossing marinas on Lake Powell (Figure 3.13-1). The State of Utah operates this ferry service year round. This ferry saves approximately 130 miles of driving and the cost is $39.50 plus tax for a one-way trip. The ferry becomes inoperable when Lake Powell elevation falls below 3,550 feet msl (Aramark 2006).

3.13.1.2 Laughlin River Taxis and Tour Boats

Privately owned river taxis and tour boats operate on the Colorado River approximately 2.5 miles downstream of Davis Dam in Laughlin, Nevada (California Department of Boating and Waterways 2006) (Figure 3.13-2). The river taxis provide transportation between the casinos located along the Colorado River in Laughlin. The tour boats offer services ranging from air-conditioned cabins, open-air top decks, wedding chapels, and full service bars. The operation of these river taxis and tour boats depends upon the Colorado River elevations that result from releases of water from Davis Dam. Many operations, especially the larger tour boats with paddle wheels, require releases of two units (approximately 9,200 cfs) from Davis Dam to operate. Although some of the river taxi operations that operate smaller boats can get by with 0.5 units (approximately 2,300 cfs), most prefer at least one unit (approximately 4,600 cfs) (Fitch 2006, personal communication).

3.13.1.3 Lake Havasu Ferry Service

The Dreamcatcher Ferry transports people between Havasu Landing Casino on the Chemehuevi Indian Reservation, California and a point near the London Bridge in Lake Havasu City, Arizona (California Department of Boating and Waterways 2006) (Figure 3.13-3). This ferry carries approximately 400,000 people per year but does not carry vehicles (Arizona State Parks 2006). Lake Havasu will continue to be operated to meet monthly elevation targets; as such, the proposed federal action is not anticipated to affect the operation of the Lake Havasu ferry service.

Laughlin River Taxi and Tour Boat Crossing

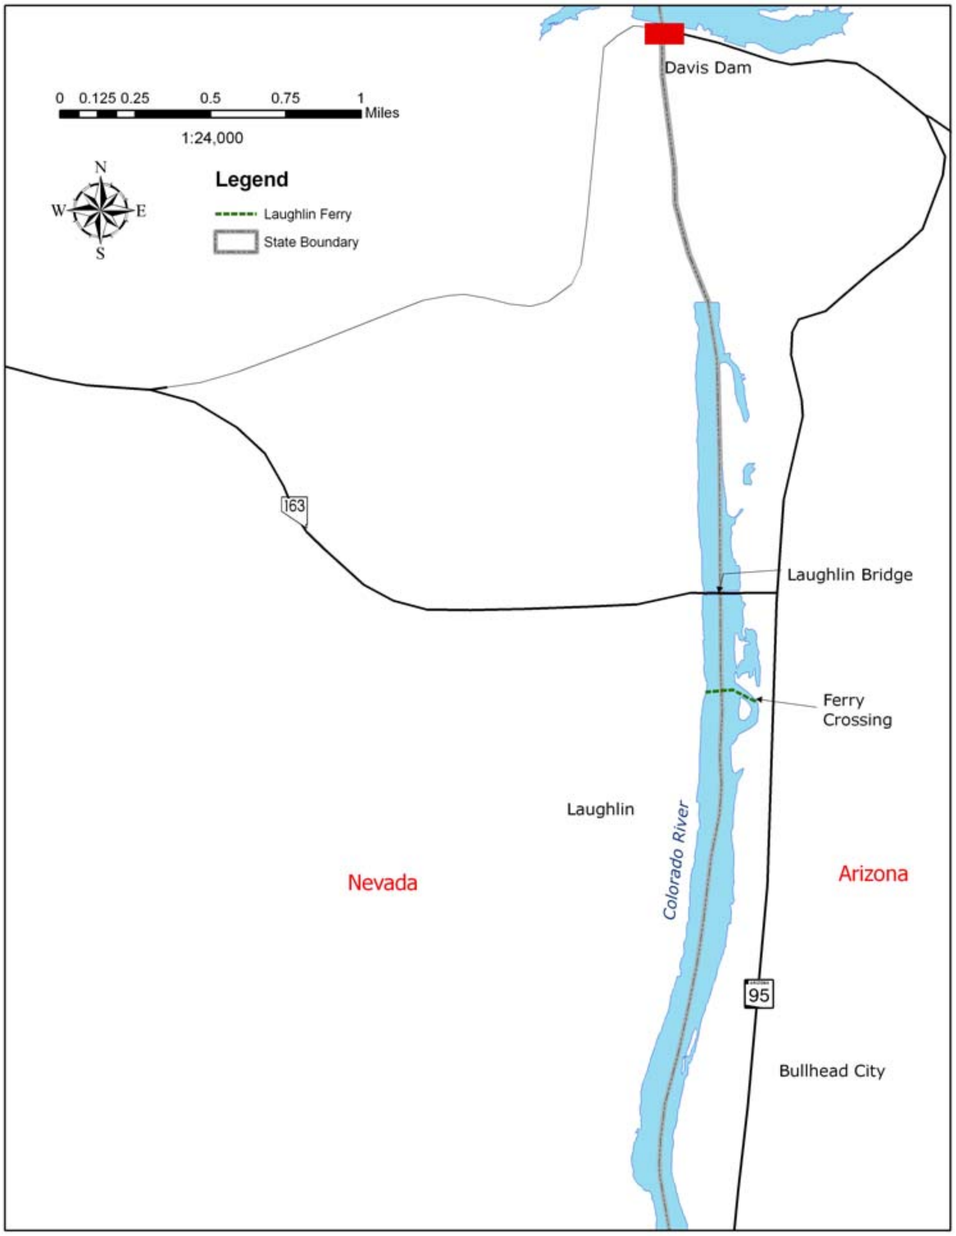

Figure 3.13-3
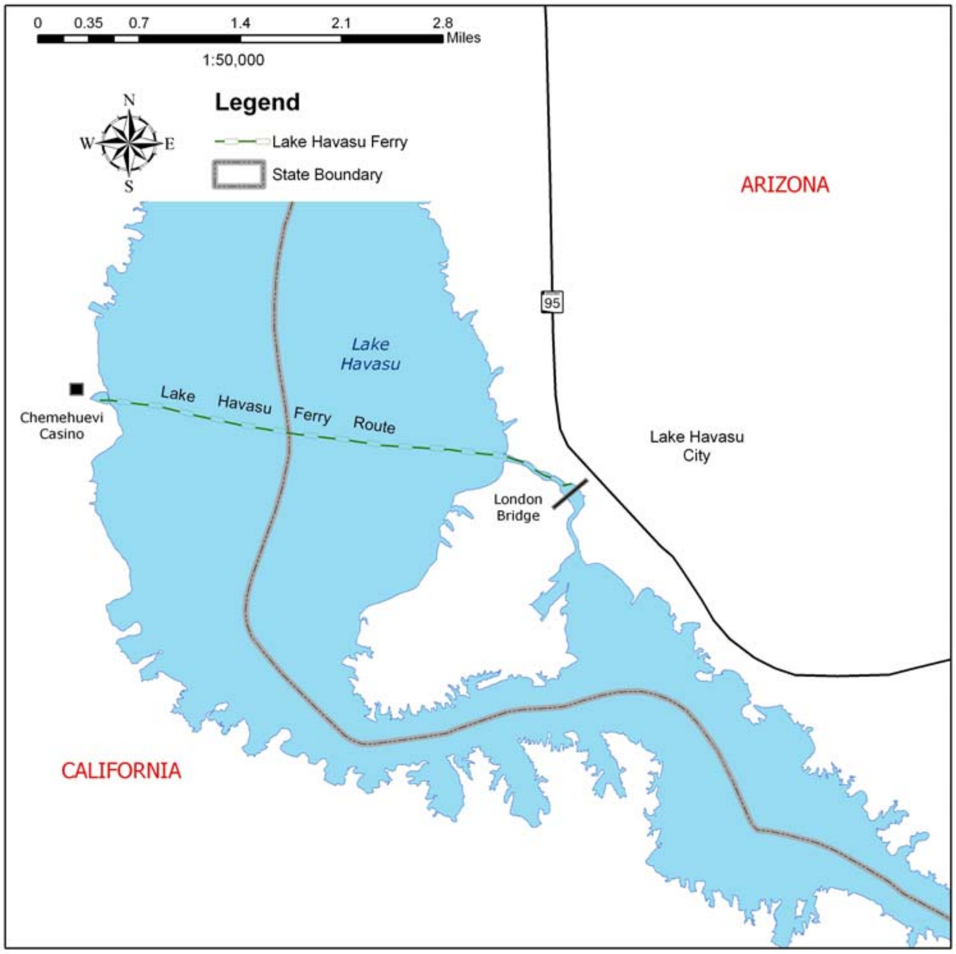
Lake Havasu Ferry Route



3.14 Socioeconomics

This section provides an overview of socioeconomic conditions within the states that could be affected by the proposed federal action. The potentially affected socioeconomic issues addressed in this section include:

- agricultural production and resulting changes in employment, income, and tax revenues;
- municipal and industrial uses and resulting changes in economic activity; and
- reservoir-related and river-related recreation activity and resulting changes in employment and income.

No long-term permanent changes in land uses are expected to be caused by the proposed federal action because only agricultural lands would be directly affected during a shortage and generally these lands would be fallowed and not permanently removed from production. In addition, the proposed federal action would not change apportionment or entitlements and changes in water deliveries would be temporary in nature. The proposed federal action will not result in permanent conversion of prime or unique farmlands pursuant to the Farmlands Protection Policy Act of 1978. Any changes in land uses are likely to be short-term and the proposed federal action would not result in or encourage the conversion of agricultural lands to other uses.

Information regarding the value of agricultural production was limited to the counties falling within the CAP service area and within Arizona along the mainstream of the Colorado River. Specific information regarding the value of agricultural production has not been included for California or Nevada. The value of agricultural production in Nevada is small relative to the sectors that drive the state and local economy. Agricultural production in California is not expected to be adversely affected because the potentially affected areas within California are almost all urbanized. Economic activity related to recreation is included in the information provided for Lake Powell, Lake Mead, and the Colorado River downstream of Lake Mead.

3.14.1 Study Area

The study area for the socioeconomics assessment was based on the states and counties in which a shortage may occur or in which changes in reservoir storage or river flow would result in a change in recreation opportunities or use. A county-level analysis was selected because information on employment and income is typically reported at the county level. The study area consists of counties in Arizona, California, Nevada, and Utah.

The Arizona study area is comprised of Coconino, La Paz, Mohave, Pima, Pinal, Yuma, and Maricopa counties. These counties were selected because they are either located directly adjacent to Lake Powell, Lake Mead, or the Colorado River, or they are counties in which shortages would likely occur. The counties in which measurable shortages could potentially occur, resulting in reduction in agricultural production or reduced municipal/industrial deliveries are Maricopa, Pinal, Pima, Mohave, La Paz, and Yuma. Although Coconino County would not experience a water shortage attributable to the proposed federal action, it is included in the study area because it is located adjacent to the Colorado River and may be affected by changes in recreation-related economic activity as a result of changes in river flows.

The California study area is comprised of Imperial, Los Angeles, Orange, Riverside, San Bernardino, and San Diego counties. These counties were selected because they are either located directly adjacent to the lower Colorado River, or they are within the MWD service area. Although Ventura County is also in MWD's service area, it does not receive any water from the Colorado River and therefore it is not included in the study area.

The Nevada study area is comprised of Clark County. The study area was limited to Clark County because it is located adjacent to Lake Mead and encompasses the service area of the SNWA. Shortages in Nevada would be limited to the SNWA service area.

The Utah study area is comprised of Garfield, Kane, and San Juan counties. Although Utah will not experience shortages under any of the alternatives, changes in storage at Lake Powell could result in changes in recreation-related expenditures made in these counties.

3.14.2 Water Use

This section provides an overview of the economic activity within Arizona, California, and Nevada that may be directly affected by water shortages occurring in the M&I and/or agricultural sectors.

3.14.2.1 State of Arizona

Agriculture. The total market value of agricultural production in Arizona was a little over $2.4 billion in 2002. The market value of agricultural production occurring within the Arizona study area accounted for nearly 90 percent of the statewide production value. In 2002, production values ranged from a low of approximately $16 million in Mohave County to a high of $802 million in Yuma County (USDA 2002).

Agricultural lands receiving water for irrigation from the CAP are located generally within Pinal, Maricopa, and Pima Counties. A list of irrigation districts and Indian communities receiving water from the CAP is provided in Appendix H.

The three counties account for approximately 53 percent of statewide irrigated and harvested cropland. These three counties also account for approximately 71 percent of Arizona's harvested cotton acreage, 18 percent of the state's vegetable crops, and approximately 48 percent of irrigated wheat cultivation (USDA 2004). Table 3.14-1 provides a summary of irrigated agricultural lands within these three counties.

Table 3.14-1
Central Arizona Irrigated Agricultural Lands in 2002

Area	Total Land in Irrigated Farms (acres)	Total Land Area (acres)	Land in Irrigated Farms as a Percentage of Total Land in 3-County Area
CAP Counties	829,957	15,205,760	5.5
Western Arizona Counties	536,152	14,928,438	3.6

Source: USDA 2004.

Agricultural resources in western Arizona are located in Mohave, La Paz, and Yuma Counties. Agricultural lands are located primarily along the Colorado River and in Yuma County along the Gila River Valley. A list of the potentially affected water agencies in these counties are provided in Appendix H.

These three western Arizona counties account for approximately 75 percent of the state's production of vegetable crops, 49 percent of irrigated wheat cultivation, and 38 percent of orchard lands (USDA 2004). Table 3.14-1 provides a summary of irrigated agricultural lands within these western Arizona counties.

Municipal and Industrial Uses. Municipalities potentially affected by the proposed federal action include the cities of Phoenix, Tucson, Scottsdale, and other Arizona towns and cities served by CAP, as well as Arizona municipalities along the Colorado River, such as Lake Havasu City, who have post-1968 Colorado River water delivery contracts. Industrial land uses located in Arizona on the Colorado River include the major power facilities of Glen Canyon Dam and Navajo Generating Station in Coconino County and Parker Dam in La Paz County (and San Bernardino County, California).

Employment. Full- and part-time employment in Arizona totaled 3,047,543 jobs in 2004, an increase of approximately 477,000 jobs from 1994 levels. Employment in the private sector represented nearly 85 percent of total employment in 2004 (United States Department of Commerce, Bureau of Economic Analysis 2006a). In 2004, employment in the arts, entertainment, and recreation sector totaled 59,022 jobs or approximately two percent of total employment in Arizona. Farm employment totaled 23,315 jobs in 2004 and accounted for less than one percent of total employment in the state.

Full- and part-time employment in La Paz, Mohave, Pima, Pinal, Maricopa, and Yuma Counties totaled 2,742,854 jobs in 2004, an increase of approximately 844,103 jobs from 1994. Total employment in the six counties represents approximately 89 percent of total employment in Arizona. Employment in the agricultural sector in the six counties totaled 17,170 jobs in 2004 and represented less than one percent of total employment in the six counties. (United States Department of Commerce, Bureau of Economic Analysis, 2006a).

Income. Total personal income in Arizona totaled just over $164.1 billion in 2004. This represents a substantial increase from the 1994 level of $81.5 billion. Statewide per capita income increased from approximately $19,000 in 1994 to approximately $29,000 in 2004 (United States Department of Commerce, Bureau of Economic Analysis, 2006b).

Among the six counties, average per capita income ranged from a low of approximately $19,815 per year in La Paz County to a high of $31,523 per year in Maricopa County. The total personal income generated in the six counties represents nearly 90 percent of the state total (United States Department of Commerce, Bureau of Economic Analysis 2006b).

3.14.2.2 State of California

The California study area is comprised of Imperial, Los Angeles, Orange, Riverside, San Bernardino, and San Diego Counties. These counties were identified because they are located within the service area of the MWD, which receives a portion of its water supply from the Colorado River.

Agriculture. Table 3.14-2 presents a summary of the amount of agricultural land present in the California counties served by the IID, the CVWD, the MWD, and the San Diego County Water Authority (SDCWA), and the percentage of land in the counties that is in agricultural use. These counties include Imperial, Los Angeles, Orange, Riverside, San Bernardino, and San Diego. The categories included in Table 3.14-3 are used by the California Department of Conservation and are based on the Important Farmland maps for California. These maps are compiled from United States Department of Agriculture (USDA) Natural Resources Conservation Service soil surveys and current land use information.

Table 3.14-2
Southern California Agricultural Land in the Six-County Study Area in 2004

Important Farmland in the Six-County area[1] (acres)	Grazing Land in the Six-County Area (acres)	Total Agricultural Land in the Six-County Area[2] (acres)	Total Six-County Area (acres)	Agricultural Land as a Percentage of Total Land in the Six-County Area (percent)
1,315,048	1,403,602	2,718,650	26,160,439	10.4

Source: California Department of Conservation 2004.

Notes:

1. *Important Farmland includes Prime Farmland, Farmland of Statewide Importance, Unique Farmland and Farmland of Local Importance.*
2. *This category includes both Important Farmland and Grazing Land.*
3. *Counties are Imperial, Los Angeles, Orange, Riverside, San Bernardino, and San Diego.*

Municipal and Industrial. Municipalities potentially affected by the proposed federal action include some 88 cities in Los Angeles County, 34 cities in Orange County, 24 cities in Riverside County, 31 cities in San Bernardino County, and 18 cities in San Diego County.

Employment. Full- and part-time employment in California totaled 20 million jobs in 2004, an increase of approximately 3.5 million jobs from 1994 levels. Employment in the private sector represented nearly 85 percent of total employment in 2004 (United States Department of Commerce, Bureau of Economic Analysis 2006c).

Full- and part-time employment in the six county study area totaled 11 million jobs in 2004, representing 55 percent of total California employment. Full- and part-time employment in the government sector was higher than the California average (13 percent) in four counties (Imperial, 24 percent; Riverside, 14 percent; San Diego, 18 percent; and San Bernardino, 15 percent) and lower in two counties (Los Angeles, 11 percent; and Orange, eight percent) (United States Department of Commerce, Bureau of Economic Analysis, 2006c).

Income. Total personal income in California totaled just over $1.2 trillion in 2004. This represents a substantial increase of $497 billion from 1994. Statewide per capita income increased from approximately $23,000 in 1994 to approximately $35,000 in 2004 (United States Department of Commerce, Bureau of Economic Analysis, 2006d).

In 2004, total personal income ranged from a low of approximately $3.3 billion in Imperial County to a high of $329 billion in Los Angeles County. When combined, the total personal income of the six counties represents 44 percent of the state total. Per capita income ranged from a low of approximately $22,000 in Imperial County to a high of approximately $42,000 in Orange County (United States Department of Commerce, Bureau of Economic Analysis 2006d).

3.14.2.3 State of Nevada

The potentially affected area within Nevada is Clark County, which is adjacent to the Colorado River.

Agriculture. Agricultural production in Clark County is very small compared to other farming areas in the study area. Table 3.14-3 provides a summary of agricultural land in this county. A small proportion of this land is used for cropland, most of which is irrigated. Cropland is used primarily for producing forage crops. Livestock and poultry are also produced in Clark County.

Table 3.14-3
Southern Nevada (Clark County) Agricultural Land in 2002

Total Land in Irrigated Farms (acres)	Total County Land (acres)	Land in Irrigated Farms as a Percentage of Total County Land (percent)
65,206	5,062,614	1.3

Source: USDA 2002.

Municipal and Industrial Uses. Municipalities potentially affected by the proposed federal action include Boulder City, Henderson, Las Vegas, and North Las Vegas due to their reliance on Colorado River water supplied by SNWA. These municipalities support urban, commercial, and industrial land uses that could be potentially affected by the proposed federal action.

Employment. Full- and part-time employment in Nevada totaled 1,430,370 jobs in 2004, an increase of approximately 521,000 jobs from 1994 levels. Employment in the private sector represented nearly 89 percent of total employment in 2004 (United States. Department of Commerce, Bureau of Economic Analysis 2006e). In 2004, employment in the arts, entertainment, and recreation sector totaled 46,137 jobs or approximately three percent of total employment in the state. Employment in the accommodations and food service sector totaled 293,157 jobs. This is the largest employment sector in Nevada, accounting for approximately 24 percent of total employment.

Full- and part-time employment in Clark County totaled 998,000 jobs in 2004, an increase of approximately 422,000 jobs from 1994. Total employment in Clark County represents almost 70 percent of total employment in Nevada. Full- and part-time employment in the Clark County government sector was lower than the Nevada average (United States Department of Commerce, Bureau of Economic Analysis 2006e). In 2004, employment in the arts, entertainment, and recreation sector totaled 30,391 jobs or approximately three percent of total employment in the county. Similar to statewide totals, the accommodations and food service sector was the largest employment sector in the county, totaling 235,632 jobs in 2004.

Income. Total personal income in Nevada totaled just over $78 billion in 2004. This represents a substantial increase from the 1994 level of $43 billion. Statewide per capita income increased from approximately $23,800 in 1994 to approximately $33,800 in 2004 (United States. Department of Commerce, Bureau of Economic Analysis 2006f).

In 2004, per capita income in Clark County was $32,900, slightly lower than the state average. The total personal income of Clark County represents more than 69 percent of the state total (United States Department of Commerce, Bureau of Economic Analysis 2006f).

3.14.3 Recreation

Economic benefits result when visitors spend dollars locally on recreational activities. Those benefits include increased sales, income, and jobs. Direct economic benefits occur when businesses sell goods and services to park visitors. Indirect economic benefits result from the circulation of spending throughout the local economy.

This section describes the direct and indirect economic value of recreation occurring in the GCNRA and the LMNRA. The NPS maintains a database of recreational visits and the economic impacts of those visits. That information is summarized here for Lake Powell and Lake Mead. Lake Mohave is included within the LMNRA. Consequently, the visitor spending associated with Lake Mohave is included as part of the LMNRA discussion further below. A discussion of recreation-related economic activity occurring on the Colorado River downstream of Lake Powell and Lake Mead was not included because no change in recreation activities and resulting change in economic activity is expected under the proposed federal action.

3.14.3.1 Glen Canyon National Recreation Area

GCNRA hosted 1.88 million recreational visits in 2003. (Section 4.12 provides additional information on recreation use occurring within the GCNRA.) Table 3.14-4 summarizes the direct and indirect effects of visitor spending at the GCNRA by sectors. Direct recreation-related expenditures totaled $86.09 million in 2003 resulting in 2,119 jobs and $31.76 million in personal income. As direct spending circulates through the local economy, secondary or indirect economic effects occur. This spending created an additional $14.11 million in personal income and 548 jobs.

Table 3.14-4
Glen Canyon National Recreation Area Economic Impacts of Visitor Spending by Sector for 2003

Sectors	Sales (millions)	Personal Incomes (millions)	Jobs	Value Added (millions)
Direct Effects				
Motel, Hotel, B&B, and Cabins	$16.36	$5.34	356	$8.11
Campsites	$13.21	$4.31	288	$6.55
Restaurants & Bars	$20.65	$7.03	590	$9.80

3.14.3.2 Lake Mead National Recreation Area

LMNRA (Lake Mead and Lake Mohave) hosted 7.92 million recreational visits in 2003. Table 3.14-5 summarizes the direct and indirect effects of visitor spending at the LMNRA by sectors. Direct recreation-related expenditures totaled $176.82 million in 2003 resulting in 5,197 jobs and $63.15 million in personal income. This direct spending created an additional 856 jobs and $18.73 million in personal income.

Table 3.14-5
Lake Mead National Recreation Area Economic Impacts of Visitor Spending by Sector for 2003

Sectors	Sales (millions)	Personal Incomes (millions)	Jobs	Value Added (millions)
Direct Effects				
Motel, Hotel, B&B, and Cabins	$27.08	$7.86	693	$11.95

3.15 Environmental Justice

Environmental justice refers to the fair treatment and meaningful involvement of all people in the development, implementation and enforcement of environmental laws, regulations and policies.

- *Fair treatment* means that no group of people, including minority and low-income populations, should bear a disproportionate share of the adverse environmental impacts of government actions.
- *Meaningful involvement* means that people who would be adversely affected by the environmental impacts of government actions should have the opportunity to participate in decisions leading up to those actions and have their views considered.

Exec. Order No. 12898, Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations, requires that all federal agencies make achieving environmental justice part of their mission by identifying and addressing, as appropriate, disproportionately high and adverse human health or environmental effects of their programs, policies, and activities on minority populations and low-income populations. Census data were used to identify the minority and low-income populations living in counties that could potentially be affected by the proposed federal action.

The affected area for environmental justice is comprised of 18 counties; eight in Arizona (Coconino, La Paz, Maricopa, Mohave, Pima, Pinal, Yavapai, and Yuma), and six counties in California (Imperial, Los Angeles, Orange, Riverside, San Bernardino, and San Diego), one county in Nevada (Clark), and three counties in Utah (Garfield, Kane, and San Juan). Ventura County in California is located within the MWD service area, but does not receive any water from the Colorado River, and therefore, it is not addressed in this section.

3.15.1 Minority, Low-Income Populations, and Indian Tribes

For purposes of this analysis, minority populations and low-income populations are defined following the CEQ’s (1997) guidance as:

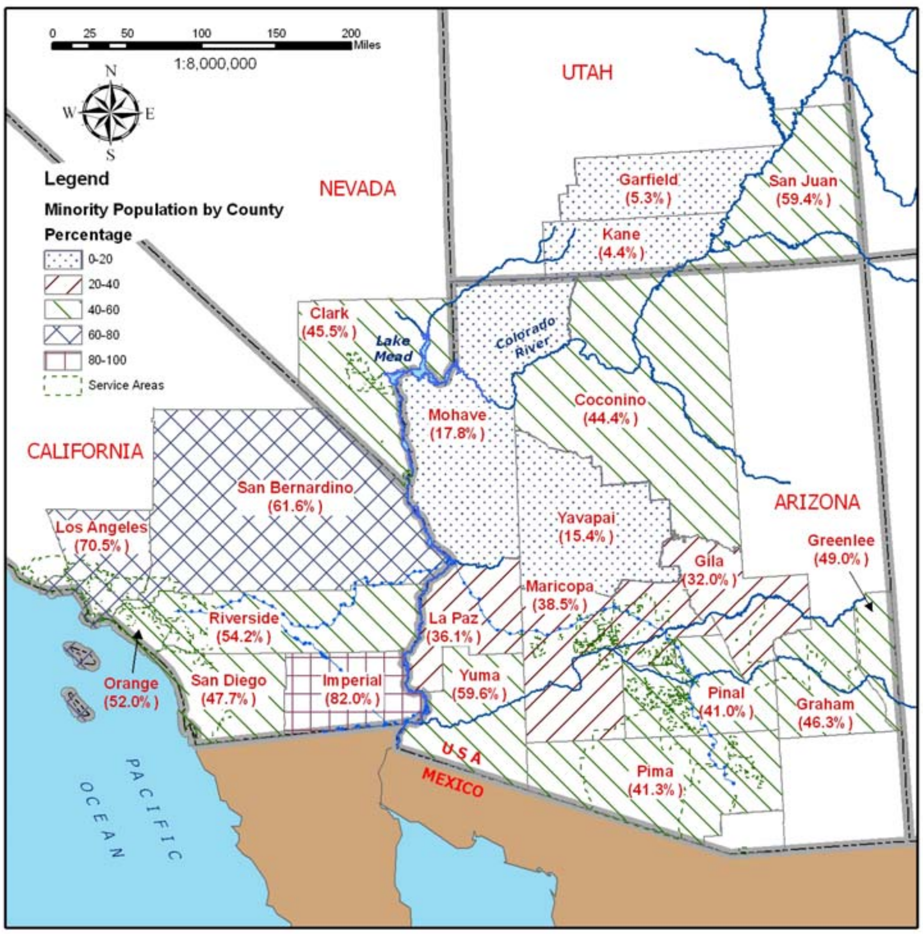
- *Minorities* – Persons of American Indian or Alaska Native; Asian or Pacific Islander; Black, not of Hispanic origin; Hispanic; or persons of two or more races (without double-counting persons of Hispanic or Latino origin who are also contained in the latter groups); and
- *Low-income populations* – As reported in the 2000 census, persons living below the poverty level, which is $19,307 for a family of four in 1999 and varies depending on family size (United States Census Bureau 2000b).

Identification of minority and low-income populations was based on the 2000 Census of Population and Housing, which estimates each of the separate categories contained in these definitions. Minority populations were estimated using 2000 Census data that report Hispanic or Latino populations by race, and, separately, populations not Hispanic or Latino by race

(United States Census Bureau 2000a). Low-income populations were estimated using the 2000 Census data that report poverty status in 1999 by age (United States Census Bureau 2000b). The population for whom poverty status is determined is generally slightly less than the total population because the 2000 Census data excludes certain groups from consideration.

Minority populations are identified where minorities of the affected area [county] exceed fifty percent of the total population. In 2000 seven of the 18 counties have a minority population percentage greater than 50 percent: Yuma County, Arizona; Imperial County, Los Angeles County, Orange County, Riverside, and San Bernardino County, California; and San Juan County, Utah; with Imperial County the highest at 82 percent. In the remaining 11 counties, minorities comprise less than 50 percent of the population and therefore, these counties are not considered environmental justice communities. Minority population percentages for various counties in Arizona, California, Nevada, and Utah are displayed in Figure 3.15-1.

Figure 3.15-1
Minority Population by County



Indians tribes are included within these census data. Following CEQ's 1997 guidance on environmental justice, as well as Exec. Order No. 13175 and the Presidential Memorandum on Government-to-Government Relations with Native American Tribal Governments, Reclamation sought input from 42 federally-recognized tribes including those with reservations located within these counties and from tribes that might have interests in the proposed federal action. A description of the consultations undertaken for this project is included in Chapter 6 of this Final EIS.

In 2000, the percent poverty for the 18 counties is between 9.3 and 25.5 percent, with San Juan County, Utah having the highest percentage. For the environmental justice analysis, low income counties were defined as those above the average poverty percentage for the 18 counties (14.8 percent) in the study area. Low income population percentages for various counties in Arizona, California, Nevada, and Utah are displayed in Figure 3.15-2. As a result five counties were added in Arizona: Coconino, La Paz, Mohave, Pinal, and Pima (five of the minority counties were also low-income).

Therefore, for purposes of this analysis, there are twelve total environmental justice counties/communities.

Chapter Four

4.1 Introduction

Chapter 4 presents the probable consequences (impacts or effects) of each of the alternatives described in Chapter 2 on the environmental resources described in Chapter 3. The potential effects of each action alternative compared to the No Action Alternative are presented for each potentially affected resource in this chapter, in the same order as described in Chapter 3.

The methodology and technical assumptions used to analyze the potential impacts to the Colorado River system (e.g., reservoir elevations, releases, flows) are described in Section 4.2. Additional methodologies and assumptions used to analyze specific resources are described in the appropriate resource section of Chapter 4.

This page intentionally left blank.

4.2 Methodology

Hydrologic modeling of the Colorado River system was conducted to determine the potential hydrologic effects of the alternatives. The hydrologic modeling provided projections of potential future Colorado River system conditions (e.g., reservoir elevations, reservoir releases, river flows) under the No Action Alternative for comparison to conditions under each action alternative. Due to uncertainties associated with future inflows into the system, multiple simulations were performed for each alternative in order to quantify the uncertainties in future conditions, and the modeling results are typically expressed in probabilistic terms.

Hydrologic modeling also provided the basis for analyzing potential effects of each alternative on other environmental resources such as recreation, biology, energy, etc. The potential effects to specific resource issues are identified and analyzed for each action alternative and compared to the potential effects to that resource issue under the No Action Alternative. These comparisons are typically expressed in terms of the incremental differences in probabilities (or projected circumstances associated with a given probability) between the No Action Alternative and the action alternatives.

This section provides an overview of the hydrologic modeling used and the framework within which the many simulations were undertaken. Further details regarding the model and modeling assumptions are also provided in Appendix A and Appendix M. For some of the resource analyses, additional modeling using other techniques was needed to analyze the potential effects to particular resource issues. In most of these cases, the output from the hydrologic modeling was used as input to these other models. The methodologies used for the additional modeling are described in each respective resource section of Chapter 4.

4.2.1 Alternatives Modeled

Five action alternatives and a No Action Alternative are considered in this Final EIS. The action alternatives are the Basin States, Conservation Before Shortage, Water Supply, and Reservoir Storage alternatives, and the Preferred Alternative. Each alternative includes specific assumptions with regard to the four operational elements of the proposed federal action: Shortage Guidelines, Coordinated Reservoir Operations, Storage and Delivery of Conserved Water, and ISG. Additional details with respect to the modeling assumptions used to represent each alternative are presented in this section, Appendix A, and Appendix M.

4.2.2 Period of Analysis

This Final EIS addresses guidelines that would be in effect for the interim period (2008 through 2026) for Lower Basin reservoir operations and the coordinated operations of Lake Powell and Lake Mead. In the modeling of the alternatives, all action alternatives are assumed to revert back to the assumptions used to represent the No Action Alternative beginning in 2027. Due to the potential for hydrologic effects of the action alternatives beyond the 19-year interim period, the hydrologic modeling for all alternatives extends through 2060.

4.2.3 Model Description

Future Colorado River system conditions under the No Action Alternative and the action alternatives were simulated using the Colorado River Simulation System (CRSS). The model framework used for this process is a commercial river modeling software called RiverWare™; a generalized river basin modeling software package developed by the University of Colorado through a cooperative arrangement with Reclamation and the Tennessee Valley Authority. CRSS was originally developed by Reclamation in the early 1970s and was implemented in RiverWare™ in 1996.

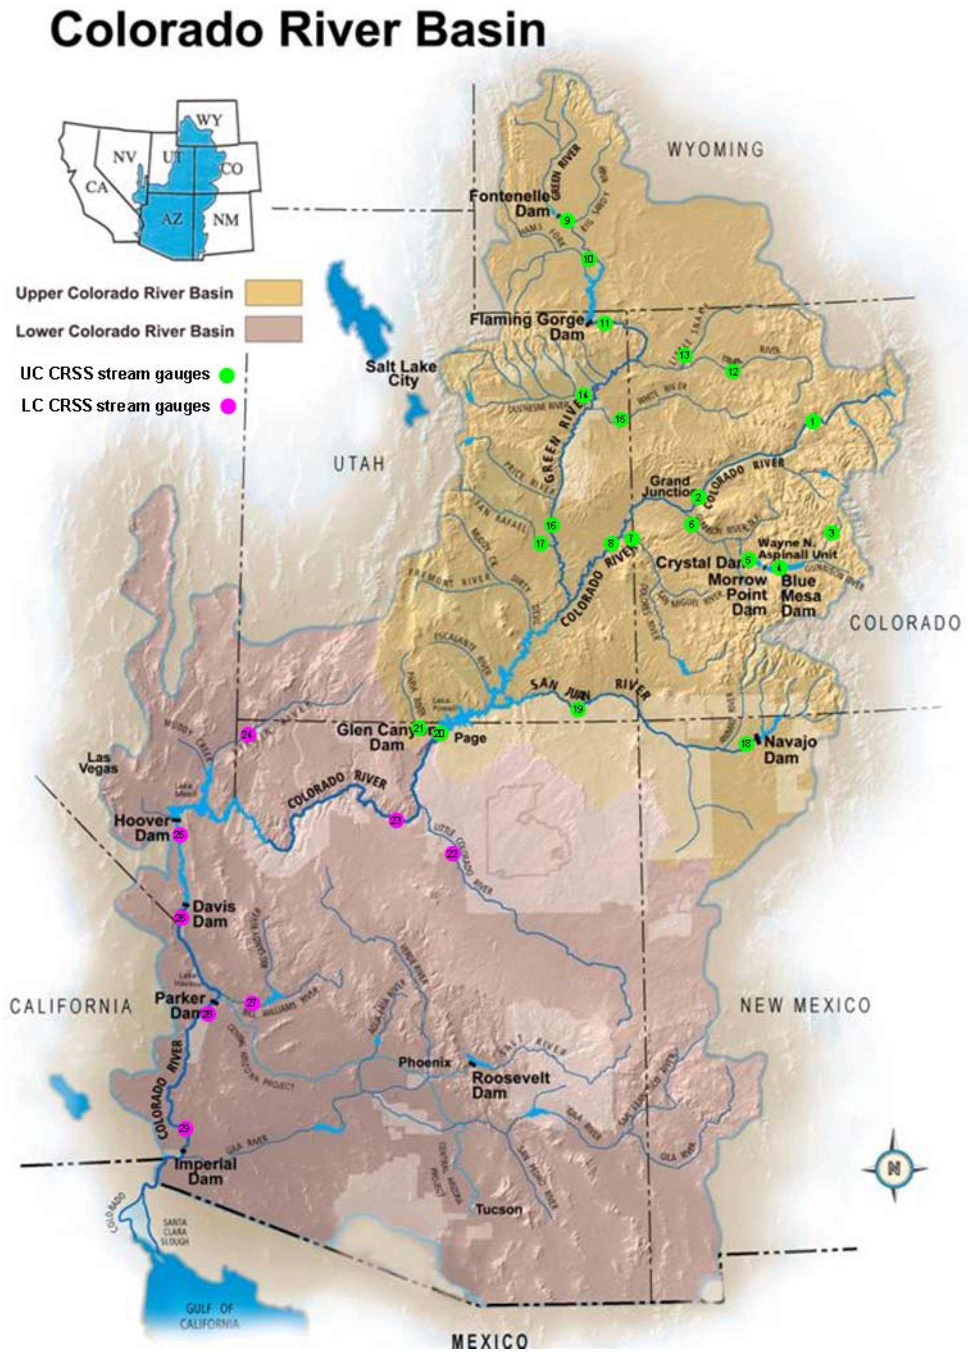
CRSS simulates the operation of the major reservoirs on the Colorado River and provides information regarding the projected future state of the system on a monthly basis in terms of output variables including the amount of water in storage, reservoir elevations, releases from the dams, the amount of water flowing at various points throughout the system, and the diversions to and return flows from the water users throughout the system. The basis of the simulation is a mass balance (or water budget) calculation that accounts for water entering the system, water leaving the system (e.g., from consumptive use of water, trans-basin diversions, evaporation), and water moving through the system (i.e., either stored in reservoirs or flowing in river reaches). Further explanation of the model is provided in Appendix A. The model was used to project the future conditions of the Colorado River system on a monthly time-step for the period 2008 through 2060.

The input data for the model includes monthly natural inflows, various physical process parameters such as the evaporation rates for each reservoir, initial reservoir conditions on January 1, 2008, and the future diversion and depletion schedules for entities in the Basin States (Appendix C and Appendix D) and for Mexico. These future schedules were based on demand and depletion projections prepared and submitted by the Basin States. For purposes of this EIS, depletions (or water use) are defined as diversions from the river less return flow credits, where applicable (Section 3.4).

The rules of operation of the Colorado River mainstream reservoirs including Lake Powell and Lake Mead for each alternative are also provided as input to the model. These sets of operating rules describe how water is released and delivered under various hydrologic conditions. Further explanation of the operating rules for each alternative is provided in Appendix A.

The future hydrology used as input to the model consisted of samples taken from the historic record of natural flow in the river system over the 100-year period from 1906 through 2005 from 29 individual inflow points (or nodes) on the system. The locations of the hydrologic input sites are shown in Figure 4.2-1. This model and other methodologies used to generate future inflow scenarios are discussed in Section 4.2.5.

Figure 4.2-1
Colorado River Simulation System
Location of Hydrologic Inputs Sites within the Colorado River Basin



4.2.4 Model Uncertainty

Long-term planning models such as CRSS are typically used to project future river and reservoir conditions over a period of decades into the future. There are numerous inputs to, and assumptions made by, these models. As the period of analysis increases (for this EIS the analysis period is 53 years), the uncertainty in those inputs and assumptions also increases. Therefore, a large amount of uncertainty in the corresponding outputs is expected. Consequently, these models are not used to predict future conditions, but rather to project what might occur. When analyzing the potential hydrologic impacts from operational alternatives, most inputs, as well as other key modeling assumptions, are held constant for each alternative so as to isolate the differences due to each alternative. In this manner, the analyses for each alternative may be compared, and thus a relative comparison between alternatives can be made.

Although there are literally hundreds of inputs to and assumptions made by CRSS, the uncertainty of some will have greater effects on the outputs than others. Another way of thinking about this is to ask “what is the sensitivity of the output to a particular set of inputs or assumptions?” This question may be answered by conducting a sensitivity analysis whereby only one or perhaps a small number of inputs are varied in order to determine how sensitive the outputs are to that change. For example, in this Final EIS, two sensitivity analyses were performed that examine the sensitivity to variable future hydrologic scenarios (Appendix N) and to modeling assumptions with regard to future water delivery reductions to Mexico (Appendix Q).

There are several sources of uncertainty in the CRSS output including the representation and parameterization of physical processes such as reservoir evaporation and bank storage, the future diversion and depletion schedules for the entities throughout the Colorado River Basin, and the future inflows into the system. In addition, much of the input data are derived from actual measurements which have uncertainties associated with them. For example, the natural flows are based primarily on data acquired from flow gages which, when calibrated properly, have uncertainties on the order of five to ten percent. Although these data are generally the best available, all of these uncertainties limit the absolute accuracy of the model However, by holding most inputs constant, the relative comparisons between the modeled conditions are still valid.

Despite the differences in some of the modeling assumptions under the No Action Alternative and each action alternative, the future conditions of the Colorado River system (e.g., future Lake Mead and Lake Powell elevations) are most sensitive to future inflows. Observations over the period of historical record (1906 through present) show that inflow into the system has been highly variable from year to year, and over decades (Section 3.3). Because it is impossible to predict the actual future inflows into the system, a range of possible future inflows are analyzed and used to quantify the probability of occurrences of particular events (e.g., higher or lower lake elevations). This technique involves multiple simulations for each alternative, one for each future hydrologic sequence, and is the procedure followed for the hydrologic analysis in this EIS.

4.2.5 Future Hydrology

There are several accepted scientific methods for projecting possible future inflow sequences. These methods include resampling the historical record (either from the measured record or a derived record using a "proxy" such as tree-ring data), deriving future inflow data by preserving key statistics of the historical record while adding a random component, and using physically-based models to simulate runoff using precipitation, temperature, and other climate data. For this EIS, Reclamation primarily utilized the existing historical record of natural flows to create a number of different future hydrologic sequences using a resampling technique known as the Indexed Sequential Method (ISM). The ISM provides the basis for quantification of the uncertainty and an assessment of the risk with respect to future inflows and is based upon the best available measured data. ISM is well-documented and has been widely accepted by Colorado River stakeholders (Reclamation 1985; Ouarda et al. 1997). These sequences were used to perform a series of simulations and the output was analyzed to quantify the uncertainty due to hydrologic variability for each variable of interest.

4.2.5.1 Computational Procedures Using the Historical Natural Flow Record

In its current configuration, the CRSS model requires hydrologic inputs at 29 sites throughout the Colorado River system: 20 sites in the Upper Basin upstream of and including the Lees Ferry gaging station in Arizona, and an additional nine sites in the Lower Basin. The locations of these 29 sites are shown in Figure 4.2-1. This level of hydrologic detail is needed to simulate the operation of the major reservoirs throughout the system including the reservoirs on the major sub-basins (the Gunnison, Green, and San Juan rivers)[1].

Reclamation uses data collected from the USGS and other gage sites[2], consumptive use records, records of reservoir releases, and other data to compute the natural flow at each of the 29 sites. In the mid-1990s, Reclamation initiated an on-going program to review and update the natural flow record, document the methodologies used to compute the natural flows, and extend the record as soon as practicable at the conclusion of each year to ensure that the best available information is always available. At this time, the natural flow record consists of monthly data for the 29 sites from 1906 through 2005, a period of 100 years. Additional information, documentation, and the natural flow data are available at http://www.usbr.gov/lc/region/g4000/NaturalFlow/index.html.

For the ISM, each future inflow scenario is generated by cycling through the historical natural flow record. For example, assuming a 100-year historical record (1906 through 2005) and that the model projects 53 years into the future (2008 through 2060), the

---

[1] Although these sub-basins are not a part of the geographic scope (Section 3.2), modeling of the reservoirs (e.g., Flaming Gorge) is necessary to simulate the future inflows into Lake Powell.

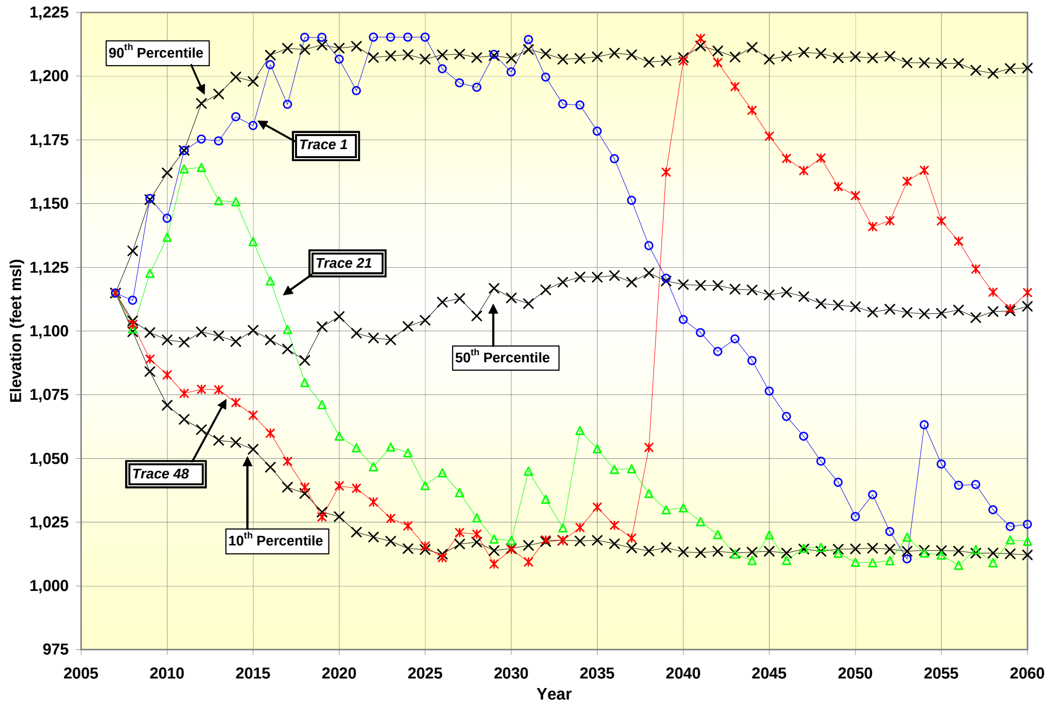
[2] Reclamation provides funding to the USGS to assist in maintaining and expanding, as appropriate, gage sites throughout the Colorado River Basin. Reclamation also installs, maintains, and operates additional gage sites in the Lower Basin.

first inflow sequence would be comprised of the series of historical natural flows from 1906 through 1958; the second inflow sequence would utilize the series of historical natural flows from 1907 through 1959; the last sequence would utilize the series of historical natural flows beginning in 2005, with historical natural flows from 1906 through 1957 appended to the end to form a complete (53-year) sequence.

The result of the ISM applied to the historical record is a set of output (referred to as traces) for 100 separate simulations for each alternative that is analyzed and compared to similar simulation results for the other alternatives. The projections of future hydrologic conditions are probabilistic, based on the hydrologic variability observed in the 100-year historic record which includes periods of severe drought as well as periods with above-average flow.

Figure 4.2-2 presents an example of the output of this technique for future Lake Mead elevations under the No Action Alternative. Three of the 100 traces are shown. Trace 1 is the output for the hydrologic sequence that begins in 1906. Trace 21 is the output for the hydrologic sequence that begins in 1926. Trace 48 is the output for the hydrologic sequence that begins in 1953. Hydrologic inflows over the 100-year record have been highly variable and these traces are representative of that variability. The traces clearly illustrate that future elevations at Lake Mead are highly dependent upon future hydrologic inflows, resulting in large uncertainty with regard to projections of future conditions. This uncertainty may be quantified, however, through the analysis of the 100 traces. An example of one type of analysis is also presented in Figure 4.2-2, where the 90th, 50th, and 10th percentiles of the 100 outputs in each year have been computed and added to the figure.

Figure 4.2-2
Lake Mead End-of-December Elevations Under the No Action Alternative
90th, 50th and 10th Percentile Values



4.2.5.2 Reclamation's Research and Development Efforts

Although the ISM methodology provides the means to compare the alternatives under a wide range of future flow conditions, it is possible that future flows may include periods of wet or dry conditions that are outside the range of sequences observed in the historical record, particularly as a result of climate change and increased hydrologic variability.

The Fourth Assessment Report of the Intergovernmental Panel on Climate Change (IPCC), published in April 2007, presented a selection of key findings regarding projected changes in precipitation and other climate variables as a result of a range of climate change scenarios projected by the IPCC over the next century. Although annual average river runoff and water availability are projected to decrease by ten to 30 percent over some dry regions at mid-latitudes, information with regard to potential impacts on specific river basins is not included. Recently published projections of potential reductions in natural flow on the Colorado River Basin by the mid 21st century range from approximately 45 percent by Hoerling and Eischeid (2006), to approximately six percent by Christensen and Lettenmaier (2006). A recent analysis of future precipitation minus evaporation (a surrogate for runoff) in the basin suggests an "imminent transition to a more arid climate in southwestern North America" (Seager et al. 2007).

While these projections are of great interest, additional research is both needed and warranted to quantify the uncertainty of these estimates in order to better understand the risks of current and future water resource management decisions. The uncertainties include the actual uncertainty in the climate response as well as the uncertainty due to differences in methodological approaches and model biases.

Recognizing this need, particularly in light of the drought in the Colorado River Basin, Reclamation's Lower Colorado (LC) Region initiated a multi-faceted research and development program in 2004 to enable the use of other methods for projecting possible future inflow sequences for Colorado River planning studies. The research and development effort has been designed to provide information for the near-term (e.g., some facets have already been completed and the information has been used in the Final EIS), as well as for the longer-term that involves collaboration with other research organizations (e.g., National Oceanic & Atmospheric Administration (NOAA) and USGS). This effort has two major thrusts:

- ♦ collaboration with other federal agencies and universities to conduct research to gain knowledge and understanding of the potential impacts of climate change and climate variability on the Colorado River; and
- ♦ improvement of Reclamation's decision support framework, including modeling and data handling capabilities, in order to utilize the new information when it becomes available.

Contributions from this research and development program have been invaluable in advising the analysis and content in the Final EIS to address future hydrologic variability and the potential for increased hydrologic variability due to climate change. These and other efforts will continue and will provide Reclamation the ability to incorporate new additional climate change information, as it becomes available, into future Colorado River Basin planning studies.

At this time, there are five key components to the research and development program:

1) Sponsorship of National Research Council's (NRC) Committee on the Scientific Bases of Colorado River Basin Water Management in collaboration with the California Department of Water Resources, the MWD, the SNWA, and the NRC's Water Science and Technology Board.

   This study culminated in a report published in early 2007, titled "Colorado River Basin Water Management: Evaluating and Adjusting to Hydroclimatic Variability." The executive summary of this report is included as Appendix T. Key conclusions and recommendations in the area of hydroclimatic data and sciences included:

   – There has been a trend of increasing mean temperatures across the Colorado River Basin over the 20th century into the 21st century. Many climate model projections show that this trend will continue. There is less consensus regarding future trends in precipitation and runoff. Several hydroclimatic studies project that increasing temperatures will result in significant decreases in precipitation and runoff while other studies suggest increases in future flows. However, the preponderance of the scientific evidence suggests warmer future temperatures will reduce future streamflow and water supplies and contribute to increased severity, frequency, and duration of future droughts.

– Recent studies based on tree-ring data affirm the large year-to-year variations in streamflow as observed in the historical record and demonstrate that multidecadal and centennial fluctuations of mean streamflow have occurred in the past. Given both natural and human-induced climate changes, fluctuations in the mean streamflow are likely to continue in the future. Furthermore, the range of natural variability derived from the tree-ring records reveals greater hydrologic variability than reflected in the gaged record, particularly with regard to drought. These observations coupled with projections of future decreasing streamflows suggest that future droughts will recur and may exceed the severity of the droughts observed in the historical record.

– Measured values of streamflow in the Colorado River Basin are critical to providing the essential information for sound water management decisions. Availability of sufficient resources should be ensured in order to maintain and where appropriate, expand the USGS gaging network.

2) Collaboration with the University of Arizona, the Arizona Water Institute, the Arizona Water Resources Research Center, and the Laboratory of Tree Ring Research on a project focused on integrating improved water supply predictive capability into Colorado River Basin policy and management to enhance water supply reliability.

Reclamation has been participating in this collaborative effort since its inception in July 2004 and the project is anticipated to be concluded in 2008. It is a multi-pronged approach that includes:

– assessing the potential for enhanced modeling capability associated with use of paleoclimatic data, climate forecasts and climate change predictions, and the water management tools that need to be developed to use that information;

– identifying strategies to better utilize paleoclimatology, climate forecasts and climate change predictions to improve water supply predictive capacity;

– evaluating existing management tools to translate improved predictive capacity into enhanced supply reliability for water users; and

– developing practical supply reliability strategies for use by water users and other stakeholders.

A significant aspect of this research involves the evaluation of the potential use of enhanced tree-ring information to improve predictive capability on the Colorado River. An important contribution has been an extension of the long-term record of flows on the Colorado River at Lees Ferry back to 762 A.D., adding to the understanding of historic climate and flow patterns and improving Reclamation’s capability to quantify the uncertainty of future hydrologic conditions. In addition, existing tree-ring information was synthesized using published tree-ring reconstructions (Stockton and Jacoby 1976; Hidalgo et al. 2000). These studies resulted in two key publications: i) Medieval Drought in the Upper Colorado River Basin (Meko et al. 2007); and ii) Updated Streamflow Reconstructions for the Upper Colorado River Basin (Woodhouse et al. 2006).

The tree-ring data resulting from this work has been used to analyze the sensitivity of the hydrologic resources to alternative future hydrologic scenarios (Appendix N).

Ongoing work includes the assessment of techniques for including additional climate prediction information, including the use of downscaled and bias-corrected climate predictions to generate alternative hydrologic scenarios at the spatial scales needed for CRSS. Additional information with regard to this work available at http://www.ag.arizona.edu/AZWATER/EWSR.

3) Collaboration with the University of Colorado and the Center for Advanced Decision Support for Water and Environmental Systems (CADSWES) on a project focused on assessing the current drought on the Colorado River in terms of its magnitude and likelihood of recurrence and investigative techniques that can be used to simulate streamflow scenarios that are consistent with the current drought and other realistic, and possible more severe, future drought conditions.

   Reclamation began this on-going collaboration effort in the fall of 2004. The major activities include:

   - Research and development of non-parametric methods for the disaggregation of streamflows at one site, both temporally and spatially, to other sites on the Colorado River Basin. This allows for the use of projections of future inflow at Lees Ferry (e.g., from tree-ring reconstructions) in CRSS.

   - Estimating and analyzing (particularly with regard to the temporal variability) the transition probabilities (i.e. probability of transitioning into a dry state in the following year from a wet state in the current year) from long records of tree-ring reconstructions of streamflows.

   - Generating new synthetic sequences of the state of the system (i.e., wet or dry) and consequently, the probabilities of long dry spells using the transitional probabilities. Conditioned on the state of the system, the flow magnitudes can be generated by conditional resampling from the historical record.

   Future work will include investigation of possible links between the historical transition probabilities and large-scale climate features of El Niño Southern Oscillation (ENSO), Pacific Decadal Oscillation (PDO), and the Atlantic Multidecadal Oscillation (AMO). Such links might provide a technique to condition future inflow sequences on information from climate models regarding these large-scale features.

The key findings and results of this research have been recently published: A Stochastic Nonparametric Technique for Space-time Disaggregation of Streamflows, Prairie et al. 2007. These methods were used to analyze the sensitivity to the hydrologic resources of alternate future hydrologic scenarios developed using the most recent tree-ring data from the University of Arizona (Appendix N).

4) Formation of a climate technical work group[3] to assess the state of knowledge with regard to climate change and modeling for the Colorado River Basin and to prioritize future research and development needs.

   This work culminated in a report that has been included in Appendix U, titled Review of Science and Methods for Incorporating Climate Change Information into Reclamation's Colorado River Basin Planning Studies.[4] Key conclusions and recommendations include:

   – Climate models project that temperatures will increase globally by one to two degrees Celsius in the next 20 to 60 years. Although the downscaling of global temperature increase to the Colorado River Basin is less certain, it is reasonable to expect that temperatures will increase. Regional precipitation response is even less certain;

   – The potential impacts of climate change on the Colorado River Basin have been a subject of research for several decades. Recent studies have been refined in several ways including how the climate change models output is bias-corrected and downscaled to the spatial resolution needed for planning studies. Due to advances in knowledge, technical abilities, and other factors, not all past studies retain the same significance today;

   – Although paleoclimatic information may not necessarily represent future climate scenarios, this information may be useful in framing assumed variability in future hydrologic sequences, particularly with respect to drought potential;

[3] Organizations represented in the work group include the University of Colorado (NOAA - Western Water Assessment), the University of Arizona, the University of Nevada – Las Vegas, the University Corporation for Atmospheric Research, Reclamation, and Hydrosphere Consultants, Inc.

[4] This report will be a forthcoming Reclamation publication with no change to content; however, the formatting will be changed from that used in Appendix U.

- System storage is very sensitive to changes in mean inflows as well as sequences of wet and dry years, highlighting the importance of properly investigating changes in both mean and variability in planning studies;

- For studies and management decisions involving shorter look-ahead horizons (e.g., less than 20 years), interannual to decadal variability may be a more significant uncertainty than that associated with near-term projected climate change. Evaluating the state of interannual/interdecadal oscillation phenomena such as ENSO, PDO, and AMO may add significant information with respect to the risk due to increased variability; and

- For longer look-ahead horizons (20+ years), further research and development is needed to translate climate protections from General Circulation Models (GCMs) to the spatial scales necessary for use in Colorado River planning studies.

In addition, several recommendations for research and development were made. These recommendations are currently being reviewed and prioritized.

5) Improvements and updates to Reclamation's Colorado River natural flow database and decision-modeling framework (including the CRSS model and associated data handling and analysis tools).

The natural flow record is critical to the understanding of the hydrology of the past 100 years and provides the basis for understanding future changes. Reclamation has an on-going program to ensure that this data is the best available. Additionally, all of the new methods have the capability to produce large numbers of possible future inflow sequences (on the order of 1000 or more possibilities), requiring sophisticated data handling, data processing and analysis tools. Furthermore, refinements to the current CRSS model that are needed to incorporate operating policies on key sub-basins have been evolving through other environmental compliance efforts (e.g., the Record of Decision for Navajo Reservoir operations in July 2006), requiring modification of the rules used by CRSS to simulate the operation of the major reservoirs in each sub-basin. These improvements are on-going.

4.2.5.3 Summary

Based on the current inability to precisely project future impacts of climate change to runoff throughout the Colorado River Basin at the spatial scale needed for CRSS, Reclamation based its hydrologic analysis for this EIS primarily on the resampled historical record. However, in order to understand the potential effects of future inflow sequences outside the range of historical flows (i.e., future sequences with increased variability including the severity, frequency, and duration of droughts), particularly during the 19-year period of the application of the proposed federal action, Reclamation analyzed the sensitivity of the hydrologic resources (including reservoir storage, reservoir releases, and river flows) to hydrologic scenarios derived from alternative methodologies (including stochastic hydrology methods and paleo-reconstruction methods) in the Draft EIS. An additional analysis has been added to Appendix N in the Final EIS that incorporates a newly published tree-ring reconstruction of hydrologic inflows at Lees Ferry (Meko et al. 2007) that extends the estimate of annual flow at Lees Ferry back to the year 762, a record length of 1,244 years.

Although precise estimates of the future impacts of climate change to runoff throughout the Colorado River Basin at appropriate spatial scales are not currently available, these impacts may include decreased mean annual flow and increased variability, including more frequent and more severe droughts. Furthermore, even without precise knowledge of the effects on runoff, increasing temperatures alone would likely increase losses (e.g., evapotranspiration and sublimation), resulting in reduced runoff.

Acknowledging the potential for impacts due to climate change and increased hydrologic variability, the Secretary proposes that these guidelines be interim in duration and extend through 2026, providing the opportunity to gain valuable operating experience for the management of Lake Powell and Lake Mead, particularly for low reservoir conditions, and improve the basis for making additional future operational decisions, whether during the interim period or thereafter. In addition, the Preferred Alternative has been crafted to include operational elements that would respond if potential impacts of climate change and increased hydrologic variability are realized. In particular, the Preferred Alternative includes a coordinated operation element that allows for the adjustment of Lake Powell’s release to respond to low reservoir storage conditions in Lake Powell or Lake Mead as described in Section 2.7 and Section 2.3. In addition, the Preferred Alternative will enhance conservation opportunities in the Lower Basin and the retention of water in Lake Mead through adoption of the ICS mechanism. Finally, the Preferred Alternative includes a shortage strategy at Lake Mead that would result in additional shortages being considered, after appropriate consultation, if Lake Mead elevations drop below 1,025 feet msl.

4.2.6 Post-processing and Interpretation Procedures

The physical, biological, and socioeconomic analyses in the Final EIS required the sorting and arranging of various types of model output data into tabulations or plots of specific operational conditions or parameters at various locations on the system. This was done through the use of statistical methods and other numerical analyses.

The hydrologic model generated data on a monthly time-step for over 300 points (or nodes) on the Colorado River system. Furthermore, through the use of ISM, the model generated 100 possible outcomes for each node for each month during the interm period (2008 through 2060). These very large data sets generated for each alternative can be visualized as three-dimensional data “cubes” with the axes of time, space (or node) and trace (or outcome for each future hydrology). The data were aggregated to reduce the volume of data and to facilitate comparison of the alternatives. The type of aggregation varies depending upon the needs of the particular resource analysis. The post-processing techniques used for this Final EIS fall into two basic categories: those that aggregate in time, space, or both, and those that aggregate the 100 possible outcomes.

For aggregation of data in time and space, simple techniques were employed. For example, deliveries of Colorado River water to all California diversion nodes in the model were summed to produce the total delivery to the state for each year. Similarly, lake elevations were chosen on an annual basis (i.e., end of December) to show long-term lake elevation trends as opposed to short-term fluctuations. In other analyses, since the proposed interim period is 2008 through 2026, those analyses found it important to aggregate the data over that period of time and compared the aggregation over the remaining years (2027 through 2060). The particular aggregation used is noted in the methodology section for each resource, where applicable.

Once the appropriate temporal and spatial aggregation was chosen, standard statistical techniques were used to analyze the 100 possible outcomes for a fixed time or particular temporal span. Statistics that were generated included the mean, standard deviation, and percentiles.

Percentiles were determined by simply ranking the outcomes at each time-step (from highest to lowest) and determining the value at the specified percentile. For example, if end-of-calendar year Lake Mead elevations are ranked for each year, the 50th percentile (median) outcome for a given year is the elevation for which half of the values are below and half are above that elevation. Similarly, the 10th percentile value is the elevation for which 10 percent of the values are lower and 90 percent are higher. This statistical method is used to view the results of all hydrologic sequences in a compact manner yet maintains the variability at high, medium, and low reservoir elevations that may be lost by averaging the results of all traces. Several presentations of the ranked data are then possible. For example, a graph (or table) may be produced that is used to compare the 90th percentile, 50th percentile, and 10th percentile outcomes from 2008 through 2060 for the No Action Alternative and the action alternatives. A statistic such as the 10th percentile is not the result of any one hydrologic trace. However, no historical sequence produced the 10th percentile. Such a statistic provides information with regard to the probability (e.g., a 10 percent probability) of the variability of interest being at or below the 10th percentile value in a specified year. However, the statistic cannot be used to understand the probability of remaining at that value in subsequent years.

4.2.7 Modeling Assumptions Common to All Alternatives

In addition to the specific operating rules necessary to model each of the alternatives (discussed in Chapter 2, Appendix A, and in the following section), the modeling of Colorado River system operations also requires certain assumptions about various aspects of water delivery and system operations that are common to all alternatives:

- all simulations were performed with a start year of 2008 and a simulation length of 53 years (2008 through 2060);

- each action alternative was assumed to be in effect for the interim period which extends from 2008 through 2026. For modeling purposes, the operating rules for all action alternatives are assumed to revert to the rules of the No Action Alternative after 2026;

- ♦ the initial conditions for the Upper Basin and Lower Basin reservoirs reflect the 2007 end-of-calendar year (EOCY) elevations as projected by the June 2007 24-Month Study. The Lake Powell and Lake Mead initial elevations (starting condition) in the model were 3,596.77 feet msl and 1,114.85 feet msl, respectively. These starting conditions were updated in the Final EIS from those used in the Draft EIS as additional information became available. Starting conditions for all reservoirs used in both the Draft EIS and the Final EIS are detailed in Appendix A;

- ♦ future hydrology was generated from the 100-year (1906 through 2005) historic record of calculated natural flows at 29 separate inflow points in the Colorado River watershed using the ISM. One hundred simulations were performed for each alternative;

- ♦ the current Upper Basin reservoir operating rules, with the exception of Lake Powell, are identical under all alternatives. Under the action alternatives, the operation of Lake Powell reflects the coordinated operations strategy of each respective alternative during the interim period;

- ♦ future water demands for Upper Division water users are based on depletion projections prepared by the Upper Division states in coordination with the Upper Colorado River Commission and Reclamation, and are as published in the SIA Final EIS (Volume II, Appendix G). These depletion schedules are also provided in Appendix C;

- ♦ Lake Mead flood control procedures are always in effect;

- ♦ except during flood control conditions, Lake Mead is operated to meet downstream demands under the water supply condition (Normal, Surplus, or Shortage condition) in effect in a particular year;

- ♦ future water demands for Lower Division water users are based on depletion schedules prepared by the Lower Division states and published in the SIA Final EIS (Volume II, Appendix G) with some exceptions. Depletion schedules under a Normal Condition for IID, CVWD, and MWD are those specified in the Colorado River Water Delivery Agreement and include accelerated Inadvertent Overrun Paybacks and any subsequent changes in payback schedules. Depletion schedules for all Arizona users were provided by the Arizona Department of Water Resources for this EIS effort. These depletion schedules are provided in Appendix D;

- ♦ if Lake Mead elevations fall below 1,000 feet msl, delivery to SNWA is reduced to zero. This reflects the limitations of the SNWA intakes which are used to pump water from Lake Mead;

- ♦ Lake Mohave and Lake Havasu are operated in accordance with their existing rule curves;

- water deliveries to Mexico are pursuant to the requirements of the 1944 Treaty. This provides annual deliveries of 1.5 maf to Mexico and up to 1.7 maf during Lake Mead flood control release conditions;

- Mexico's principal diversion is at Morelos Diversion Dam where most of its Colorado River apportionment of 1.5 mafy is diverted. In practice, up to 140 kafy is delivered to Mexico near the SIB. The model, however, extends to just south of the NIB to include the Morelos Diversion Dam and accounts for the entire 1944 Treaty delivery at that point;

- for 2008 and 2009, the model sets the delivery schedule to Mexico at the NIB to 1.577 mafy. The additional 77 kafy reflects the average annual volume of non-storable flows that are delivered to Mexico for the period 1964 through 2005, excluding years when there were flood control releases on the mainstream Colorado River or Gila River;

- beginning in 2010, the proposed Drop 2 Storage Reservoir is assumed to be in operation and is assumed to conserve an average of 69 kafy, reducing the average annual volume of non-storable flows that are delivered to Mexico from 77 kafy to 8 kafy;

- the bypass of return flows from the Welton-Mohawk Irrigation and Drainage District to the Cienega de Santa Clara in Mexico is assumed to be 109 kafy, the historical average for the period 1990 through 2005, and is not counted as part of the 1944 Treaty delivery;

- except under the Conservation Before Shortage and the Reservoir Storage alternatives, replacement of the bypassed water is not assumed to occur in the future. The United States recognizes that it has an obligation to replace, as appropriate, the bypass flows, and the assumptions made herein for modeling purposes do not necessarily represent the policy that Reclamation will adopt for replacement of bypass flows. The assumptions made with respect to modeling the bypass flows are intended only to provide a thorough and comprehensive accounting of the Lower Basin water supply. The United States is exploring options for replacement of the bypass flows, including options that would not require operation of the Yuma Desalting Plant; and

- for modeling purposes, the Yuma Desalting Plant is not assumed to operate over the modeling period.

Assumptions with regard to reduction of deliveries to the Lower Division states and Mexico are as described below.

4.2.7.1 Shortage Sharing and Water Delivery Reduction Assumptions

A summary of modeling assumptions with respect to the reduction of deliveries to the Lower Division states and Mexico was provided in Section 2.2. These modeling assumptions are identical for all alternatives and are explained further in this section. Shortage sharing assumptions within a particular state are detailed in Section 4.4 and in Appendix G.

It was assumed that shortages would be allocated to each Lower Division state. Two sets of percentages were assumed depending upon the amount of total Lower Basin shortage to be applied. Shortages less than or equal to the magnitude that would cause Arizona 4^{th} priority users to be reduced to zero are termed Stage 1 shortages. This magnitude is dependent upon the scheduled depletions for the Arizona 4^{th} priority users (post-September 30, 1968 contractors, including CAP), which vary over the period of analysis. In a Stage 2 shortage, additional shortages above that magnitude are applied.

In order to assess the potential effects of the proposed federal action in this Final EIS, certain modeling assumptions were used that display projected water deliveries to Mexico. These modeling assumptions assume that Mexico would share proportionately in Lower Basin shortages. An analysis that considers the sensitivity of the hydrologic resources to these assumptions is presented in Appendix Q. In that analysis, a different set of modeling assumptions were used that assume that Mexico would share proportionally in both Upper Basin and Lower Basin shortages.

Allocation of Colorado River water to Mexico is governed by the 1944 Treaty. The proposed federal action is for the purpose of adopting additional operational guidelines to improve the Department's annual management and operation of key Colorado River reservoirs for an interim period through 2026. As such, Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 Treaty or to represent current United States policy or a determination of future United States policy regarding deliveries to Mexico. The United States will conduct all necessary and appropriate discussions regarding the proposed federal action and implementation of the 1944 Treaty with Mexico through the IBWC in consultation with the Department of State.

Therefore, for purposes of modeling and the resource analyses, the shortage-sharing percentages were computed as follows:

Stage 1 Shortage Sharing Modeling Assumptions. Shortages are first imposed under Stage 1 and would be applied to the most junior users within Arizona (those with post-1968 water rights, i.e., 4th and 5th priority rights within Arizona), Nevada and Mexico. Stage 1 shortages would continue until the deliveries to the post-1968 water rights holders in Arizona (including CAP) are reduced to zero. The maximum amount of Stage 1 shortages during the period of analysis is dependent on the scheduled depletions for the post-1968 water rights holders and decreases in time (2008 through 2060) from approximately 1.8 maf to 1.7 maf[5].

The assumed Stage 1 shortage sharing percentages are explained in Table 4.2-1.

Stage 2 Shortage Sharing Modeling Assumptions. After deliveries to those with 4th and 5th priority rights within Arizona are reduced to zero, it is assumed that any additional delivery reductions would be distributed to Arizona, California, Nevada, and Mexico. The assumed Stage 2 shortage sharing percentages are explained in Table 4.2-2. Under a Stage 2 Shortage, the total Lower Basin shortage is the sum of the computed Stage 1 and Stage 2 shortage amounts.

Table 4.2-1
Modeling Assumptions for Distribution of Stage 1 Shortages

Entity	Percentage of Stage 1 Shortage	Calculation
Arizona[1]	80	▪ Computed assuming that Arizona takes the remaining amount of shortage after Nevada and Mexico take their respective shares ▪ Calculated as: 1.0 – 0.1667 – 0.0333 = 0.80 or 80.0 percent
California	0	▪ Does not receive shortage under Stage 1
Nevada	3.33	▪ Computed as a ratio of Nevada's allotment to the total allotments of the Lower Division states and Mexico ▪ Calculated as: 0.3 maf / 9.0 maf = 0.0333 or 3.33 percent
Mexico[2]	16.67	▪ Computed as a ratio of Mexico's allotment to the total allotments of the Lower Division states and Mexico ▪ Calculated as: 1.5 maf / 9.0 maf = 0.1667 or 16.67 percent

1. *Within CAP, Ak-Chin and Salt River Pima-Maricopa Indian Community tribes have contracts for the delivery of 72 kaf that is not reduced until a Stage 2 Shortage is applied as the associated water rights have a pre-1968 priority date.*
2. *These modeling assumptions do not reflect policy decisions and are not intended to constitute an interpretation or application of the 1944 Treaty.*

[5] Although these assumptions are common to all alternatives, shortages of high magnitudes either occur infrequently or not at all for all alternatives (Section 4.4.4).

Table 4.2-2
Modeling Assumptions for Distribution of Stage 2 Shortages

Entity	Percentage of Stage 2 Shortage	Calculation
Arizona	15-20	▪ The percentage changes as Arizona's 4th priority use schedule changes and ranges between 15 and 20 percent ▪ Computed as a ratio of Arizona's allotment less the amount of shortage applied to Arizona under Stage 1, to the total allotments of the Lower Division states and Mexico less the total amount shorted to users under Stage 1 ▪ Calculated as: (2.8 – Arizona Stage 1 shortage) / (9.0 – total Stage 1 shortage)
California	60-65	▪ California shortage sharing percentage changes as Arizona's 4th priority use schedule changes and ranges between 60 and 65 percent ▪ Computed assuming that California takes the remaining amount of the additional shortage ▪ Calculated as: 1.0 – 0.1667 – 0.0333 – Arizona's Stage 2 percentage expressed as a fraction
Nevada	3.33	▪ Computed as a ratio of Nevada's allotment less the amount of shortage applied to Nevada under Stage 1, to the total allotments of the Lower Division states and Mexico less the amount shorted to users under Stage 1 ▪ Calculated as: (0.3 – Nevada Stage 1 shortage) / (9.0 – total Stage 1 shortage) = 0.0333 or 3.33 percent
Mexico[1]	16.67	▪ Computed as a ratio of Mexico's allotment less the amount of shortage applied to Mexico under Stage 1, to the total allotments of the Lower Division states and Mexico less the total amount shorted to users under Stage 1 ▪ Calculated as: (1.5 – Mexico Stage 1 shortage) / (9.0 – total Stage 1 shortage) = 0.1667 or 16.67 percent

1. *These modeling assumptions do not reflect policy decisions and are not intended to constitute an interpretation or application of the 1944 Treaty.*

4.2.7.2 Shortage Sharing Between Arizona and Nevada

Pursuant to the Arizona Nevada Shortage Sharing Agreement dated February 9, 2007, Arizona and Nevada have agreed to share shortages during the interim period (2008 through 2026) between the two states by specified amounts at each discrete level of total Lower Basin shortage. The shortage amounts that are allocated to Arizona and Nevada pursuant to the Arizona Nevada Shortage Sharing Agreement are shown in Table 4.2-3.

In the Draft EIS, the distribution of shortages among the Lower Division states was made according to assumed percentages (Section 2.2.1). This modeling assumption allocated 80 percent and 3.33 percent of the total Lower Basin shortage amount to Arizona and Nevada, respectively. Reclamation used the same assumption in the Final EIS. This modeling assumption is common among all alternatives and enabled Reclamation to model the distribution of shortages to the Lower Division states for volumes different than those considered in the Arizona Nevada Shortage Sharing Agreement.

Table 4.2-3 provides a comparison of the shortage amounts to Arizona and Nevada based on the shortage distribution assumptions used in the modeling to the amounts specified in the Arizona-Nevada Shortage Sharing Agreement. As shown on this table, the shortage amounts allocated to Arizona are the same under both methodologies and the shortage amounts allocated to Nevada differ slightly. Also, these differences exist only when the total Lower Basin shortages shown in this table occur. Additional details on the assumptions used to model the distribution of shortages between the Lower Division states are provided in Appendix A and Appendix G.

Table 4.2-3
Comparison of Shortage Allocation to Arizona and Nevada for the Specified Lower Basin Shortage
Differences Between Modeling Assumptions and Arizona-Nevada Shortage Sharing Agreement

Total Lower Basin Shortage (af)	Distribution of Shortage per Arizona-Nevada Shortage Sharing Agreement (af)		Distribution of Shortages per Modeling Assumptions (af)	
	Arizona Share	Nevada Share	Arizona Share[1]	Nevada Share[2]
400,000	320,000	13,000	320,000	13,333
500,000	400,000	17,000	400,000	16,667
600,000	480,000	20,000	480,000	20,000

1. *The allocation of Arizona's share of a shortage is calculated in the model by multiplying the total Lower Basin shortage amount by 80 percent.*
2. *The allocation of Nevada's share of a shortage is calculated in the model by multiplying the total Lower Basin shortage amount by 3.333333 percent.*

4.2.8 Modeling Assumptions Specific to Alternatives

Each alternative includes specific assumptions with regard to the four operational elements of the proposed federal action. Assumptions with regard to Shortage Guidelines, Coordinated Reservoir Operations, and the ISG were presented in Chapter 2 and are detailed in Appendix A. Assumptions with regard to the Storage and Delivery of Conserved Water element are detailed in Appendix M.

4.3 Hydrologic Resources

This section identifies the potential effects on hydrologic resources that may occur as a result of implementing the No Action Alternative and the action alternatives.

4.3.1 Methodology

The methodology and the CRSS model used to analyze the potential impacts of the alternatives to reservoir storage, reservoir releases, and the corresponding changes in river flows downstream of the reservoirs are described in Section 4.2 and Appendix A.

The CRSS model is a monthly time-step model and its output for simulated water system conditions, such as reservoir elevations or releases, can be provided on monthly and annual bases. The data and output used in the impact analysis may vary depending on the specific issue being addressed. An example of how specific months are considered to represent certain issues or conditions in the analyses follows:

Lake Powell:

- **March:** representative of months (or period) with seasonal low Lake Powell elevations;
- **July:** representative of months (or period) with seasonal high Lake Powell concentration of visitors; and
- **September:** month representing End-of-Water Year, used for water accounting and reporting in Upper Basin.

Lake Mead:

- **July:** representative of months (or period) with seasonal low Lake Mead elevations; and
- **December:** month representing End-of-Calendar Year, used for water accounting and reporting in Lower Basin.

The specific data and output used in the different resource analyses are presented in this section.

4.3.1.1 Methodology Used To Estimate a Range of Daily Glen Canyon Dam Releases

The observed CRSS model output for individual traces for specific annual Lake Powell release volumes or volume ranges was used to estimate the monthly volumes that would likely be seen under water year release volumes that were less than, equal to, and greater than 8.23 maf. These annual release volumes consisted of 7.00, 7.48, 7.80, 8.23, 9.00, 9.50, 9.50 to 11.0, and 11.0 to 16 mafy, corresponding to the Glen Canyon Dam release volumes observed under the modeled alternatives. For each month corresponding to each of these annual flow volumes, the average, maximum, and minimum daily flow volumes were then calculated using the allowable daily fluctuation parameters specified in the 1996 Glen Canyon ROD. It is recognized that monthly and daily flow patterns observed in the different release years could potentially deviate somewhat from the flow values and patterns calculated using this approach although they would most likely be very close to the calculated value. It is also noted that the release patterns for the 7.0 maf release are not as consistent because the monthly volumes would be affected by balancing of Lake Powell and Lake Mead storage. When balancing takes place, monthly release volumes shift as forecast inflow shifts, resulting in more than one possible pattern for the 7.0 maf release years.

4.3.1.2 Methodology Used To Estimate Evaporation Loss from Lake Powell and Lake Mead

Evaporation at Lake Powell and Lake Mead is simulated in CRSS by multiplying the monthly average reservoir surface area by monthly evaporation coefficients. A description of the methodology and the monthly evaporation coefficients is provided in Appendix A. A comparison of the mean and median evaporation volumes for Lake Powell and Lake Mead for the No Action Alternative and the action alternatives is provided in Appendix P.

4.3.1.3 Methodology Used To Estimate the Effect on Groundwater

The annual median elevation of the water surface in the lower Colorado River has been used as an indicator of groundwater elevations adjacent to the Colorado River within the potentially affected river reaches. This is due to the slow movement of groundwater and the time required for the decline in the groundwater table to stabilize at a decline equal to that of the river (Reclamation 2004a, Appendix J and Appendix K). The methodology used to analyze the potential effects to groundwater followed the methodology established in the LCR MSCP analysis.

4.3.2 Lake Powell and Glen Canyon Dam

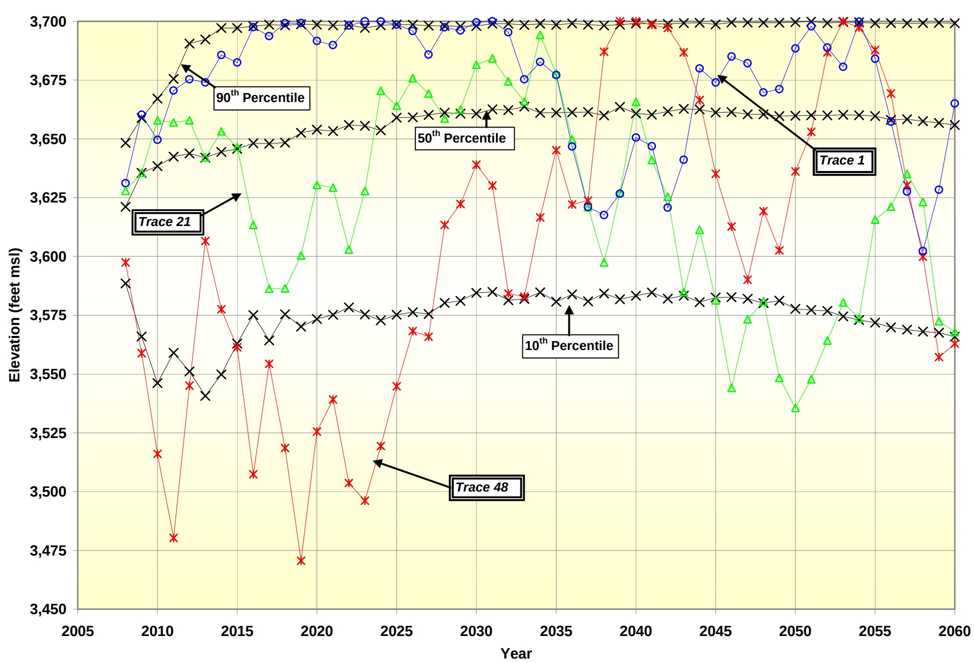
Future elevations of Lake Powell are expected to be within the range of historic water levels (Section 3.3). However, each action alternative may alter the probability (when compared to the No Action Alternative) that the reservoir may be at a given elevation in the future.

Under the No Action Alternative, the elevation of Lake Powell is projected to fluctuate between full and lower levels during the period of analysis (2008 through 2060). Figure 4.3-1 illustrates the range of reservoir elevations by three plots, labeled 90th percentile, 50th percentile and 10th percentile. The 50th percentile plot shows the modeled median elevation for each future year. The median elevation gradually increases from about 3,620 feet msl to about 3,655 feet msl in the year 2060. The 10th percentile plot shows the elevations that would be exceeded 90 percent of the time for each future year. The 10th percentile lake elevation would gradually decline from about 3,590 feet msl to about 3,565 feet msl in the year 2060.

Lake Powell elevations depicted in Figure 4.3-1 (and in Figure 4.3-2) are for modeled lake elevations at the end of July. Lake Powell elevation generally reaches its seasonal high in July whereas the seasonal low generally occurs in March.

Three distinct traces were added to Figure 4.3-1 to illustrate what was actually simulated under the various traces and respective hydrologic sequences and to highlight that the 90th, 50th, and 10th percentile plots do not represent actual traces, but rather the ranking of each year's data from the 100 traces for the conditions modeled. The traces also illustrate the variability among the different traces and that the reservoir elevations could temporarily decline below the 10th percentile line. Trace 1 represents the hydrologic sequence that begins in 1906. Trace 21 represents the hydrologic sequence that begins in 1926. Trace 48 represents the hydrologic sequence that begins in 1953.

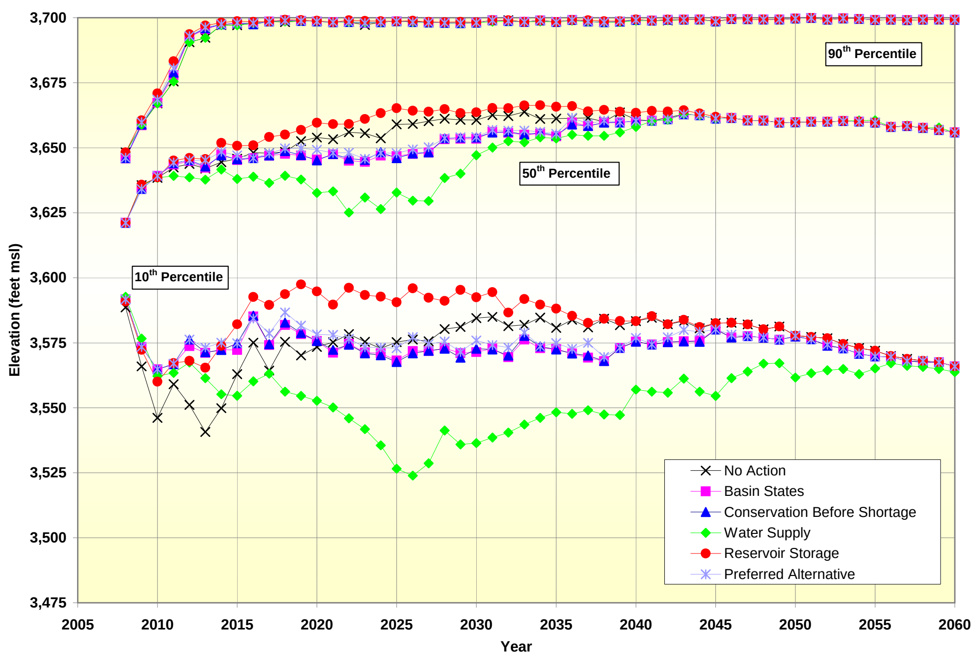
Figure 4.3-1
Lake Powell End-of-July Elevations Under the No Action Alternative
90th, 50th and 10th Percentile Values



In Figure 4.3-1, the 90th and 10th percentile lines bracket the range where 80 percent of the elevations simulated for the No Action Alternative occurred. The highs and lows shown on the three traces would likely be temporary conditions. The reservoir elevation would tend to fluctuate in the range through multi-year periods of above-average and below average inflows. Neither the timing of reservoir elevation variations, nor the length of time the elevations would remain high or low can be predicted. These events would depend on the future variation in basin runoff conditions and therefore, only projections of the likelihood of these events are possible.

Figure 4.3-2 presents a comparison of the 90th, 50th, and 10th percentile values obtained for the No Action Alternative to those of the action alternatives. This figure is best used for comparing the relative differences in the general lake elevation trends that result from the simulation of the different alternatives.

Figure 4.3-2
Lake Powell End-of-July Elevations
Comparison of Action Alternatives to No Action Alternative
90th, 50th, and 10th Percentile Values



As illustrated in Figure 4.3-2, the 90th percentile results were nearly identical for all of the alternatives. For the 50th and the 10th percentile results, the Reservoir Storage Alternative had the highest Lake Powell elevations and the Water Supply Alternative had the lowest elevations. Reservoir elevations under the Basin States and the Conservation Before Shortage alternatives, and the Preferred Alternative were similar and were generally lower than those under the No Action Alternative.

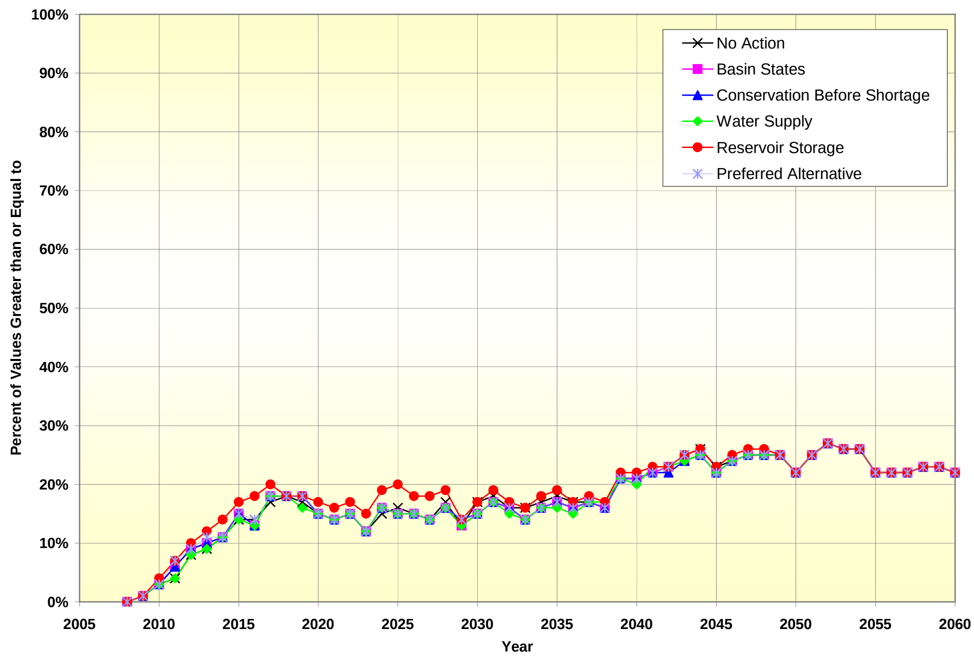
Table 4.3-1 provides a summary of the data illustrated in Figure 4.3-2, which is the 90th percentile, median (50th percentile), and 10th percentile values of the action alternatives compared to those of the No Action Alternative. The values presented in this table include those for 2026 and 2060 only. Results for the 90th percentile show that Lake Powell elevations under the action alternatives were almost the same as those under the No Action Alternative. For the 50th percentile, lake elevations under the Water Supply, Basin States, and the Conservation Before Shortage alternatives, and the Preferred Alternative were lower than those under the No Action Alternative during 2026, but were almost the same by 2060. The 10th percentile trend was very similar to the 50th percentile trend.

Table 4.3-1
Lake Powell End-of-July Elevations (feet msl)
Comparison of Action Alternatives to No Action Alternative
90th, 50th, and 10th Percentile Values

Alternative	Year 2026			Year 2060		
	90th Percentile	50th Percentile	10th Percentile	90th Percentile	50th Percentile	10th Percentile
No Action	3,698.52	3,659.17	3,576.25	3,699.21	3,655.92	3,565.89
Basin States	3,698.29	3,647.56	3,571.83	3,699.21	3,655.92	3,565.89
Conservation Before Shortage	3,698.35	3,647.79	3,570.92	3,699.21	3,655.92	3,565.89
Water Supply	3,698.31	3,629.62	3,523.95	3,699.21	3,655.87	3,563.72
Reservoir Storage	3,698.80	3,664.23	3,595.91	3,699.21	3,655.93	3,565.89
Preferred Alternative	3,698.29	3,649.33	3,577.15	3,699.21	3,655.92	3,565.89

When the Lake Powell elevation is at or exceeds 3,695 feet msl, the reservoir is considered to be essentially full. Figure 4.3-3 shows the frequency that future Lake Powell End-of-July elevations would exceed 3,695 feet msl under the No Action Alternative and the action alternatives. This type of graphical representation is best used to compare the likelihood that Lake Powell would be at or above the noted elevation (3,695 feet msl in this example) under an action alternative as compared to the No Action Alternative. Figure 4.3-3 illustrates that the percent of values that were above elevation 3,695 feet msl under the action alternatives were similar to the No Action Alternative throughout the period of analysis. The exception to this is the Reservoir Storage Alternative which provides slightly higher exceedence values than the No Action Alternative between 2010 through 2037. This means that Lake Powell elevations would generally tend to be higher under the Reservoir Storage Alternative, as compared to the No Action Alternative.

Figure 4.3-3
Lake Powell End-of-July Elevations
Comparison of Action Alternatives to No Action Alternative
Percent of Values Greater Than or Equal to Elevation 3,695 feet msl



As summarized in Table 4.3-2, the exceedence values under the Basin States, Conservation Before Shortage, and Water Supply alternatives, and the Preferred Alternative were essentially the same as those observed under the No Action Alternative in most years. The probability values under the Reservoir Storage Alternative were slightly higher than those under the No Action Alternative.

Table 4.3-2
Lake Powell End-of-July Elevations
Comparison of Action Alternatives to No Action Alternative
Percent of Values Greater Than or Equal to Elevation 3,695 feet msl

Alternatives	Year						
	2008	2016	2026	2030	2040	2050	2060
No Action	0	14	15	17	21	22	22
Basin States	0	13	15	15	21	22	22
Conservation Before Shortage	0	13	15	15	21	22	22
Water Supply	0	13	15	15	20	22	22
Reservoir Storage	0	18	18	17	22	22	22
Preferred Alternative	0	14	15	15	21	22	22

The threshold for water access to Rainbow Bridge is elevation 3,650 feet msl. Below this threshold elevation, access to Rainbow Bridge would require hiking. As shown in Figure 4.3-4, the Reservoir Storage Alternative had the lowest frequency of occurrences below this threshold, and the Water Supply Alternative had higher frequency of occurrences below elevation 3,650 feet msl relative to the No Action Alternative.

Figure 4.3-4
Lake Powell End-of-September Elevations
Comparison of Action Alternatives to No Action Alternative
Percent of Values Less Than or Equal to Elevation 3,650 feet msl

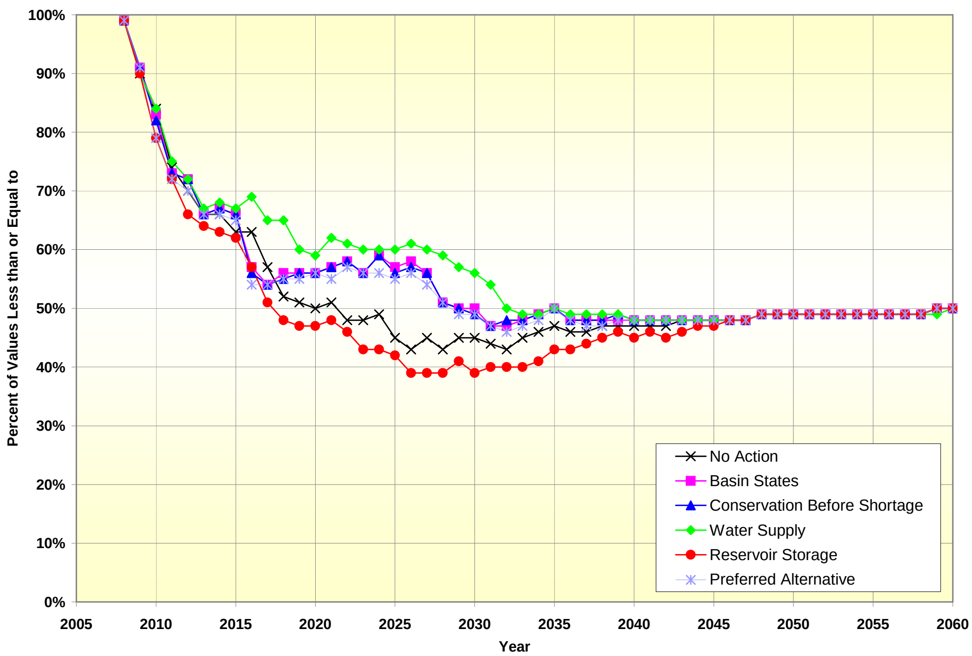


Table 4.3-3 summarizes the results shown in Figure 4.3-4 for elevation 3,650 feet msl for the No Action Alternative and the action alternatives for selected years. All alternatives were similar at the beginning and end of the modeled years, but variation did occur from about 2016 until about 2040. During that period, Lake Powell elevations under the Reservoir Storage Alternative were below elevation 3,650 feet msl less frequently than those under the No Action Alternative; the elevations under the Basin States, Conservation Before Shortage, and Water Supply alternatives, and the Preferred Alternative were below elevation 3,650 feet msl more frequently than those under the No Action Alternative.

Table 4.3-3
Lake Powell End-of-September Elevations
Comparison of Action Alternatives to No Action Alternative
Percent of Values Less Than or Equal to Elevation 3,650 feet msl

Alternatives	Year						
	2008	2016	2026	2030	2040	2050	2060
No Action	99	63	43	45	47	49	50
Basin States	99	57	58	50	48	49	50
Conservation Before Shortage	99	56	57	49	48	49	50
Water Supply	99	69	61	56	48	49	50
Reservoir Storage	99	57	39	39	45	49	50
Preferred Alternative	99	54	56	49	48	49	50

Figure 4.3-5 illustrates the results for elevations equal to or less than 3,626 feet msl. An elevation of 3,626 feet msl is the level at which there is a navigational detour at the Wahweap Marina and at Gregory Butte. As is shown on this figure, the Reservoir Storage Alternative had less impact on this threshold than the No Action Alternative. The elevations under the Water Supply, Basin States, and Conservation Before Shortage alternatives, and the Preferred Alternative, were below elevation 3,626 feet msl more frequently than those under the No Action Alternative. All alternatives were similar by about 2053.

Figure 4.3-5
Lake Powell End-of-September Elevations
Comparison of Action Alternatives to No Action Alternative
Percent of Values Less Than or Equal to Elevation 3,626 feet msl

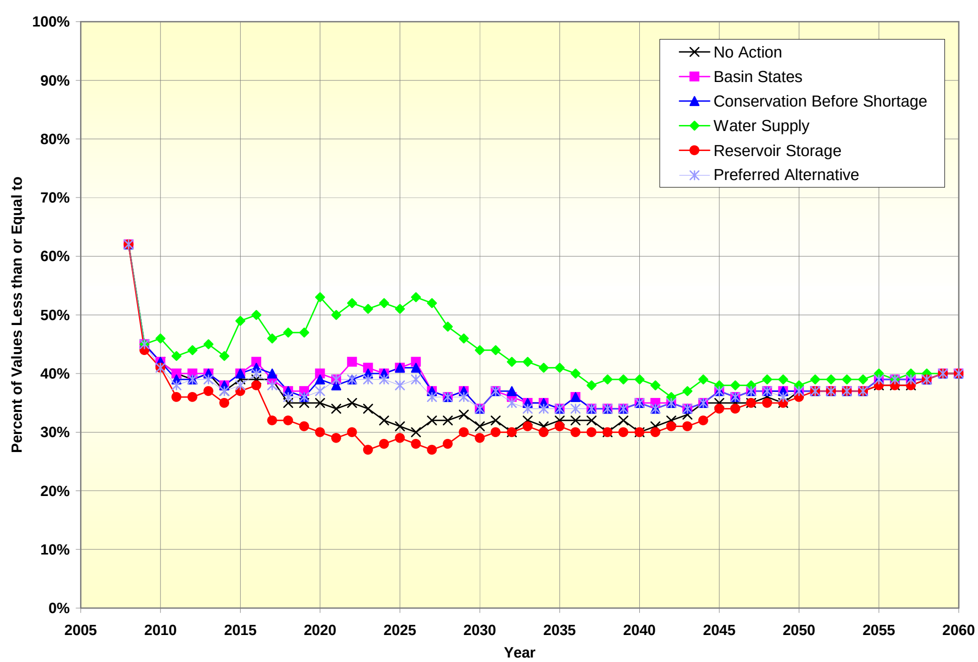

Table 4.3-4 summarizes the data illustrated in Figure 4.3-5 for elevation 3,626 feet msl. Lake Powell elevations under the Reservoir Storage Alternative were below 3,626 feet msl less frequently than those under the No Action Alternative. Lake elevations under the Water Supply, Basin States, and Conservation Before Shortage alternatives, and the Preferred Alternative, were below elevation 3,626 feet msl more frequently than those under the No Action Alternative.

Reservoir Storage	62	38	28	29	30	36	40
Preferred Alternative	62	40	39	34	35	37	40

Figure 4.3-6 compares the percent of values less than or equal to elevation 3,620 feet msl for the No Action Alternative and the action alternatives. The Hite Marina, Hite Public Launch Ramp, and Castle Rock Cut are closed at elevation 3,620 feet msl. Lake Powell elevations under the Water Supply, Basin States, and Conservation Before Shortage alternatives, and the Preferred Alternative were below 3,620 feet msl more frequently than those under the No Action Alternative. Lake Powell elevations under the Reservoir Storage Alternative were below 3,620 feet msl less frequently than those under the No Action Alternative for most of the modeled years.

Table 4.3-5 shows that all of the action alternatives varied from the No Action Alternative from about 2016 until about 2040. During this period, most of the alternatives, including the No Action Alternative, were below 3,620 feet msl between 25 and 40 percent of the time. The exceptions were elevations under the Water Supply Alternative which were below 3,620 feet msl between 37 and 52 percent of the time and elevations under the Reservoir Storage Alternative which were below 3,620 feet msl between 24 and 33 percent of the time.

Preferred Alternative	56	37	32	31	31	35	37

Figure 4.3-7 compares the percent of values less than or equal to elevation 3,588 feet msl for the No Action Alternative and the action alternatives. When Lake Powell elevations are below 3,588 feet msl, the Antelope Point Public Launch Ramp is closed. Lake elevations under the Reservoir Storage Alternative were below 3,588 feet msl less frequently than those under the No Action Alternative for most of the modeled years. Lake elevations under the Water Supply, Basin States, and Conservation Before Shortage alternatives, and the Preferred Alternative were below 3,588 feet msl more frequently than those under the No Action Alternative.

Figure 4.3-7

Comparison of Action Alternatives to No Action Alternative
Percent of Values Less Than or Equal to Elevation 3,588 feet msl

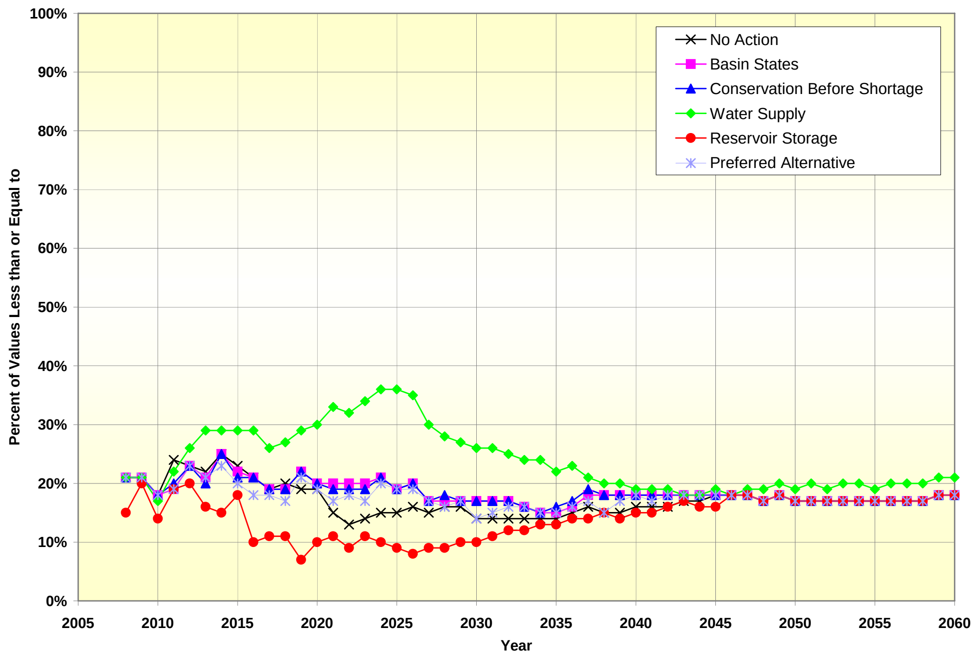

Table 4.3-6 provides a summary of the data illustrated in Figure 4.3-7 for an elevation of 3,588 feet msl. In general, lake elevations for all alternatives were below 3,588 feet msl between 14 and 21 percent of the time. The exceptions are the elevations under the Water Supply Alternative which were below 3,588 feet msl between 19 and 35 percent of the time and elevations under the Reservoir Storage Alternative which were below 3,588 feet msl between 8 and 18 percent of the time.

Figure 4.3-8 compares the percent of values less than or equal to elevation 3,560 feet msl for the No Action Alternative and the action alternatives. Below an elevation of 3,560 feet msl, the Wahweap and Stateline Public Launch Ramps, the Bullfrog Low Water Alternative Launch Ramp, and the Halls Crossing Public Launch Ramps are closed. Results indicate that for most alternatives, the Lake Powell end-of-September elevations were lower than 3,560 feet msl between zero and 15 percent of the time, with the exception of the Water Supply Alternative. Lake elevations under the Water Supply Alternative were below 3,560 feet msl as much as 23 percent of the time.

Figure 4.3-8

Figure 4.3-9 compares the percent of values equal to or less than elevation 3,555 feet msl for the No Action Alternative and the action alternatives. Below an elevation of 3,555 feet msl, the Wahweap, Antelope Point, Bullfrog, and Halls Crossing marinas are closed. Results indicate that for most alternatives, the Lake Powell end-of-September elevations were lower than 3,555 feet msl between zero and 12 percent of the time. The exceptions are the elevations under the Water Supply Alternative which were lower than 3,555 feet msl up to 23 percent of the time.

Figure 4.3-9
Lake Powell End-of-September Elevations
Comparison of Action Alternatives to No Action Alternative
Percent of Values Less Than or Equal to Elevation 3,555 feet msl

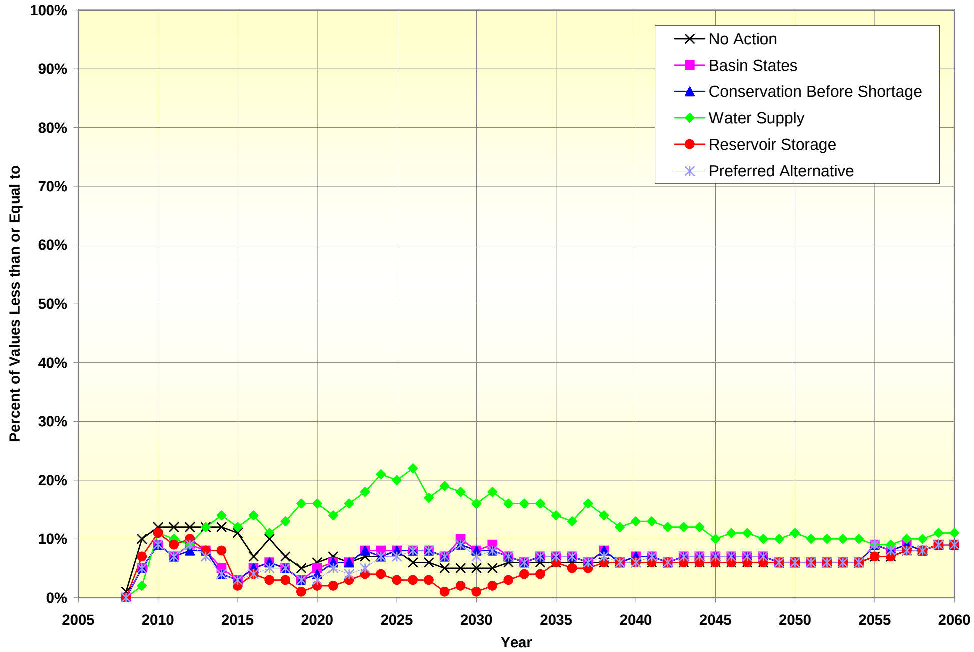

Table 4.3-8 provides a summary of the data illustrated in Figure 4.3-9 for elevation 3,555 feet msl. Lake Powell elevations under the Water Supply Alternative were below 3,555 feet msl more frequently than those under the No Action Alternative. Elevations under the Reservoir Storage Alternative were below 3,555 feet msl less frequently than those under the No Action Alternative through year 2035 and thereafter, the values were similar.

Table 4.3-8
Lake Powell End-of-September Elevations
Comparison of Action Alternatives to No Action Alternative
Percent of Values Less Than or Equal to Elevation 3,555 feet msl

Alternative	Year						
	2008	2016	2026	2030	2040	2050	2060
No Action	1	7	6	5	6	6	9
Basin States	0	5	8	8	7	6	9
Conservation Before Shortage	0	5	8	8	7	6	9
Water Supply	0	14	22	16	13	11	11
Reservoir Storage	0	4	3	1	6	6	9
Preferred Alternative	0	4	8	7	6	6	9

Figure 4.3-10 compares the percent of values equal to or less than 3,550 feet msl projected under the No Action Alternative and the action alternatives. Below this elevation, the operation of the John Atlantic Burr Ferry may be affected. The Lake Powell end-of-September elevations under the alternatives were lower than 3,550 feet msl infrequently, ranging between zero and 12 percent. The exception to this was the Water Supply Alternative, which had elevations that were below 3,550 feet msl up to 20 percent of the time. Elevations under the Reservoir Storage, Basin States, and Conservation Before Shortage alternatives, and the Preferred Alternative, were all very similar to those under the No Action Alternative throughout the period of analysis.

Figure 4.3-10
Lake Powell End-of-September Elevations
Comparison of Action Alternatives to No Action Alternative
Percent of Values Less Than or Equal to Elevation 3,550 feet msl

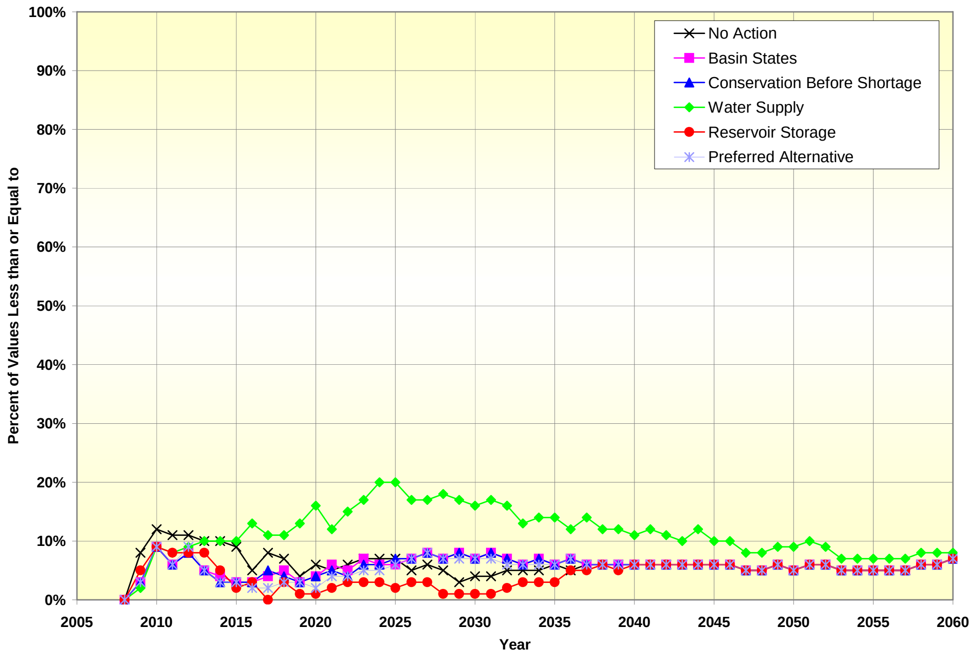

Table 4.3-9 provides a summary of the data illustrated in Figure 4.3-10 and shows that Lake Powell elevations under the Basin States, Conservation Before Shortage, and Reservoir Storage alternatives, and the Preferred Alternative, were generally within the same range of those observed under the No Action Alternative. Elevations under the Water Supply Alternative were below 3,550 feet msl more frequently compared to the other alternatives.

Table 4.3-9
Lake Powell End-of-September Elevations
Comparison of Action Alternatives to No Action Alternative
Percent of Values Less Than or Equal to Elevation 3,550 feet msl

Figure 4.3-11 compares the percent of values for Lake Powell end-of-March elevations that were less than or equal to 3,490 feet msl, the minimum power pool for efficient electrical generation at the Glen Canyon Powerplant, between the No Action Alternative and the action alternatives. Lake Powell generally reaches its seasonal low water elevation in March. Figure 4.3-11 shows that Lake Powell end-of-March elevation were below 3,490 feet msl infrequently under the No Action, Basin States, Conservation Before Shortage, and Reservoir Storage alternatives, and the Preferred Alternative. Lake Powell end-of-March elevations under the Water Supply Alternative were below 3,490 feet msl more frequently than those under the No Action Alternative, with the differences up to eight percent.

Figure 4.3-11
Lake Powell End-of-March Elevations
Comparison of Action Alternatives to No Action Alternative
Percent of Values Less Than or Equal to Elevation 3,490 feet msl

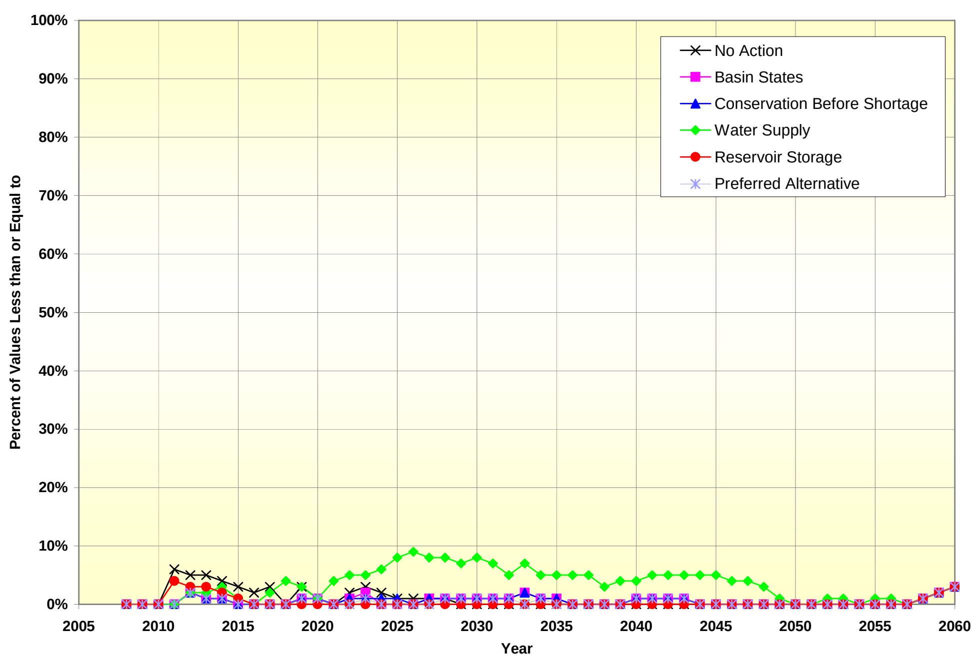

Table 4.3-10 provides a summary of the data illustrated in Figure 4.3-11 for elevation 3,490 feet msl. As presented in this table, elevations under all alternatives, with the exception of the Water Supply Alternative, were below 3,490 feet msl no more than three percent of the time in the years displayed.

Table 4.3-10

4.3.3 Glen Canyon Dam to Lake Mead

The river flows that occur between Glen Canyon Dam and Lake Mead result primarily from controlled releases from Glen Canyon Dam (Lake Powell). The gains from tributaries in this reach on average are less than three percent of the total flow, are concentrated over very short periods of time, and will not be affected by the proposed federal action. However, future annual and the monthly distribution of releases from Glen Canyon Dam may be affected by the proposed federal action (Section 3.3).

Table 4.3-11 provides a comparison of the relative frequency of occurrence of different annual release volumes from Glen Canyon Dam under the No Action Alternative and the action alternatives for the period 2008 through 2026. Table 4.3-12 provides a similar comparison for the period 2008 through 2060. The reported values are water year values. Releases greater than 9.5 maf generally correspond to years where either equalization or spill avoidance releases are made from Glen Canyon Dam.

Table 4.3-11
Glen Canyon Dam Annual Water Releases
Probability of Occurrence of Different Release Volumes (percent)
Comparison of Action Alternatives to No Action Alternative
Water Years 2008 through 2026

Glen Canyon Dam Release Volumes	Alternative

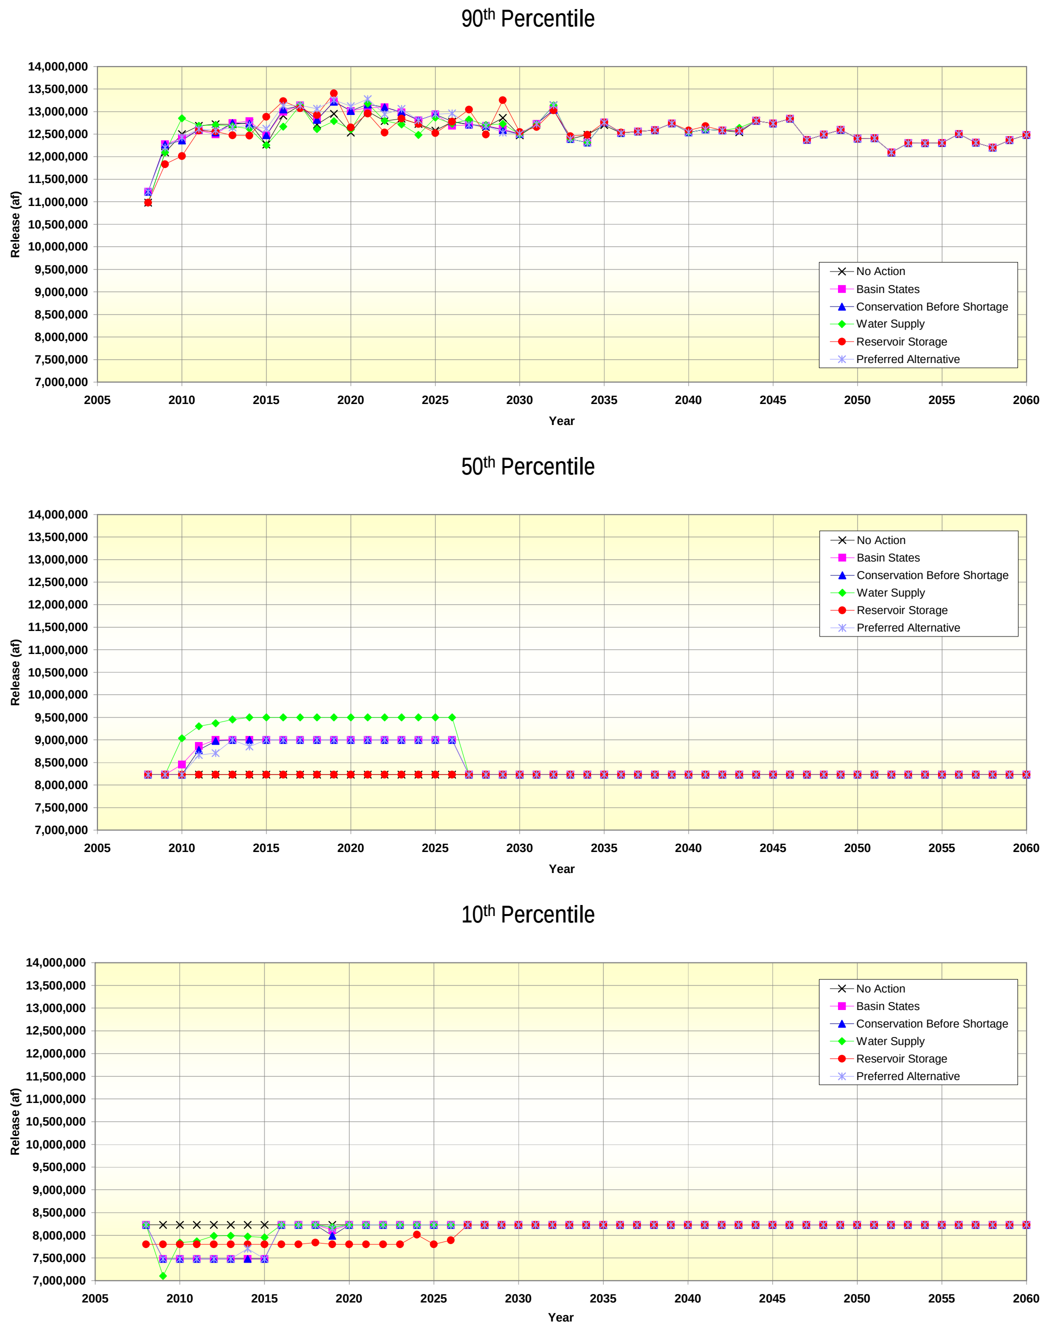
Glen Canyon Dam Release Volumes	Alternative					
	No Action	Basin States	Conservation Before Shortage	Water Supply	Reservoir Storage	Preferred Alternative
Greater than 16.00 maf	4.00	3.83	3.85	3.19	4.04	3.96
Between 11.01 to 16.00 maf	14.08	13.85	13.92	14.49	14.40	13.72
Between 9.01 to 11.00 maf	12.81	12.36	12.28	20.91	13.08	12.66
Between 8.51 to 9.00 maf	3.72	11.53	11.30	4.30	3.68	10.19
Between 8.24 to 8.50 maf	2.25	2.08	2.11	2.77	2.36	2.00
Minimum Objective Release of 8.23 maf	63.04	52.68	52.91	50.68	56.25	53.87
Between 7.51 to 8.22 maf	0.08	0.34	0.28	1.57	6.21	0.25
Between 7.01 to 7.50 maf	0.02	2.98	2.96	1.55	0.00	2.91
Less than or equal to 7.00 maf	0.02	0.36	0.38	0.55	0.00	0.45
Total	100.00	100.00	100.00	100.00	100.00	100.00

As is shown in Table 4.3-11, during the interim period (2008 through 2026), the most frequently occurring releases under the No Action Alternative are 8.23 maf, occurring approximately 58 percent of the time. The frequency of releases equal to the annual minimum objective release of 8.23 maf under the action alternatives ranged from approximately 21 to 39 percent. Releases less than the annual minimum objective release of 8.23 maf occurred less than one percent of the time under the No Action Alternative, approximately 10 percent under the Basin States, Conservation Before Shortage, and Water Supply alternatives, and the Preferred Alternative, and approximately 17 percent under the Reservoir Storage Alternative. Releases greater than the annual minimum objective release of 8.23 maf occurred approximately 42 percent under the No Action Alternative, approximately 62 percent under the Basin States and Conservation Before Shortage alternatives, approximately 69 percent under the Water Supply Alternative, approximately 59 percent under the Preferred Alternative, and approximately 44 percent under the Reservoir Storage Alternative.

The distribution of the modeled annual Glen Canyon Dam releases is different if the values for the entire period of analysis are considered as compared to those during the interim period. As is shown in Table 4.3-12, during the entire period (2008 through 2060), the most frequently occurring releases for all alternatives are 8.23 maf, primarily due to the assumption that operations under all action alternatives revert to those of the No Action Alternative after 2026. Releases equal to the annual minimum objective release of 8.23 maf occurred approximately 63 percent under the No Action Alternative, approximately 53 percent under the Basin States, and Conservation Before Shortage alternatives, and the Preferred Alternative, approximately 51 percent under the Water Supply Alternative, and approximately 56 percent under the Reservoir Storage Alternative. Releases less than the annual minimum objective release of 8.23 maf occurred less than one percent of the time under the No Action Alternative, approximately four percent under the Basin States, Conservation Before Shortage, and Water Supply alternatives, and the Preferred Alternative, and approximately six percent under the Reservoir Storage Alternative.

Figure 4.3-12 presents a comparison of the 90th, 50th, and 10th percentile values of the Glen Canyon Dam water year releases observed under the action alternatives to those under the No Action Alternative. As illustrated in Figure 4.3-12, the 90th percentile values under all of the alternatives fluctuate and range between 11.0 mafy to about 13.4 mafy, primarily due to spill avoidance releases. For the 50th percentile values, the Reservoir Storage Alternative and the No Action Alternative are nearly identical, with consistent releases of 8.23 maf. The Basin States and Conservation Before Shortage alternatives, and the Preferred Alternative show releases greater than the minimum objective release of 8.23 maf, a result of balancing with a 9.0 maf maximum release constraint. The Water Supply Alternative shows releases greater than the minimum objective release of 8.23 maf due to balancing with a 9.5 maf maximum release constraint.

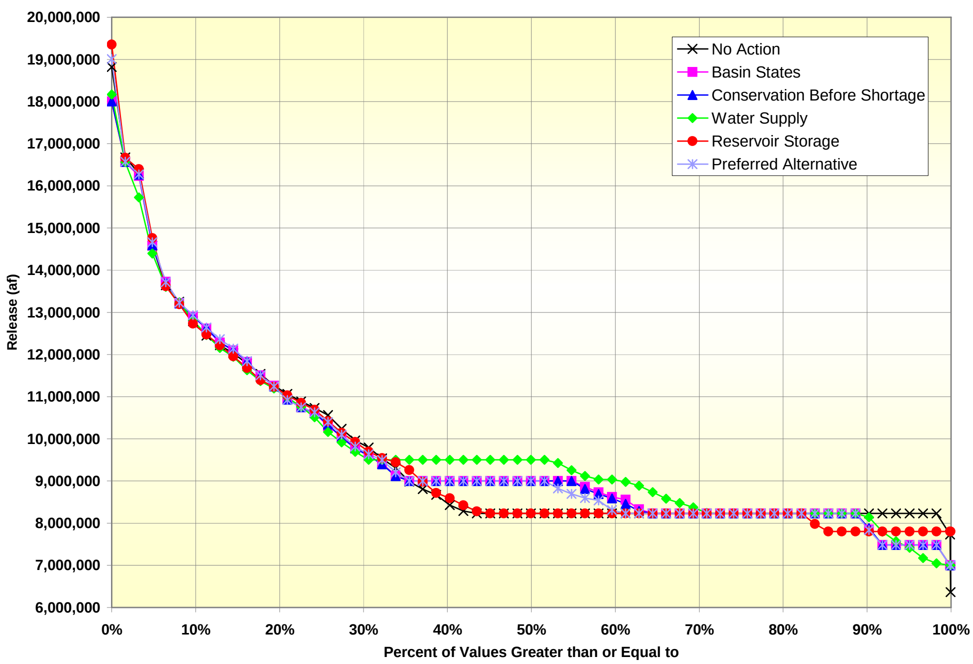
Figure 4.3-12
Glen Canyon Dam Water Year Releases
Comparison of Action Alternatives to No Action Alternative
90th, 50th, and 10th Percentile Values



The 10th percentile values showed that the Water Supply Alternative provided lower releases than the No Action Alternative from 2009 and 2015, and thereafter, were similar to those observed under the No Action Alternative. The Basin States and Conservation Before Shortage alternatives, and the Preferred Alternative also provided lower annual release volumes than the No Action Alternative from 2009 through 2015. The 10th percentile values for releases under the Reservoir Storage Alternative are below those of the No Action Alternative through 2026.

Figure 4.3-13 illustrates the cumulative distribution of the Glen Canyon Dam water year releases under the No Action Alternative and the action alternatives for the interim period (2008 through 2026). This figure provides a means for comparing the frequency that the minimum objective release of 8.23 maf is made under the different alternatives as well as identifying the frequency and magnitude of Glen Canyon Dam releases above and below the minimum objective release of 8.23 maf. As illustrated in Figure 4.3-13, the minimum objective release of 8.23 maf under the No Action Alternative is met or exceeded approximately 98 percent or more of the time. The minimum objective release of 8.23 maf under the action alternatives is met or exceeded approximately 86 percent or more of the time. The exception to this is the Reservoir Storage Alternative under which the minimum objective release of 8.23 maf is met or exceeded approximately 82 percent of the time.

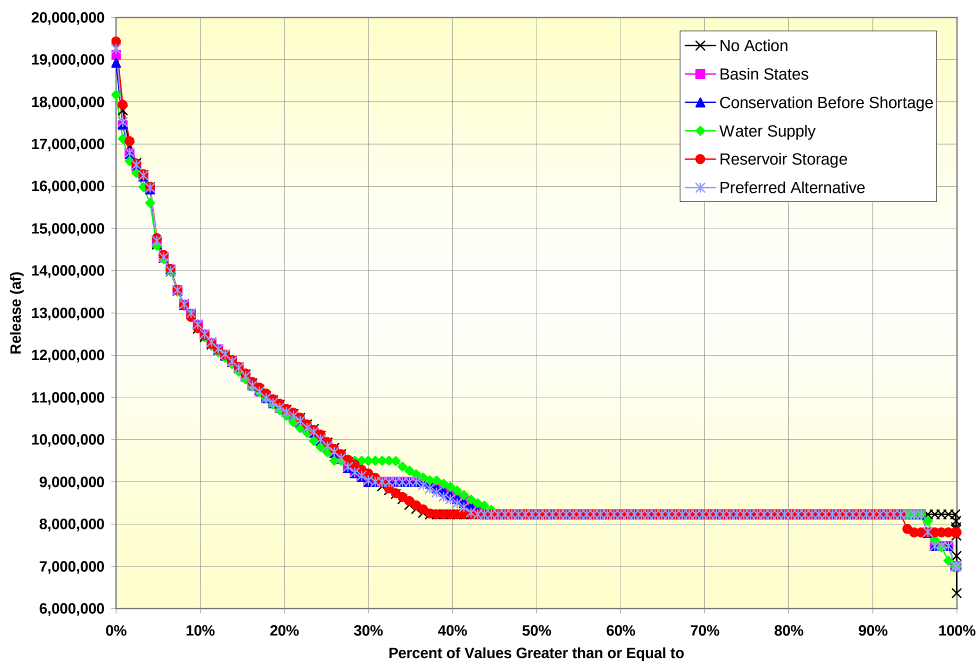
Figure 4.3-13
Glen Canyon Dam Water Year Releases
Comparison of Action Alternatives to No Action Alternative
Water Years 2008 through 2026



The minimum observed release volume of 6.36 maf occurs under the No Action Alternative. Unlike the action alternatives, the No Action Alternative does not include a range of elevations where annual releases less than 8.23 maf are permitted. A release of less than 8.23 maf can only occur under the No Action Alternative due to physical release constraints at Lake Powell (approximately elevation 3,460 feet msl). Appendix B, Section B.2 describes this physical release constraint in more detail. By providing for releases less than 8.23 maf (as low as 7.0 maf), the action alternatives avoid reaching elevations where releases are physically constrained. The minimum observed water year release volume under the Preferred Alternative and the Basin States, Conservation Before Shortage, and Water Supply alternatives is 7.0 maf. The minimum observed water year release volume under the Reservoir Storage Alternative is 7.8 maf.

Figure 4.3-14 illustrates the cumulative distribution of the Glen Canyon Dam water year releases under the No Action Alternative and the action alternatives for the modeling period 2008 through 2060. As illustrated in Figure 4.3-14, the minimum objective release of 8.23 maf in the alternatives is met or exceeded 96 percent or more of the time. The exception to this is the Reservoir Storage Alternative under which the minimum objective release of 8.23 maf is met or exceeded approximately 93 percent of the time. The minimum releases observed during the interim period in Figure 4.3-13 are also observed in Figure 4.3-14, which reflects the overlap in the modeling period covered for these analyses.

Figure 4.3-14
Glen Canyon Dam Water Year Releases
Comparison of Action Alternatives to No Action Alternative
Water Years 2008 through 2060



4.3.3.1 Effect of Glen Canyon Dam Annual Releases on Daily River Flows Below Glen Canyon Dam

Table 4.3-11 and Figure 4.3-13 compare the probabilities of occurrence of different Glen Canyon Dam annual release volumes for each alternative relative to the No Action Alternative. Relatively small differences are seen at the higher releases (above 9.5 maf) that are primarily a result of equalization and spill avoidance releases. The majority of differences are due to operations under each action alternative that deviate from the minimum objective release of 8.23 maf – when releases are being made to balance Lake Powell and Lake Mead contents and when Glen Canyon Dam releases are constrained to specific values other than 8.23 maf.

Changes in the annual release volume will likely result in changes to the monthly distribution of releases. Furthermore, even though future daily and hourly releases are expected to continue to be made according to the parameters of the 1996 Glen Canyon Dam ROD (Section 3.3.2), changes in monthly releases may result in different distributions of daily and hourly releases.

To assess the potential impacts of such changes, monthly release patterns were developed for a set of annual release volumes and/or ranges (7.0, 7.48, 7.8, 8.23, 9.0, 9.5, 9.5 to 11.0, and 11.0 to 16.0 maf). The monthly release patterns were the result of an analysis of the monthly modeled releases and are considered to be representative of all of the alternatives. Based on the monthly release patterns, the 1996 Glen Canyon Dam ROD parameters were applied to determine the average, minimum, and maximum daily releases for each month and each annual release volume (Tables 4.3-13, Table 4.3-14, and Table 4.3-15 respectively). These data show the correlation between annual release volumes and the likely daily and hourly flows; however, actual daily and hourly flows will be the result of decisions based on actual operating conditions and other factors considered in real-time.

The information in Tables 4.3-13, Table 4.3-14, and Table 4.3-15 may be coupled with the information in Table 4.3-11 to determine the probability of occurrence for each alternative of specific minimum, maximum, and average daily flows for specific months. This information can then be used to evaluate potential downstream impacts to water quality and other environmental resources.

Table 4.3-13
Average Daily Glen Canyon Dam Releases (cfs)
Corresponding to Various Annual Release Volumes

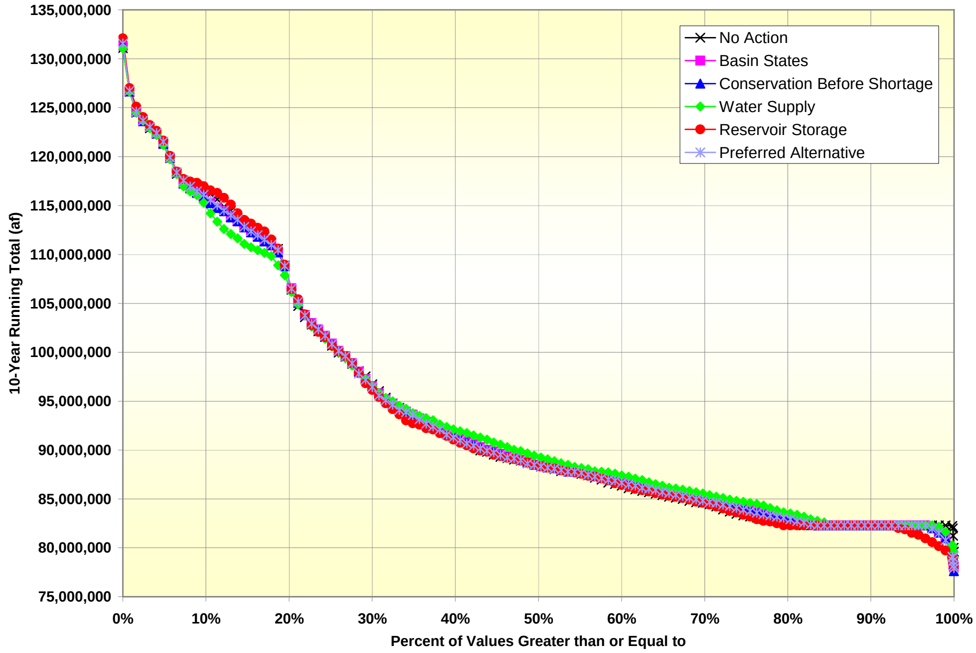
1. *The analysis showed that a consistent monthly release pattern was not evident for 7.0 maf annual release years, primarily due to the variability in forecasted inflows. The monthly pattern shown was taken from a representative trace (Trace 89 for WY 2017 from the Water Supply Alternative)*

4.3.3.2 10-year Running Total of Glen Canyon Dam Releases

Figure 4.3-15 compares the 10-year running totals of the Glen Canyon Dam water year releases under the action alternatives to the No Action Alternative. The values used to compute the 10-year running total for 2008 through 2017 included a combination of historical values for years prior to 2006, projections from the 24-month study for 2007 (Section 4.2 and Appendix A), and output from the CRSS model for 2008 and later. The upper limit of the 10-year running total was similar under the No Action Alternative and the action alternatives and equaled approximately 131 maf. The 10-year running total under all of the alternatives, including the No Action Alternative, was always above 75 maf.

The 10-year running total under the No Action Alternative was less than 82.3 maf in less than one percent of the years with a minimum value of 79.6 maf. The 10-year running totals under the Basin States and Conservation Before Shortage alternatives, and the Preferred Alternative were less than 82.3 maf in approximately three percent of the years and the minimum value was 77.6 maf. The 10-year running total under the Water Supply Alternative was less than 82.3 maf in two percent of the years and the minimum value was 79.0 maf. The 10-year running total under the Reservoir Storage Alternative was less than 82.3 maf in approximately 7.2 percent of the years and the minimum value was 78.1 maf.

Figure 4.3-15
Glen Canyon Dam 10-Year Running Total of Annual Releases
Comparison of Action Alternatives to No Action Alternative
Water Years 2008 through 2060



4.3.3.3 Beach/Habitat-Building Flows

The frequencies at which BHBF releases from Glen Canyon Dam would occur under the No Action Alternative and under the action alternatives were estimated using CRSS. The model simulates BHBF releases by using the BHBF triggering criteria (described in Appendix P, Section P-HR.1) and computes the probability of occurrence of BHBF releases for each calendar year throughout the modeling period. The results of this analysis for each alternative are presented in Appendix P (Section P-HR.1), and a summary is presented below.

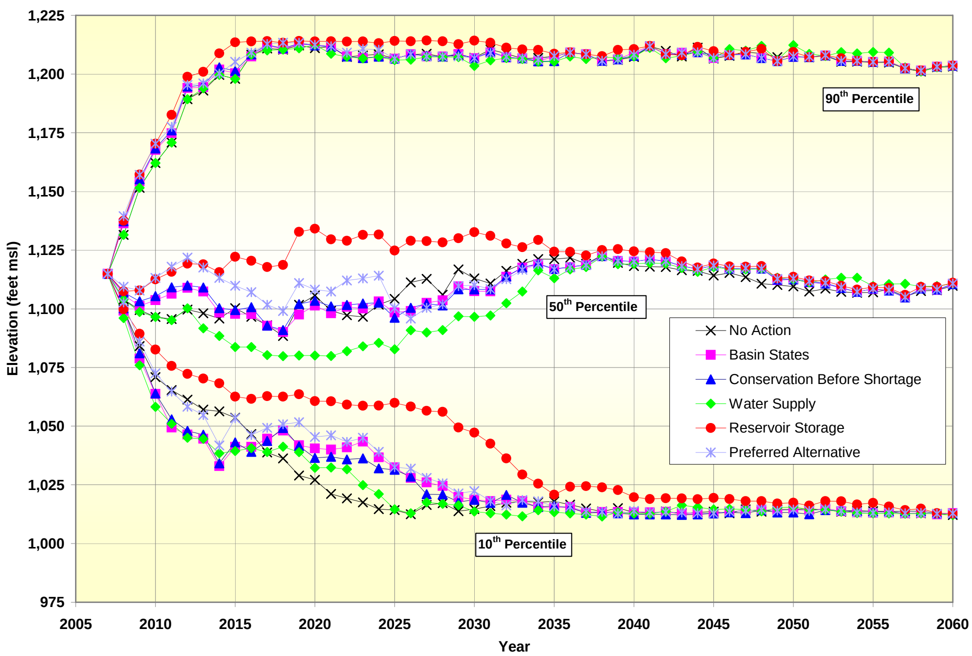
In general, the average probability that BHBF releases could be made under the No Action Alternative and the action alternatives are similar (approximately seven percent) during the interim period (2008 through 2026). The exception to this is the Reservoir Storage Alternative which has an average probability of BHBF releases that is approximately one percent higher than that of the No Action Alternative and the other action alternatives. The average probabilities for all of the alternatives are lower during the interim period as compared to the average probabilities observed during the post-interim period (2027 through 2060). This is primarily due to the low reservoir starting conditions. The average probability that BHBF releases under the No Action Alternative and the action alternatives are approximately 11.5 percent during the post-interim period (2027 through 2060). The exception to this is the Reservoir Storage Alternative which has an average probability of BHBF releases that is approximately half a percent higher than that of the No Action Alternative and the other action alternatives. The Reservoir Storage Alternative generally provides a slightly higher probability of BHBF releases than the No Action Alternative and the other action alternatives because this alternative generally provides higher reservoir elevations.

4.3.4 Lake Mead and Hoover Dam

Future elevations of Lake Mead are expected to be within the range of historic water levels (Section 3.3). However, each alternative may alter the probability (when compared to the No Action Alternative) that the reservoir may be at a given elevation in the future.

Figure 4.3-16 presents a comparison of the 90th, 50th, and 10th percentile values observed for the action alternatives to those under the No Action Alternative for Lake Mead end-of-December elevations. Under the No Action Alternative, Lake Mead is projected to fluctuate between full pool (elevation 1,219.6 feet msl) and lower elevations during the period of analysis (2008 through 2060). The 90th percentile plot increases from starting conditions to nearly full pool, about elevation 1,212 feet msl. The median elevation values (50th percentile) under the No Action Alternative fluctuated between approximately 1,090 feet msl and approximately 1,120 feet msl from 2008 through 2035. The 10th percentile values show a declining trend between 2008 and 2025, from about elevation 1,115 feet msl to about 1,015 feet msl.

Figure 4.3-16
Lake Mead End-of-December Elevations
Comparison of Action Alternatives to No Action Alternative
90th, 50th, and 10th Percentile Values



All action alternatives showed similar 90th percentile values compared to the No Action Alternative. Lake Mead elevations depicted in Figure 4.3-16 represent values at the end of December which is when lake elevations are typically at a seasonal high. Conversely, the Lake Mead elevation generally reaches its seasonal low in July.

Values at the 50th percentile under the Basin States and Conservation Before Shortage alternatives, and the Preferred Alternative were at or above the No Action Alternative prior to 2025. The Water Supply Alternative had lower 50th percentile values than the No Action Alternative during the interim period. The Reservoir Storage Alternative had higher 50th percentile values than the No Action Alternative throughout the entire period. During the interim period, the 10th percentile values for the Basin States, Conservation Before Shortage, and Water Supply alternatives, and the Preferred Alternative were higher than the No Action Alternative, and the values for the Reservoir Storage Alternative were significantly higher than the No Action Alternative.

Table 4.3-16 provides a summary of the data illustrated in Figure 4.3-16 which reflects the 90th, 50th, and 10th percentile end-of-December elevations for Lake Mead observed under the No Action Alternative and the action alternatives. The values presented in this table include those for years 2026 and 2060 only.

Table 4.3-16
Lake Mead End-of-December Elevations (feet msl)
Comparison of Action Alternatives to No Action Alternative
90th , 50th , and 10th Percentile Values

Alternative	Year 2026			Year 2060		
	90th Percentile	50th Percentile	10th Percentile	90th Percentile	50th Percentile	10th Percentile
No Action	1,208.27	1,111.31	1,012.48	1,203.15	1,109.73	1,012.14
Basin States	1,208.44	1,099.06	1,027.98	1,203.52	1,110.50	1,012.95
Conservation Before Shortage	1,208.44	1,100.41	1,028.45	1,203.52	1,110.50	1,012.87
Water Supply	1,206.11	1,090.89	1,012.88	1,203.43	1,110.66	1,012.14
Reservoir Storage	1,214.02	1,129.00	1,058.40	1,203.62	1,111.10	1,012.74
Preferred Alternative	1,208.44	1,095.83	1,031.95	1,203.52	1,110.75	1,012.93

The 90th percentile values in year 2026 vary little between the action alternatives and the No Action Alternative. The exception to this is the Reservoir Storage Alternative which is approximately seven feet higher than that of the No Action Alternative.

The 50th percentile values for the Basin States, Conservation Before Shortage, and Water Supply alternatives, and the Preferred Alternative in year 2026 are approximately 12, 11, 20, and 16 feet lower than that of the No Action Alternative, respectively. In contrast, the 50th percentile value for the Reservoir Storage Alternative in year 2026 is approximately 18 feet higher than that of the No Action Alternative.

The 10th percentile values for the Basin States, Conservation Before Shortage, Water Supply, and Reservoir Storage alternatives, and the Preferred Alternative were all higher than that of No Action Alternative in year 2026 (Table 4.3-16). The greatest difference of elevations observed occurs between the Reservoir Storage Alternative and No Action Alternative, which is about 46 feet.

Figure 4.3-17 illustrates the results for exceedence values above an elevation of 1,200 feet msl, nearly the full pool elevation of Lake Mead. All of the action alternatives were very similar to the No Action Alternative throughout the modeled years, with exceedence values ranging between zero and 20 percent.

Figure 4.3-17
Lake Mead End-of-December Elevations
Comparison of Action Alternatives to No Action Alternative
Percent of Values Greater Than or Equal to Elevation 1,200 feet msl

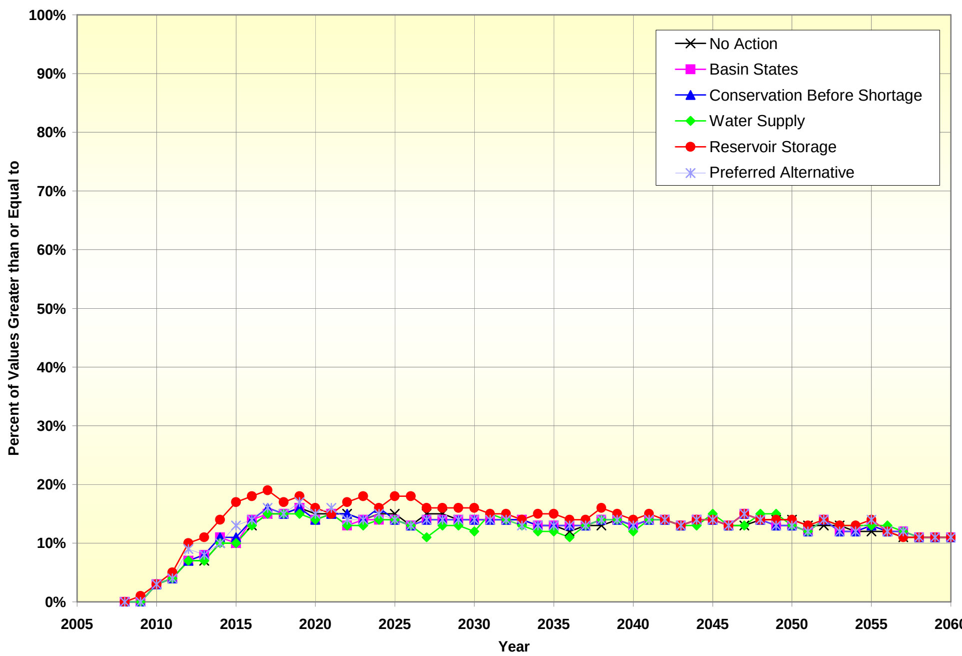


Table 4.3-17 provides a summary of the exceedence values for elevation 1,200 feet msl for selected years. As listed in this table, the exceedence values for the alternatives are similar, although the Reservoir Storage Alternative provides slightly higher exceedence values.

Table 4.3-17
Lake Mead End-of-December Elevations
Comparison of Action Alternatives to No Action Alternative
Percent of Values Greater Than or Equal to Elevation 1,200 feet msl

Alternatives	Year						
	2008	2016	2026	2030	2040	2050	2060
No Action	0	13	13	14	13	14	11
Basin States	0	14	13	14	13	13	11
Conservation Before Shortage	0	14	13	14	13	13	11
Water Supply	0	13	13	12	12	13	11
Reservoir Storage	0	18	18	16	14	14	11
Preferred Alternative	0	14	13	14	13	13	11

Figure 4.3-18 illustrates the frequency that future Lake Mead end-of-December elevations would be below 1,178 feet msl. Lake Mead elevations of 1,178 feet msl and 1,000 feet msl were used by the Clean Water Coalition as reference elevations for its Lake Mead water quality analysis (Systems Conveyance and Operations Program Final Environmental Impact Statement [SCOP FEIS] Clean Water Coalition 2006). The SCOP FEIS analyzed water quality changes corresponding to Lake Mead elevation drawdown from 1,178 feet msl to 1,000 feet msl. These potential Lake Mead water quality changes are discussed in Section 4.5. As shown in Figure 4.3-18, the results for the Basin States and Conservation Before Shortage alternatives, and the Preferred Alternative are similar to those of the No Action Alternative. Elevations under the Reservoir Storage Alternative were below 1,178 feet msl less frequently than those under the No Action Alternative. Elevations under the Water Supply Alternative were below 1,178 feet msl more frequently than those under the No Action Alternative.

Figure 4.3-18
Lake Mead End-of-December Elevations
Comparison of Action Alternatives to No Action Alternative
Percent of Values Less Than or Equal to Elevation 1,178 feet msl

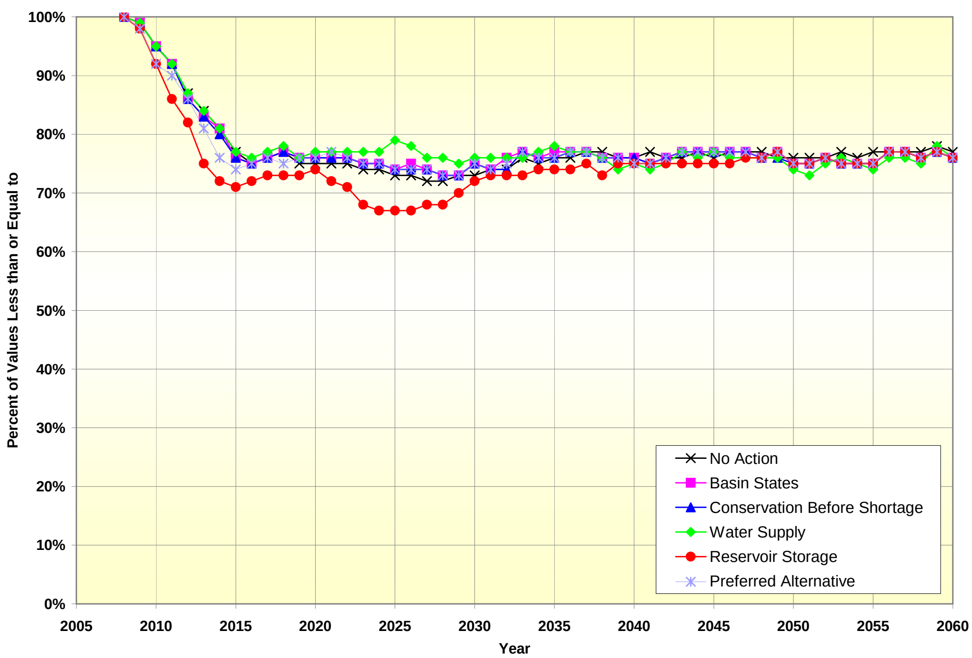

Table 4.3-18 provides a summary of the results illustrated in Figure 4.3-18 for elevation 1,178 feet msl in tabular form for selected years. As shown in Table 4.3-18, Lake Mead elevations under the Basin States and Conservation Before Shortage alternatives, and the Preferred Alternative are similar to those under the No Action Alternative. Elevations under the Reservoir Storage Alternative were below 1,178 feet msl less frequently than those under the No Action Alternative. Elevations under the Water Supply Alternative were below elevation 1,178 feet msl more frequently than those under the No Action Alternative.

Table 4.3-18
Lake Mead End-of-December Elevations
Comparison of Action Alternatives to No Action Alternative
Percent of Values Less than or Equal to Elevation 1,178 feet msl

Alternatives	Year						
	2008	2016	2026	2030	2040	2050	2060
No Action	100	75	73	73	76	76	77
Basin States	100	75	75	75	76	75	76
Conservation Before Shortage	100	75	74	75	76	75	76
Water Supply	100	76	78	76	75	74	76
Reservoir Storage	100	72	67	72	75	75	76
Preferred Alternative	100	75	74	75	75	75	76

Figure 4.3-19 illustrates the frequency that future Lake Mead end-of-July elevations would be below elevation 1,175 feet msl. Lake Mead generally reaches its seasonal low elevation in July. Below this elevation, the Pearce Bay Launch Ramp is closed and whitewater boaters must paddle an additional 16 miles to South Cove. As illustrated in Figure 4.3-19, the results for the Basin States, Conservation Before Shortage, and Water Supply alternatives, and the Preferred Alternative are similar to those of the No Action Alternative. Elevations under the Reservoir Storage Alternative were below 1,175 feet msl less frequently than those under the No Action Alternative.

Figure 4.3-19
Lake Mead End-of-July Elevations
Comparison of Action Alternatives to No Action Alternative
Percent of Values Less Than or Equal to Elevation 1,175 feet msl

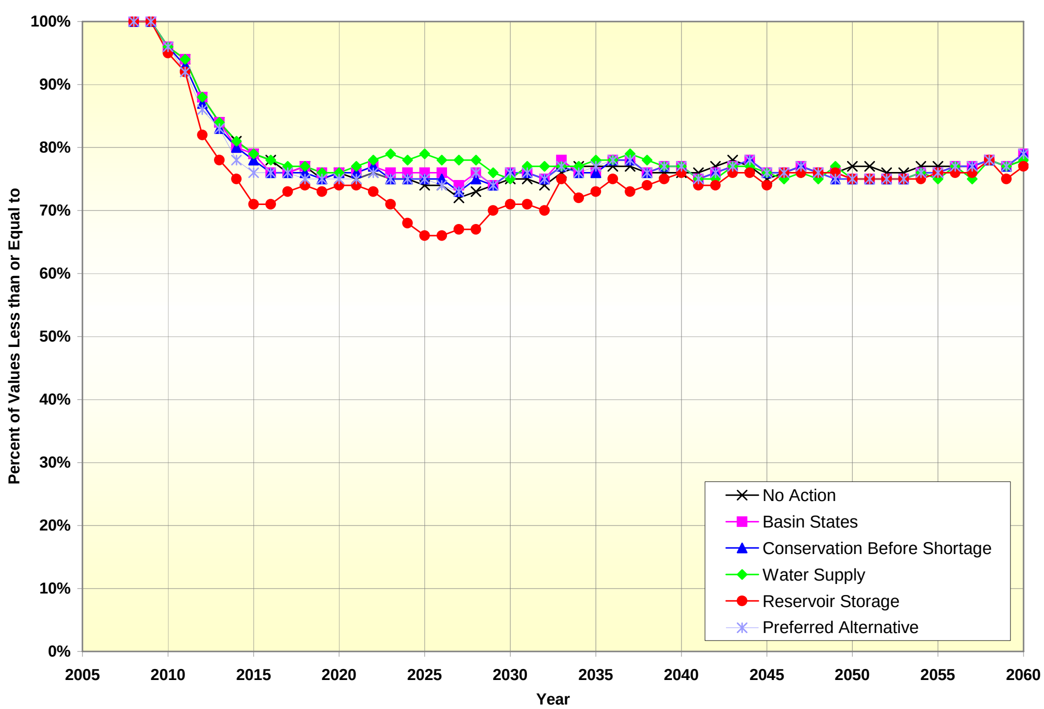

Table 4.3-19 provides a summary of the results illustrated in Figure 4.3-19 for elevation 1,175 feet msl for selected years. As shown in Table 4.3-19, Lake Mead elevations under the Basin States, Conservation Before Shortage, and Water Supply alternatives, and the Preferred Alternative are similar to those under the No Action Alternative. Elevations under the Reservoir Storage Alternative were below 1,175 feet msl less frequently than those under the No Action Alternative.

Table 4.3-19
Lake Mead End-of-July Elevations
Comparison of Action Alternatives to No Action Alternative
Percent of Values Less Than or Equal to Elevation 1,175 feet msl

Alternatives	Year						
	2008	2016	2026	2030	2040	2050	2060
No Action	100	78	74	75	76	77	78
Basin States	100	76	76	76	77	75	79
Conservation Before Shortage	100	76	75	76	77	75	79
Water Supply	100	78	78	75	77	75	78
Reservoir Storage	100	71	66	71	76	75	77
Preferred Alternative	100	76	74	76	77	75	79

Figure 4.3-20 illustrates the frequency that Lake Mead end-of-July elevations would be below elevation 1,170 feet msl, the minimum elevation needed to maintain navigation between Grand Wash and Pearce Ferry. At elevations below 1,170 feet msl, potential sediment aggradation could potentially impair navigation between these two locations. As illustrated in Figure 4.3-20, the results for the Basin States and Conservation Before Shortage alternatives, and the Preferred Alternative are similar to those observed under the No Action Alternative. Lake Mead elevations under the Water Supply Alternative were below 1,170 feet msl more frequently than those under the No Action Alternative through 2033. Elevations under the Reservoir Storage Alternative were below 1,170 feet msl less frequently than those under the No Action Alternative.

Figure 4.3-20
Lake Mead End-of-July Elevations
Comparison of Action Alternatives to No Action Alternative
Percent of Values Less Than or Equal to Elevation 1,170 feet msl

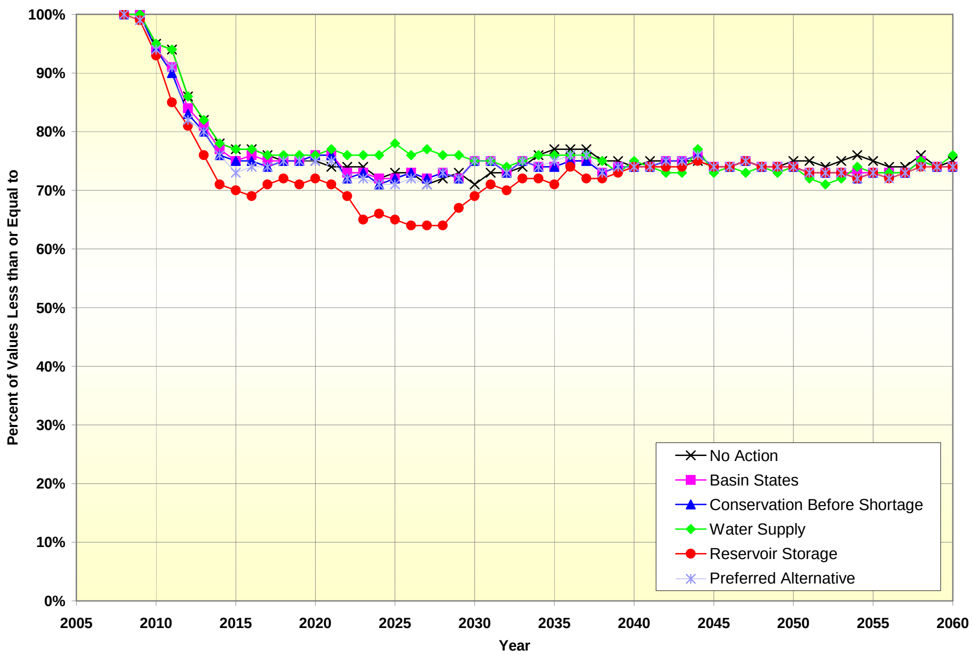

Table 4.3-20 provides a summary of the results illustrated in Figure 4.3-20 for the Lake Mead end-of-July elevation of 1,170 feet msl for selected years.

Table 4.3-20
Lake Mead End-of- July Elevations
Comparison of Action Alternatives to No Action Alternative
Percent of Values Less Than or Equal to Elevation 1,170 feet msl

Alternatives	Year						
	2008	2016	2026	2030	2040	2050	2060
No Action	100	77	73	71	74	75	75
Basin States	100	76	73	75	74	74	74
Conservation Before Shortage	100	75	73	75	74	74	74
Water Supply	100	77	76	75	75	74	76
Reservoir Storage	100	69	64	69	74	74	74
Preferred Alternative	100	74	72	75	74	74	74

Figure 4.3-21 illustrates the frequency that Lake Mead end-of-July elevations were below elevation 1,125 feet msl. At lake elevations lower than 1,125 feet msl, the Overton Beach Marina and South Cove Ramp are closed. As illustrated in Figure 4.3-21, Lake Mead elevations under the Basin States and Conservation Before Shortage alternatives, and the Preferred Alternative were below 1,125 ft msl less frequently than under the No Action Alternative prior to 2025. Elevations under the Water Supply Alternative were below 1,125 feet msl more frequently than those under the No Action Alternative between 2015 and 2041. Elevations under the Reservoir Storage Alternative were below 1,125 feet msl less frequently than those under the No Action Alternative.

Figure 4.3-21
Lake Mead End-of-July Elevations
Comparison of Action Alternatives to No Action Alternative
Percent of Values Less Than or Equal to Elevation 1,125 feet msl

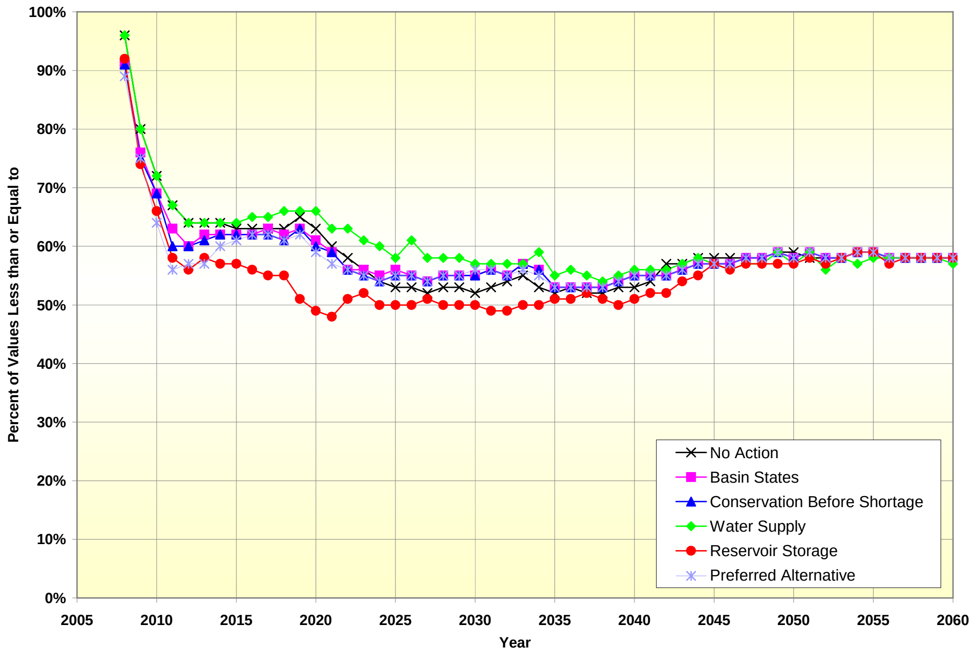

Table 4.3-21 provides a summary of the results for the Lake Mead end-of-July elevation of 1,125 feet msl for selected years.

Table 4.3-21
Lake Mead End-of-July Elevations
Comparison of Action Alternatives to No Action Alternative
Percent of Values Less Than or Equal to Elevation 1,125 feet msl

Alternatives	Year						
	2008	2016	2026	2030	2040	2050	2060
No Action	96	63	53	52	53	59	58
Basin States	91	62	55	55	55	58	58
Conservation Before Shortage	91	62	55	55	55	58	58
Water Supply	96	65	61	57	56	57	57
Reservoir Storage	92	56	50	50	51	57	58
Preferred Alternative	89	62	55	56	55	58	58

Figure 4.3-22 illustrates the frequency that Lake Mead end-of-July elevations would be below elevation 1,080 feet msl. At Lake Mead elevations below 1,080 feet msl, operations of the Lake Mead Marina Public Launch Ramp, Hemenway Public Launch Ramp, and Temple Bar Public Launch Ramp could potentially be affected. As illustrated in Figure 4.3-22, Lake Mead elevation was below 1,080 feet msl under the Reservoir Storage Alternative less frequently than under the No Action Alternative between 2010 and 2045. Elevations under the Preferred Alternative were below 1,080 feet msl less frequently than under the No Action Alternative during the period between 2010 and 2025. Elevations under the Basin States and Conservation Before Shortage alternatives were below 1,080 feet msl slightly more frequently between 2015 and 2030. Elevations under the Water Supply Alternative were below 1,080 feet msl more frequently than those under the No Action Alternative between 2015 and 2033.

Figure 4.3-22
Lake Mead End-of-July Elevations
Comparison of Action Alternatives to No Action Alternative
Percent of Values Less Than or Equal to Elevation 1,080 feet msl

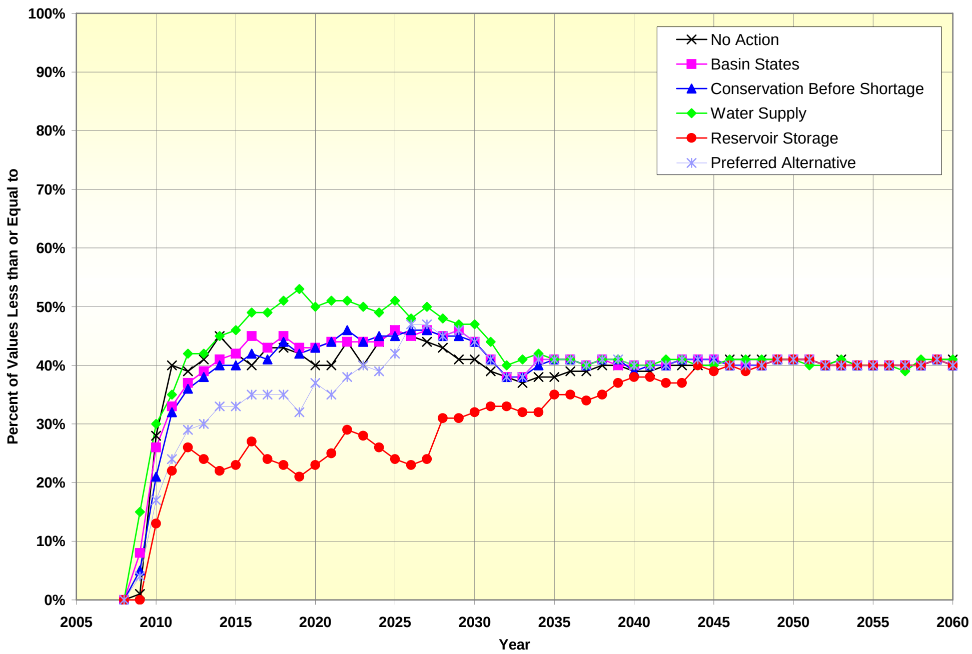

Table 4.3-22 provides a summary of the results for the Lake Mead-end-of-July elevation of 1,080 feet msl for selected years. As listed in Table 4.3-22, the action alternatives vary from the No Action Alternative mostly between years 2010 and 2030 and are similar in subsequent years.

Table 4.3-22
Lake Mead End-of-July Elevations
Comparison of Action Alternatives to No Action Alternative
Percent of Values Less Than or Equal to Elevation 1,080 feet msl

Alternatives	Year						
	2008	2016	2026	2030	2040	2050	2060
No Action	0	40	45	41	39	41	41
Basin States	0	45	45	44	40	41	40

Reservoir Storage	0	27	23	32	38	41	40
Preferred Alternative	0	35	47	44	40	41	40

Figure 4.3-23 illustrates the frequency that Lake Mead end-of-July elevations would be below elevation 1,050 feet msl. Lake Mead elevation of 1,050 feet msl is the minimum elevation needed for efficient power generation at the Hoover Powerplant, the minimum elevation for operation of the upper intake of SNWA, and the minimum elevation for the Echo Bay Boat Launch. As illustrated in Figure 4.3-23, Lake Mead elevations under the Basin States and Conservation Before Shortage alternatives were below 1,050 feet msl less frequently than those under the No Action Alternative from 2016 through 2028. The same pattern held for the Preferred Alternative beginning in 2013. Elevations under the Water Supply Alternative were below 1,050 feet msl less frequently than under the No Action Alternative between 2018 and 2026. Elevations under the Reservoir Storage Alternative were below 1,050 feet msl less frequently than those under the No Action Alternative (lower by as much as 10 to 20 percent), reflecting higher reservoir elevations.

Figure 4.3-23
Lake Mead End-of-July Elevations
Comparison of Action Alternatives to No Action Alternative
Percent of Values Less Than or Equal to Elevation 1,050 feet msl

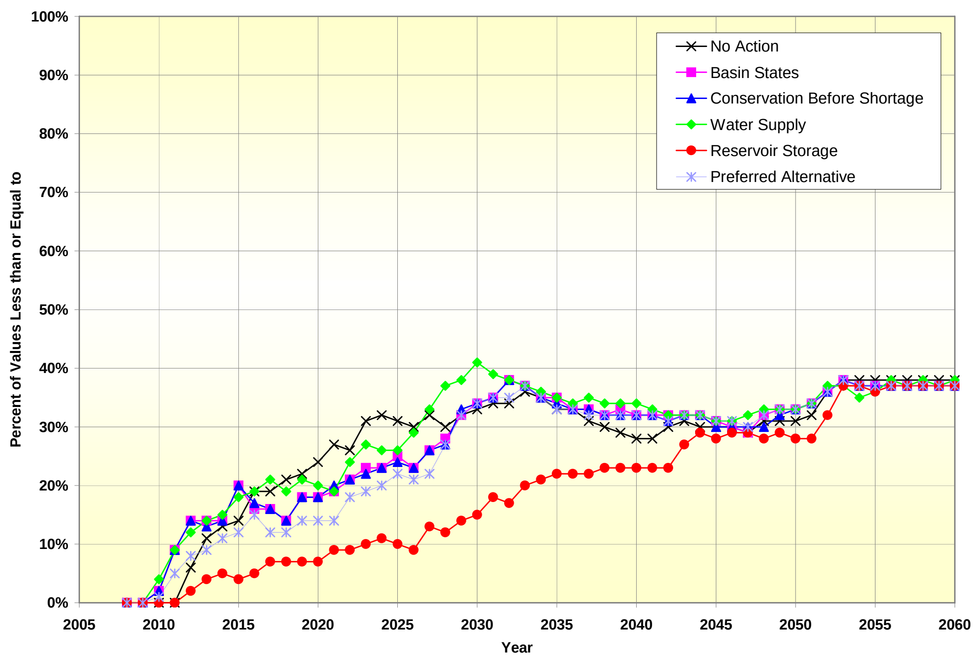

Table 4.3-23 provides a summary of the results illustrated in Figure 4.3-23 for the Lake Mead end-of-July elevation of 1,050 feet msl for selected years.

Table 4.3-23
Lake Mead End-of-July Elevations
Comparison of Action Alternatives to No Action Alternative
Percent of Values Less Than or Equal to Elevation 1,050 feet msl

Alternatives	Year						
	2008	2016	2026	2030	2040	2050	2060
No Action	0	19	30	33	28	31	38
Basin States	0	16	23	34	32	33	37
Conservation Before Shortage	0	17	23	34	32	33	37
Water Supply	0	19	29	41	34	33	38
Reservoir Storage	0	5	9	15	23	28	37
Preferred Alternative	0	15	21	34	32	33	37

Figure 4.3-24 illustrates the frequency that Lake Mead end-of-July elevations would be below elevation 1,000 feet msl. Lake Mead elevation of 1,000 feet msl is the minimum elevation needed by SNWA, to pump water from Lake Mead through its lower intake. Lake Mead elevation 1,000 feet msl was also a reference elevation for the Lake Mead water quality analysis. The SCOP FEIS analyzed water quality changes corresponding to Lake Mead elevation drawdown from 1,178 feet msl to 1,000 feet msl. These potential water quality changes are discussed in Section 4.5. As illustrated in Figure 4.3-24, Lake Mead end-of-July elevations under the No Action Alternative, and the Conservation Before Shortage and Reservoir Storage alternatives were not below 1,000 feet msl. Elevations under the Basin States Alternative and the Preferred Alternative do show some instances below 1,000 feet msl, although the frequency is very low. The maximum observed probability for elevations below 1,000 feet msl under the Water Supply Alternative is 12 percent and occurs towards the end of the interim period. Under the Basin States Alternative and the Preferred Alternative, the maximum observed probability for elevations below 1,000 feet msl is two percent and also occurs toward the end of the interim period.

Figure 4.3-24
Lake Mead End-of-July Elevations
Comparison of Action Alternatives to No Action Alternative
Percent of Values Less Than or Equal to Elevation 1,000 feet msl

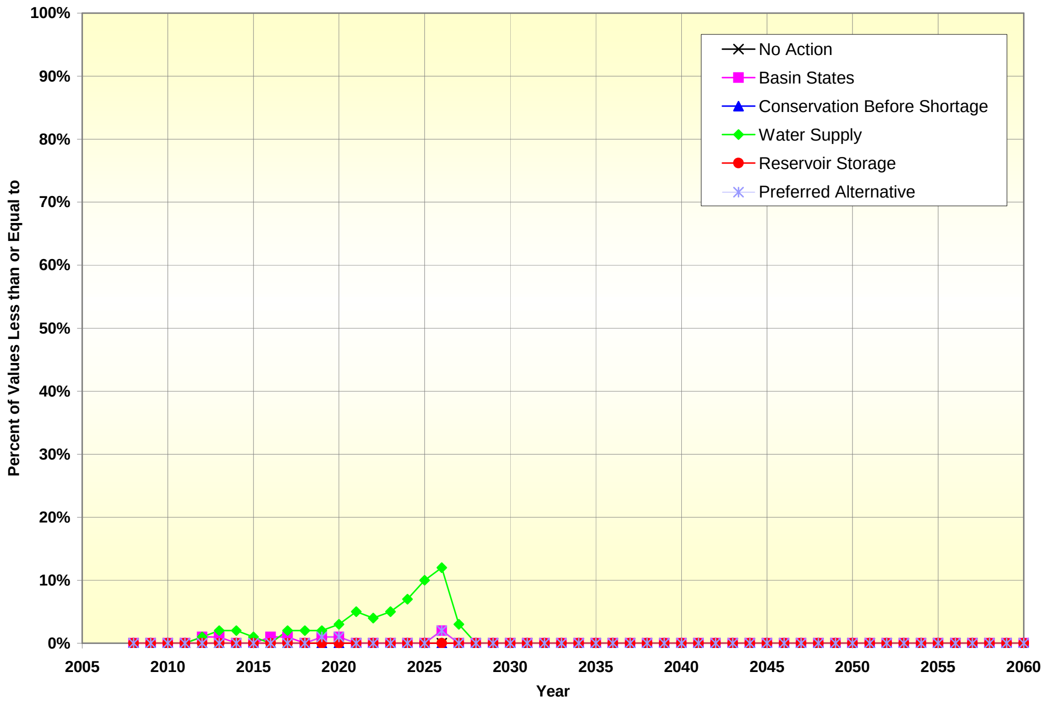

Table 4.3-24 provides a summary of the results illustrated in Figure 4.3-24 for the Lake Mead end-of-July elevation of 1,000 feet msl for selected years. The Water Supply and Basin States alternatives, and the Preferred Alternative are the only alternatives that show instances where lake elevations were below 1,000 feet msl.

Table 4.3-24
Lake Mead End-of-July Elevations
Comparison of Action Alternatives to No Action Alternative
Percent of Values Less Than or Equal to Elevation 1,000 feet msl

Alternatives	Year						
	2008	2016	2026	2030	2040	2050	2060
No Action	0	0	0	0	0	0	0
Basin States	0	1	2	0	0	0	0
Conservation Before Shortage	0	0	0	0	0	0	0
Water Supply	0	0	12	0	0	0	0
Reservoir Storage	0	0	0	0	0	0	0
Preferred Alternative	0	0	2	0	0	0	0

Figure 4.3-25 illustrates the minimum Lake Mead end-of-July elevations that were observed in the modeling of the action alternatives and No Action Alternative during the period of analysis (2008 through 2060). The minimum lake elevations under the No Action Alternative were not below 1,000 feet msl throughout the period of analysis. Similarly, the minimum lake elevations under the Conservation Before Shortage and Reservoir Storage Alternatives were not below 1,000 feet msl throughout the period of analysis. The minimum lake elevations under the Reservoir Storage Alternative are generally higher than those observed under the No Action Alternative. The minimum lake elevations under the Water Supply Alternative are generally lower than those observed under the No Action Alternative and were below 1,000 feet msl for nearly all years of the interim period. The minimum lake elevations under the Basin States Alternative are also below 1,000 feet msl during the interim period, but at higher elevations compared to the Water Supply Alternative. Lake Mead elevations modeled under the Preferred Alternative were below 1,000 feet msl, albeit only in a few years and only a few feet below elevation 1,000 feet msl. The minimum Lake Mead end-of-July elevation values under the action alternatives and the No Action Alternative remain at about 1,000 feet msl after 2030 due to the modeling assumptions after 2026.

Figure 4.3-25
Lake Mead End-of-July Elevations
Comparison of Action Alternatives to No Action Alternative
Minimum Elevation Values (feet msl)

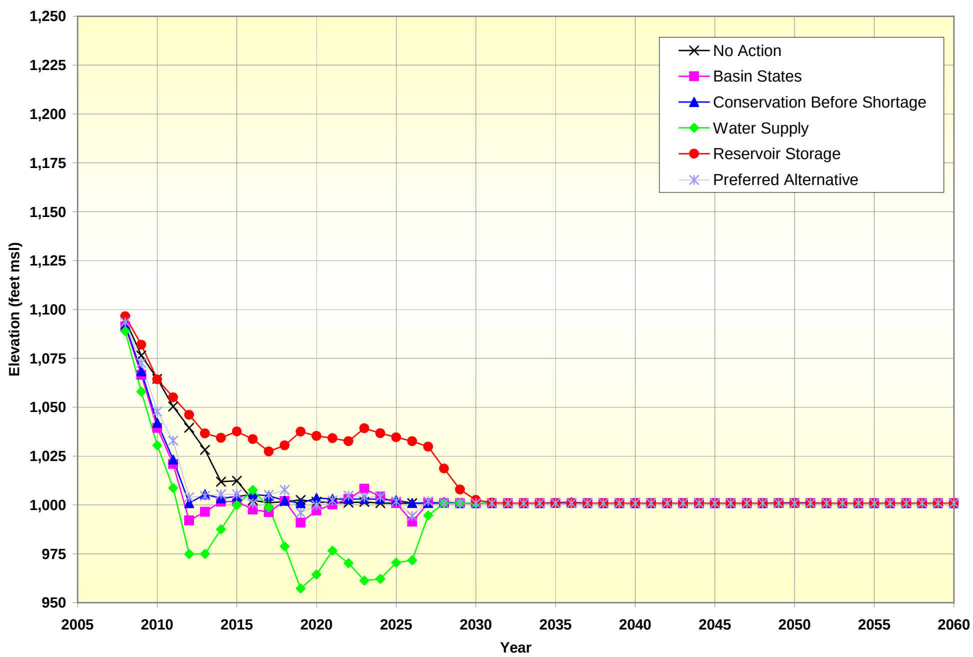

Table 4.3-25 provides a summary of the results illustrated in Figure 4.3-25 for the Lake Mead end-of-July minimum elevations for selected years. As listed in this table, the greatest variability between the action alternatives and the No Action Alternative occurs during the interim period.

Table 4.3-25
Lake Mead End-of-July Elevations
Comparison of Action Alternatives to No Action Alternative
Minimum Elevation Values (feet msl)

Water Supply	1,088.9	1,007.6	971.7	1,000.9	1,000.9	1,000.9	1,000.9
Reservoir Storage	1,096.5	1,033.7	1,032.6	1,002.6	1,000.9	1,000.9	1,000.9
Preferred Alternative	1,093.5	1,000.9	994.4	1,000.9	1,000.9	1,000.9	1,000.9

4.3.4.1 Probability of Reaching Other Key Lake Mead Elevations

The Basin States Alternative and the Preferred Alternative provide discrete levels of shortage associated with specific Lake Mead elevations (Section 2.3 and Section 2.7, respectively). These alternatives provide for shortages of 333 kaf, 417 kaf, and 500 kaf to users within the Lower Division states at Lake Mead elevations of 1,075 feet msl, 1,050 feet msl, and 1,025 feet msl, respectively. Additionally, when Lake Mead is below elevation 1,025 feet msl, additional consultations would occur under the Basin States Alternative and the Preferred Alternative to discuss further measures that may be undertaken consistent with the Law of the River. Lake Mead elevations of 1,075 feet msl, 1,050 feet msl, and 1,025 feet msl are also the conservation trigger elevations provided in the Conservation Before Shortage Alternative and correlate with voluntary water conservation actions of 400 kaf, 500 kaf, and 600 kaf, respectively.

Figure 4.3-26 compares the percent of values less than or equal to the shortage trigger elevations of Lake Mead (1,075 feet msl, 1,050 feet msl, and 1,025 feet msl) under the Basin States and Conservation Before Shortage Alternatives, and the Preferred Alternative. These three key elevations are relevant only to the Basin States and Conservation Before Shortage Alternatives, and the Preferred Alternative, and therefore, the plots for the No Action Alternative, and the Water Supply and Reservoir Storage Alternatives are not shown. Figure 4.3-26 is best used to assess the probability of occurrence of the shortages or conservation actions associated with the three different trigger elevations. For example, in 2026, the probability that Lake Mead would be below the trigger elevation of 1,075 feet msl is 42 percent under the Basin States Alternative and Preferred Alternative and 41 percent under the Conservation Before Shortage Alternative. Additional comparisons of the probabilities are provided in tabular format in Table 4.3-26, Table 4.3-27, and Table 4.3-28.

4.3.4.2 Storage of Conserved Water in Lake Mead

Under the Basin States, Conservation Before Shortage, and Reservoir Storage Alternatives, and the Preferred Alternative, the assumptions made for the storage and delivery mechanism for conserved system and non-system water could potentially impact the volume of water in storage in Lake Mead. An overall increase in the volume of water in Lake Mead is likely due to the system assessment whereby a percentage of the conserved water is retained in Lake Mead.

An analysis of the sensitivity of the volume of water in storage in Lake Mead to the storage and delivery mechanism was performed by comparing these four alternatives with and without the mechanism in place. Without the mechanism in place, it was assumed that the voluntary shortages (i.e., reduced water deliveries due to conservation proposed to occur at and below Lake Mead elevations of 1,075 feet msl) proposed in the Conservation Before Shortage Alternative would occur. Under this assumption, the conserved water would remain in Lake Mead. All other conservation activities assumed to be associated with the storage and delivery mechanism as described in Appendix M were assumed not to exist for the Conservation Before Shortage, Basin States, and Reservoir Storage Alternatives, and the Preferred Alternative.

Figure 4.3-27 presents a comparison of the 90th, 50th, and 10th percentile values observed for the action alternatives to those under the No Action Alternative. This figure illustrates Lake Mead elevations for the Basin States, Conservation Before Shortage, and Reservoir Storage Alternatives, and the Preferred Alternative if the storage and delivery mechanism is not in place. Lake Mead elevations illustrated in Figure 4.3-27 for these alternatives can be contrasted to those shown in Figure 4.3-16 which shows Lake Mead elevations for these alternatives if the storage and delivery mechanism is in place. As illustrated by this comparison, the inclusion of mechanism in these alternatives would have a tendency to provide higher Lake Mead elevations.

Figure 4.3-27
Lake Mead End-of-December Elevations
Comparison of Action Alternatives With Storage and
Delivery Mechanism Removed to No Action Alternative
90th, 50th, and 10th Percentile Values

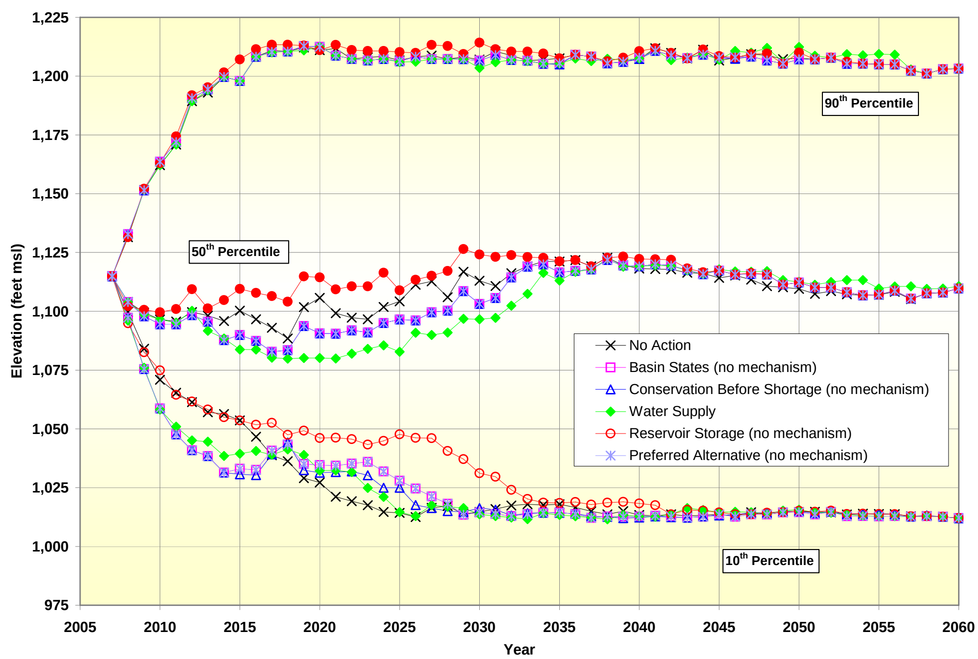

Figure 4.3-28 compares the 90th, 50th, and 10th percentile Lake Mead elevations for the Basin States, Conservation Before Shortage, and Reservoir Storage Alternatives, and the Preferred Alternative with a storage and delivery mechanism, to the same alternatives without a storage and delivery mechanism.

Figure 4.3-28
Lake Mead End-of-December Elevations
Comparison of Action Alternatives With and Without a Storage and Delivery Mechanism
90th, 50th, and 10th Percentile Values

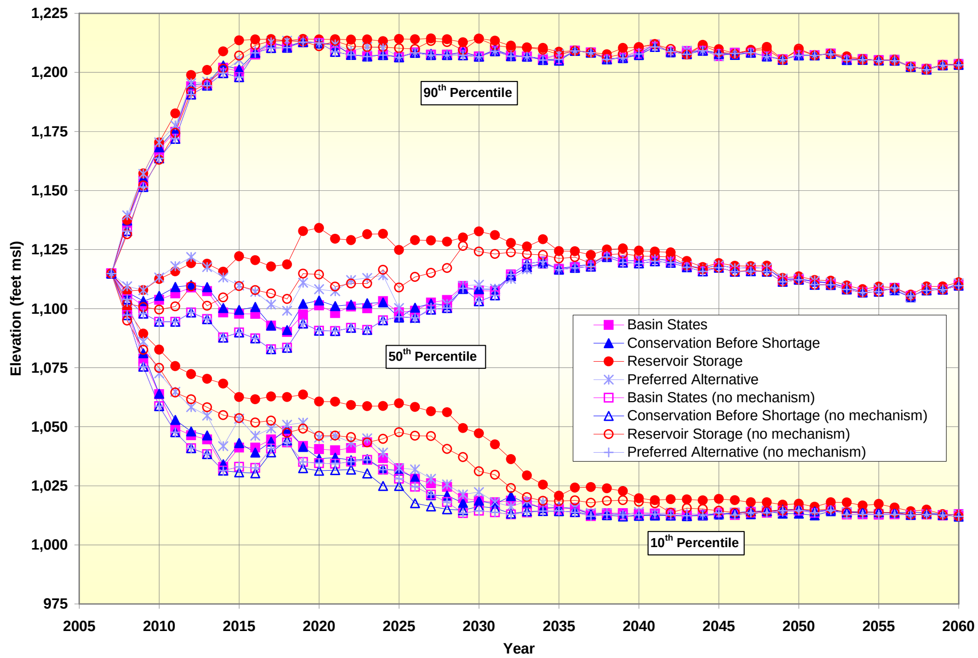

Table 4.3-29 provides a summary of the increases in Lake Mead elevations for selected years that can be attributed to the inclusion of the storage and delivery mechanism in the Basin States, Conservation Before Shortage, and Reservoir Storage Alternatives, and the Preferred Alternative. As listed in this table for the 50th and 10th percentile values, the storage and delivery mechanism could potentially provide higher Lake Mead elevations, by as much as 15.6 feet under the Reservoir Storage Alternative, 13.3 feet under the Conservation Before Shortage Alternative, 10.3 feet under the Basin States Alternative, and 19.7 feet under the Preferred Alternative.

2060	0.5	1.4	0.6	0.4	1.0	0.8

4.3.5 Hoover Dam to Davis Dam

The river flows between Hoover Dam and Lake Mohave are comprised mainly of releases from Hoover Dam (Lake Mead) and tributary inflows. These tributary inflows, mostly from side washes, comprise less than one percent of the total annual flow in this reach. During the 10-year period between 1996 and 2005, the annual Hoover Dam releases have ranged between 8.274 maf and 12.774 maf, and averaged 10.415 maf.

Future annual and monthly releases may be affected by the proposed federal action (Section 3.3). Each action alternative may alter the probability (when compared to the No Action Alternative) of the magnitude and timing of particular releases. However, due to the presence of Lake Mohave immediately downstream, these potential changes in releases will have an effect only on hydropower generation.

Figure 4.3-29 presents a comparison of the 90th, 50th, and 10th percentile values observed under the action alternatives and the No Action Alternative for Hoover Dam annual (calendar year) releases. The greatest variability between the action alternatives and the No Action Alternative generally occurs during the period between 2008 and 2026. Also, the greatest variability occurs between the Reservoir Storage Alternative and the No Action Alternative and is consistent with the underlying strategy of the Reservoir Storage Alternative which is to maintain more water in storage. This is facilitated through more frequent involuntary delivery reductions and is reflected in the 50th and 10th percentile values which are lower for this alternative between 2008 and 2026. Since more water is held in storage, as compared to the No Action Alternative, the Reservoir Storage Alternative provides more opportunities for more frequent and higher flood control and surplus releases, which is reflected in the 90th percentile values for this alternative. In contrast, the strategy of the Water Supply Alternative is to meet the water users' delivery requirements with less regard to preserving water in storage. As such, the 50th and 10th percentile values under the Water Supply Alternative show that more water is delivered under this alternative between 2008 and 2026, as compared to the No Action Alternative. The ranges of water releases at the 90th, 50th, and 10th percentiles that occur under the Basin States and Conservation Before Shortage Alternatives, and the Preferred Alternative generally coincide with the range of releases observed under the No Action Alternative and differences, where they occur, are relatively small.

Another observation relates to the 50th and 10th percentile annual Hoover Dam release volumes that are slightly below those of the No Action Alternative under the Basin States, Conservation Before Shortage, and Reservoir Storage Alternatives, and the Preferred Alternative after 2026. This difference can be attributed to the assumption that SNWA would develop additional permanent non-system water supplies from sources located downstream of Hoover Dam (described as system augmentation in Appendix M) that would be delivered to Lake Mead through some form of transfer or exchange with another agency that has a point of delivery also located downstream of Hoover Dam, thereby reducing the release from Hoover Dam.

Figure 4.3-30 illustrates the cumulative distribution of Hoover Dam annual releases under the action alternatives and the No Action Alternative for the interim period (2008 through 2060). The observed minimum and maximum annual releases under the No Action Alternative are 7.46 maf and 17.13 maf, respectively. By comparison, the minimum annual release under the action alternatives is 7.3 maf, and occurs under the Conservation Before Shortage Alternative; the maximum annual release is 17.16 maf, and occurs under the Basin States, Conservation Before Shortage, and Reservoir Storage Alternatives, and the Preferred Alternative. In general, the observed annual release volumes under the Basin States and Conservation Before Shortage Alternatives, and the Preferred Alternative are similar to those observed under the No Action Alternative. The annual releases observed under the Water Supply Alternative are generally higher than those observed under the No Action Alternative. The annual releases observed under the Reservoir Storage Alternative are generally lower than those observed under the No Action Alternative.

Figure 4.3-29

10th Percentile

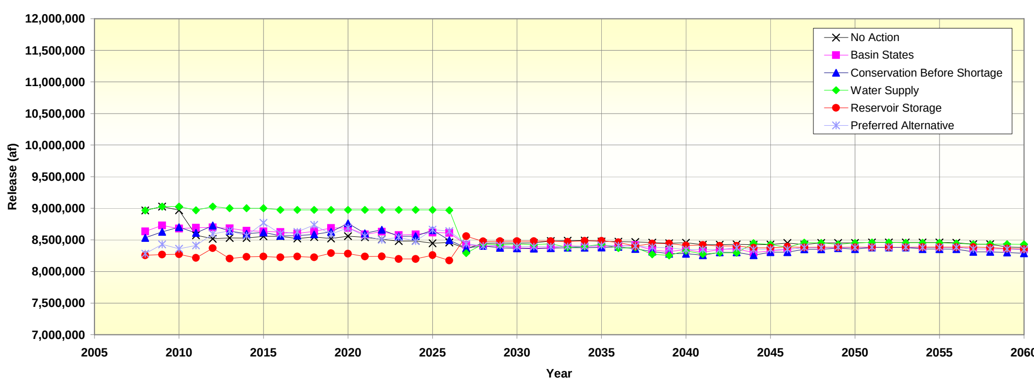

Figure 4.3-30
Hoover Dam Cumulative Annual Releases
Comparison of Action Alternatives to No Action Alternative
Years 2008 through 2026

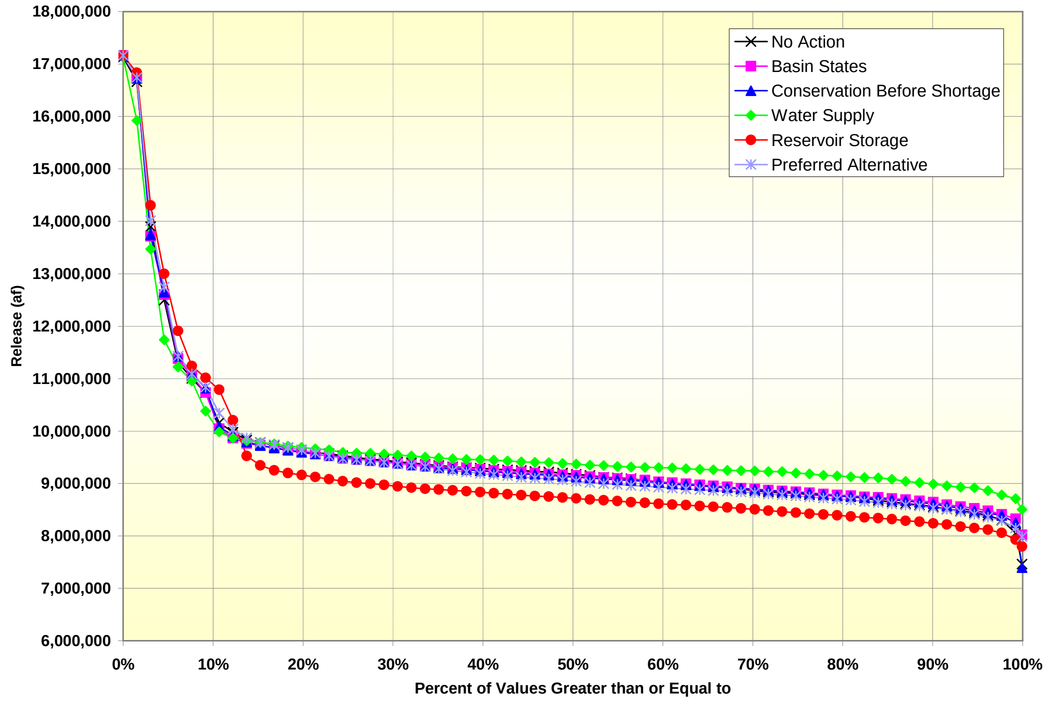

Figure 4.3-31 illustrates the cumulative distribution of Hoover Dam annual releases under the action alternatives and the No Action Alternative for years 2008 through 2060. The observed annual releases under all the alternatives (including the No Action Alternative) fluctuate between 6.33 maf and about 17.2 maf. The minimum annual release is 6.33 maf and occurs under the Water Supply Alternative, although it only occurs less than one percent of the time.

Figure 4.3-31
Hoover Dam Cumulative Annual Releases
Comparison of Action Alternatives to No Action Alternative
Years 2008 through 2060

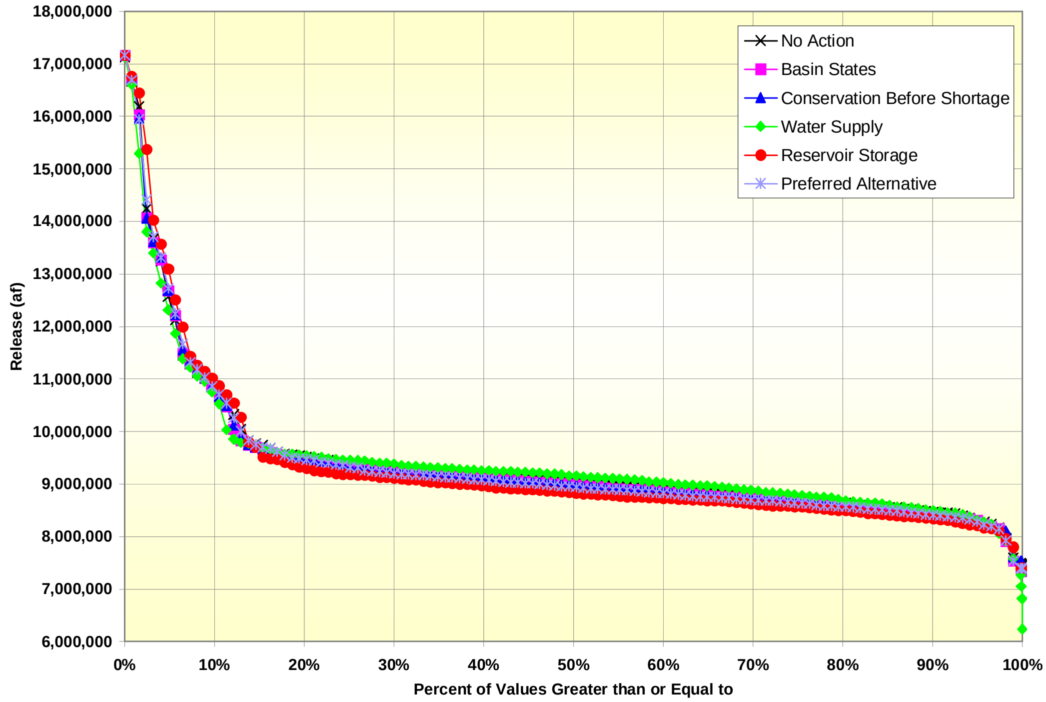

Table 4.3-30 and Table 4.3-31 provide a summary of the distribution of the Hoover Dam releases within different flow ranges of interest over the periods 2008 through 2026 and 2008 through 2060, respectively.

As shown in Table 4.3-30, the frequency of Hoover Dam releases greater than 10.0 mafy are similar under all the alternatives. The greatest variability between the action alternatives and the No Action Alternative occurs in the range of 8.01 to 10.0 mafy. The Water Supply Alternative generally provides higher annual release volumes and this is made apparent in Table 4.3-30 by the high frequency of releases in the range of 9.01 to 10.0 mafy. In contrast, the Reservoir Storage Alternative provides the lowest annual releases as illustrated by the percentage of annual releases less than 9.0 mafy.

Table 4.3-30
Hoover Dam Annual Releases
Probability of Occurrence of Different Annual Release Volumes (percent)
Comparison of Action Alternatives to No Action Alternative
Years 2008 through 2026

Hoover Dam Release Volumes	Alternative					
	No Action	Basin States	Conservation Before Shortage	Water Supply	Reservoir Storage	Preferred Alternative
Greater than 10.0 mafy	11.89	11.26	11.16	10.68	12.79	12.58
Between 9.01 to 10.0 mafy	48.53	50.47	49.42	78.68	14.26	40.53
Between 8.01 to 9.00 mafy	39.05	38.26	39.26	10.63	71.58	46.74
Less than or equal to 8.00 mafy	0.53	0.00	0.16	0.00	1.37	0.16
Total	100.0	100.0	100.0	100.0	100.0	100.0

As provided in Table 4.3-31 for the modeled period between 2008 to 2060, Hoover Dam releases in the range of 8.01 mafy to 10.0 mafy differ mostly under the Water Supply and Reservoir Storage Alternatives. The Water Supply Alternative provides more frequent annual releases greater than 9.0 mafy and the Reservoir Storage Alternative provides annual releases equal to or greater than 9.0 mafy less often as compared to the No Action Alternative and the other action alternatives. The other action alternatives are similar to the No Action Alternative.

Table 4.3-31
Hoover Dam Annual Releases
Probability of Occurrence of Different Annual Release Volumes (percent)
Comparison of Action Alternatives to No Action Alternative
Years 2008 through 2060

Hoover Dam Release Volumes	Alternative					
	No Action	Basin States	Conservation Before Shortage	Water Supply	Reservoir Storage	Preferred Alternative
Greater than 10.0 mafy	13.17	12.49	12.43	11.47	13.60	12.98
Between 9.01 to 10.0 mafy	38.00	36.94	36.53	49.85	24.47	33.45
Between 8.01 to 9.00 mafy	46.60	48.51	49.81	36.30	60.00	51.49
Less than or equal to 8.00 mafy	2.23	2.06	1.23	2.38	1.92	2.08
Total	100.0	100.0	100.0	100.0	100.0	100.0

4.3.5.1 Lake Mohave Water Levels

Lake Mohave is operated under a rule curve that provides specific target elevations at the end of each month (Section 3.3). The same rule curve would be used and applied in future operations under the action alternatives and the No Action Alternative. Therefore, Lake Mohave end-of-month elevations are not affected by the proposed federal action.

4.3.6 Davis Dam to Parker Dam

4.3.6.1 River Flows

River flows between Davis Dam and Parker Dam are comprised mainly of releases from Davis Dam (Lake Mohave) and tributary inflows from the Bill Williams River. During the 10-year period between 1996 and 2005, the annual Davis Dam releases have ranged between 8.1 maf and 12.6 maf and averaged 10.2 maf. Releases greater than 9.5 maf generally correspond to years when surplus or flood flow releases are made at Hoover Dam and are passed through Lake Mohave. Flows less than 8.5 maf are associated with voluntary or involuntary delivery reductions to water users in the Lower Basin.

Figure 4.3-32 presents a comparison of the 90th, 50th, and 10th percentile values for Davis Dam observed for the action alternatives to those under the No Action Alternative. The values and variability of the 90th, 50th, and 10th percentile values under the No Action Alternative and action alternatives are similar to those in Figure 4.3-29 (Hoover Dam releases) because the releases from Hoover Dam are passed through Lake Mohave. The differences are mostly due to losses attributed to evaporation at Lake Mohave, which would be the same in all of the alternatives due to rule curve operations.

Figure 4.3-33 illustrates the cumulative distribution of the Davis Dam releases for the No Action Alternative and the action alternatives during the interim period (2008 through 2060). The range and frequency of the releases under the different alternatives are similar to those shown for Hoover Dam in Figure 4.3-30. Again, the reason for this is that releases from Hoover Dam are essentially passed through Lake Mohave to meet downstream demands.

Figure 4.3-34 illustrates the cumulative distribution of the Davis Dam releases for the No Action Alternative and the action alternatives for the period 2008 through 2060. The range and frequency of the releases under the different alternatives are similar to those shown for Hoover Dam in Figure 4.3-31.

4.3.6.2 Colorado River Annual Flows Near Havasu NWR

A point located immediately downstream of the Havasu NWR was used to further analyze the river flows for this reach.

The 90th, 50th, and 10th percentile annual flow volumes at this point are shown in Figure 4.3-35. These river flows show the same general patterns that were observed in the corresponding plots for Hoover Dam and Davis Dam releases (Figure 4.3-29 and Figure 4.3-32 respectively) since those dams are operated, except during flood control operations, to meet downstream demands. The differences in magnitudes between the releases from Hoover Dam, releases from Davis Dam, and flows near Havasu NWR are due to evaporation loss at Lake Mohave (which would be the same in all of the alternatives due to rule curve operations) and the relatively small diversions along this stretch of the river.

4.3.6.3 Groundwater

Flows in the Davis Dam to Parker Dam reach are primarily composed of water released from Davis Dam (Section 3.3). Therefore, the annual median releases are representative of the annual median flows in this reach. When converted to stage, a comparison of the annual median releases for each alternative may be used as the indicator to analyze potential effects to groundwater adjacent to the river in this reach.

Figure 4.3-36 illustrates the annual median releases from Davis Dam for each alternative for the years 2008 through 2060. These are the same data shown in Figure 4.3-32 converted from acre-feet per year to cubic feet per second. In general, the median releases for the Water Supply and Reservoir Storage Alternatives bracket the median releases for the other four alternatives due primarily to the different shortage assumptions for each of the alternatives.

Table 4.3-33 compares the annual median values relative to the No Action Alternative for specific years (each action alternative value less the No Action Alternative value). Using appropriate relationships to convert flow-to-stage (LCR MSCP BA [Reclamation 2004c], Appendix J, Attachment D), these relative flow differences would result in minor reductions in river stage (on the order of 0.5 feet). Based on the relationships used in the LCR MSCP BA, Appendix K, such river stage reductions would result in corresponding reductions in groundwater elevations adjacent to the river (approximately 0.25 feet to 0.5 feet for gaining and losing reaches respectively).

Figure 4.3-36
Davis Dam Annual Releases
Comparison of Action Alternatives to No Action Alternative
Annual Median (50th Percentile) Values

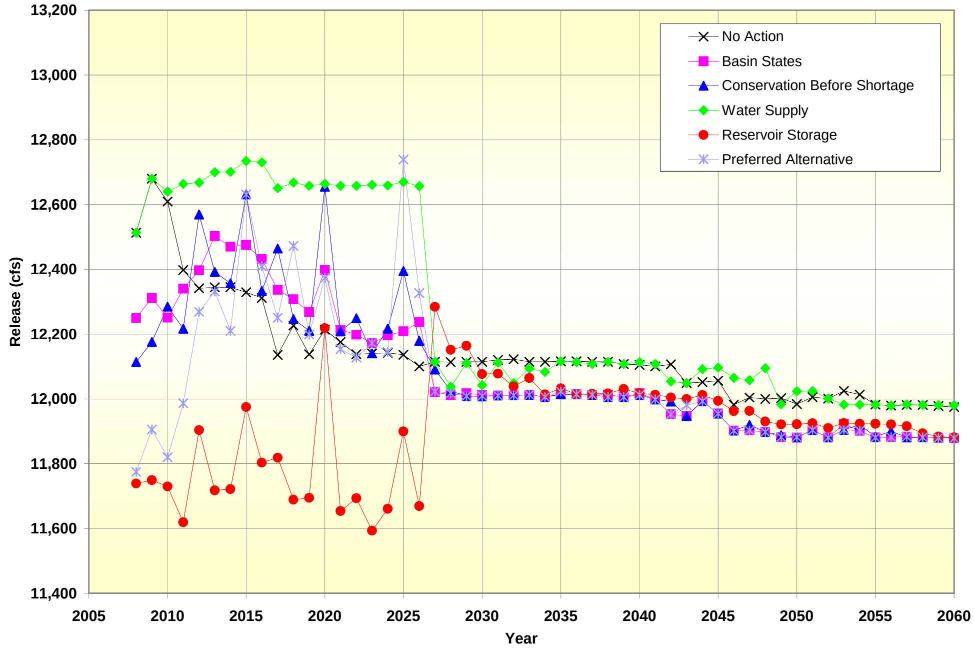

Table 4.3-33
Davis Dam Annual Median Releases
Differences of Action Alternatives Compared to No Action Alternative[1] (cfs)

Year	Basin States	Conservation Before Shortage	Water Supply	Reservoir Storage	Preferred Alternative
2008	(264)	(399)	0	(774)	(738)
2011	(57)	(181)	266	(779)	(412)
2016	119	21	418	(509)	97
2017	201	329	515	(318)	114
2026	137	79	557	(431)	227
2027	(93)	(24)	0	170	(91)
2040	(88)	(93)	8	(88)	(93)
2060	(96)	(94)	5	(94)	(96)

1 *Value of the action alternative minus the value from the No Action Alternative provides the difference shown. Values shown in parenthesis indicate that the value under the action alternative is lower than that of the No Action Alternative, i.e. a flow reduction.*

4.3.6.4 Lake Havasu Elevations

Similar to Lake Mohave, Lake Havasu is also operated under a rule curve. This method of operation provides specific target elevations at the end of each month (Section 3.3). The same rule curve would be used and applied in the future operations under the action alternatives and the No Action Alternative. Therefore, end-of-month elevations of Lake Havasu are not affected by the proposed federal action.

4.3.7 Parker Dam to Cibola Gage and Cibola Gage to Imperial Dam

Parker Dam provides the last opportunity to re-regulate Hoover Dam releases because Lake Havasu is the last facility in the lower Colorado River with significant storage (Section 3.3). Releases from Parker Dam are made primarily to meet downstream water demands. Once released from Parker Dam, the flow is essentially unregulated until it reaches Imperial Dam.

4.3.7.1 River Flows

The river flows in this reach are essentially the releases from Parker Dam. Releases greater than 7.0 maf generally correspond to years when flood flow releases are being made from Hoover Dam and these flows are passed through Davis Dam and Parker Dam. Releases less than 6.0 maf are generally associated with delivery reductions, which occur more frequently under the Conservation Before Shortage and Reservoir Storage Alternatives than under the No Action Alternative.

Figure 4.3-37 presents a comparison of the 90^{th}, 50^{th}, and 10^{th} percentile lines for Parker Dam annual releases under the action alternatives and the No Action Alternative. The 90^{th} percentile values represent releases due to flood control operations. The Reservoir Storage Alternative tends to release greater volumes during flood control when compared to the other alternatives since it keeps Lake Mead elevations higher. Beyond year 2045 all flow volumes converged to a release of about 7.40 maf. At the 50^{th} percentile, the Basin States, Conservation Before Shortage, and Reservoir Storage Alternatives, and the Preferred Alternative had less release volume than the No Action Alternative until the year 2026 due to a combination of the assumptions under each of those alternatives with regard to shortages and participation in the storage and delivery mechanism. The Water Supply Alternative generally released more volume over that same period. At year 2027, all alternatives converged to about 6.50 maf, with differences due to the assumption that SNWA would develop additional non-system water supplies that are permanent. The comparison of the 10^{th} percentile showed similar results that mirror the 50^{th} percentile values, except the release volumes were about 6.25 maf.

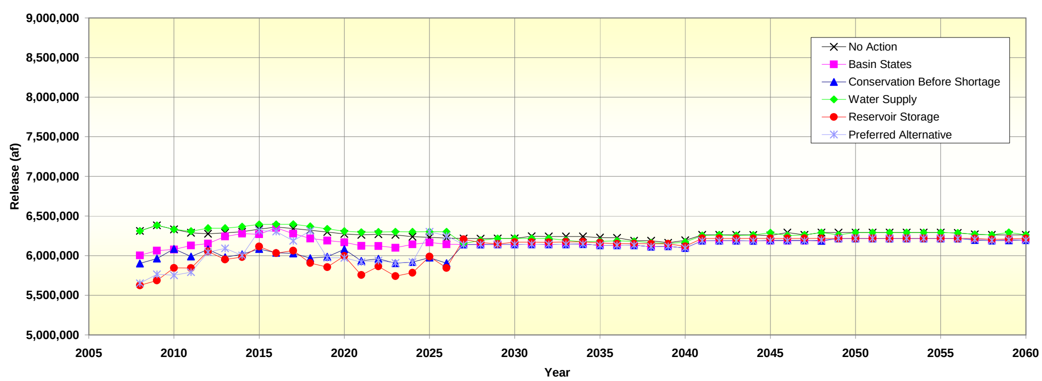

Figure 4.3-38 illustrates the cumulative distribution for Parker Dam annual releases for the interim period (2008 through 2026). The releases under the No Action Alternative range between 14.0 maf to 6.0 maf. The maximum annual releases under the action alternatives are similar to those of the No Action Alternative. The minimum annual release of 5.35 maf is observed under the Reservoir Storage Alternative. The Reservoir Storage Alternative generally provides the lowest annual releases while the Water Supply Alternative generally provides the highest annual releases of the action alternatives.

Figure 4.3-38
Parker Dam Cumulative Annual Releases
Comparison of Action Alternatives to No Action Alternative
Years 2008 through 2026

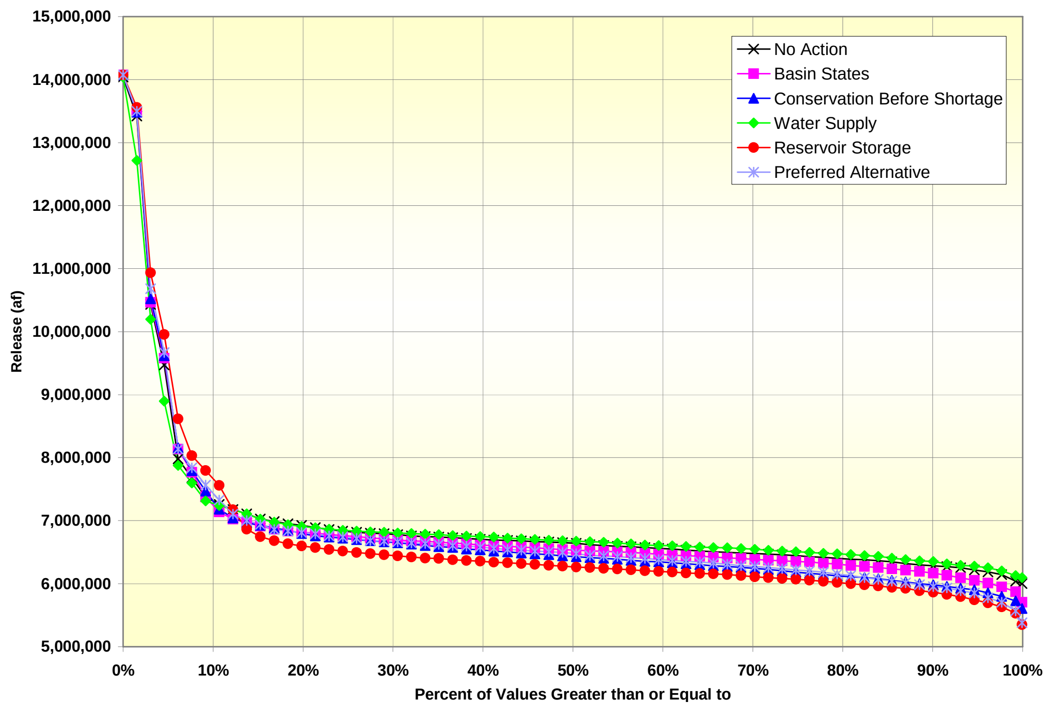

Figure 4.3-39 illustrates the cumulative distribution for the Parker Dam annual releases for the period of 2008 through 2060. The observed annual releases under all alternatives (including the No Action Alternative) fluctuate between approximately 14.0 maf to 5.35 maf. The lowest annual releases of 5.35 maf and 5.38 maf were observed under the Reservoir Storage Alternative and the Preferred Alternative, respectively.

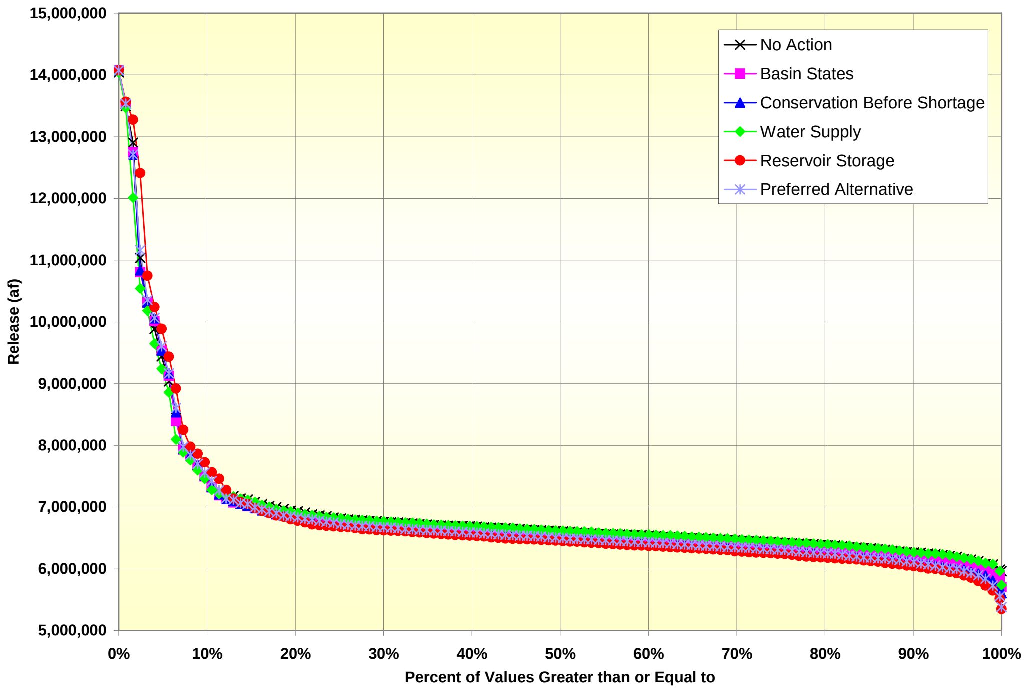
Figure 4.3-39
Parker Dam Cumulative Annual Releases
Comparison of Action Alternatives to No Action Alternative
Years 2008 through 2060



River Flows Near the Colorado River Indian Reservation. Two other points on the Colorado River were used to analyze flows in the reach between Parker Dam and Imperial Dam. These include a point located immediately upstream of the Colorado River Indian Reservation (CRIR) and a point located immediately downstream of the Palo Verde Diversion Dam.

The CRIR diversion is located at Headgate Rock Dam, approximately 14 miles downstream of Parker Dam. Flows in this reach of the river result primarily from releases at Parker Dam and would be affected by delivery reductions to water users located downstream from this location.

Figure 4.3-40 illustrates that the 90th, 50th, and 10th percentile annual flow values at this location generally reflect the releases from Parker Dam, as shown on Figure 4.3-38 and Figure 4.3-39. Since there is no significant storage capacity above Headgate Rock Dam, the differences between the flows at this location and the Parker Dam releases are due only to the attenuation of the flows that occurs in the 14 miles of river within this reach.

Colorado River Annual Flow Upstream of CRIR Diversion - RM 180.8 (mafy)
Comparison of Action Alternatives to No Action Alternative
90th, 50th, and 10th Percentile Values

Alternative	Year 2016			Year 2026			Year 2040			Year 2060		
	90th	50th	10th	90th	50th	10th	90th	50th	10th	90th	50th	10th
No Action	7.242	6.177	5.845	7.188	6.048	5.703	7.089	6.019	5.676	6.753	6.093	5.746
Basin States	7.328	6.156	5.836	7.188	5.998	5.628	7.089	5.945	5.580	6.678	6.025	5.687
Conservation Before Shortage	7.328	5.993	5.517	7.188	5.837	5.386	7.089	5.956	5.582	6.678	6.040	5.686
Water Supply	7.242	6.187	5.876	6.802	6.094	5.782	7.123	6.026	5.655	6.693	6.100	5.746
Reservoir Storage	7.688	5.680	5.513	7.226	5.679	5.325	7.381	5.946	5.601	6.678	6.025	5.699
Preferred Alternative	7.328	6.119	5.787	7.188	6.009	5.733	7.089	5.944	5.580	6.678	6.025	5.686

River Flows Downstream of the Palo Verde Diversion Dam. The flow of the Colorado River between Palo Verde Diversion Dam and Imperial Dam is normally the amount needed to meet both the consumptive use requirements in the United States downstream of the Palo Verde Diversion Dam and deliveries to Mexico. The river location that was used to analyze the flows in the reach of the river between Palo Verde Diversion and Imperial Dam is located immediately downstream of the Palo Verde Diversion.

The 90th, 50th, and 10th percentile annual flow volumes for the Colorado River at this point are shown on Figure 4.3-41. The greatest variability between alternatives occurs during the interim period (2008 through 2026). After 2026, the action alternatives converge to the No Action Alternative.

The 90th percentile flow volumes for the action alternatives were generally similar to those of the No Action Alternative, although there was some variability observed under the Water Supply and Reservoir Storage Alternatives. The greatest variability occurs during the interim period and reflects the difference in the assumptions with regard to shortage and water conservation. The 50th percentile annual flow volumes for all alternatives are generally similar with the Reservoir Storage Alternative having the lowest values. At the 10th percentile level, the Water Supply Alternative shows slightly higher flow volumes compared to the No Action Alternative. The Basin States, Conservation Before Shortage, and Reservoir Storage Alternatives, and the Preferred Alternative show progressively lower flow volumes than the No Action Alternative.

4.3.7.2 Groundwater

Flows in the Parker Dam to Imperial Dam reach are primarily composed of water released from Parker Dam and therefore, the annual median releases are representative of the annual median flows in each reach (Section 3.3). When converted to stage, a comparison of the annual median releases for each alternative may be used as the indicator to analyze potential effects to groundwater adjacent to the river in this reach.

Figure 4.3-42 illustrates the annual median releases from Parker Dam for the action alternatives and the No Action Alternative for 2008 through 2060. As was the case for the Davis Dam releases, the median releases for the Water Supply and Reservoir Storage Alternatives bracket the median releases for the other four alternatives due primarily to the different shortage assumptions for each of the alternatives. Table 4.3-36 compares the annual median values of the action alternatives relative to the No Action Alternative for specific years (each action alternative value less the No Action Alternative value). Using appropriate relationships to convert flow-to-stage (LCR MSCP BA, Appendix J, Attachment D), these relative flow differences would result in minor reductions in river stage (on the order of 0.25 feet). Based on the relationships used in the LCR MSCP BA, Appendix K, such river stage reductions would result in corresponding reductions in groundwater elevations adjacent to the river (approximately 0.15 feet to 0.30 feet reduction for gaining and losing reaches, respectively).

Figure 4.3-42
Parker Dam Annual Releases
Comparison of Action Alternatives to No Action Alternative
Annual Median (50th Percentile) Values

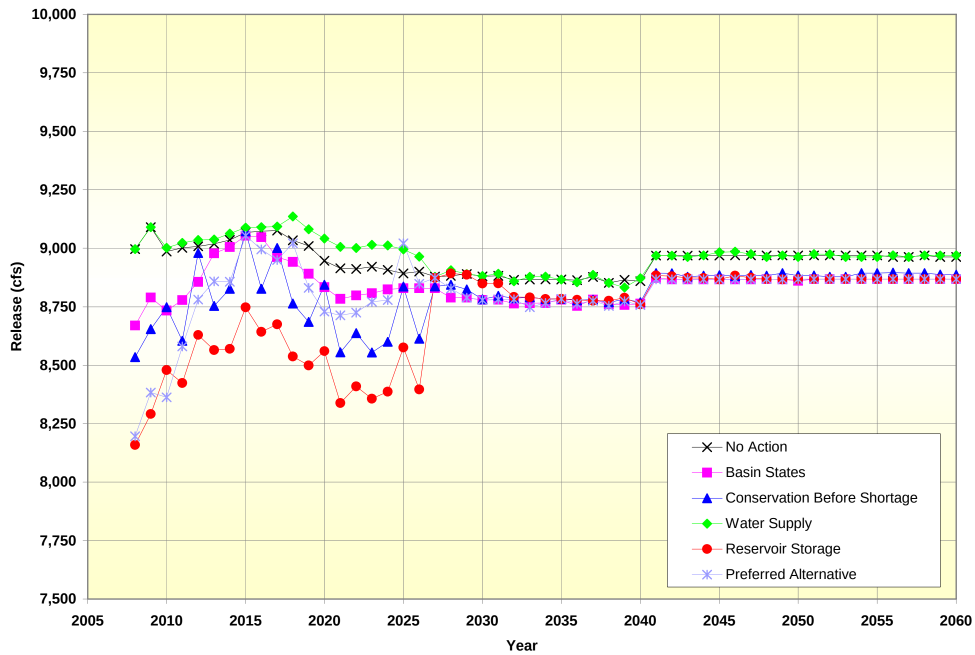

Table 4.3-36
Parker Dam Annual Median Releases
Differences of Action Alternatives Compared to No Action Alternative[1], (cfs)

Year	Basin States	Conservation Before Shortage	Water Supply	Reservoir Storage	Preferred Alternative
2008	(327)	(462)	0	(837)	(801)
2011	(224)	(398)	21	(578)	(422)
2016	(25)	(246)	17	(430)	(78)
2017	(114)	(75)	17	(401)	(126)
2026	(72)	(288)	64	(504)	(52)
2027	(50)	(420)	(1)	(6)	(6)
2040	(96)	(90)	13	(99)	(102)
2060	(95)	(76)	7	(95)	(95)

1 Value of the action alternative minus the value from the No Action Alternative provides the difference shown. Values shown in parenthesis indicate that the value under the action alternative is lower than that of the No Action Alternative, i.e. a flow reduction.

4.3.8 Imperial Dam to NIB

Most of the water delivered to Mexico is diverted at Imperial Dam, conveyed via the AAC, and then returned to the Colorado River through the Pilot Knob and Siphon Drop Powerplants and their respective wasteway channels, 2.1 miles and 7.6 miles upstream of the NIB, respectively (Section 3.3). The proposed federal action will not alter the operation of these diversions and wasteways and therefore, will not have an effect on this river reach.

4.3.9 NIB to SIB

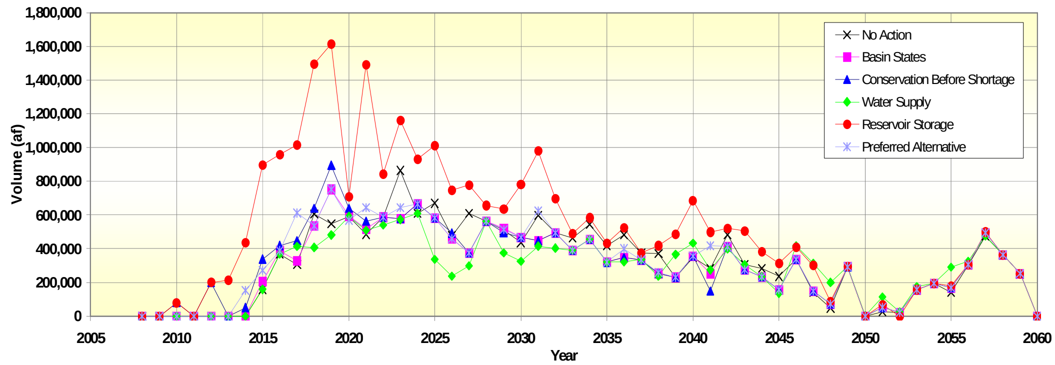
Mexico diverts most of its Colorado River water supply at the Morelos Diversion Dam, and except during flood control operations, only limited flows actually pass Morelos Diversion Dam (Section 3.3). During flood control operations, releases are made from Hoover Dam as dictated by the flood control criteria established with the USACE (Section 3.3). These releases are dependent upon the amount of available storage in the system (including Lake Powell and Lake Mead) and the hydrologic inflow forecast. The proposed federal action could potentially change the volume of water in storage in Lake Powell and Lake Mead, thereby affecting the frequency and/or volume of flood control releases.

In addition, the modeling assumptions used to model the storage and delivery mechanism for the Conservation Before Shortage and Reservoir Storage Alternatives could potentially alter the flows in this reach. It was assumed that water conservation activities in Mexico would result in conserved water that would be stored in Lake Mead and delivered on a periodic basis to Mexico through the NIB to the SIB reach. These modeling assumptions (described in Appendix M) were used in this Final EIS in order to analyze the potential impacts to resources of the storage and delivery mechanism, particularly with regard to reservoir elevations and river flow impacts. The use of these modeling assumptions does not represent any determination by Reclamation as to whether, or how, any storage/delivery arrangements would actually be implemented in the future. These modeling assumptions are not intended to constitute an interpretation or application of the 1944 Treaty or to represent current United States policy or a determination of future United States policy regarding deliveries to Mexico. Details of these assumptions are discussed in Section 4.2 and Appendix M.

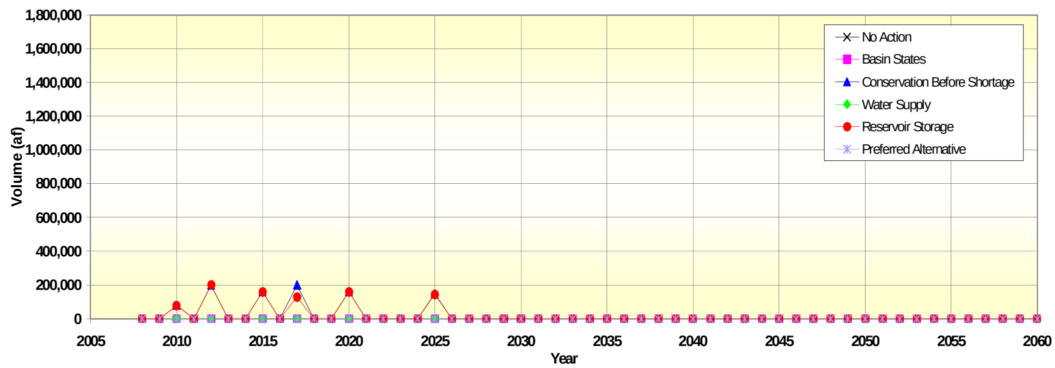
The 90th, 50th, and 10th percentile annual flow volumes for this reach are shown in Figure 4.3-43.

Figure 4.3-43
Colorado River Annual Flow Below Mexico Diversion at Morelos Diversion Dam - RM 21.1
Comparison of Action Alternatives to No Action Alternative
90th, 50th, and 10th Percentile Values

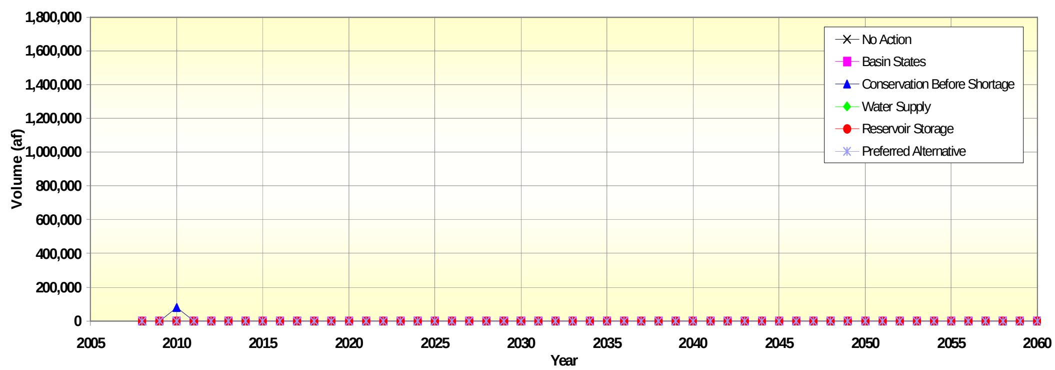
90th Percentile



50th Percentile



10th Percentile



Flows at the 90th percentile are produced by flood control operations. The values for the Reservoir Storage Alternative were generally greater than for the other alternatives due to higher reservoir levels. After 2048, the 90th percentile annual flow volumes are all similar. The 90th percentile annual flow volumes for the Water Supply Alternative were generally lower than the other alternatives through about 2030, whereas the volumes for the Reservoir Storage Alternative were higher through about 2045. Flows at the 50th percentile are comprised solely of non-flood control flows. The Basin States and Water Supply alternatives, and the No Action Alternative assume no activity with regard to delivery of conserved water to Mexico. The 50th percentile flows for the Conservation Before Shortage and Reservoir Storage Alternatives show intermittent annual flow volumes of from about 40 kaf to 200 kaf during the interim period. At the 10th percentile, the Conservation Before Shortage is the only alternative that shows an annual flow value that is greater than zero, in the year 2010 at a volume of 80 kaf.

Table 4.3-37 provides a comparison of the 90th, 50th, and 10th percentile annual flow volumes below the Mexico diversion at Morelos Diversion Dam between the action alternatives and No Action Alternative for selected years.

Table 4.3-37

Preferred Alternative	0.388	0.000	0.000	0.459	0.000	0.000	0.355	0.000	0.000	0.000	0.000	0.000

Figure 4.3-44 shows the cumulative distribution for annual volumes of excess flows occurring below the Mexico diversion at the Morelos Diversion Dam for the interim period (2008 through 2026). At flows less than about 250 kaf, the differences are mostly due to the assumed delivery of conserved water to Mexico under the Conservation Before Shortage and Reservoir Storage Alternatives. Flows greater than about 250 kaf are the result of flood control operations at Lake Mead. As shown in Figure 4.3-44, the probability of excess flows of any magnitude under the No Action Alternative, Preferred Alternative, and the Basin States and Water Supply alternatives during the interim period are approximately nine to ten percent. The probability of excess flows of any magnitude under the Conservation Before Shortage and Reservoir Storage Alternatives are 33 and 30 percent, respectively.

Figure 4.3-44
Excess Flows Below Mexico Diversion at Morelos Diversion Dam
Comparison of Action Alternatives to No Action Alternative
Cumulative Distribution - Years 2008 through 2026

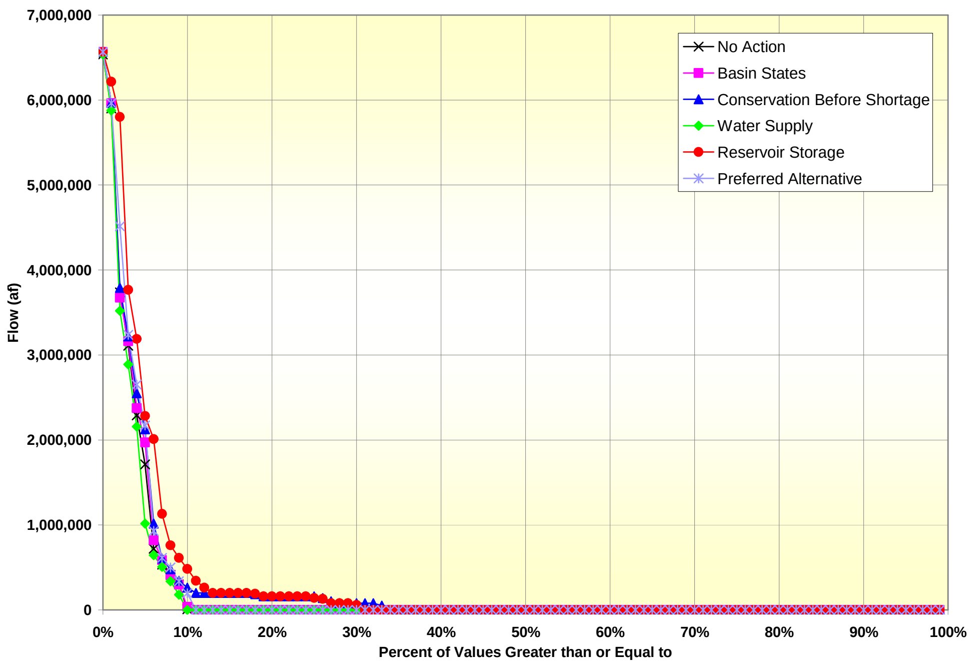

Figure 4.3-45 shows the cumulative distribution for annual volumes of excess flows below the Mexico diversion at Morelos Diversion Dam for the period between 2008 through 2060. Again, flows less than about 250 kaf are due to the assumed delivery of conserved water to Mexico under the Conservation Before Shortage and Reservoir Storage Alternatives and occur during the interim period only.

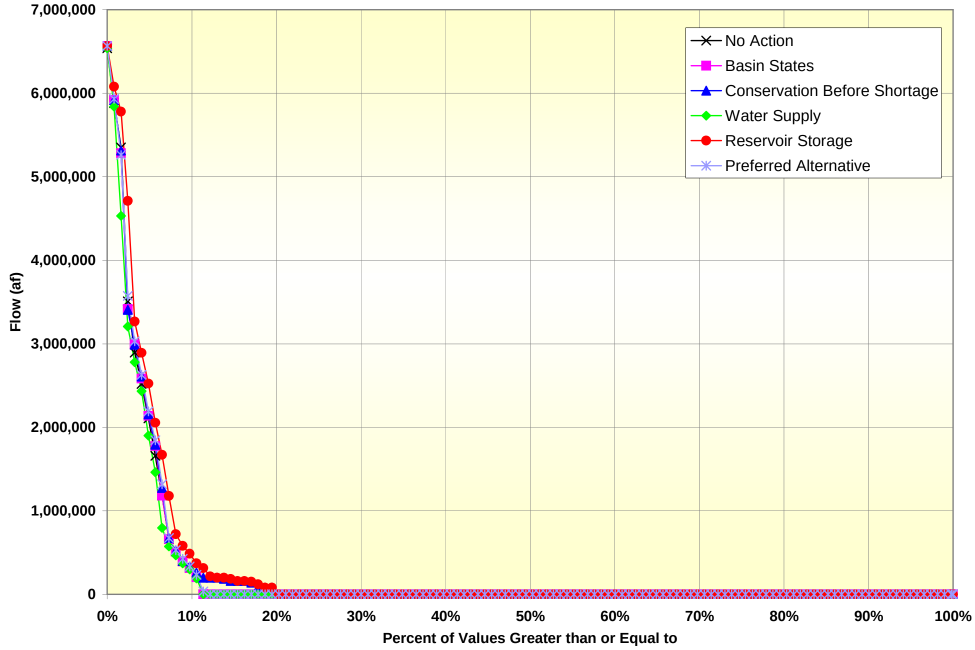
Figure 4.3-45
Excess Flows Below Mexico Diversion at Morelos Diversion Dam
Comparison of Action Alternatives to No Action Alternative
Cumulative Distribution - Years 2008 through 2060



4.3.10 Summary

The following conclusions were drawn from the analyses of hydrologic resources.

4.3.10.1 Reservoir Storage

The Water Supply Alternative generally provides lower Lake Powell elevations than the No Action Alternative. Conversely, the Reservoir Storage Alternative provides higher Lake Powell elevations than the No Action Alternative. The observed Lake Powell elevations under the Basin States and Conservation Before Shortage Alternatives, and the Preferred Alternative are similar to each other because these action alternatives assume the same operation at Lake Powell. The 50th and 10th percentile values of these three alternatives vary less than those of the Water Supply and Reservoir Storage Alternatives. The greatest difference in Lake Powell elevation between the Basin States and Conservation Before Shortage Alternatives, and the Preferred Alternative relative to the No Action Alternative in any one year is about 33 feet occurring at the 10th percentile.

The Lake Mead 50th percentile elevations under the Water Supply Alternative are generally lower than those under the No Action Alternative. However, the Lake Mead 10th percentile elevations under the Water Supply Alternative vary and are sometimes higher and sometimes lower than those under the No Action Alternative. These fluctuations are due to balancing releases from Lake Powell that are greater than releases under the No Action Alternative (resulting in higher Lake Mead elevations) and shortage amounts that are less than those in the No Action Alternative (resulting in lower Lake Mead elevations). The Reservoir Storage Alternative generally provides higher Lake Mead elevations than the No Action Alternative. The observed Lake Mead elevations under the Basin States and Conservation Before Shortage Alternatives, and the Preferred Alternative are similar to each other because these alternatives assume the same operation at Lake Powell and the same release reductions corresponding to the same Lake Mead elevations. The 50th and 10th percentile values of these three alternatives vary less than those of the Water Supply and Reservoir Storage Alternatives. Both the 50th and 10th percentile values of the Basin States and Conservation Before Shortage Alternatives, and the Preferred Alternative vary from being higher and sometimes lower than those of the No Action Alternative.

Lake Mohave and Lake Havasu are operated on a rule curve and have target end-of-month elevations. This manner of operation will continue in the future and would apply to operations under any of the action alternatives. Therefore, future Lake Mohave and Lake Havasu elevations would be expected to be similar between the action alternatives and the No Action Alternative.

4.3.10.2 Reservoir Releases

During the interim period (2008 through 2026), Glen Canyon Dam releases less than the annual minimum objective release of 8.23 maf occurred less than one percent of the time under the No Action Alternative, approximately ten percent of the time under the Basin States, Conservation Before Shortage, and Water Supply alternatives, and the Preferred Alternative, and approximately 17 percent of the time under the Reservoir Storage Alternative. Over the interim period, releases greater than the annual minimum objective release of 8.23 maf occurred approximately 42 percent of the time under the No Action Alternative, approximately 62 percent of the time under the Basin States and Conservation Before Shortage Alternatives, 69 percent of the time under the Water Supply Alternative, 44 percent of the time under the Reservoir Storage Alternative, and 59 percent of the time under the Preferred Alternative.

During the interim period (2008 through 2026), the observed minimum and maximum Hoover Dam annual releases under the No Action Alternative are 7.46 maf and 17.13 maf, respectively. By comparison, the minimum annual release under the action alternatives is 7.3 maf and occurs under the Conservation Before Shortage Alternative. The maximum annual release of 17.16 maf occurs under the Basin States, Conservation Before Shortage, and Reservoir Storage Alternatives, and the Preferred Alternative. In general, the annual release volumes under the Basin States, Conservation Before Shortage, and Reservoir Storage Alternatives, and the Preferred Alternative are similar to those under the No Action Alternative. The Hoover Dam annual releases under the Water Supply Alternative are generally higher than under the No Action Alternative. The Hoover Dam annual releases under the Reservoir Storage Alternative are generally lower than under the No Action Alternative.

The releases from Davis Dam and Parker Dam generally reflect the same pattern of releases under the different action alternatives as those from Hoover Dam. The differences in the release volumes are mostly attributed to the depletions that occur upstream of each respective dam.

4.3.10.3 River Flows

The river flows that occur between Glen Canyon Dam and Lake Mead result mostly from controlled releases from Glen Canyon Dam. Since the gains from tributaries in this reach on average are less than three percent of the total flow and would not be affected by the proposed federal action, the relative comparison of annual river flows would be essentially the same as the comparison made for the annual releases from Glen Canyon Dam. Daily and hourly releases from Glen Canyon Dam would continue to be made consistent with the 1996 Grand Canyon ROD pending the outcome of the long-term experiment program.

The river flows that occur downstream of Hoover Dam also result mostly from controlled releases from Hoover, Davis, and Parker dams. For all reaches, the projected river flows are bound by the Water Supply Alternative (at the high end) and the Reservoir Storage Alternative (at the low end). Differences in river flows for each alternative relative to this No Action Alternative are small (less than 1 percent).

4.3.10.4 Groundwater

The river flow reductions were determined to have no effect on the groundwater resources within the river reach that extends from Glen Canyon Dam to Lake Mead. The river flow reductions that occur below Hoover Dam could potentially affect groundwater resources within the different river reaches where they occur. However, the potential changes in median flows, river stage reductions, and corresponding potential effects on groundwater elevations relative to the No Action Alternative were shown to be small (less than 0.5 feet).

4.4 Water Deliveries

This section compares water deliveries from the Colorado River mainstream to the Lower Division states and Mexico under the No Action Alternative and the action alternatives. In addition, potential impacts of shortages to water user categories (agricultural, M&I, and Tribal) within Arizona are compared. The allocation of shortages to California and Nevada generally affect single entities within each state (MWD in California and SNWA in Nevada) and therefore analyses of potential impacts to other Colorado River water users within these two states were not performed. Additional details with regard to potential shortages to specific water users within each Lower Division state are presented in Appendix G.

4.4.1 Methodology

The methodology used to analyze total water deliveries to each Lower Division state and Mexico for each alternative is based on the hydrologic model CRSS described in Section 4.2 and in Appendix A. Modeling assumptions with respect to the distribution of shortages and related water delivery reductions to the Lower Division states and Mexico are summarized in Section 2.2 and Section 4.2.

4.4.1.1 Shortage Allocation Model

To analyze the potential impacts of shortages to water users within each Lower Division state, a more detailed model, the Shortage Allocation Model, was developed. The Shortage Allocation Model was used to estimate delivery of water to Colorado River water entitlement holders within the Lower Division states under varying levels of shortages. The entitlements, along with consumptive use schedules and established priorities within each Lower Division state, were included as parameters in the Shortage Allocation Model. In addition, the shortage distribution within the CAP is consistent with the Arizona Water Settlements Act (AWSA).

The Shortage Allocation Model allocates shortages to the Lower Division states consistent with the shortage sharing assumptions used in the CRSS model. The Shortage Allocation Model then distributes Colorado River water to entitlement holders within each state based on the priority of water rights within each respective state using the assumption that shortages will be shared on a pro-rata basis by users of the same priority. Within Arizona, certain modeling assumptions were adjusted between the Draft EIS and the Final EIS based on information received from the ADWR during the public comment period. A detailed description of the Shortage Allocation Model and the methodologies used to distribute the shortages is provided in Appendix G. A list of each Lower Division state's Colorado River water entitlement holders, listed by priority, is included in Appendix E.

Total Lower Basin shortages of 100 kaf to 2.5 maf (in increments of 100 kaf) were analyzed in the Shortage Allocation Model, covering the range of total Lower Basin shortages projected to occur under the No Action Alternative and the action alternatives[1]. The output for each model run shows how shortages were distributed to each entitlement holder within each state. The Shortage Allocation Model also summarized shortages into three water user categories in Arizona (agricultural, M&I, and Tribal), which are presented in Section 4.4.5. Detailed output from the Shortage Allocation Model is provided in Appendix G.

4.4.2 Apportionments to the Upper Division States

The proposed federal action will not affect the apportionments to the Upper Division states nor their ability to use their Compact apportionments. Therefore no resource impact analysis was considered necessary.

4.4.3 Apportionments to the Lower Division States and Water Entitlements within Each State

The proposed federal action will not affect the apportionments to the Lower Division states or the water entitlements to water users within those states and therefore no resource impact analysis was considered necessary. However, water deliveries to each state and to users within each state may be affected and are analyzed in the following sections.

4.4.4 Lower Division States Water Supply Determination

The proposed federal action would provide guidance to the Secretary's annual determination of the water supply condition (Surplus, Normal, or Shortage) for the Lower Division states. This section compares the probabilities of the determinations that would be made under each alternative.

4.4.4.1 Shortage Conditions

A Shortage Condition exists in a particular year when the Secretary determines that there is insufficient mainstream water available to satisfy the 7.5 maf of consumptive use in the Lower Division states. The elements of the proposed federal action include shortage guidelines and each alternative assumes a specific formulation for determining a Shortage Condition (Chapter 2).

[1] As a result of updating the CRSS initial conditions to reflect the June 2007 projections of January 1, 2008 reservoir contents, water delivery reductions with volumes greater than 2.5 maf were observed in four out of 100 hydrologic sequences under the Water Supply Alternative and only in year 2027. These shortage volumes were primarily the result of the assumption that operations would revert back to the assumptions made under the No Action Alternative after the interim period. Consequently, analysis of shortages greater than 2.5 maf in the Final EIS was not considered necessary due to their low probability of occurrence.

Probability of Involuntary and Voluntary Shortage. The Conservation Before Shortage proposal suggested an approach to the management of shortages in the Lower Basin whereby voluntary water delivery reductions would occur at specific Lake Mead elevations in order to delay the onset of larger, involuntary water reductions. The voluntary water reductions would occur through a compensation program whereby willing Lower Basin Colorado River water users, including Mexico, would be paid to voluntarily and temporarily reduce their water use (Section 2.4). Conversely, involuntary water delivery reductions might be imposed by the Secretary through the determination of a Shortage Condition pursuant to Article II(B)(3) of the Consolidated Decree.

Although the mechanism for voluntary and involuntary water delivery reductions would be different, the potential hydrologic impacts of voluntary or involuntary shortages would be the same. Similarly, the potential impacts to other environmental resources would be the same with the possible exception of socioeconomic impacts (Section 4.14). In this and in subsequent sections of the Final EIS, voluntary water delivery reductions proposed by the Conservation Before Shortage Alternative are termed “voluntary shortages”, and involuntary water delivery reductions imposed by a Secretarial determination of a Shortage Condition are termed “involuntary shortages”. Voluntary and involuntary shortages are analyzed separately or together in subsequent analyses as appropriate.

The probability of the determination of a Shortage Condition and associated involuntary shortages for all alternatives is illustrated in Figure 4.4-1. Under the No Action Alternative, the probability of involuntary shortage increases throughout the interim period from four percent in 2010 to about 50 percent in 2026. All action alternatives have lower probabilities of involuntary shortage when compared to the No Action Alternative from 2013 through 2026, with the Water Supply and Conservation Before Shortage Alternatives showing the lowest probabilities. Table 4.4-1 provides a comparison of the alternatives with respect to the first year of involuntary shortage and the probability of occurrence. Table 4.4-2 provides the probability of any amount of involuntary Lower Basin shortage for specific years.

The Conservation Before Shortage and Water Supply alternatives result in relatively infrequent, involuntary shortages during the interim period due to quite different reasons. The Conservation Before Shortage Alternative assumes that voluntary shortages would occur prior to the onset of involuntary shortages, whereas the Water Supply Alternative imposes involuntary shortages only if Lake Mead storage approaches the top of the dead pool elevation or when Lake Mead’s elevation falls below 1,000 feet msl (the current limit of SNWA’s lower intake). Figure 4.4-1 shows that the probability of involuntary shortages ranges from zero to 12 percent over the interim period for the Water Supply Alternative. Figure 4.4-1 also shows that the probability of involuntary shortages under the Conservation Before Shortage Alternative is similar (approximately zero to nine percent over the interim period) since involuntary shortages are imposed under that alternative only to protect Lake Mead from falling below elevation 1,000 feet msl.

2060	69	67	67	66	66	67

Figure 4.4-2, Table 4.4-3, and Table 4.4-4 present comparisons for all alternatives when both involuntary and voluntary shortages are considered. When both involuntary and voluntary shortages are considered, the occurrence of the first shortage in 2010 is identical for the Basin States and Conservation Before Shortage Alternatives, and the Preferred Alternative. The probability of shortages in 2010 differs (seven percent, four percent, and two percent for the Basin States Alternative, Conservation Before Shortage Alternative, and the Preferred Alternative, respectively) due to the different assumptions with regard to the participation in the storage and delivery mechanism for those alternatives. The Preferred Alternative also shows lower probabilities (up to approximately ten percent) of voluntary and involuntary shortage over the entire interim period when compared to the Basin States and Conservation Before Shortage Alternatives.

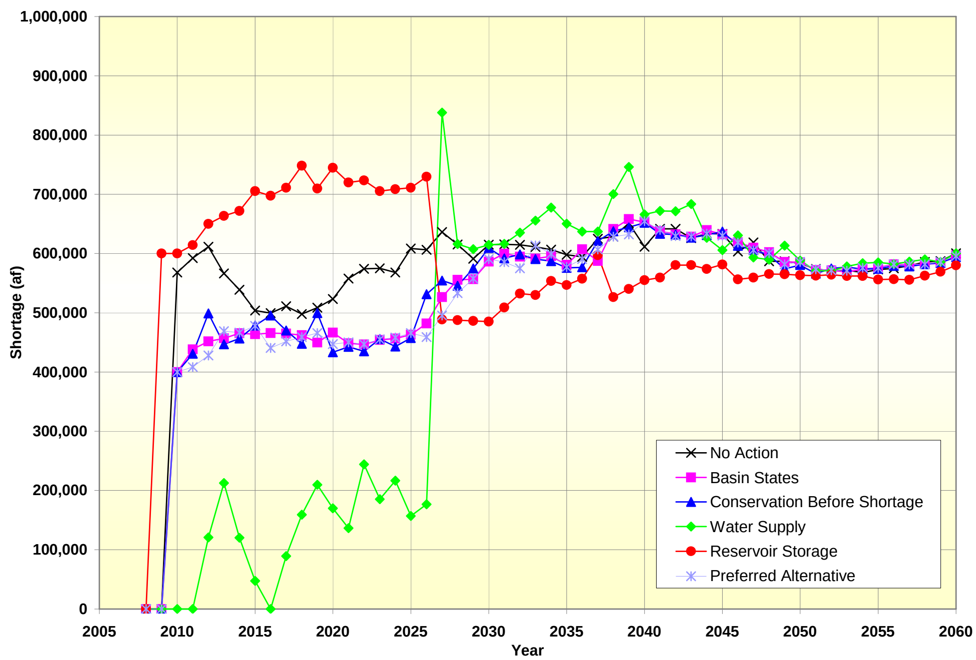
2060	69	67	67	66	66	67

Magnitude of Involuntary and Voluntary Shortages. Although the probability of a shortage occurring is an important factor, the magnitude of the shortage is also important. Each alternative has specific assumptions with regard to when and by how much deliveries would be reduced.

The average shortage volumes for each year provide a weighted measure that considers both the frequency and magnitude of the potential shortages. The average shortage volumes for each year are calculated by multiplying the observed volumes of shortages by their respective frequency of occurrence and summing those values (or alternatively, by simply summing the shortages for all traces and dividing by the total number of traces). A comparison of the average shortage volumes (of both involuntary and voluntary shortages) under the action alternatives to those of the No Action Alternative is provided in Figure 4.4-3.

Figure 4.4-3
Involuntary and Voluntary Lower Basin Shortage
Comparison of Action Alternatives to No Action Alternative
Average Shortage Volumes

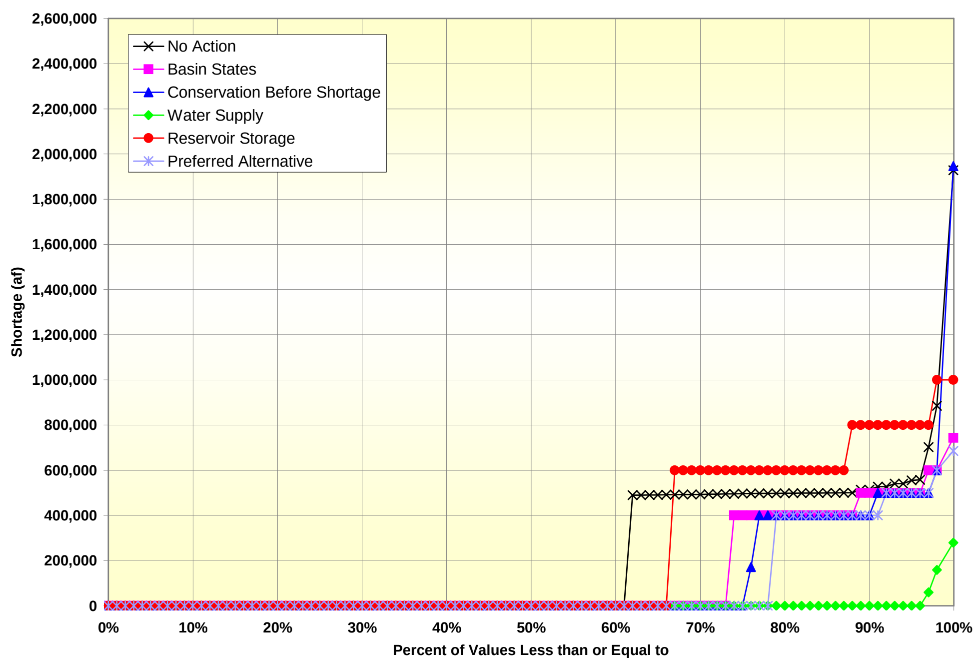


The average shortage volumes under the No Action Alternative from 2010 (the year of first shortage occurrence) through the interim period range between about 500 and 610 kafy and are reflective of the occurrence of the more frequent shortages which are on the order of 400 to 500 kafy based on Lake Mead trigger elevations (Section 2.2) as well as infrequent but larger shortages (on the order of 800 kafy to 2,000 kafy) necessary to keep Lake Mead above elevation 1,000 feet msl. The average shortages volume under the Water Supply Alternative from 2012 (the year of first shortage occurrence) through the interim period are between zero and 240 kafy and are indicative of the strategy which essentially determines no shortage except when Lake Mead elevation approaches the top of the dead pool elevation or is below 1,000 feet msl and there is no delivery to SNWA. The Reservoir Storage Alternative from 2009 (the year of first shortage occurrence) through the interim period shows average shortage volume between 600 and 750 kafy since shortages are applied both more often and at higher magnitudes. The Conservation Before Shortage Alternative shows average shortage volumes between 400 and about 530 kafy over the interim period with shortages first appearing in 2010. These average shortage volumes are lower than the average values under the No Action Alternative since the shortages under this alternative, although similar in magnitude, are applied less often than those under the No Action Alternative. The same factors underlie the average shortage volumes between 400 and 480 kafy associated with the Basin States Alternative and the Preferred Alternative. Shortages under these two alternatives also first appear in 2010.

The Conservation Before Shortage Alternative shows higher average shortage volumes in the latter years of the interim period when compared to the Basin States Alternative and the Preferred Alternative. This is due to involuntary shortages of higher magnitudes occurring at higher frequencies in the latter years under the Conservation Before Shortage Alternative to keep Lake Mead above elevation 1,000 feet msl. Conversely, the Basin States Alternative and the Preferred Alternative assume that when Lake Mead is at or below elevation 1,025 feet msl, additional consultations will occur in order to determine what further actions might be necessary. For modeling purposes, it was assumed that shortages with a magnitude of 600 kaf would continue for Lake Mead elevations below 1,025 feet msl for the Basin States Alternative and the Preferred Alternative.

An alternate way to analyze the probability and magnitude of shortages between alternatives is to compare the cumulative distribution of shortages over a period of time. Figure 4.4-4 presents the cumulative distribution of both voluntary and involuntary shortages for the interim period, 2008 through 2026.

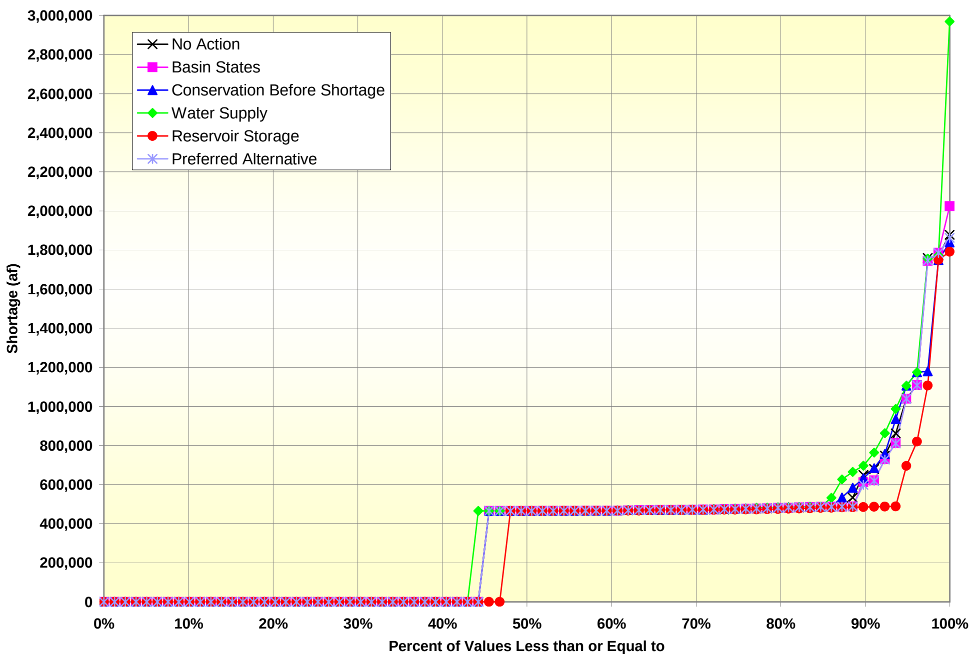
Figure 4.4-4
Involuntary and Voluntary Lower Basin Shortages
Comparison of Action Alternatives to No Action Alternative
Years 2006 through 2026



Under the No Action Alternative, shortages between 490 and 560 kafy would be applied about 35 percent of the time, with shortages of greater magnitudes occurring about three percent of the time over the interim period. Under the Basin States and Conservation Before Shortage Alternatives, and the Preferred Alternative, shortages occur less often than under the No Action Alternative (about 26, 24, and 21 percent of the time, respectively), with the slightly lower probability of the Preferred Alternative due to the assumption of larger volumes of conserved water being stored in Lake Mead. The Reservoir Storage Alternative shows that shortages of magnitudes greater than 600 kafy would occur about 12 percent of the time.

Figure 4.4-5 provides the cumulative distribution of shortages for the period between 2027 through 2060. Although all alternatives were assumed to revert back to the modeled operational criteria used under the No Action Alternative in 2027, the differences in the cumulative distribution are attributed to differences in Lake Powell and Lake Mead elevations between the alternatives at the end of the interim period (2026). For example, the occurrence of large shortages (up to 2.97 maf) at low probabilities under the Water Supply Alternative is due to large shortages that must be applied in order to return Lake Mead to above elevation 1,000 feet msl for some traces in 2027 and 2028.

Figure 4.4-5
Involuntary and Voluntary Lower Basin Shortages
Comparison of Action Alternatives to No Action Alternative
Years 2027 through 2060



Tables 4.4-5 through 4.4-9 present the probability of occurrence of shortages of various magnitudes for years 2017, 2026, 2027, 2040, and 2060 for each alternative. Also shown are the probabilities of involuntary shortages only and the probabilities of both voluntary and involuntary shortages for the Conservation Before Shortage Alternative.

2,000 – 2,499	0	0	0	0	0	0	0
> 2,500	0	0	0	0	0	0	0

The maximum amount of shortage for each alternative for each year is presented in Figure 4.4-6. Table 4.4-10 lists the maximum values for specific years. The large shortages in 2027 and 2028 shown for the Water Supply Alternative (Figure 4.4-6) are due to shortages that must be applied in order to return Lake Mead to above elevation 1,000 feet msl after the interim period. By contrast, the Reservoir Storage Alternative has the lowest maximum shortage of any of the alternatives in 2027 because the reservoirs would be maintained at relatively higher elevations. By 2040, all alternatives have converged essentially to the No Action Alternative values.

Sensitivity of Shortage Conditions to Storage and Delivery Mechanism. The mechanism to store and deliver conserved system and non-system water assumed as part of the Basin States, Conservation Before Shortage, and Reservoir Storage Alternatives, and the Preferred Alternative, could potentially affect the probability of shortages. Because a potential effect of the storage and delivery mechanism is an increase in the volume of water in Lake Mead, a Shortage Condition is likely to occur less often with the storage and delivery mechanism in place.

Figure 4.4-6
Involuntary and Voluntary Lower Basin Shortages
Comparison of Action Alternatives to No Action Alternative
Maximum Shortage Volumes

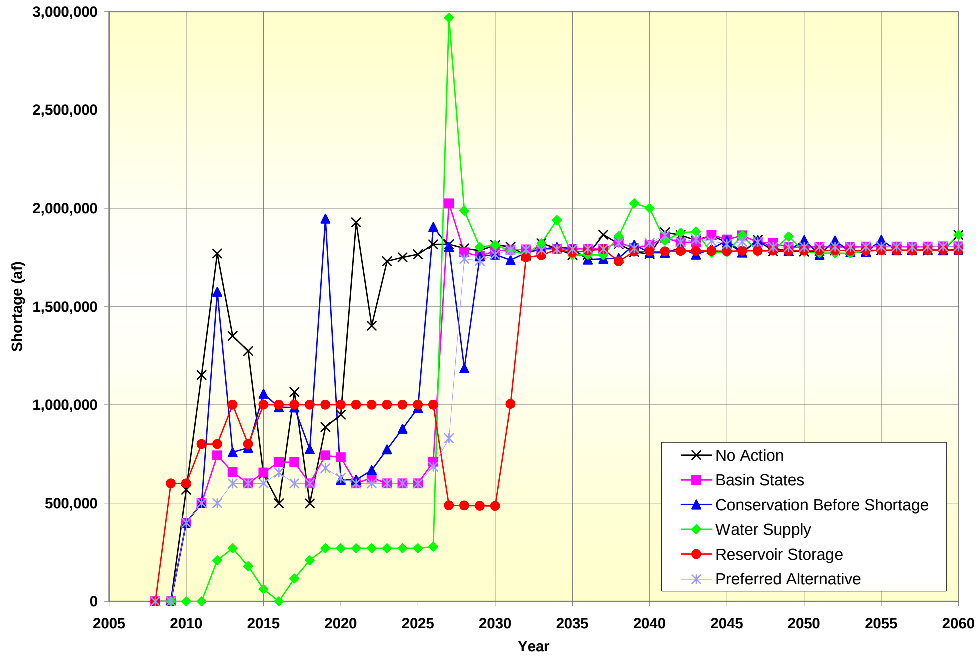

Table 4.4-10
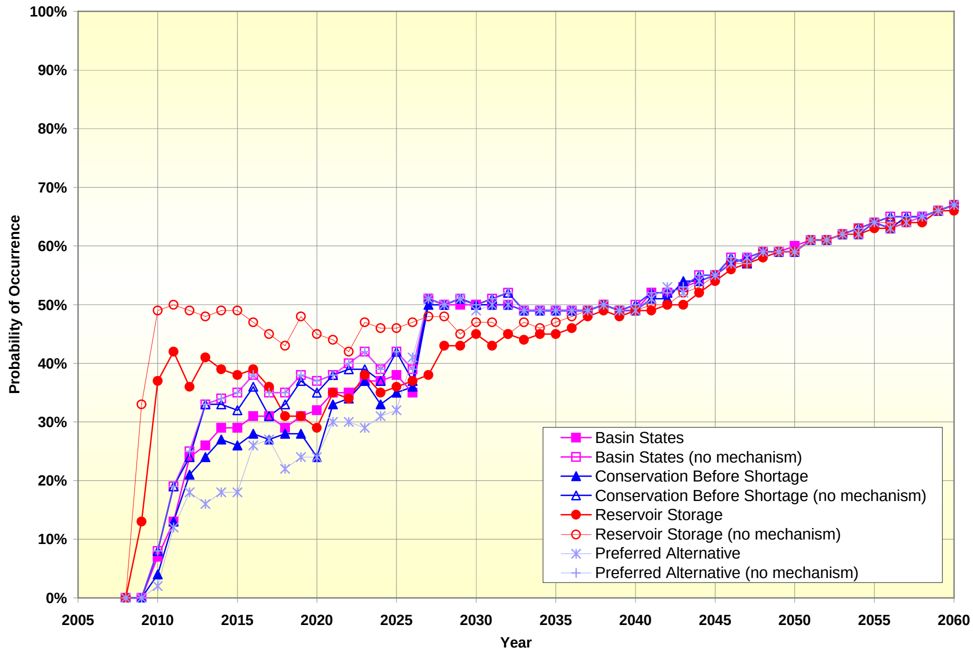
Maximum Volume of Involuntary and Voluntary Shortage to the Lower Basin for Specific Years (af)
Comparison of Action Alternatives to No Action Alternative

Year	No Action	Basin States	Conservation Before Shortage	Water Supply	Reservoir Storage	Preferred Alternative
2008	0	0	0	0	0	0
2017	1,065,961	707,930	987,421	116,530	1,000,000	600,000
2026	1,816,439	711,370	1,904,067	279,000	1,000,000	685,470
2027	1,817,357	2,024,093	1,803,329	2,969,371	488,644	829,717
2040	1,766,650	1,812,428	1,774,108	1,999,447	1,779,919	1,823,325
2060	1,864,875	1,805,591	1,788,498	1,864,875	1,787,346	1,805,591

An analysis of the sensitivity of the occurrence of a Shortage Condition to the storage and delivery mechanism was performed by comparing these four alternatives with and without the mechanism in place. Without the mechanism in place, it was assumed that the voluntary shortages (i.e., reduced water deliveries due to conservation proposed to occur at Lake Mead elevations at and below 1,075 feet msl) proposed in the Conservation Before Shortage Alternative would occur. Under this assumption, the conserved water would remain in Lake Mead. All other conservation activities assumed to be associated with the storage and delivery mechanism as described in Appendix M were assumed not to exist for the Conservation Before Shortage, Basin States and Reservoir Storage Alternatives, and the Preferred Alternative.

Figure 4.4-7 presents the probability of involuntary and voluntary shortages for each of the four alternatives with and without the mechanism in place. For each alternative, the inclusion of the mechanism has the effect of decreasing the probability of shortages. Under the Basin States and Conservation Before Shortage Alternatives, the probability of shortage is reduced an average of about five percent from 2010 through 2026. Although the Conservation Before Storage Alternative assumes a greater participation in the storage and delivery mechanism relative to the Basin States Alternative, these results are similar due to the assumption that voluntary conservation would occur under the Conservation Before Storage Alternative even without the mechanism in place. Under the Reservoir Storage Alternative and the Preferred Alternative, the reduction in the probability of shortage is greater, an average of approximately ten percent from 2010 through 2026. Without the storage and delivery mechanism, the probabilities under the Preferred Alternative and the Basin States Alternative are identical because the other modeled operational assumptions are identical.

Figure 4.4-7
Involuntary and Voluntary Lower Basin Shortages
Comparison of Action Alternatives With and Without a Storage and Delivery Mechanism
Probability of Occurrence of Any Shortage Volume



Probability of Multi-year Shortages. It is possible that under some hydrologic conditions, water supply in the Colorado River system may be insufficient to satisfy 7.5 maf of consumptive use in the Lower Division states in two or more consecutive years. In this and subsequent sections, these occurrences of shortages in consecutive years are termed "multi-year shortages". In this section, an analysis of the probability of multi-year shortages is presented. Two factors were considered in this analysis: 1) the frequency of occurrence of multi-year shortages of specific durations; and 2) the magnitude of the shortages observed in those consecutive years.

Multi-year shortages with volumes per year greater than or equal to 400 kafy, 500 kafy, and 600 kafy with durations of two or more years, five or more years, ten or more years, and fifteen or more years were analyzed. No multi-year shortages with volumes per year equal to or greater than 1.0 mafy were observed to occur under any of the alternatives. The results of analyses of multi-year shortages with annual shortage volumes greater than or equal to 400 kafy of durations of two or more years, five or more years, ten or more years and 15 or more years, are shown in Figures 4.4-8 through 4.4-11. The figures and tables that present the results of the analyses of multi-year shortages with annual shortage volumes greater than or equal to 500 kafy and 600 kafy are provided in Appendix P.

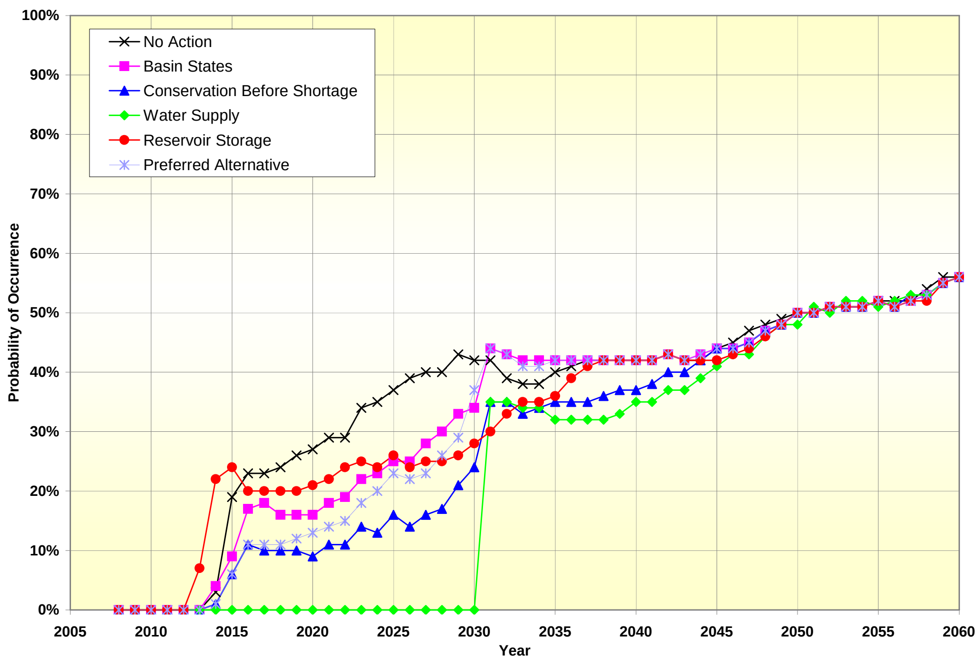

Figure 4.4-10
Consecutive Shortages of Ten Years or Greater
Comparison of Action Alternatives to No Action Alternative
Probability of Shortage per Year Greater Than or Equal to 400 kaf

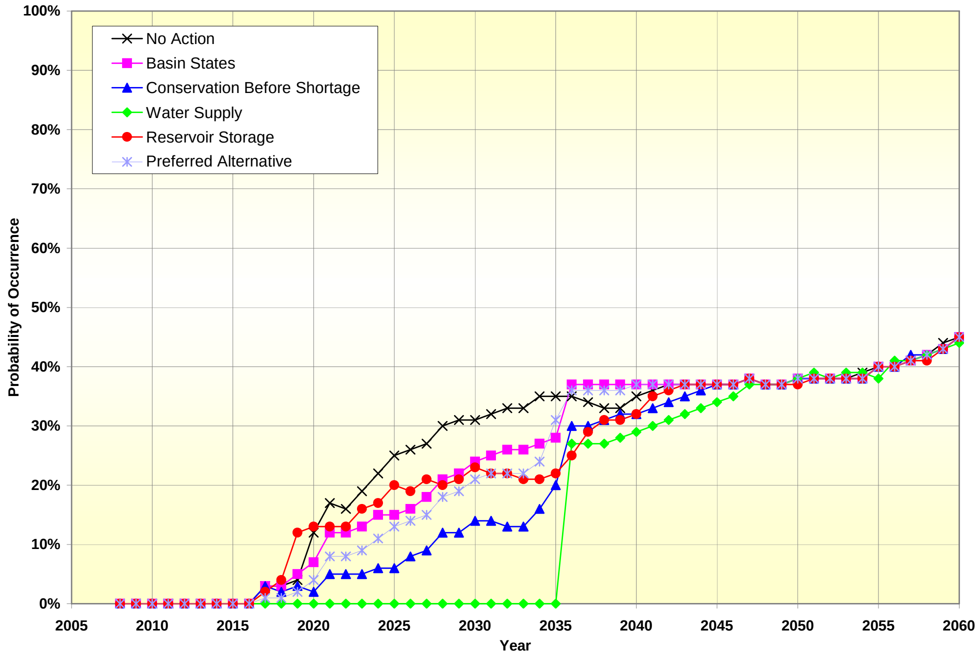

Figure 4.4-11
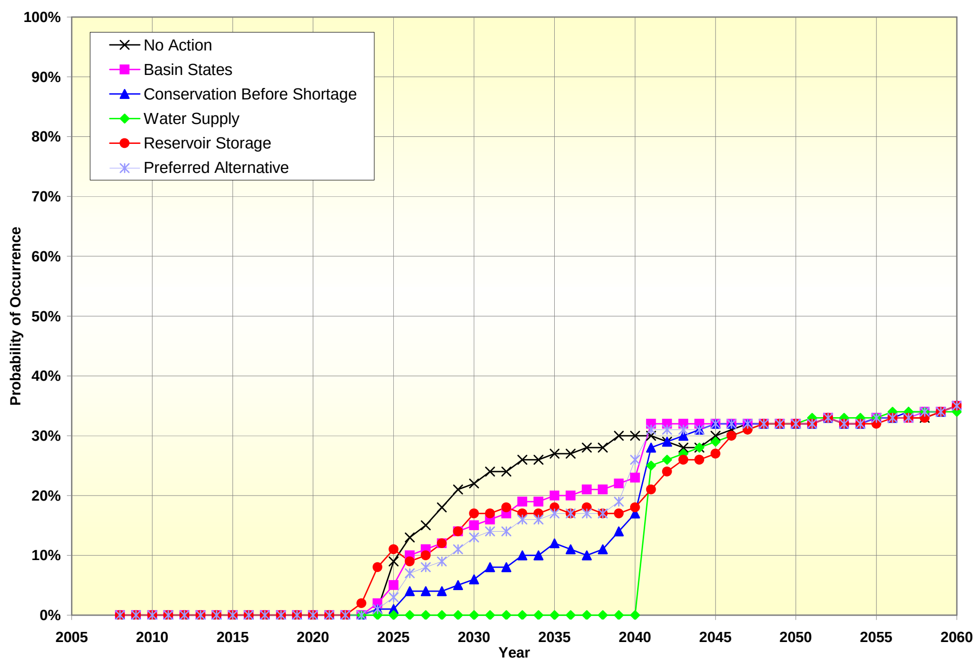
Consecutive Shortages of 15 Years or Greater
Comparison of Action Alternatives to No Action Alternative
Probability of Shortage per Year Greater Than or Equal to 400 kaf



As shown in Figures 4.4-8 through 4.4-11, the probability of multi-year shortages for volumes greater than or equal to 400 kafy decreases as the duration of the multi-year shortage increases for all alternatives. For all durations (greater than or equal to two, five, ten and 15 years), the No Action Alternative has the highest probability of multi-year shortages and the Water Supply Alternative has the lowest probability (zero) during the interim period. The Conservation Before Shortage Alternative and the Preferred Alternative have lower probabilities of multi-year shortages of greater than 400 kafy for all durations than the Basin States Alternative, due primarily to the assumption of increased participation in the storage and delivery mechanism.

Table 4.4-11 presents the probabilities of occurrence depicted in Figures 4-4.8 through 4.4-11 for various durations of selected years during the interim period. The Preferred Alternative and the Conservation Before Shortage Alternative show an approximately 11 percent probability of a multi-year shortage with annual shortage volumes greater than or equal to 400 kaf lasting for five or more years by the year 2016 as compared to 17 percent, 20 percent, and 23 percent for the Basin States and Reservoir Storage Alternatives, and the No Action Alternative, respectively.

The results of the analyses of multi-year shortages with annual shortage volumes greater than or equal to 500 kafy are presented in Table P-WD2 and Figures P-WD-5 through P-WD-8 in Appendix P; a summary is presented here. Multi-year shortages with annual shortage volumes equal to or greater than 500 kaf are most likely to occur under the Reservoir Storage Alternative with probabilities of approximately 35 percent for durations of two or more years and 26 percent for durations of five or more years. Multi-year shortages with annual shortage volumes greater than 500 kaf also occur under the No Action Alternative at durations of two and five or more years, but only in the years up to about 2015 due to the assumptions regarding shortages under the No Action Alternative and the assumed decreasing 4th priority schedules (Appendix D). These assumptions result in shortages of less than 500 kafy in years after 2015. Multi-year shortages of 500 kafy or greater also occur under the Basin States, Conservation Before Shortage, and Water Supply alternatives, with relatively low probabilities of one to four percent over the interim period. Multi-year shortages of 500 kafy or greater were not observed under the Preferred Alternative.

The results of the analyses of multi-year shortages with annual shortage volumes greater than or equal to 600 kafy are shown in Table P-WD-3 and Figures P-WD-9 through P-WD-12 in Appendix P; a summary is presented here. Multi-year shortages with annual shortage volumes equal to or greater than 600 kafy are likely to occur only under the Reservoir Storage Alternative. The probabilities of shortages occurring in two or more consecutive years are identical to the probabilities seen at the 400 and 500 kaf level because 600 kaf is the lowest shortage level in the Reservoir Storage Alternative. For the No Action Alternative, and the Conservation Before Shortage and Water Supply alternatives, multi-year shortages with annual shortage volumes greater than 600 kaf are only observed for durations of two or more years and with very small probabilities (one to three percent in just a few years during the interim period). Multi-year shortages of 600 kafy or greater were not observed under the Basin States Alternative and the Preferred Alternative.

Table 4.4-11
Multi-year Shortages with Durations of Two or More Years, Five or More Years, Ten or More Years, and 15 or More Years
Comparison of Action Alternatives to No Action Alternative, Probability of Shortage per Year Greater Than or Equal to 400 kaf

	No Action	Basin States	Conservation Before Shortage	Water Supply	Reservoir Storage	Preferred Alternative
Probability of Annual Shortage Volume Equal to or Greater Than to 400 kaf Occurring in Two or More Consecutive Years (percent)

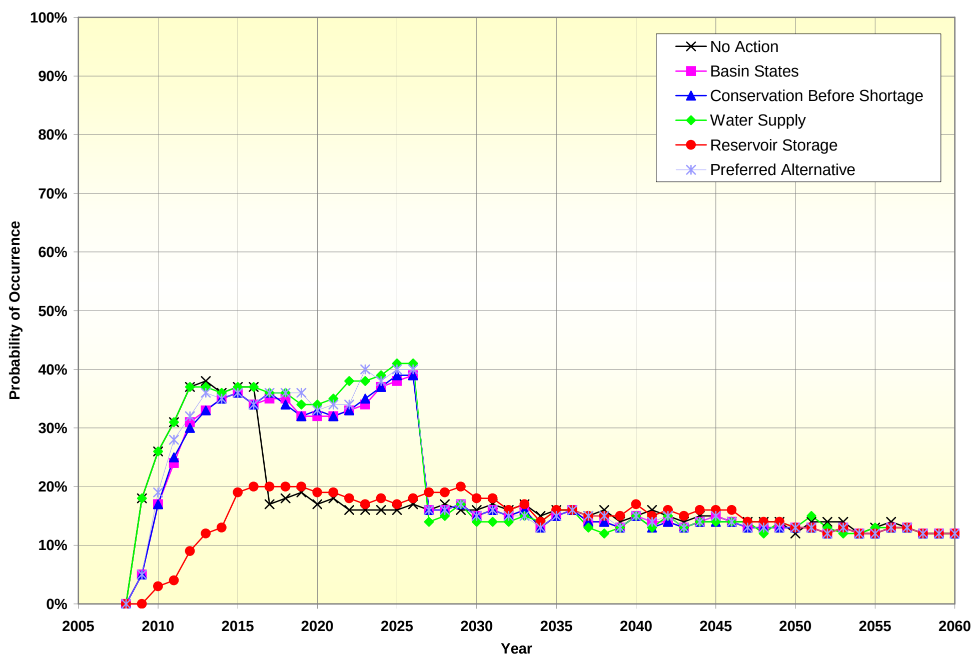
4.4.4.2 Surplus Conditions

A Surplus Condition exists in a particular year when the Secretary determines that there is sufficient mainstream water available to satisfy in excess of 7.5 maf of consumptive use in the Lower Division states. The elements of the proposed federal action include a modification and/or extension of the ISG and each alternative expresses a particular assumption for determining Surplus conditions (Chapter 2).

Probability of Surplus of Any Amount. Figure 4.4-12 compares the probabilities of a Surplus Condition between the alternatives. For the No Action Alternative, the probability of surplus drops from 37 percent to 17 percent in 2017 due to the expiration of the ISG. For the Basin States, Conservation Before Shortage, and Water Supply alternatives, and the Preferred Alternative, the probabilities of surplus are between 30 percent and 40 percent through 2026 since they assume an extension of some provisions of the ISG. Probabilities for the Basin States and Conservation Before Shortage Alternatives, and the Preferred Alternative are lower compared to the Water Supply Alternative since all three alternatives assume that the ISG would be modified and the more permissive provisions (e.g., Partial Domestic Surplus) would be eliminated. For the Reservoir Storage Alternative, surplus determinations are limited to Quantified Surplus (70R Strategy) and Flood Control Surplus Conditions, beginning in 2008, and that assumption is reflected in the lower probabilities compared to the other action alternatives throughout the interim period. The probabilities for all alternatives converge to around 15 percent after the interim period since they all revert to the modeled operational assumptions used under the No Action Alternative after 2026.

Figure 4.4-12
Surplus Conditions
Comparison of Action Alternatives to No Action Alternative
Probability of Occurrence



Probability of Various Types of Surplus. Figure 4.4-13 presents a comparison of the probability of occurrence of the Partial Domestic Surplus Condition for each alternative. The probability is zero for the Basin States, Conservation Before Shortage, and Reservoir Storage Alternatives, and the Preferred Alternative since no provisions for Partial Domestic Surplus are contained in those alternatives. The probability of Partial Domestic Surplus for the No Action Alternative and the Water Supply Alternative are identical through 2016. After 2016, the probability of Partial Domestic Surplus under the No Action Alternative drops to zero since the ISG expire, while the Water Supply Alternative assumes an extension of the existing ISG through 2026.

Figure 4.4-13
Partial Domestic Surplus Deliveries to Lower Basin States
Comparison of Action Alternatives to No Action Alternative
Probability of Occurrence

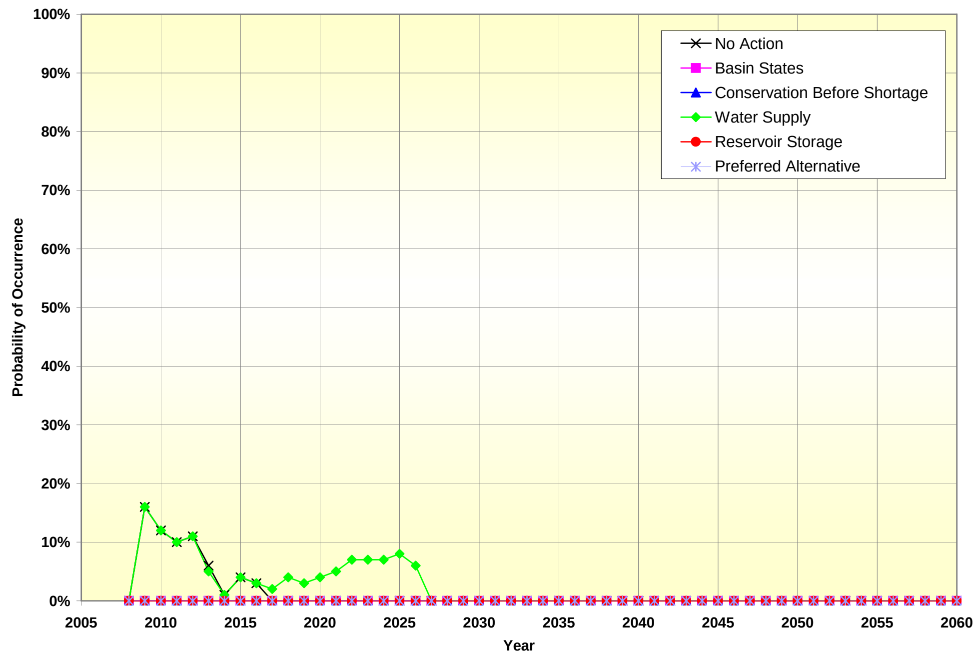


Figure 4.4-14 presents a comparison of the probability of occurrence of the Full Domestic Surplus Condition for each alternative. The probability is zero for the Reservoir Storage Alternative since it does not include a provision for this condition. The probability of Full Domestic Surplus for the No Action Alternative and the Water Supply Alternative are nearly identical through 2016 since they have the same assumptions during that period, with the Water Supply Alternative continuing the Full Domestic Surplus provision through 2026. The Basin States and Conservation Before Shortage Alternatives, and the Preferred Alternative, also have nearly identical probabilities through 2026 since they have the same assumptions during that period. The probabilities for the Basin States and Conservation Before Shortage Alternatives, and the Preferred Alternative are slightly higher than the No Action Alternative and the Water Supply Alternative since they do not have a provision for Partial Domestic Surplus. This keeps the reservoir elevations slightly higher, increasing the chances of a Full Domestic Surplus determination.

Figure 4.4-14
Full Domestic Surplus Deliveries to Lower Basin States
Comparison of Action Alternatives to No Action Alternative
Probability of Occurrence

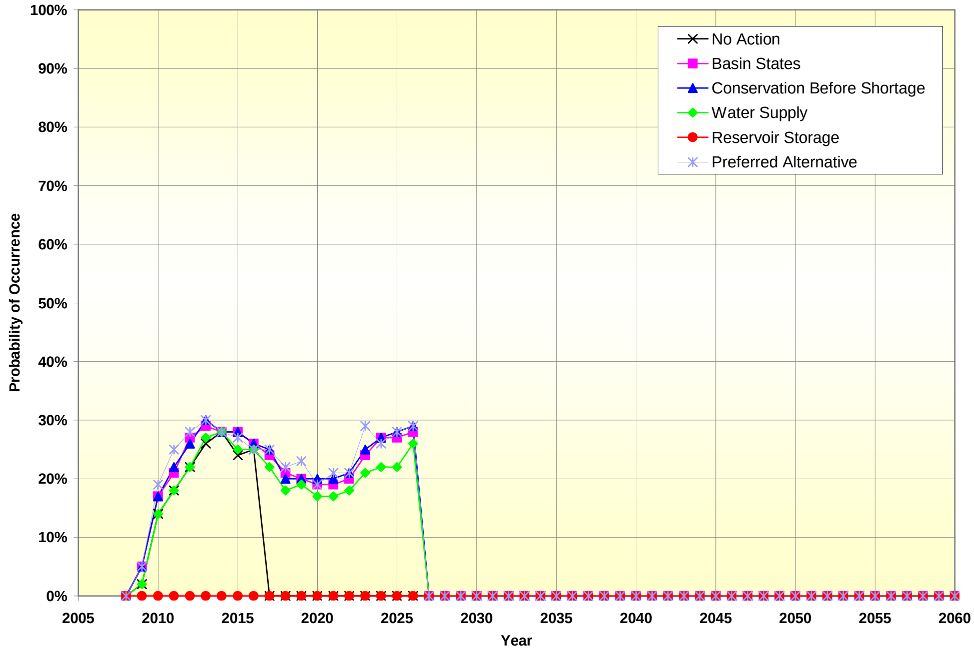

Figure 4.4-15 presents a comparison of the probability of the Quantified (70R) Surplus Condition for each alternative. The probabilities for the No Action Alternative, the Basin States, Conservation Before Shortage, and Water Supply alternatives, and the Preferred Alternative, are nearly identical, with the Reservoir Storage Alternative being slightly higher since it tends to keep the reservoir at higher elevations.

Figure 4.4-15
Quantified Surplus (70R Strategy) Deliveries to Lower Basin States
Comparison of Action Alternatives to No Action Alternative
Probability of Occurrence

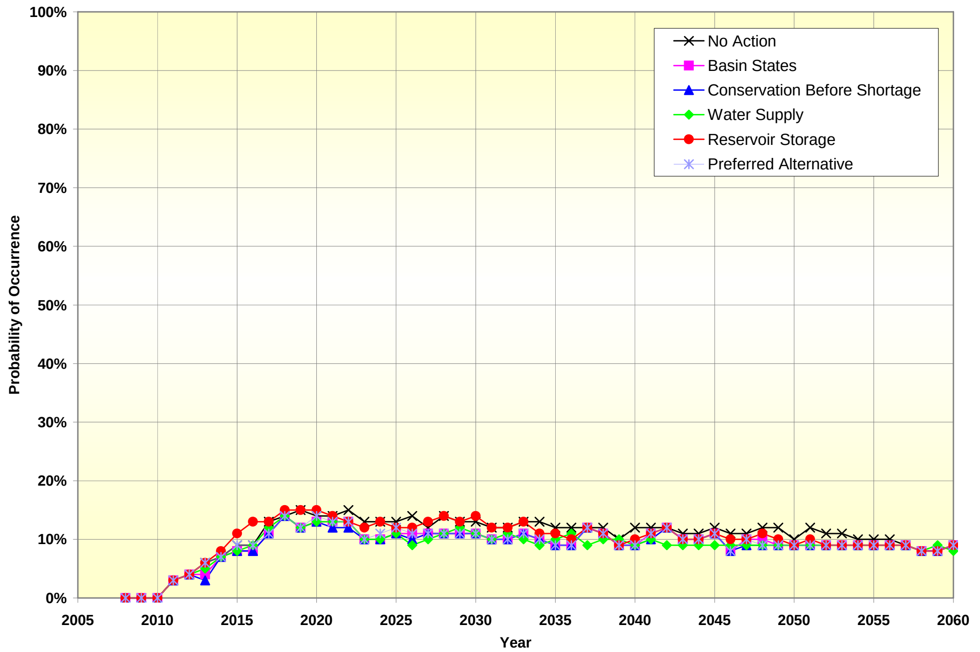

Figure 4.4-16 presents a comparison of the probability of the Flood Control Surplus Condition for each alternative. The probabilities for the No Action Alternative, the Basin States, Conservation Before Shortage, and Water Supply alternatives, and the Preferred Alternative, are nearly identical, with the Reservoir Storage Alternative being slightly higher since it tends to keep the reservoir at higher elevations.

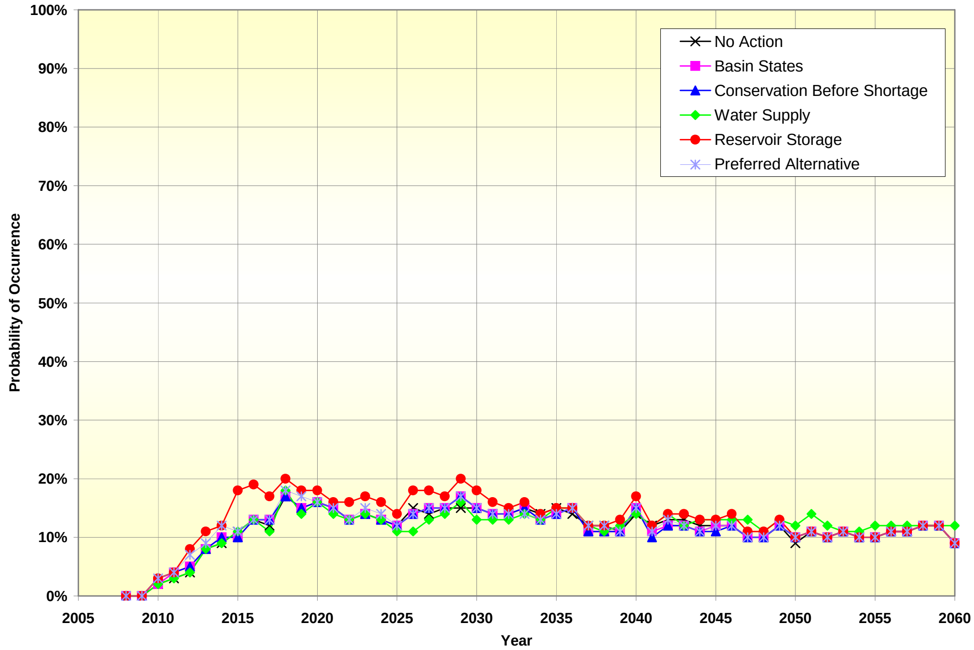
Figure 4.4-16
Flood Control Surplus Deliveries to Lower Basin States
Comparison of Action Alternatives to No Action Alternative
Probability of Occurrence



Sensitivity of Surplus Conditions to Storage and Delivery Mechanism. The mechanism to deliver and store conserved system and non-system water assumed as part of the Basin States, Conservation Before Shortage, and Reservoir Storage Alternatives, and the Preferred Alternative could potentially have an effect on the probability of surplus occurrences. Because a potential outcome of the storage and delivery mechanism is an increase in the volume of water in Lake Mead, a Surplus Condition is likely to occur more often with the storage and delivery mechanism in place.

Figure 4.4-17 presents the sensitivity of the occurrence of a Surplus Condition to the storage and delivery mechanism by comparing these four alternatives with and without the mechanism in place. For each alternative, the inclusion of the mechanism has the effect of slightly increasing the probability of a surplus. An increase of about five percent under the Basin States and Reservoir Storage Alternatives occurs in 2011 and 2015, respectively. The maximum increase under the Conservation Before Shortage Alternative is four percent occurring in 2011. The overall maximum increase in the occurrence of a Surplus Condition is seven percent occurring under the Preferred Alternative in 2011 and 2023.

4.4.4.3 Normal Conditions

The probability of a Normal Condition is shown in Figure 4.4-18. Under the assumption of an initial Lake Mead elevation of 1,114.85 feet msl on January 1, 2008, a Normal Condition would occur for all alternatives with a 100 percent probability in 2008.

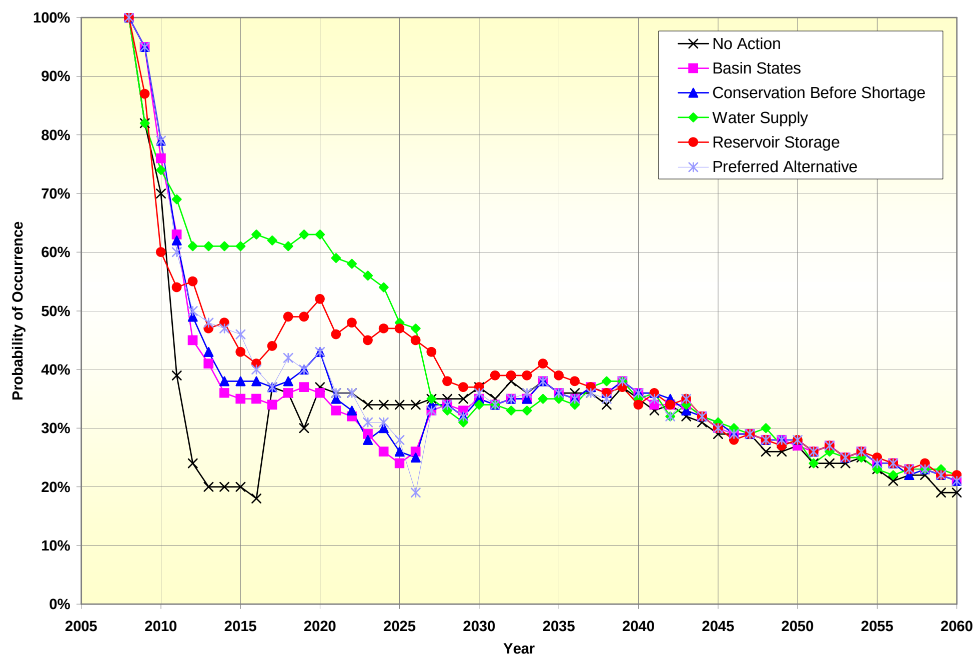
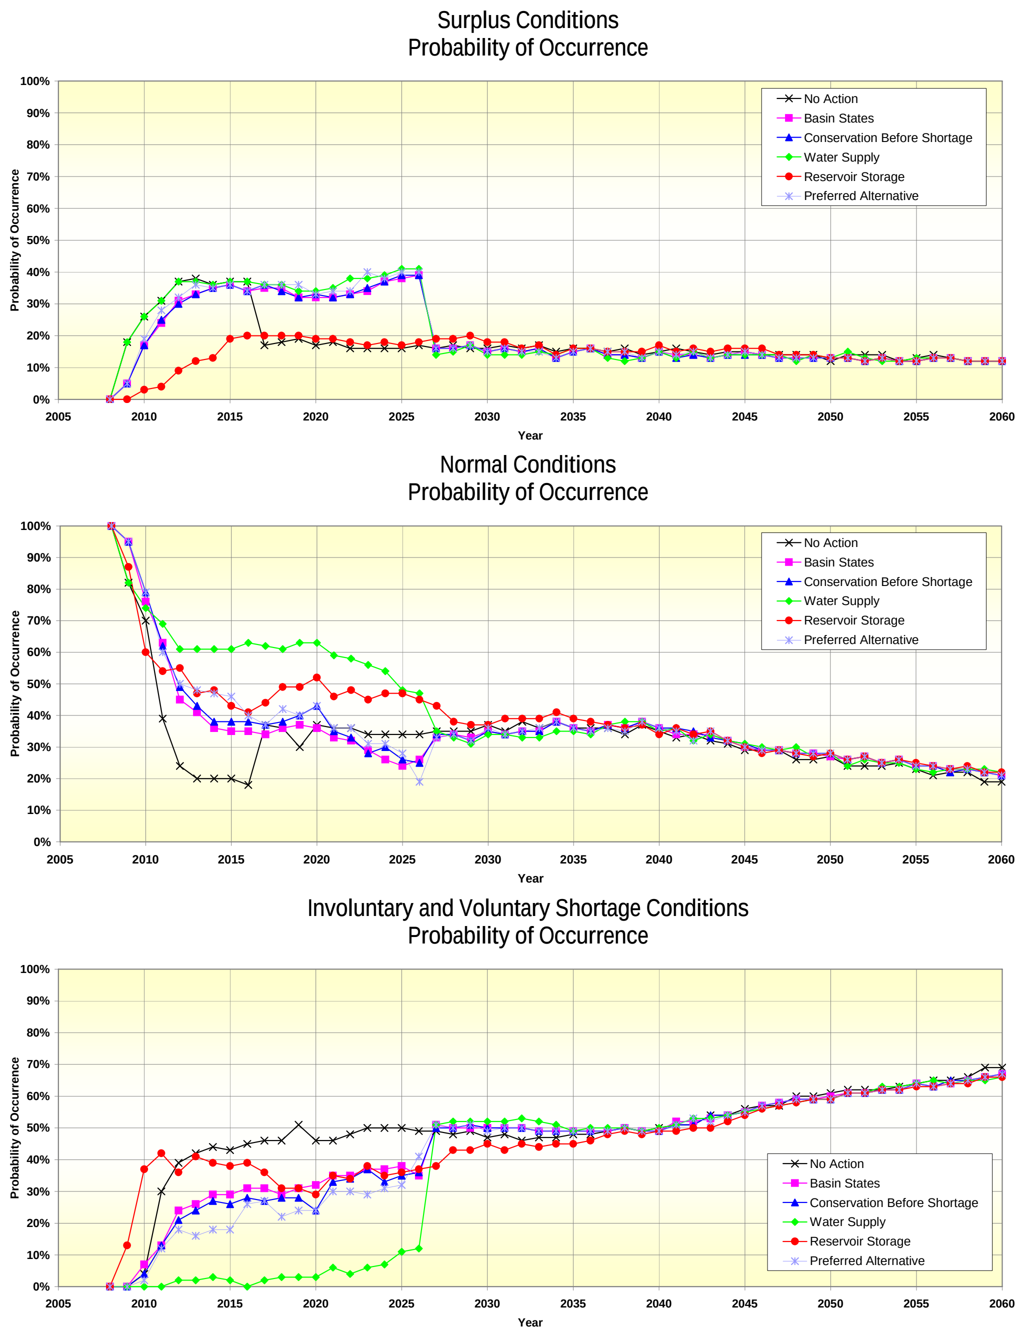
Normal Conditions
Comparison of Action Alternatives to No Action Alternative
Probability of Occurrence



4.4.4.4 Summary of Water Supply Conditions

Figure 4.4-19 illustrates the probabilities of occurrence for the three water supply conditions (Surplus, Normal, and Shortage) under all alternatives.

Figure 4.4-19
Surplus, Normal, and Shortage (Involuntary and Voluntary) Conditions
Comparison of Action Alternatives to No Action Alternative



4.4.5 Total Water Deliveries to the Lower Division States

This section presents the simulated water deliveries to the three Lower Division states. Deliveries to each state may deviate from a state's normal apportionment due to Surplus or Shortage conditions as well as the storage and delivery of conserved water to and from Lake Mead. For the alternatives that do not include some form of a storage and delivery mechanism (the No Action Alternative and the Water Supply Alternative), water deliveries above or below a state's apportionment occur only during Surplus conditions or Shortage conditions respectively. Water deliveries under the Basin States, Conservation Before Shortage, and Reservoir Storage Alternatives, and the Preferred Alternative in excess of a state's apportionment can occur due to a Surplus Condition as well as when conserved water previously stored in Lake Mead is delivered. Also under these alternatives, water deliveries less than a state's apportionment can occur due to a Shortage Condition as well as when water is being conserved within that state and stored in Lake Mead. In the following sections, the modeled water deliveries are presented with and without the storage and delivery mechanism to facilitate understanding of the differences.

4.4.5.1 Total Water Deliveries to Arizona

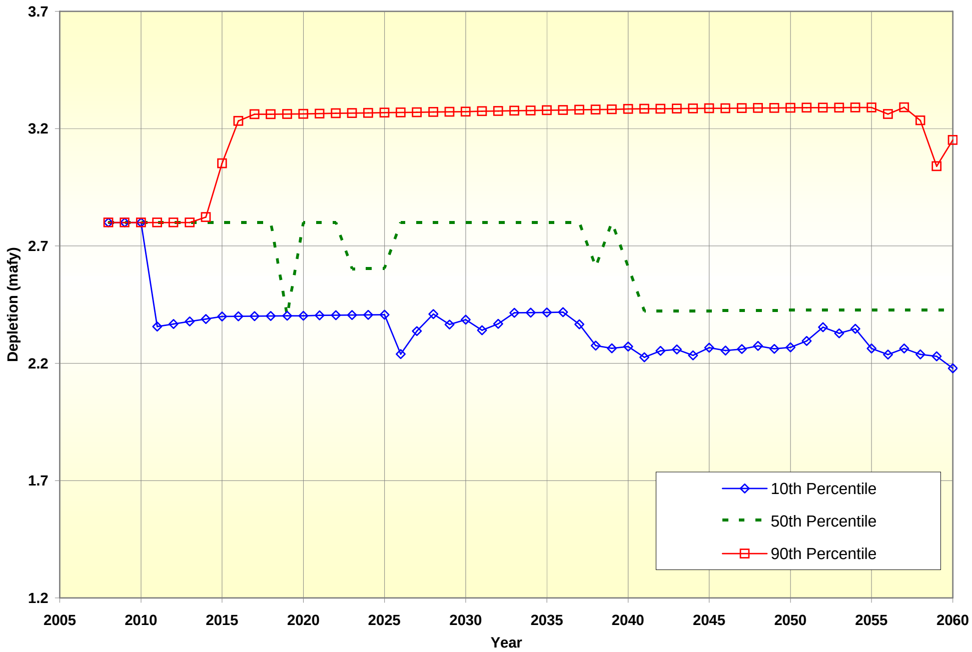
This section presents the simulated water deliveries to Arizona under the No Action Alternative and the action alternatives.

No Action Alternative. Water deliveries to Arizona are projected to fluctuate throughout the 53-year period of analysis reflecting variations in hydrologic conditions. The 90th, 50th, and 10th percentile ranking of modeled water deliveries to Arizona under the No Action Alternative are presented in Figure 4.4-20. Since the No Action Alternative does not include a storage and delivery mechanism, deviations from annual deliveries of 2.8 mafy are due to Shortage and Surplus conditions.

The 90th percentile line generally coincides with Arizona's depletion schedule during full surplus water supply conditions. The exceptions to this are the periods from 2008 through 2015 and 2056 through 2060. As indicated by this 90th percentile line, the probability that the No Action Alternative would provide Arizona's Full Surplus depletion schedule is at least ten percent for the period 2016 through 2055.

The 50th percentile line represents the median annual depletion values. This 50th percentile line generally coincides with Arizona's projected depletion schedule under Normal conditions through year 2018. After 2018, the median annual Arizona modeled depletion values fluctuate between 2.40 maf and 2.80 maf.

Figure 4.4-20
Arizona Modeled Annual Depletions
No Action Alternative
90th, 50th, and 10th Percentile Values



The 10th percentile line represents the depletion values above which 90 percent of the annual depletion values were observed. The 10th percentile annual depletion values were 2.80 maf from 2008 through 2010 and approximately 2.4 maf from 2011 through 2025. Between 2025 and 2037, the 10th percentile annual depletion values fluctuated between 2.24 maf and 2.42 maf, and after 2037, the annual depletion values fluctuated between 2.18 maf and 2.35 maf.

Comparison of Action Alternatives Without the Storage and Delivery Mechanism to No Action Alternative. Figure 4.4-21 provides a comparison of the cumulative distribution of Arizona's depletions under the action alternatives without the storage and delivery mechanism to depletions under the No Action Alternative during the interim period, 2008 through 2026. The results presented in Figure 4.4-21 can be used to compare how often Arizona might expect deliveries above and below its 2.8 mafy apportionment due to surplus and shortage conditions under the different alternatives. The relatively larger shortages occurring at probabilities of about five percent or less under the Conservation Before Shortage Alternative and the No Action Alternative are the result of shortages implemented to keep Lake Mead elevation above 1,000 feet msl.

Figure 4.4-21
Arizona Modeled Annual Depletions
Comparison of Action Alternatives (Without Storage and Delivery Mechanism) to No Action Alternative
Years 2008 through 2026

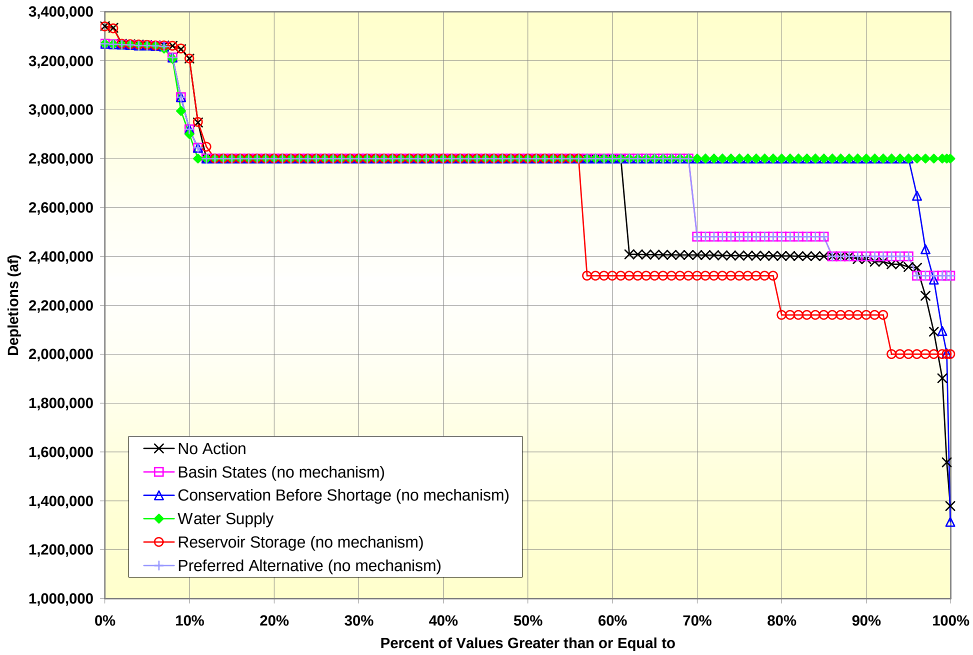


Figure 4.4-22 provides a similar comparison of the cumulative distribution of water deliveries to Arizona under the action alternatives without the storage and delivery mechanism to depletions under the No Action Alternative for the 34-year period 2027 through 2060, that would follow the interim period.

Sensitivity of Total Water Deliveries to Arizona to Storage and Delivery Mechanism. Arizona water deliveries under the Basin States, Conservation Before Shortage, and Reservoir Storage Alternatives, and the Preferred Alternative are impacted by the modeling assumptions made to postulate potential future participation in a storage and delivery mechanism (Appendix M). This section isolates the impacts of those assumptions on Arizona's modeled depletions.

Figure 4.4-22
Arizona Modeled Annual Depletions
Comparison of Action Alternatives (Without Storage and Delivery Mechanism) to No Action Alternative
Years 2027 through 2060

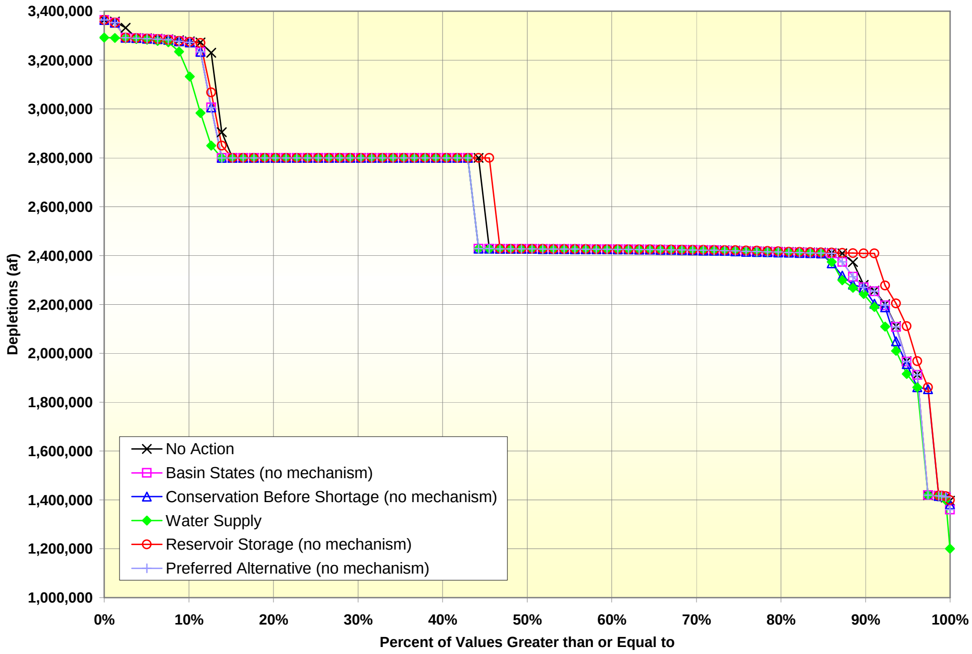

Figure 4.4-23 provides a comparison of the cumulative distribution of Arizona's depletions under the Basin States, Conservation Before Shortage, and Reservoir Storage Alternatives, and the Preferred Alternative, with and without the mechanism in place during the interim period. With the mechanism in place, deliveries of 2.7 mafy are due to the storage of conserved water. With the mechanism removed, occurrences of deliveries less than 2.8 mafy or greater than 2.8 mafy reflect only shortage or surplus conditions respectively. These observations mirror the effects of the mechanism on the probability of voluntary and involuntary total Lower Basin Shortage and Surplus conditions presented in the previous subsection.

Figure 4.4-23
Arizona Modeled Annual Depletions
Comparison of Action Alternatives With and Without Storage and Delivery Mechanism
Years 2008 through 2026

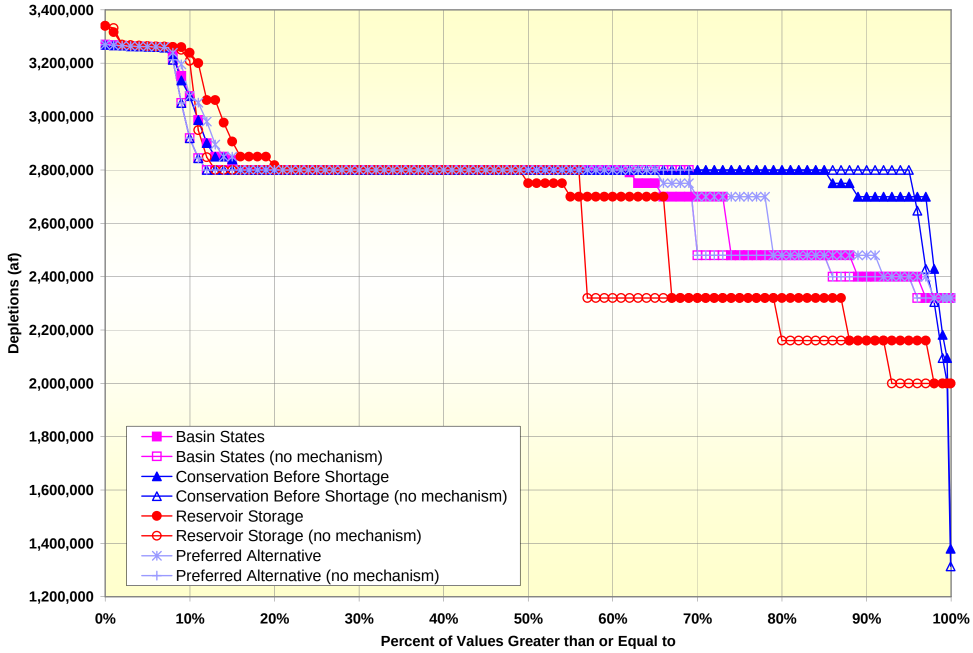

Figure 4.4-24 provides a comparison of the cumulative distribution of Arizona's depletions under the action alternatives that include a storage and delivery mechanism, with and without the mechanism in place for the 34-year period that would follow the interim period. There is almost no effect of the mechanism during these years as it is assumed that only conserved water previously stored in Lake Mead may be delivered during this period.

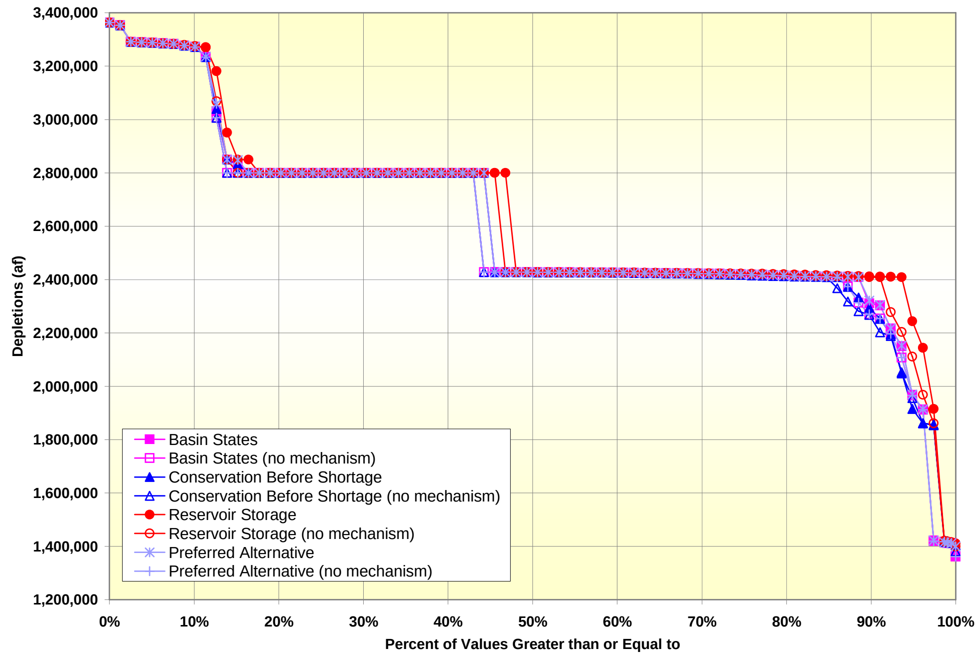
Figure 4.4-24
Arizona Modeled Annual Depletions
Comparison of Action Alternatives With and Without Storage and Delivery Mechanism
Years 2027 through 2060

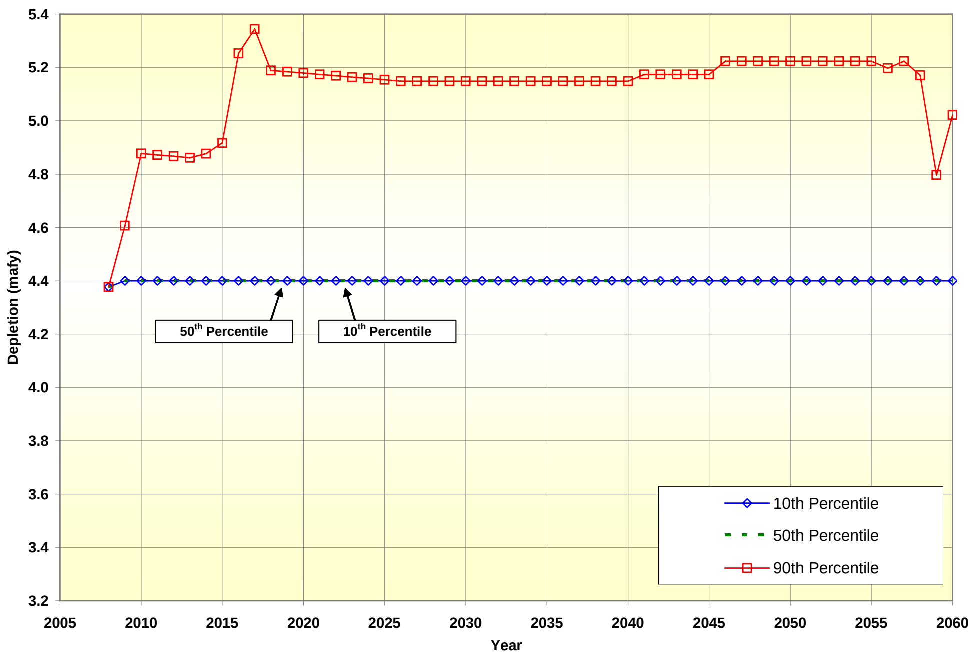


4.4.5.2 Total Water Deliveries to California

This section presents the simulated water deliveries to California under the No Action Alternative and the action alternatives.

No Action Alternative. Water deliveries to California are projected to fluctuate throughout the 53-year period of analysis reflecting variations in hydrologic conditions. The 90th, 50th, and 10th percentile ranking of modeled water deliveries to California under the No Action Alternative are presented in Figure 4.4-25. Since the No Action Alternative does not include a storage and delivery mechanism, deviations from annual deliveries of 4.4 mafy are due to Shortage and Surplus conditions.

Figure 4.4-25
California Modeled Annual Depletions
No Action Alternative
90th, 50th, and 10th Percentile Values



The 90th percentile line generally coincides with California's depletion schedule during full surplus water supply conditions. The exceptions to this are the periods from 2008 through 2015 and from 2056 through 2060. As indicated by this 90th percentile line, the probability that the No Action Alternative would provide California's Full Surplus depletion schedule is at least ten percent for the period from 2016 through 2055.

The 50th percentile line represents the median annual depletion values. This 50th percentile line coincides with California's projected depletion schedule under Normal conditions throughout the 53-year period of analysis.

The 10th percentile line represents the depletion values above which 90 percent of the annual depletion values were observed. The 10th percentile annual depletion values also coincide with California's projected depletion schedule under a Normal Condition throughout the 53-year period of analysis. This means that there is at least a 90 percent probability that California will receive its normal deliveries from 2008 through 2060.

Comparison of Action Alternatives Without the Storage and Delivery Mechanism to No Action Alternative. Figure 4.4-26 provides a comparison of the cumulative distribution of California's depletions under the action alternatives without the storage and delivery mechanism to those of the No Action Alternative during the interim period, 2008 through 2026. The results presented in Figure 4.4-26 can be used to compare how often California might expect deliveries above and below its 4.4 mafy apportionment due to Surplus and Shortage conditions under the different alternatives. Very infrequent (less than one percent of the time) shortages are observed only for the No Action Alternative and the Conservation Before Shortage Alternative due to the assumption that shortages are implemented to keep Lake Mead above elevation 1,000 feet msl. The five percent occurrence of deliveries less than 4.4 mafy when the mechanism is not in place reflects California's scheduled delivery of less than 4.4 maf in 2008 which coincides with scheduled repayment of overruns by IID and CVWD.

Figure 4.4-26
California Modeled Annual Depletions
Comparison of Action Alternatives (Without Storage and Delivery Mechanism) to No Action Alternative
Years 2008 through 2026

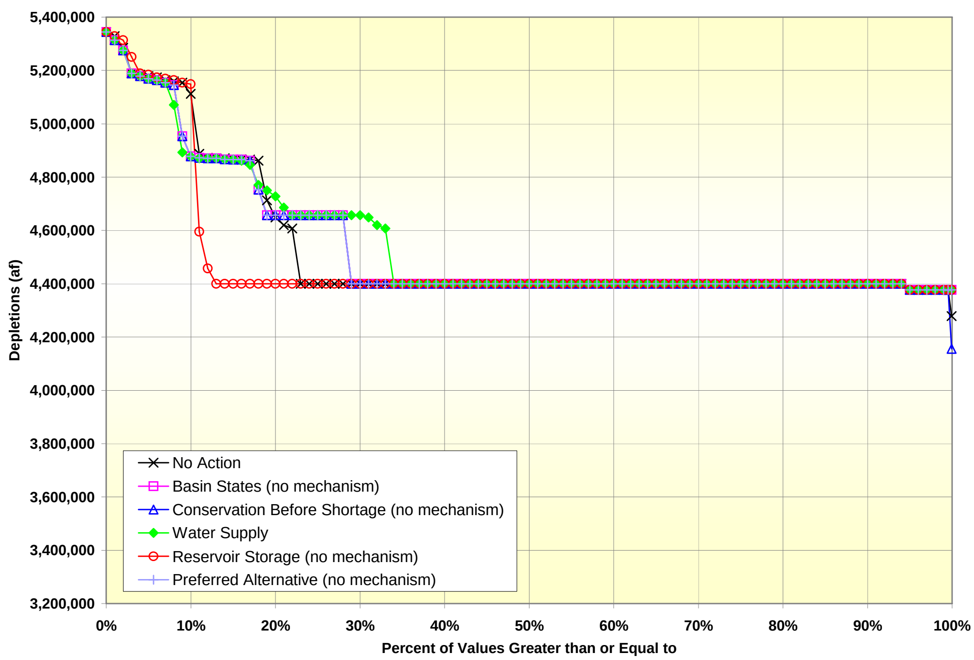


Figure 4.4-27 provides a similar comparison of the cumulative distribution of water deliveries to California under the action alternatives without the storage and delivery mechanism to those of the No Action Alternative for the 34-year period, 2027 through 2060, that would follow the interim period.

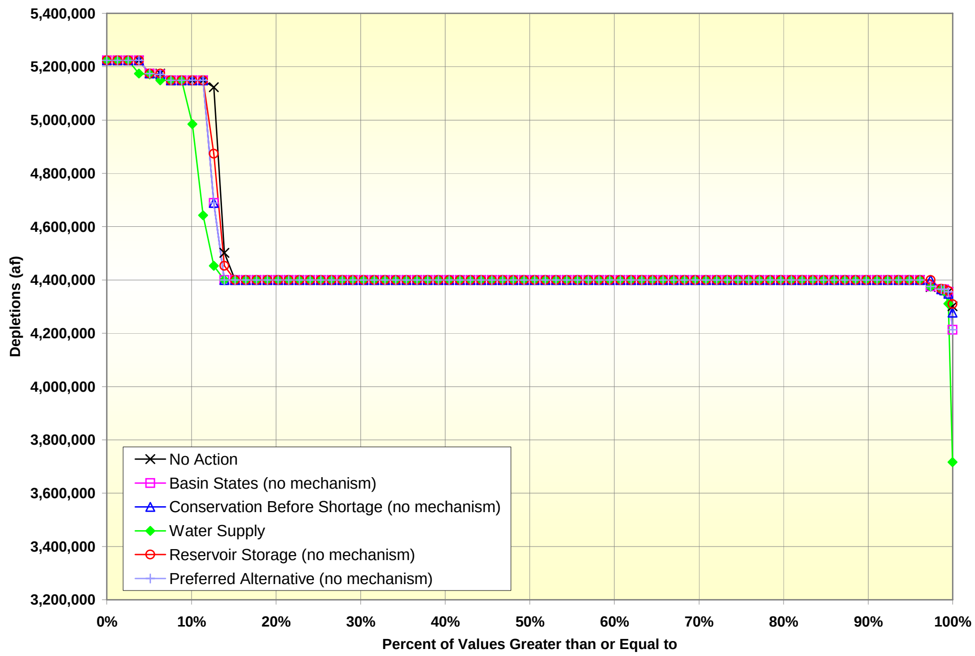
Figure 4.4-27
California Modeled Annual Depletions
Comparison of Action Alternatives (Without Storage and Delivery Mechanism) to No Action Alternative
Years 2027 through 2060



Sensitivity of Total Water Deliveries to California to Storage and Delivery Mechanism. California water deliveries under the Basin States, Conservation Before Shortage, and Reservoir Storage Alternatives, and the Preferred Alternative are impacted by modeling assumptions made to postulate potential future participation in a storage and delivery mechanism (Appendix M). This section isolates the impacts of those assumptions on California's depletions.

Figure 4.4-28 provides a comparison of the cumulative distribution of California's depletions under the action alternatives with and without a storage and delivery mechanism in place during the interim period. For alternatives with the mechanism removed, occurrences of deliveries less than 4.4 mafy reflect only Shortage conditions. Removing the mechanism shows that there is almost no occurrence of deliveries less than 4.4 mafy due to shortage conditions. The five percent occurrence of deliveries less than 4.4 mafy when the mechanism is not in place reflects California's scheduled delivery of less than 4.4 maf in 2008 which coincides with scheduled repayment of overruns by IID and CVWD.

Figure 4.4-28
California Modeled Annual Depletions
Comparison of Action Alternatives With and Without Storage and Delivery Mechanism
Years 2008 through 2026

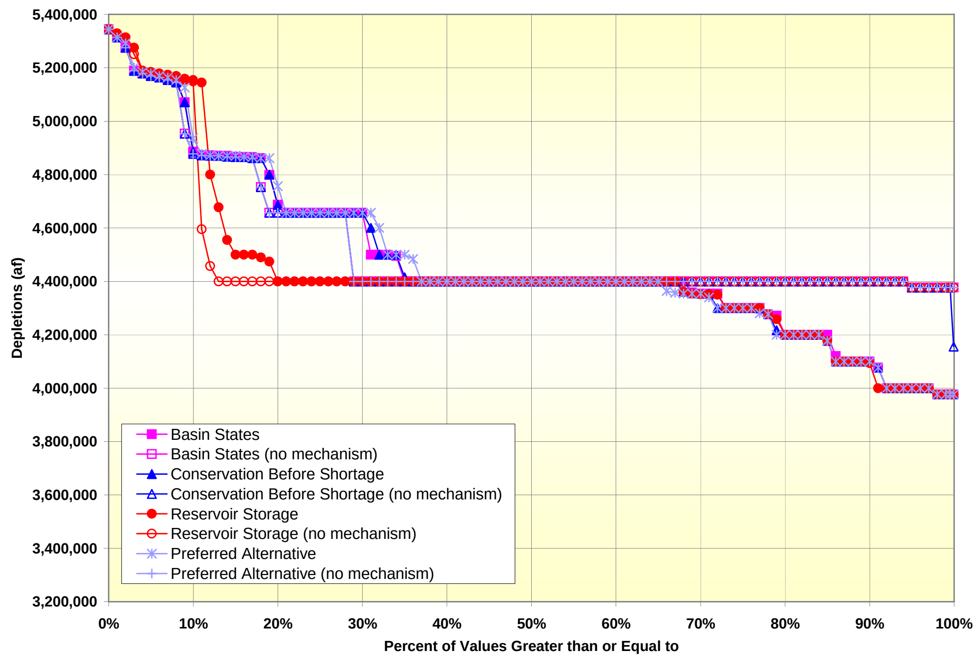


Figure 4.4-29 provides a comparison of the cumulative distribution of California's depletions under the action alternatives that include a storage and delivery mechanism, with and without the mechanism in place for the 34-year period that would follow the interim period. There is almost no effect of the mechanism during these years as it is assumed only conserved water previously stored in Lake Mead may be delivered during this period.

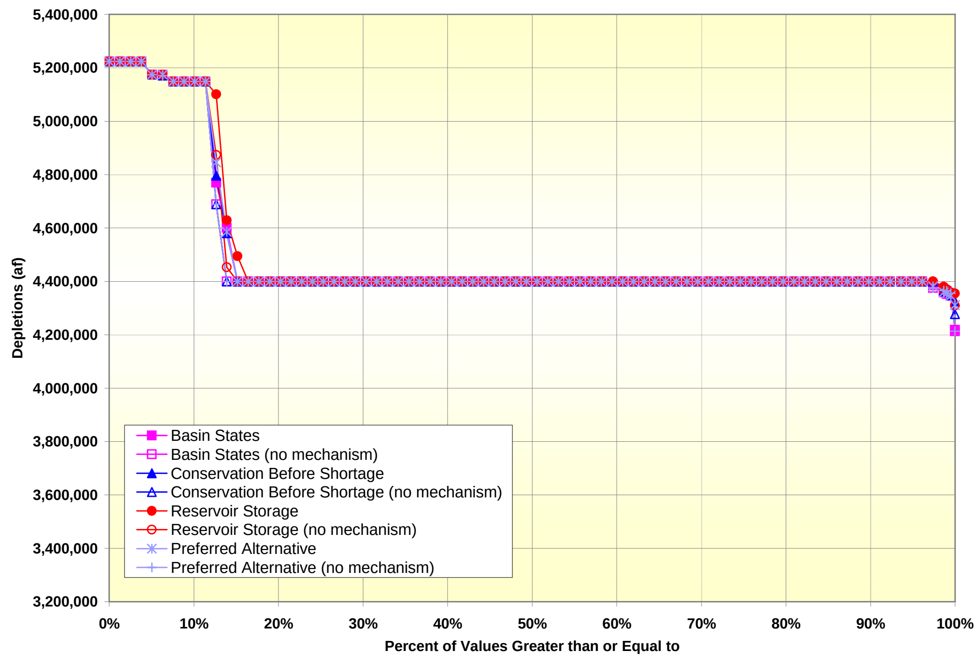
Figure 4.4-29
California Modeled Annual Depletions
Comparison of Action Alternatives With and Without Storage and Delivery Mechanism
Years 2027 through 2060

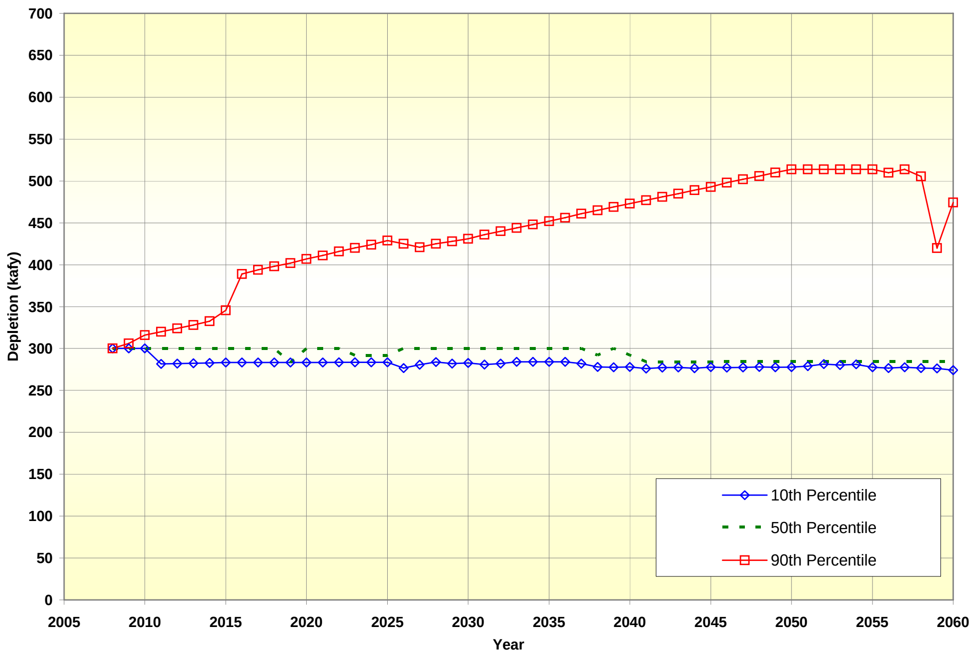


4.4.5.3 Total Water Deliveries to Nevada

This section presents the simulated water deliveries to Nevada under the No Action Alternative and the action alternatives.

No Action Alternative. Water deliveries to Nevada are projected to fluctuate throughout the 53-year period of analysis reflecting variations in hydrologic conditions. The 90th, 50th, and 10th percentile ranking of modeled water deliveries to Nevada under the No Action Alternative are presented in Figure 4.4-30. Since the No Action Alternative does not include a storage and delivery mechanism, deviations from annual deliveries of 300 kafy are due to Shortage and Surplus conditions.

Figure 4.4-30
Nevada Modeled Annual Depletions
No Action Alternative
90th, 50th, and 10th Percentile Values



The 90th percentile line generally coincides with Nevada's depletion schedule during full surplus water supply conditions. The exception to this is the period of 2056 through 2060. As indicated by this 90th percentile line, the probability that the No Action Alternative would provide Nevada's Full Surplus depletion schedule is at least ten percent for the period of 2008 through 2055.

The 50th percentile line represents the median annual depletion values. This 50th percentile line generally coincides with Nevada's projected depletion schedule under a Normal Condition throughout the 53-year period of analysis.

The 10th percentile line represents the depletion values above which 90 percent of the annul depletion values were observed. The 10th percentile annual depletion values were 300 kaf from 2008 to 2010 and fluctuated between 274.1 kaf and 284.1 kaf for the remainder of the 53-year period.

Comparison of Action Alternatives Without the Storage and Delivery Mechanism to No Action Alternative. Figure 4.4-31 provides a comparison of the cumulative distribution of Nevada's depletions under the action alternatives without the storage and delivery mechanism to those of the No Action Alternative during the interim period, 2008 through 2026. The results presented in Figure 4.4-31 can be used to compare how often Nevada might expect deliveries above and below its 300 kafy apportionment due to Surplus and Shortage conditions under the different alternatives. Deliveries of less than 250 kafy observed infrequently under the Basin States and Water Supply alternatives, as well as under the Preferred Alternative, are the result of Lake Mead elevation declining below 1,000 feet msl. Deliveries of less than 250 kafy observed infrequently under the Conservation Before Shortage Alternative, as well as the No Action Alternative, are the result of Lake Mead larger shortages to keep Lake Mead above elevation 1,000 feet msl.

Figure 4.4-31
Nevada Modeled Annual Depletions
Comparison of Action Alternatives (Without Storage and Delivery Mechanism) to No Action Alternative
Years 2008 through 2026

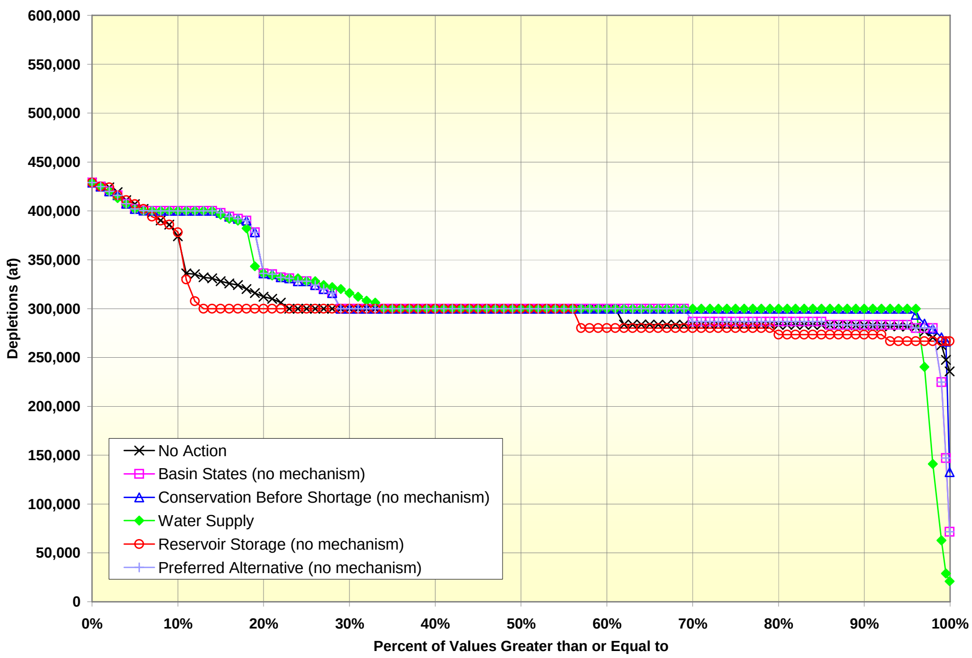


Figure 4.4-32 provides a similar comparison of the cumulative distribution of water deliveries to Nevada under the action alternatives without the storage and delivery mechanism to those of the No Action Alternative for the 34-year period, 2027 through 2060, that would follow the interim period.

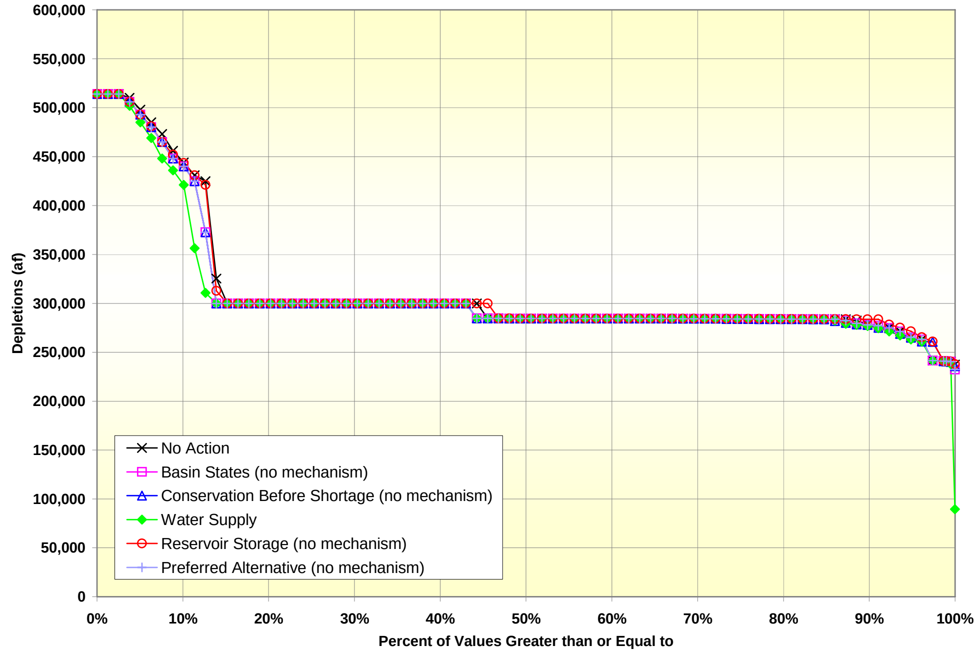
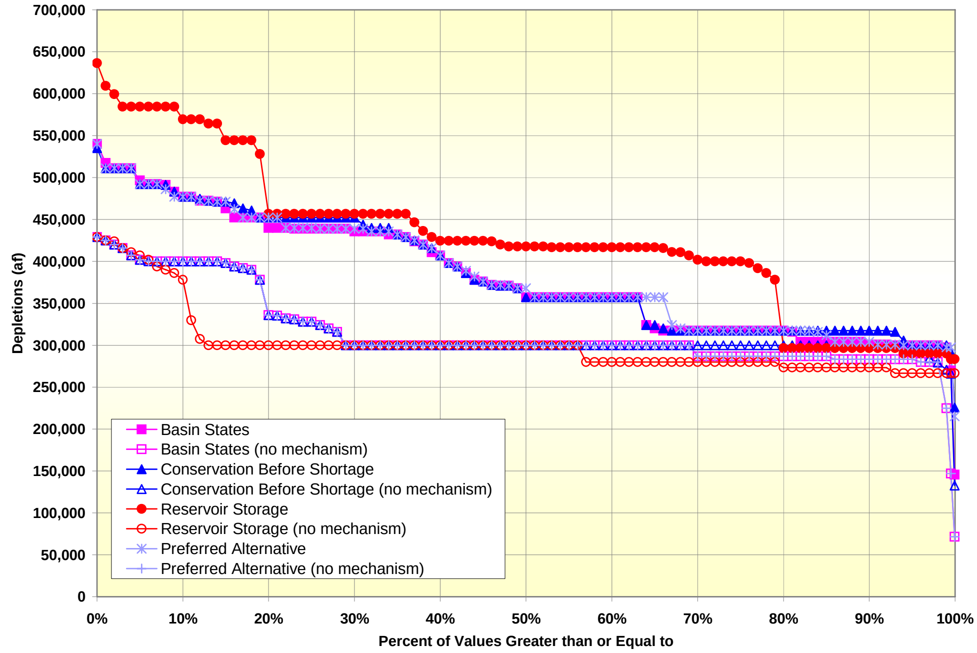
Figure 4.4-32
Nevada Modeled Annual Depletions
Comparison of Action Alternatives (Without Storage and Delivery Mechanism) to No Action Alternative
Years 2027 through 2060



Sensitivity of Total Water Deliveries to Nevada to Storage and Delivery Mechanism. Nevada water deliveries under the Basin States, Conservation Before Shortage, and Reservoir Storage Alternatives, and the Preferred Alternative are impacted by the modeling assumptions made to postulate potential future participation in a storage and delivery mechanism (Appendix M). This section isolates the impacts of those assumptions on Nevada's modeled depletions.

Figure 4.4-33 provides a comparison of the cumulative distribution of Nevada's depletions under the action alternatives with and without a storage and delivery mechanism in place during the interim period. With the mechanism removed the occurrence of deliveries greater than 300 kafy is about 65 percent less under the Reservoir Storage and Conservation Before Shortage Alternatives. Under the Basin States Alternative and the Preferred Alternative, the occurrence of deliveries above 300 kafy is about 55 percent less with the mechanism removed. This indicates that the majority of the occurrences of deliveries above 300 kafy under the Basin States, Conservation Before Shortage, and Reservoir Storage Alternatives, and the Preferred Alternative can be attributed to the delivery of conserved system and non-system water to Nevada. Also, the magnitude of deliveries above 300 kafy is less with the storage and delivery mechanism not in place. Under the Basin States and Conservation Before Shortage Alternatives, and the Preferred Alternative, deliveries range from about 55 kaf to 140 kaf less. Under the Reservoir Storage Alternative, deliveries range from about 100 kaf to 265 kaf less.

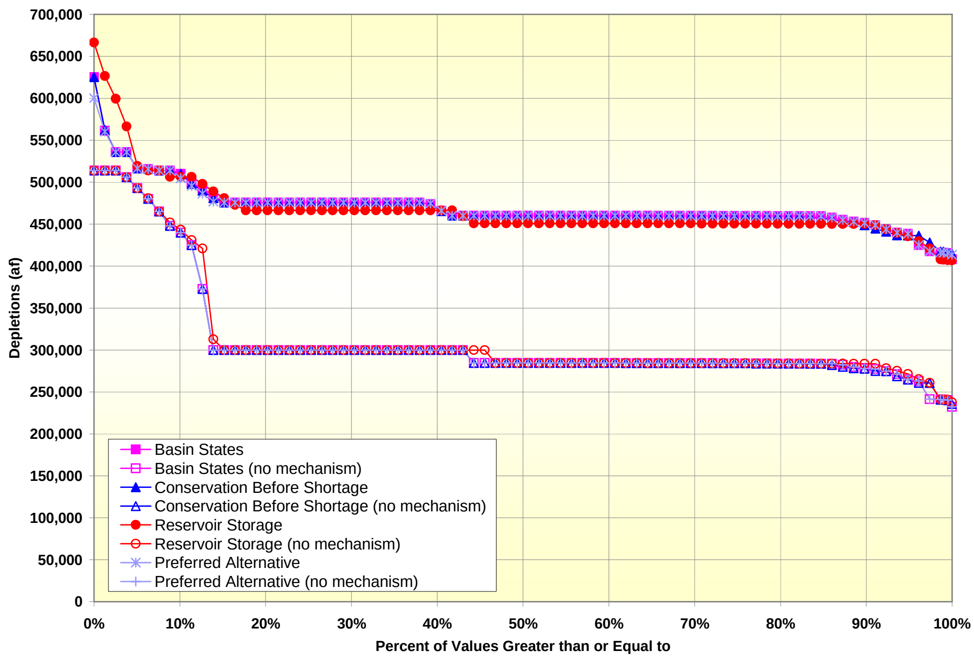
Figure 4.4-33
Nevada Modeled Annual Depletions
Comparison of Action Alternatives With and Without Storage and Delivery Mechanism
Years 2008 through 2026



With the mechanism removed the occurrence of deliveries less than 300 kafy is about 30 percent greater under the Basin States Alternative, two percent greater under the Conservation Before Shortage Alternative, about 40 percent greater under the Reservoir Storage Alternative, and about 30 percent greater under the Preferred Alternative. This indicates that as a result of the delivery of conserved system and non-system water, Nevada does not often receive deliveries less than 300 kafy.

Figure 4.4-34 provides a comparison of the cumulative distribution of Nevada's depletions under the action alternatives that include a storage and delivery mechanism, with and without the mechanism in place for the 34-year period that would follow the interim period. The results of the mechanism removed emphasize the modeling assumption that there is about 170 kafy of conserved system and non-system water available to Nevada after the interim period under these alternatives (Appendix M).

Figure 4.4-34
Nevada Modeled Annual Depletions
Comparison of Action Alternatives With and Without Storage and Delivery Mechanism
Years 2027 through 2060

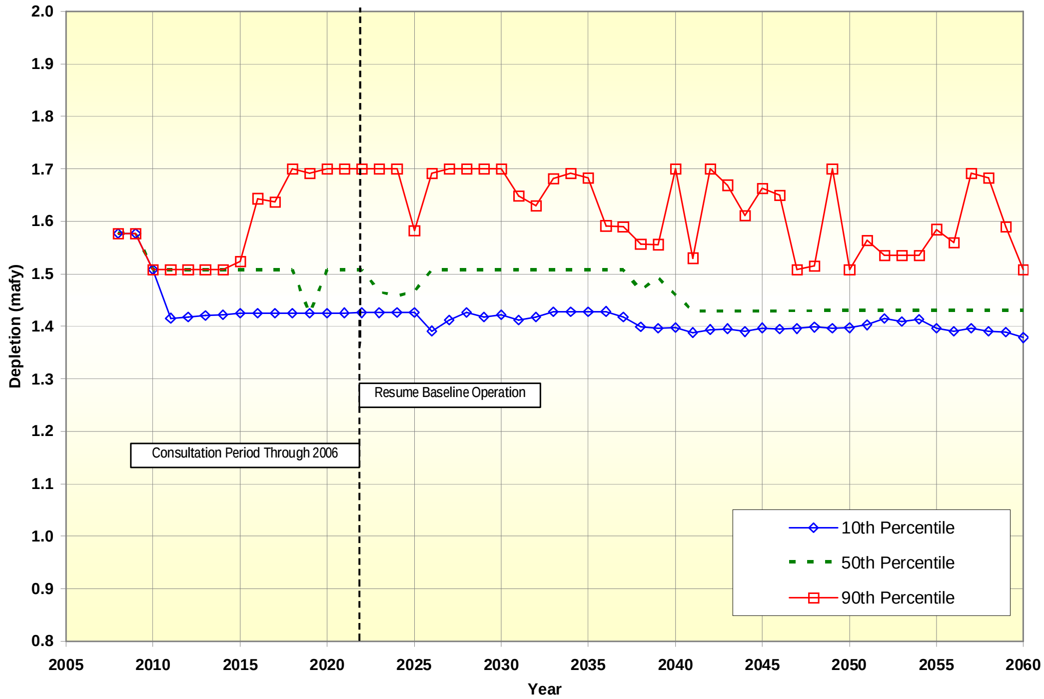


4.4.6 Water Deliveries to Mexico

This section presents the simulated water deliveries to Mexico under the No Action Alternative and the action alternatives. The model assumes a delivery to Mexico of 1.5 mafy with additional deliveries of up to 200 kaf when Lake Mead is in flood control operations. Reductions in deliveries to Mexico are simulated consistent with the modeling assumptions noted in Section 2.2, Section 4.2, and Appendix A. Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 Treaty or to represent current United States policy or a determination of future United States policy regarding deliveries to Mexico. The sensitivity of water deliveries to Mexico and other hydrologic variables (e.g., Lake Mead elevation) to these modeling assumptions was analyzed and the results of this analysis are presented in Appendix Q.

No Action Alternative. Water deliveries to Mexico are projected to fluctuate throughout the 53-year period of analysis reflecting variations in hydrologic conditions. The 90th, 50th, and 10th percentile ranking of modeled water deliveries to Mexico under the No Action Alternative are presented in Figure 4.4-35. Since the No Action Alternative does not include a storage and delivery mechanism, deviations from annual deliveries of 1.5 mafy are due to the modeling assumptions with respect to water delivery reductions and additional deliveries to Mexico as described in Section 2.2, Section 4.2, and Appendix A.

Figure 4.4-35
Mexico Modeled Annual Depletions
No Action Alternative
90th, 50th, and 10th Percentile Values



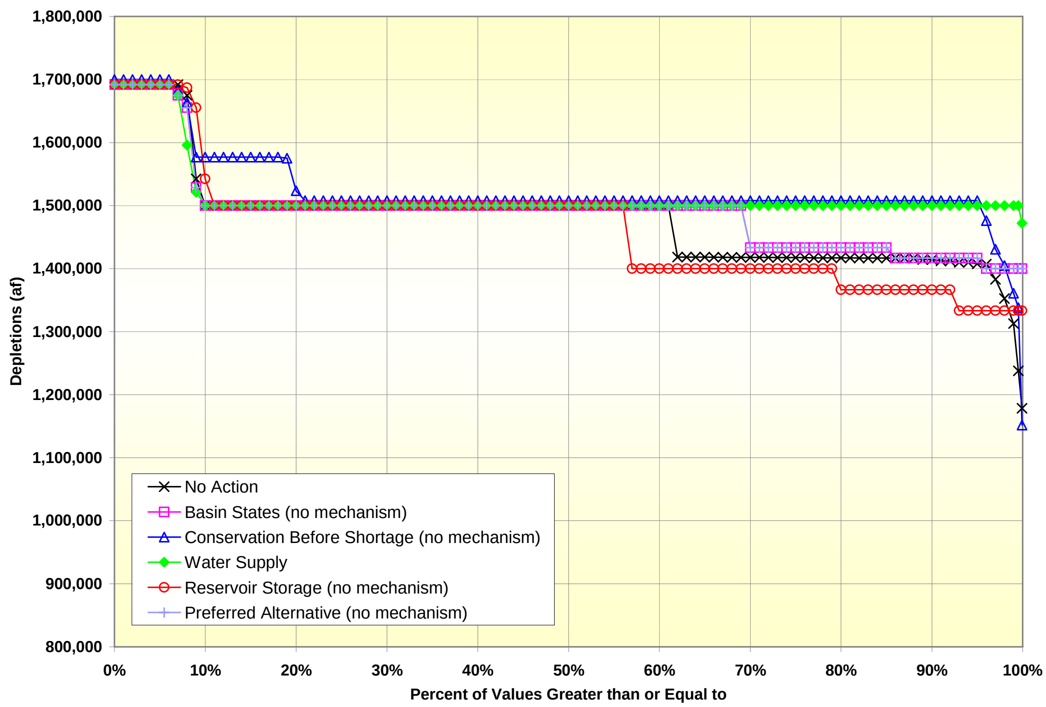
The upper range of 90th percentile annual depletion values shown on Figure 4.4-35 generally coincides with Mexico's depletion schedule during Lake Mead flood control operations. The 90th percentile values fluctuate between 1.5 mafy to 1.7 mafy between 2008 through 2060.

The 50th percentile line represents the median annual depletion values (1.5 mafy) from 2008 through 2018. After 2018, the 50th percentile annual depletion values fluctuate between 1.425 maf and 1.5 maf. The drop in the modeled water deliveries to Mexico below Mexico's 1.5 maf allotment reflects the modeling assumptions with respect to reductions in water deliveries.

The 10th percentile line coincides with the median annual depletion values (1.5 mafy) from 2008 through 2009 and falls to 1.416 mafy in 2011. After 2011, the annual depletion values fluctuate between 1.378 mafy and 1.428 mafy. The drop in the modeled water deliveries to Mexico below Mexico's 1.5 maf allotment reflects the modeling assumptions with respect to reductions in water deliveries.

Comparison of Action Alternatives Without the Storage and Delivery Mechanism to No Action Alternative. Figure 4.4-36 provides a comparison of the cumulative distribution of Mexico's depletions under the action alternatives without the storage and delivery mechanism to those of the No Action Alternative during the interim period, 2008 through 2026. The results presented in Figure 4.4-36 can be used to compare how often Mexico might expect deliveries above and below its 1944 Treaty allocation of 1.5 mafy under the different alternatives. The occurrences of deliveries greater than 1.5 mafy reflect times when Hoover Dam is under flood control operations (Mexico can order additional water up to 1.7 mafy).

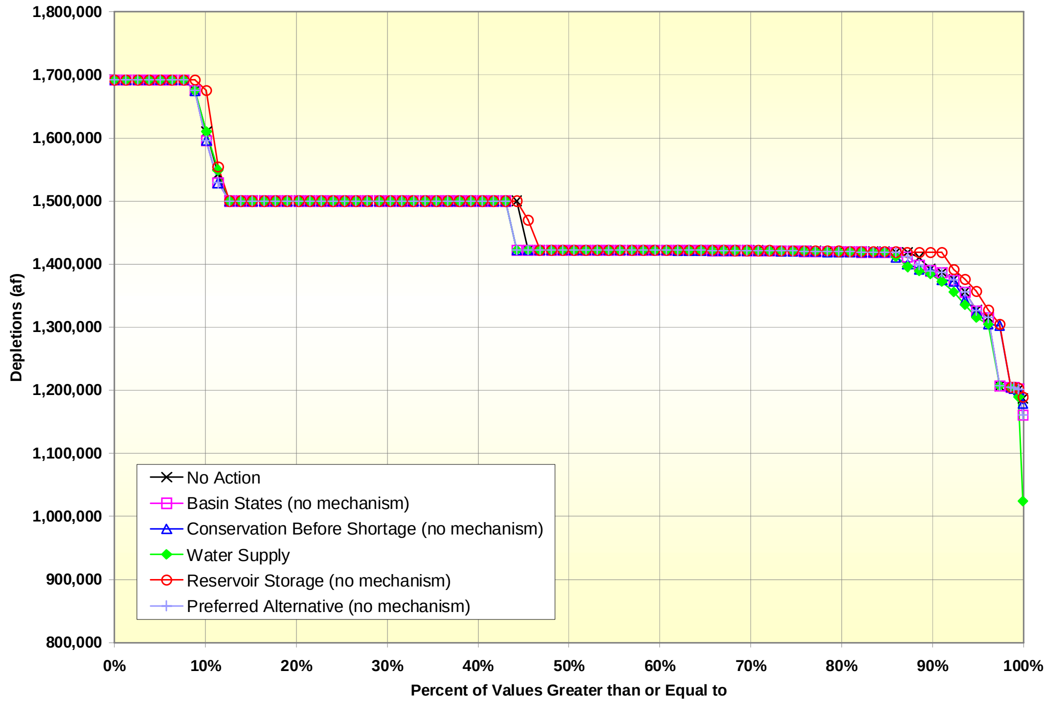
Figure 4.4-36
Mexico Modeled Annual Depletions
Comparison of Action Alternatives (Without Storage and Delivery Mechanism) to No Action Alternative
Years 2008 through 2026



The occurrences of deliveries less than 1.5 mafy reflect the modeling assumptions with regard to reductions in water deliveries to Mexico (Section 2.2 and Appendix Q).

Figure 4.4-37 provides a similar comparison of the cumulative distribution of the water deliveries to Mexico under the action alternatives without the storage and delivery mechanism to those of the No Action Alternative for the 34-year period, years 2027 through 2060, that would follow the interim period.

Figure 4.4-37
Mexico Modeled Annual Depletions
Comparison of Action Alternatives With and Without Storage and Delivery Mechanism
Years 2027 through 2060



4.4.7 Distribution of Shortages to and within the Lower Division States

Although the Consolidated Decree and the CRBPA provide some direction to the Secretary with regard to the distribution of shortages to the Lower Division states, no specific guidelines exist with regard to exactly how those shortages would be distributed. Furthermore, although priority systems exist within each state, exactly how shortages would be distributed to water users of equal priority within a state is unknown. Therefore, specific modeling assumptions were made in order to facilitate the comparison of each alternative. These assumptions, discussed in Section 4.2, Appendix A, and Appendix G are consistent among all alternatives.

Total Lower Basin shortages of 200 kaf to 2.5 maf were analyzed to consider how shortages within this range would be distributed among and within the Lower Division states. Because the shortage sharing assumptions are identical under all alternatives, the distribution of the shortage volumes would be identical under the different alternatives. The factor that changes is the probability or frequency that the different shortage volumes would occur under the different alternatives.

Table 4.4-12 and Table 4.4-13 provide the probability of occurrence of the total Lower Basin shortage volumes that are less than or equal to those shown in Table 4.4-12 for two periods, 2008 through 2026 and 2027 through 2060, respectively. The probability of shortages with a magnitude of zero includes periods when a Surplus Condition or a Normal Condition are in effect.

Table 4.4-12
Probability of Occurrence of Shortages Less Than or Equal to, Years 2008 through 2026 (percent)

Alternative	Total Voluntary or Involuntary Lower Basin Shortage (af)									
	0	200,000	400,000	500,000	600,000	800,000	1,000,000	1,200,000	1,800,000	2,500,000

4.4.7.1 Distribution of Shortages within Arizona

Table 4.4-14 provides Lower Basin shortage volumes up to 2.5 maf and the portions of these shortage amounts that were assumed to be distributed to Arizona. This table shows the shortage distribution in different years because the distribution changes at the higher magnitudes of shortage due to the changes in the scheduled use of the Arizona 4th Priority water users (Appendix G).

Table 4.4-14
Shortage Allocation to Arizona (af)

Year	Total Lower Basin Shortage								
	200,000	400,000	500,000	600,000	800,000	1,000,000	1,200,000	1,800,000	2,500,000
2008	160,000	320,000	400,000	480,000	640,000	800,000	960,000	1,440,000	1,587,484
2017	160,000	320,000	400,000	480,000	640,000	800,000	960,000	1,397,578	1,533,925
2026	160,000	320,000	400,000	480,000	640,000	800,000	960,000	1,394,205	1,530,879
2027	160,000	320,000	400,000	480,000	640,000	800,000	960,000	1,393,837	1,530,547
2040	160,000	320,000	400,000	480,000	640,000	800,000	960,000	1,388,281	1,525,531
2060	160,000	320,000	400,000	480,000	640,000	800,000	960,000	1,388,281	1,525,531

Under most circumstances, the probabilities of involuntary and voluntary shortages being allocated to Arizona are the same as the probability of shortage allocations to the Lower Basin under the No Action Alternative for each of the action alternatives. The overall probabilities are presented in Table 4.4-12 and Table 4.4-13. Table 4.4-15 presents the maximum observed reductions in water deliveries to Arizona under the No Action Alternative and the five action alternatives for selected years.

Table 4.4-15
Maximum Observed Reductions in Water Deliveries to Arizona for Selected Years (af)

Year	No Action	Basin States	Conservation Before Shortage	Water Supply	Reservoir Storage	Preferred Alternative
2008	0	0	0	0	0	0
2017	852,769	480,000	789,937	0	800,000	480,000
2026	1,397,415	480,000	1,414,524	0	800,000	480,000
2027	1,397,227	1,437,602	1,394,487	1,599,660	390,915	663,773
2040	1,381,742	1,390,718	1,383,204	1,424,813	1,384,344	1,392,854
2060	1,401,001	1,389,377	1,386,026	1,401,001	1,385,800	1,389,377

While shortage allocations to California and Nevada would affect single entities within each state (MWD in California and SNWA in Nevada) allocations within Arizona are distributed among a number of water users based upon Arizona's system of water rights priorities and recommendations provided by ADWR during the public comment period (Section 3.4 and Appendix G). This shortage distribution does not reflect management decisions that may be taken by Arizona entities to obtain additional water supplies to offset shortages. Tables 4.4-16 through 4.4-20 summarize how shortages of different volumes in Arizona would be distributed among Arizona's priorities and how this distribution changes over time. These tables do not show 5th priority users and the CAP Bank who now rely on unused and surplus water because the assumption is that by 2017, no unused water will be available to the 5th priority users.

The allocation of shortages to individual users within the CAP is affected by the water priority system within the CAP, the AWSA, and the water use buildup schedules for the CAP users. A major change in the allocation of Arizona shortages within the CAP occurs during the period between 2017 and 2040 and can be seen in Table 4.4-16 through Table 4.4-19. Over time, the impact of a given shortage to the CAP increasingly impacts the higher priority Indian and M&I users as their use builds up, and the shortage cannot be absorbed by the lower priorities.

Prior to the enactment of the AWSA, there were differing views as to how smaller shortages would be distributed between the CAP Indian and M&I priority users. As part of the AWSA, a compromise was reached. Also, under the AWSA, the CAP irrigation districts agreed to relinquish their long-term water service subcontracts for Non-Indian Agricultural priority water. Approximately 300 kaf was relinquished, with approximately 200 kaf being made available for Indian water rights settlements and approximately 100 kaf being made available for future M&I use. In return, the irrigation districts obtained CAP distribution system debt relief, relief from the acreage limitation provisions of federal Reclamation law, and a commitment from the CAP to receive an interim water supply at an affordable rate.

Table 4.4-16
Distribution of Shortages Among Arizona Entities[1] (af), Year 2017

Lower Basin Shortage Allocations	200,000	400,000	500,000	600,000	800,000	1,000,000	1,200,000	1,800,000	2,500,000

1 *CAP users incur five percent conveyance loss through the CAP system due to seepage and therefore the sum of the Arizona shortages in any one column do not add up to the total shortage volume allocated to Arizona at each Lower Basin Shortage increment noted at the top of the table.*

4.4.7.2 Distribution of Shortages within California

This section provides a discussion of how shortages that are allocated to California are distributed to the Colorado River water entitlement holders, based on the shortage sharing assumptions programmed into the Shortage Allocation Model.

The distribution or allocation of California shortages among California's Colorado River water entitlement holders is based on California's system of water entitlement priorities. Of particular note is the frequency and magnitude of the shortages that are allocated to California. Because California's deliveries are not affected by Stage 1 shortages (Section 4.2), the total Lower Basin shortage has to exceed approximately 1.7 maf before deliveries to California are affected. As a result of this, California receives less frequent shortages than Arizona and Nevada, and the magnitude of shortages to California are smaller in proportion to the total Lower Basin shortage, as compared to those of Arizona.

Table 4.4-21 provides an overview of the portion of the total Lower Basin shortage that is allocated to California. As shown on this table, only Stage 2 shortages (Section 4.2) affect California water deliveries. A Stage 2 shortage would occur if the total Lower Basin shortage exceeds 1.83 maf in year 2008. This threshold decreases to 1.72 maf in 2060.

Table 4.4-21
Shortage Allocation to California (af)

Lower Basin Shortage Allocations	200,000	400,000	500,000	600,000	800,000	1,200,000	1,800,000	2,500,000
Shortage allocation to California – 2008	0	0	0	0	0	0	0	409,516
Shortage allocation to California – 2017	0	0	0	0	0	0	39,422	462,876
Shortage allocation to California – 2026	0	0	0	0	0	0	42,795	465,882
Shortage allocation to California – 2027	0	0	0	0	0	0	43,163	466,210
Shortage allocation to California – 2040	0	0	0	0	0	0	48,719	471,162
Shortage allocation to California – 2060	0	0	0	0	0	0	48,719	471,162

The probability of shortage volumes that are less than or equal to those presented in Table 4.4-21 are presented in Tables 4.4-12 and 4.4-13.

Table 4.4-22 provides the maximum observed reductions in water deliveries to California under the No Action Alternative and the five action alternatives for selected years. Because of the large magnitude of Lower Basin shortages assumed to be required to trigger shortages in California, many shortages declared in the Lower Basin would not trigger water delivery reductions to California.

Table 4.4-22
Maximum Observed Reductions in Water Deliveries to California for Selected Years (af)

Year	No Action	Basin States	Conservation Before Shortage	Water Supply	Reservoir Storage	Preferred Alternative
2008	0	0	0	0	0	0
2017	0	0	0	0	0	0
2026	55,737	0	108,730	0	0	0
2027	56,659	181,672	48,176	683,502	0	0
2040	31,578	59,225	36,082	164,243	39,592	65,806
2060	90,899	55,096	44,773	90,899	44,077	55,096

The maximum observed reductions in water deliveries presented in Table 4.4-22 for California vary with both the maximum level of declared shortage in the Lower Basin and with the timing of the shortage. Under almost all conditions, the California shortage is allocated to the MWD. However, for the maximum shortage analyzed (2.94 maf, which occurs less than one percent of the time under the Water Supply Alternative), the shortage allocated to California would include a very small portion of shortage (15,464 af) that would be allocated to other California users. Due to the observed low probability of occurrence of reductions in water deliveries to California of this magnitude, further analysis was not considered to be warranted.

4.4.7.3 Distribution of Shortages to Nevada

Table 4.4-23 shows different Lower Basin shortage volumes and the portion of the shortage that is allocated to Nevada. The shortage allocation to Nevada represents approximately 3.33 percent of the total Lower Basin shortage amount. This percentage does not vary with time and is distributed among users served by the SNWA.

Table 4.4-23
Shortage Allocation to Nevada (af)

Lower Basin Shortage Allocations	200,000	400,000	500,000	600,000	800,000	1,200,000	1,800,000	2,500,000
Shortage allocation to Nevada	6,667	13,333	16,667	20,000	26,667	40,000	60,000	83,333

The probability of occurrence of shortage volumes that are less than or equal to those presented in Table 4.4-23 are presented in Tables 4.4-12 and 4.4-13.

Table 4.4-24 provides the maximum observed reductions in water deliveries to Nevada under the No Action Alternative and five action alternatives for selected years.

Table 4.4-24
Maximum Observed Reductions in Water Deliveries to Nevada for Selected Years (af)

Year	No Action	Basin States	Conservation Before Shortage	Water Supply	Reservoir Storage	Preferred Alternative
2008	0	0	0	0	0	0
2017	35,532	127,930	32,914	116,530	33,333	20,000
2026	60,548	131,370	63,469	279,000	33,333	105,470
2027	60,579	67,470	60,111	210,547	16,288	27,657
2040	58,888	60,414	59,137	79,338	59,331	60,777
2060	62,163	60,186	59,617	62,163	59,578	60,186

Table 4.4-24 indicates that Nevada receives water delivery reductions greater than the maximum volumes presented in Table 4.4-23 under the Basin States and Water Supply alternatives, and the Preferred Alternative. The larger reductions in water deliveries presented in Table 4.4-24 include reductions to SNWA associated with the physical constraints of SNWA's Lake Mead intake. For example, under the Basin States Alternative, in year 2017, the shortage related water delivery reduction to Nevada is approximately 20,000 af (3.33 percent of the total 600 kaf Lower Basin shortage). However, in the model, Lake Mead elevation is below 1,000 feet msl (the SNWA lower intake elevation) for four months (April through July). During these four months, the model reduces water deliveries to SNWA to zero. The cumulative water delivery reduction to Nevada for this four month period due to the SNWA intake constraints is 107,930 af. Therefore, the maximum observed reductions in water deliveries to Nevada in 2017 under the Basin States Alternative is 127,930 af (20,000 af + 107,930 af = 127,930 af). Similar conditions are observed in Table 4.4-24 under the Basin States Alternative in year 2026; under the Water Supply Alternative in years 2017, 2026, and 2027; and under the Preferred Alternative in year 2026.

4.4.7.4 Water Reductions to Mexico

For modeling purposes, an assumption was made that Mexico's delivery would be reduced below 1.5 mafy when Lower Basin shortages occur (Section 4.2). The amount of the reduction is assumed to be 16.67 percent of the total Lower Basin shortage volume, resulting in a proportional reduction to Mexico equivalent to the proportional reduction to users in the Lower Division States. The portion of the Lower Basin water delivery reductions that are assumed to be assigned to Mexico, based on the aforementioned assumptions, are summarized in Table 4.4-25. The sensitivity of water reductions to Mexico and other hydrologic variables (e.g., Lake Mead elevation) to this modeling assumption was analyzed and the results of this analysis are presented in Appendix Q.

Table 4.4-25
Water Reductions to Mexico[1] (af)

Lower Basin Shortage Allocations	200,000	400,000	500,000	600,000	800,000	1,200,000	1,800,000	2,500,000
Water reduction to Mexico	33,333	66,667	83,333	100,000	133,333	200,000	300,000	416,667

1. These modeling assumptions do not reflect policy decisions and are not intended to constitute an interpretation or application of the 1944 Treaty.

The probability of water reductions to Mexico are the same as the probability of Lower Basin shortage. The probability of shortage volumes that are less than of equal to those presented in Table 4.4-25 under the No Action Alternative and for each of the action alternatives are presented in Tables 4.4-13 and 4.4-14.

Table 4.4-25 indicates that, while the proportion of the Lower Basin shortage distributed to Mexico is constant, the probability of the occurrence of water reduction increases over time. Table 4.4-26 provides the maximum observed reductions of water deliveries to Mexico under the No Action Alternative and the five action alternatives for selected years.

Table 4.4-26
Maximum Observed Reductions in Water Deliveries to Mexico[1] for Selected Years (af)

Year	No Action	Basin States	Conservation Before Shortage	Water Supply	Reservoir Storage	Preferred Alternative
2008	0	0	0	0	0	0
2017	177,660	100,000	164,570	0	166,667	100,000
2026	302,740	100,000	317,344	0	166,667	100,000
2027	302,893	337,349	300,555	475,663	81,441	138,286
2040	294,442	302,071	295,685	331,053	296,653	303,887
2060	310,813	300,932	298,083	310,813	297,891	300,932

1. These modeling assumptions do not reflect policy decisions and are not intended to constitute an interpretation or application of the 1944 Treaty.

4.4.8 Summary

The following conclusions may be drawn from the analyses of water deliveries.

4.4.8.1 Normal Conditions

All of the action alternatives increase the probability that normal deliveries will be met over the interim period relative to the No Action Alternative. The differences between the action alternatives and the No Action Alternative, in terms of the probability of occurrence for water supply deliveries under a Normal Condition, begin to diminish after 2027 and are nearly zero by about 2038.

4.4.8.2 Surplus Conditions

The Water Supply Alternative exhibits the same probability of surplus deliveries as the No Action Alternative (between about 30 to 40 percent) between 2008 and 2016 due to identical assumptions regarding surplus during this period. The ISG provisions terminate under the No Action Alternative in 2016. However, these provisions are retained in the Water Supply Alternative through 2026 and therefore this alternative consistently provides the highest probability of surplus deliveries during the interim period. The Reservoir Storage Alternative exhibits the lowest probabilities (between about ten to 20 percent) during the interim period because surplus determinations are limited to Quantified and Flood Control Surplus Conditions beginning in 2008. The surplus provisions under the Basin States and the Conservation Before Shortage Alternatives, and under the Preferred Alternative, are similar and the probability of a Surplus Condition from 2010 through 2016 is slightly less than under the No Action Alternative due to the absence of the Partial Domestic Surplus provision in these three alternatives. After the end of the interim period in 2026, the probability for all alternatives converges to between ten and 20 percent.

The storage and delivery mechanism and related storage and delivery of conserved system and non-system water were modeled under the Basin States, Conservation Before Shortage, and Reservoir Storage Alternatives, and the Preferred Alternative. This modeling assumption has the effect of increasing the probability of occurrence of a Surplus Condition. The maximum increase in the probability of occurrence of a Surplus Condition is seven percent, occurring in two years under the Preferred Alternative.

4.4.8.3 Shortage Conditions

During most of the interim period, the probability of involuntary and voluntary shortage is less under all of the action alternatives than under the No Action Alternative. The probability of occurrence of shortages under the Water Supply Alternative is less than under the No Action Alternative and the other action alternatives during the interim period because reductions in water deliveries under the Water Supply Alternative only occur if Lake Mead's elevation is below 1,000 (the minimum elevation for operation of SNWA's lower intake) or if Lake Mead is drawn down to the top of its dead pool elevation (895 feet msl). However, after 2026, the Water Supply Alternative has the highest probability of shortage due to the depleted storage conditions and the assumption that the operations revert back to the criteria used in the modeling of the No Action Alternative after 2026. In terms of magnitude, the average shortages that occur under the Water Supply Alternative (zero and 240 kafy) are significantly less than those observed under the No Action Alternative (500 and 610 kafy) during the interim period. After 2026, higher average and maximum shortage volumes are observed under the Water Supply Alternative relative to the No Action Alternative and the other action alternatives.

The probability of occurrence of shortages under the Reservoir Storage Alternative is slightly higher than under the No Action Alternative between 2008 and 2013. However, after 2013 and through about 2037, shortages under the Reservoir Storage Alternative occur less frequently as compared to the No Action Alternative. In terms of magnitude, the average shortage volumes that are observed during the interim period are highest under the Reservoir Storage Alternative (between 600 and 750 kafy). This occurs because the Reservoir Storage Alternative contains the most aggressive shortage strategy that applies shortages starting at higher elevations in Lake Mead and at higher magnitudes.

Shortages also occur less frequently under the Basin States and Conservation Before Shortage Alternatives, and the Preferred Alternative during the interim period as compared to the No Action Alternative and are similar after 2026. The Preferred Alternative also shows somewhat lower probabilities (up to approximately ten percent) of shortages over the entire interim period when compared to the Basin States and Conservation Before Shortage Alternatives. In terms of magnitude, the average shortages that are observed under the Basin States and Conservation Before Shortage Alternatives, and the Preferred Alternative are similar to each other (between 400 and 530 kafy) and are less than those observed under the No Action Alternative during the interim period.

Multi-year shortages with annual shortage volumes equal to or greater than 400 kaf are likely for all alternatives with the exception of the Water Supply Alternative, with the Conservation Before Shortage Alternative and the Preferred Alternative exhibiting probabilities of between ten and 30 percent over the interim period for durations of two or more years. Multi-year shortages with annual shortage volumes equal to or greater than 500 kafy are most likely for the Reservoir Storage Alternative with probabilities of approximately 35 percent for durations of two or more years and 26 percent for durations of five or more years. Multi-year shortages with annual shortage volumes equal to or greater than 600 kafy are likely only for the Reservoir Storage Alternative. No alternatives exhibited shortages of greater than or equal to 1.0 mafy for any duration.

The mechanism to deliver and store conserved system and non-system water assumed as part of the Basin States, Conservation Before Shortage, and Reservoir Storage Alternatives, and under the Preferred Alternative has the effect of decreasing the occurrence of shortages. Due to the assumptions of increased participation in the storage and delivery mechanism, the greatest differences (up to a ten percent reduction in shortage probability during the interim period) were observed under the Reservoir Storage Alternative and under the Preferred Alternative.

4.5 Water Quality

4.5.1 Introduction

This section describes the methods used to determine the potential effects to water quality associated with each alternative considered in the proposed federal action, and discusses the results of these analyses.

4.5.2 Methodology

The salinity module of the CRSS RiverWare™ model was used to analyze changes in salinity concentration under each of the alternatives for Colorado River reaches from Lake Powell to Imperial Dam.

Using the hydrologic output from CRSS, the CE-QUAL-W2 model was used to simulate temperatures of Lake Powell releases, and the Generalized Environmental Modeling System for Surfacewater (GEMSS) was used to simulate river temperatures between Glen Canyon Dam and Lake Mead for each of the alternatives. Detailed descriptions of these models are provided in Appendix F. Qualitative assessments of other water quality parameters in Lake Powell were based on historical data.

For all parameters other than salinity, the analysis of potential impacts to Lake Mead water quality were based on a combination of detailed water quality modeling and analysis conducted for the SCOP FEIS (Clean Water Coalition 2006), and historical data. Modeling for the SCOP FEIS analyzed the potential effects on water quality as a result of rerouting effluent from Las Vegas Wash to Lake Mead's Boulder Basin via a pipeline. The modeling considered lake elevations down to 1,000 feet msl and two levels of total annual average effluent flows: 462 cfs expected by 2030 and 616 cfs expected by 2050. Under the SCOP FEIS preferred alternative referred to as the Boulder Islands North Alternative, impacts to water quality are considered to be insignificant and negligible with no violation of drinking water regulations for Lake Mead elevations down to 1,000 feet msl with projected effluent inflow levels for 2025. This information was combined with the probabilities of Lake Mead elevations reaching 1,000 feet msl under the No Action Alternative and the action alternatives considered in this Final EIS to assess potential water quality impacts.

Furthermore, an adaptive management plan for Boulder Basin would be implemented as part of the SCOP preferred alternative. The Boulder Basin Adaptive Management Plan (BBAMP) would establish objectives regarding drinking water quality, downstream water quality, nutrient management, and recreational use including sport fisheries. As part of the BBAMP, water quality parameters would be monitored to establish baseline conditions and analyzed for the need of potential future mitigation measures (Clean Water Coalition 2006).

4.5.2.1 Salinity

Reclamation developed a computational model for salinity to aid in the development of salinity reduction targets for the Colorado River Basin Salinity Control Program (SCP) (Prairie and Callejo 2005). The salinity model simulates the effects of water development projects on future salinity concentration levels in the Colorado River. The model includes future salinity control units that have been authorized for construction but have not yet been completed. The salinity control criteria are purposely designed to be long-term and non-degradational goals, rather than exceedence standards such as those used for industry or drinking water. Efforts of the SCP are designed to meet the criteria by implementing, as needed, the most cost effective salinity control projects. This ensures that the salinity control criteria will continue to be met in the future, even with the salinity impacts produced by increasing Upper Basin depletions.

The data used in the CRSS salinity model are based on a monthly regression of natural flow and salinity data from 1971 through 1995 in the Upper Basin (Prairie and Callejo 2005). The Lower Basin monthly regressions are based on the 1971 through 2005 natural flow and salinity data. The monthly regression models allow extension of the CRSS salinity model data from 1906 through 2005, the period for which natural flow data is available. The CRSS salinity model data includes salinity control levels and salt loading due to agricultural return flows as used in the 2005 Triennial Review (Colorado River Basin Salinity Control Forum 2005). The model simulates annual average salinity concentrations for locations downstream of Hoover Dam and Parker Dam, and at Imperial Dam.

The CRSS salinity model is intended for long-term (15 to 20 years) simulation and it is highly sensitive to initial conditions during the first 10 to 12 years. The model assumes salinity is a conservative water quality parameter, and reservoirs are modeled as fully mixed systems.

4.5.2.2 Temperature

Lake Powell undergoes seasonal transformations that can dramatically affect the temperatures of both the reservoir and Glen Canyon Dam releases. During the spring, solar radiation and warmer air temperatures begin to warm the upper surface layers of the reservoirs. This warming is also affected by spring inflow volumes and temperatures. Larger inflows bring greater volumes of warmer water that can cause higher release temperatures. Reservoir drawdowns can bring the warmer surface water closer to the powerplant intake penstocks, also producing warmer releases. As summer progresses, surface warming of reservoirs increases, as does the warming of releases as the water moves downstream. During the winter months, reservoir temperature stratification is usually eliminated by reservoir mixing, and both reservoir and downstream water cooling occurs. The CE-QUAL-W2 model simulates this annual process and can analyze reservoir and dam release temperatures for various reservoir starting elevations and inflows. The CRSS output of dam release and reservoir elevations was used in the CE-QUAL-W2 model to establish a relationship between reservoir elevations and dam release temperatures and to project the impact of reservoir drawdown on dam release temperatures. Calibration of the CE-QUAL-W2 model for Lake Powell used historic temperature profiles from 1990 through 2005 at 13 reservoir stations.

This 15-year data set provided a limited range of historic reservoir elevations, inflows and releases. By using a combination of historic and modeled data for various reservoir elevations, and by analyzing the impact of a repetition of the recent drought years, dam release temperatures for a larger range of reservoir elevations could be analyzed.

The GEMSS used the Glen Canyon Dam release temperatures to model downstream temperatures through Grand Canyon to Lake Mead. The GEMSS model was calibrated for water temperatures at three locations in this river reach: Lees Ferry, 15.9 miles downstream of Glen Canyon Dam; a point one mile downstream of the Little Colorado River confluence; and the Diamond Creek Gaging Station located 240 miles downstream of Glen Canyon Dam. Water temperatures downstream of Diamond Creek approached equilibrium with the ambient air temperature, and the rate of temperature change decreased. Since Lees Ferry temperatures are nearly identical to Glen Canyon Dam release temperatures, only the results for the Little Colorado River confluence and Diamond Creek sites are included in this EIS.

For any specific reservoir starting elevation, there is a range of potential dam release temperatures because the reservoir is affected by the magnitude of spring inflow and summer meteorological conditions. Downstream water temperatures produced by a routing of these releases are also affected by meteorological conditions and the magnitude of dam releases. Thus, for a single reservoir elevation the CE-QUAL-W2 and GEMSS modeling resulted in a range of water temperatures.

The assessment of potential effects of the alternatives on water temperatures in Lake Mead was based on the Lake Mead water quality information provided in the SCOP FEIS.

4.5.2.3 Other Water Quality Parameters

Historic water quality data from Lake Powell and Lake Mead and water quality information from the SCOP FEIS for Lake Mead were used to develop qualitative assessments of potential effects of the alternatives on sediment, nutrients and algae, dissolved oxygen, metals, and perchlorate.

4.5.3 Salinity

Table 4.5-1 presents the SCP salinity control criteria and the CRSS salinity model simulations of salinity concentrations for the years 2008, 2016, 2026, and 2060. The projected salinity concentrations presented are the flow-weighted annual averages for the selected years under the No Action Alternative and the action alternatives. The results assume continuation of existing and implementation of planned salinity control programs and projects. As a result, the flow-weighted annual average salinity concentrations do not increase over time or exceed the SCP salinity control criteria under any of the alternatives for the current plan of implementation, which extends through 2025 (Colorado River Basin Salinity Control Forum 2005). At all times the differences in salinity concentrations among the different alternatives is less than three percent.

Table 4.5-1
Projected Colorado River Salinity (mg/L)[1]
Comparison of Action Alternatives to No Action Alternative

Alternative	Downstream of Hoover Dam SCP Salinity Control Criteria 723 mg/L	Downstream of Parker Dam SCP Salinity Control Criteria 747 mg/L	At Imperial Dam SCP Salinity Control Criteria 879 mg/L

Water Supply	626	646	776
Preferred Alternative	630	650	782

1 CRSS Salinity model simulation of salinity concentration

Salinity of water delivered to Mexico at the NIB pursuant to the 1944 Treaty is limited by Minute 242 (Section 3.5). Accordingly, Minute 242 limits the differential in annual salinity between Imperial Dam and the NIB to 115 ppm (± 30 ppm). Reclamation will continue to take the appropriate actions needed to meet the requirements of Minute 242.

4.5.4 Temperature

4.5.4.1 Lake Powell and Glen Canyon Dam

The release temperature ranges presented in Figure 4.5-1 are comprised of historic and modeled data and represent a yearly range including seasonal fluctuations. This graph shows that as Lake Powell's elevation decreases, the range of annual release temperature fluctuations increases. The minimum release temperatures occur in the winter and are fairly consistent at 7°C to 10°C (44.6ºF to 50ºF). The peak summer release temperature varies significantly with elevation, peaking at about 25°C (77ºF) as the reservoir elevation drops to near the minimum power pool elevation of 3,490 feet msl. The model predicts a wider range of potential temperatures the nearer the reservoir elevation is to the powerplant penstock intakes. Reservoir elevations near the full pool elevation of 3,700 feet msl show much less variation among seasons, with releases consistently cold from 8°C to 12°C (46.4ºF to 53.6ºF). During extreme drought events, the elevation of Lake Powell may drop below the minimum power pool elevation of 3,490 feet msl. If this occurs, releases would be discontinued from the powerplant penstocks and releases would be made through the river outlet tubes, which are located at elevation 3,374 feet msl. Under these conditions, the temperature of water released from Glen Canyon Dam could potentially change from about 25°C to less than 10°C (77ºF to less than 50ºF). If the reservoir elevations were to drop further, closer to the elevation of the river outlet tubes, the releases would again gradually warm.

Figure 4.5 -1
Historic Data and CE-QUAL-W2 Model Results for Lake Powell Release Temperatures by Reservoir Elevation

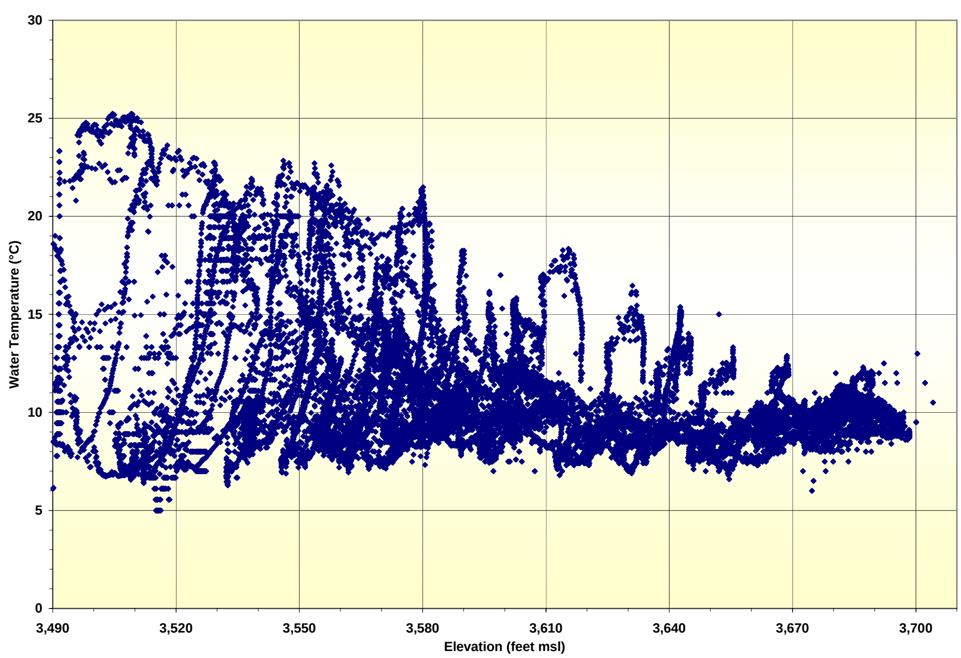

Table 4.5-2 and Table 4.5-3 present projected release temperature ranges associated with the CRSS projected 90th, 50th, and 10th percentile elevations of Lake Powell in 2008, 2016, 2026, and 2060 for the months of July and October, respectively. July and August represent the times of the year when maximum warming occurs in Lake Powell and in Glen Canyon Dam releases. The release temperature ranges in Table 4.5-2 and Table 4.5-3 reflect the variability of hydrologic, meteorological, and hydraulic conditions. The sensitivity of release temperatures to these conditions increases with decreasing reservoir elevations. This sensitivity causes a wide range of possible release temperatures at similar reservoir elevations. In general, for a given month and reservoir elevation, a higher release temperature is associated with an above-average inflow volume and a lower release temperature is associated with a below-average inflow volume. Therefore, the ranges shown in these tables reflect different release temperatures for these specific months and reservoir elevations, ranges which are due primarily to large differences in reservoir inflows.

For reservoir elevations at or above the 90th percentile for all years there are no differences among the alternatives. Overall, the temperature ranges for July and October under the No Action Alternative, Basin States Alternative, Conservation Before Shortage Alternative, and the Preferred Alternative are similar for 2008, 2016, 2026, and 2060 at the 50th and 10th percentiles of reservoir elevations, respectively. The temperature range for the Water Supply Alternative is warmer in 2016 and 2026 due to the corresponding lower Lake Powell reservoir elevations at the 10th and 50th percentiles. The Reservoir Storage Alternative results in cooler water temperatures at the 10th and 50th percentiles of reservoir elevations for some years, due to higher reservoir elevations.

4.5.4.2 Glen Canyon Dam to Lake Mead

Using historic data and output from the CE-QUAL-W2 model as input, the GEMSS model analyzed monthly temperatures for the CRSS at the 90th, 50th, and 10th percentile projected reservoir release flows. Temperatures are presented for each alternative in Table 4.5-4 and Table 4.5-5 for the confluence with the Little Colorado River, and in Table 4.5-6 and Table 4.5-7 for the gage downstream of Diamond Creek for July and October, respectively. The temperature data listed in these tables are averages for each percentile. The projected temperatures vary due to three factors: variable release volume; release temperature ranges; and downstream meteorology. The rate at which the water released from a reservoir approaches ambient air temperature as it travels downstream depends on these factors as well.

Table 4.5-2
Lake Powell End-of-July Elevations and Release Temperatures
Comparison of Action Alternatives to No Action Alternative
90th, 50th, 10th Percentile Values

Alternative	90th Percentile		50th Percentile		10th Percentile	
	Elevation (feet msl)	Temperature (°C)	Elevation (feet msl)	Temperature (°C)	Elevation (feet msl)	Temperature (°C)
Year 2008

In general, warmer downstream water temperatures are caused by smaller release volumes, higher release temperatures, and warmer ambient air temperatures. However, the relationship between release temperature and downstream temperature is nonlinear (e.g., a 1°C (1.8ºF) increase in release temperature does not necessarily result in a 1°C (1.8ºF) increase downstream). The temperatures projected for 2008 and 2060 are the same for all alternatives. In 2016 and 2026 the Basin States and Conservation Before Shortage Alternatives, and the Preferred Alternative, have the same projected average temperatures as the No Action Alternative for both October and July at both modeled locations. In general, the Water Supply and Reservoir Storage Alternatives differ from the No Action Alternative in 2016 and 2026 at the 10th and 50th percentile release volumes. The Water Supply Alternative average temperatures are higher than the No Action Alternative's by 0 to 4°C (0 to 7°F). The projected Reservoir Storage Alternative average temperatures are typically 1°C (1.8°F) less than the No Action Alternative temperatures at the 10th and 50th percentiles of river flows due to higher Lake Powell elevations under this alternative.

These small temperature differences are potentially meaningful in the context of fish habitat (Section 4.8 and Appendix R).*

4.5.4.3 Lake Mead and Hoover Dam

Water quality modeling provided in the SCOP FEIS showed that Lake Mead temperatures would change by no more than 1ºC (1.8°F) when lake elevations are drawn down from 1,178 feet msl to 1,000 feet msl (Clean Water Coalition 2006). The probability of Lake Mead elevations less than 1,000 feet msl is small (zero to two percent) over the interim period for all alternatives, with the exception of the Water Supply Alternative, which has a maximum of 12 percent probability in 2026 (Section 4.3). Based on these results, the potential impact of the alternatives on Lake Mead water temperature is considered negligible.

4.5.5 Sediment and Dissolved Oxygen

The maximum headcutting of sediment deltas occurs when a deeply drawn down reservoir receives very high inflows, similar to that observed in Lake Powell in 2005. This condition is very dependent on the reservoir elevation and spring inflow volume. Compared to the No Action Alternative, the projected additional reservoir drawdown under the Water Supply Alternative could result in additional headcutting of sediment deltas and accompanying water quality impacts. The Reservoir Storage Alternative could result in a decrease in sediment delta headcutting if the projected reservoir elevations remain higher than under the No Action Alternative. Since the projected reservoir drawdown under the Basin States and Conservation Before Shortage Alternatives, and the Preferred Alternative are similar, headcutting of sediment deltas would likely be similar.

Quantified water quality impacts from reservoir sediment delta headcutting are not currently available, nor is it possible to quantitatively distinguish the impact of sediment headcutting among the alternatives. However, recent history shows that high inflows causing sediment delta headcutting likely increases phosphorus release and biological oxygen demand. Large spring inflows then can bring this plume of low dissolved oxygen laden water near the powerplant intakes and result in low dissolved oxygen carrying releases. There may be short term impacts to food base and trout resources between Glen Canyon Dam and Lees Ferry due to these occurrences. Recurrences of low dissolved oxygen such as the one that occurred in 2005 downstream of Glen Canyon Dam may result from reservoir drawdown cycles under any of the alternatives. This condition mostly affects the reach between Glen Canyon Dam and Lee's Ferry since the Colorado River reaerates itself after passing through the rapids downstream of Lees Ferry.

With respect to riverine sediment transport in the Glen Canyon Dam to Lake Mead reach, annual releases lower than 8.23 maf associated with the action alternatives would transport less sediment through Grand Canyon into Lake Mead than under the No Action Alternative. However, some of this effect could be offset by a slightly higher proportion of equalization or balancing releases in these alternatives (Figure 4.3-13).

To estimate the sediment transport impacts of potentially modifying the annual Glen Canyon Dam releases, the USGS prepared an analysis relating normalized sediment transport from Grand Canyon to these annual releases. Table 4.5-8 shows this relationship, with 8.23 maf release volumes as the basis for normalization.

Table 4.5-8
Relationship of Glen Canyon Dam Annual Release Volumes
to Sediment Transport from Grand Canyon

Release (maf)	Normalized Sediment Transport
6.00	0.26
7.00	0.51
8.00	0.89
8.23	1.00
9.00	1.43
10.00	2.15
11.00	3.03
12.00	4.11
13.00	5.43
14.00	7.01
15.00	8.88
16.00	11.02
17.00	13.53
18.00	16.67
19.00	19.72
20.00	23.40

Annual release values obtained from all the traces of RiverWare™ analyses for all the alternatives were applied to this sediment transport relationship for the years 2008, 2016, 2026, and 2060. Relative differences among the alternatives were calculated by comparing the action alternatives to the No Action Alternative at the 10th, 50th, and 90th percentiles of sediment transport. These normalized comparisons are shown in Table 4.5-9 for the years 2008, 2016, 2026, and 2060, respectively.

The data provided in Table 4.5-9 show that in the near term, nearly the same amount of sediment is transported under the alternatives, but that in 2016 and 2026, under the Basin States and Conservation Before Shortage Alternatives, and the Preferred Alternative, potentially more sediment can be transported as water is moved from Lake Powell to Lake Mead under the coordinated operations where balancing results in increased releases from Lake Powell. Under the Water Supply Alternative even more sediment can be transported as a greater amount of water is moved to Lake Mead between 2016 and 2026. Under the Reservoir Storage Alternative, the amount of sediment transport is reduced as releases and water deliveries are reduced to keep Lake Mead, and subsequently Lake Powell, at higher pool elevations.

Modeling completed for the SCOP FEIS determined that there would be no adverse effects on dissolved oxygen as a result of the SCOP project or due to drawdown of Lake Mead from elevation 1,178 feet msl to 1,000 feet msl. The probability of Lake Mead elevations less than 1,000 feet msl is small (zero to two percent) over the interim period for all alternatives, with the exception of the Water Supply Alternative, which has a maximum of 12 percent probability in 2026 (Section 4.3). Based on these results, potential effects of the alternatives on dissolved oxygen in Lake Mead are considered negligible. Futhermore, monitoring of dissolved oxygen levels in Lake Mead will be conducted as part of the SCOP BBAMP (Clean Water Coalition 2006).

4.5.6 Nutrients and Algae

Most of the 1.0 mg/L of total phosphorus concentration entering Lake Powell from the major tributaries is bound to the sediment and primarily settles out with the sediment (Section 3.5). Bioavailable phosphorus from the major inflows is generally only 0.007 to 0.009 mg/L and phosphorus concentrations released from Glen Canyon Dam and Hoover Dam generally range from only 0.004 to 0.008 mg/L with occasional spikes to near 0.012 mg/L. Sediment delta headcutting releases phosphorus. This release can significantly boost primary productivity in reservoir inflow areas. A decrease in reservoir elevation could result in additional headcutting in the sediment deltas; however, data is not available to project the amount of headcutting and phosphorous release for different reservoir elevations.

When Lake Powell is full, Glen Canyon Dam release temperatures and inflow temperatures into Lake Mead are cool, and the plume of water entering Lake Mead drops to depths below which algae can grow. Therefore, much of the inflowing phosphorus that is not settled out with the sediment in Lake Mead travels to Hoover Dam. However, when Lake Powell elevations are low enough to produce warm Glen Canyon Dam releases and inflow temperatures into Lake Mead, the inflow plume into Lake Mead will remain nearer the surface where light would increase productivity. The algae thus produced would settle out, trap more phosphorus in the sediment in Lake Mead, and reduce the phosphorus transport down-reservoir into Boulder Basin. Due to the complexity of the system, the direct impact due to the different alternatives can not be projected.

Modeling results provided in the SCOP FEIS showed that there would be no adverse effects on phosphorous concentrations, other nutrients or algae as a result of the SCOP or from Lake Mead being drawn down from elevation 1,178 feet msl to 1,000 feet msl (Clean Water Coalition 2006). The probability of Lake Mead elevations less than 1,000 feet msl is small (zero to two percent) over the interim period for all alternatives, with the exception of the Water Supply Alternative, which has a maximum of 12 percent probability in 2026 (Section 4.3). Based on these results, the concentrations of phosphorus in Boulder Basin and Las Vegas Bay should remain within the Nevada TMDL under all alternatives. Furthermore, the SCOP BBAMP will monitor nutrients and chlorophyll levels in Lake Mead and manage nutrient loadings if water quality objectives are not met (Clean Water Coalition 2006).

4.5.7 Metals

Modeling results provided in the SCOP FEIS for Lake Mead show that the lake's ability to dilute contaminant and nutrient loadings from Las Vegas Valley wastewater treatment plants is not significantly diminished when Lake Mead elevation is 1,000 feet msl in comparison to 1,178 feet msl (Clean Water Coalition 2006). The probability of Lake Mead elevations less than 1,000 feet msl is small (zero to two percent) over the interim period for all alternatives, with the exception of the Water Supply Alternative, which has a maximum of 12 percent probability in 2026 (Section 4.3). Therefore, it is anticipated that drawdown of Lake Mead under any of the alternatives will not increase metals concentrations as a result of reduced dilution.

4.5.8 Perchlorate

Since 1999, perchlorate containment and reduction strategies have resulted in the decline of detectable concentrations in Lake Mead, Willow Beach, Lake Havasu, and other sampling locations in the lower Colorado River, as well as in areas using Colorado River water in Arizona. Perchlorate concentrations are ranging from non-detectable levels to six parts per billion (ppb), indicating a slow and steady decline (Blasius 2006, personal communication). Modeling provided for the SCOP FEIS included a perchlorate analysis and showed that the dilution capacity of Lake Mead did not significantly change when Lake Mead elevations are drawn down from 1,178 feet msl to 1,000 feet msl. The probability of Lake Mead elevations less than 1,000 feet msl is small (zero to two percent) over the interim period for all alternatives, with the exception of the Water Supply Alternative, which has a maximum of 12 percent probability in 2026 (Section 4.3). Therefore, Lake Mead drawdown under any of the action alternatives is not expected to affect perchlorate concentrations.

4.5.9 Summary

The following conclusions were drawn from the analyses of potential effects on water quality constituents of concern.

4.5.9.1 Salinity

The future average annual salinity levels under the action alternatives are not expected to exceed the salinity numeric criteria established by the Colorado River Basin Salinity Control Forum for different locations on the lower Colorado River.

4.5.9.2 Temperature

The temperature range for Glen Canyon Dam releases under the Water Supply Alternative is warmer due to the corresponding lower Lake Powell reservoir elevations at the 10^{th} and 50^{th} percentiles. The Reservoir Storage Alternative results in cooler temperatures for Glen Canyon Dam release at the 10^{th} and 50^{th} percentiles of reservoir elevations for some years. The temperature of Glen Canyon Dam releases under the Basin States Alternative, Conservation Before Shortage Alternative, and the Preferred Alternative are similar to those under the No Action Alternative.

For Lake Mead, modeling performed for the SCOP FEIS showed that lake temperatures would change by no more than 1ºC (1.8º F) when Lake Mead elevations are drawn down from 1,178 feet msl to 1,000 feet msl (Clean Water Coalition 2006). The probability of Lake Mead being drawn down to below elevation 1,000 feet msl is low for all alternatives. Therefore, potential effects of the alternatives on Lake Mead water temperatures are considered to be negligible.

4.5.9.3 Other Water Quality Parameters

The following findings relate to other water quality parameters assessed:

- for Lake Powell, quantified water quality impacts from reservoir sediment delta headcutting are not currently available;
- for Lake Mead, the projected elevations and corresponding changes in dilution capacity are not expected to result in any increase in metals concentrations of concern; and
- for Lake Mead, it is not anticipated that any of the action alternatives would result in a significantly increased concentration of perchlorate.

For Lake Mead, hydrologic and water quality modeling provided in the SCOP FEIS determined that drawing down Lake Mead elevations to 1,000 feet msl would not have a significant effect on water quality in Lake Mead, Hoover Dam releases, and the SNWA water pumped from Lake Mead. The probability of Lake Mead being drawn down below elevation 1,000 feet msl is small for all alternatives with the exception of the Water Supply Alternative. Therefore, potential effects of the alternatives on water quality parameters in Lake Mead are considered negligible.

This page intentionally left blank.

4.6 Air Quality

This section describes the methods of analysis and potential effects on air quality at Lake Powell and Lake Mead, focusing on particulate matter. Potential effects on Glen Canyon Dam to Lake Mead reach from particulate emissions at the Lake Mead delta are also considered.

4.6.1 Methodology

Fugitive emissions can result from exposed sediment on the shorelines of Lake Powell and Lake Mead as a result of fluctuations in the elevations of these reservoirs. The mass of particulates generated per acre of exposed shoreline will vary depending upon sediment characteristics and other factors such as saturation, sediment disturbance, wind speeds, and topography. The method for assessing potential fugitive emissions from exposed shoreline sediments at Lake Powell and Lake Mead includes the following assumptions.

- the area of exposed shoreline for Lake Powell was developed using an average shoreline slope of 45 degrees. The area of exposed shoreline for Lake Mead was developed from bathymetry data; and
- incremental changes to Lake Powell and Lake Mead elevations were developed corresponding to the years 2008 through 2060 from the CRSS modeling output. The 10^{th} percentile elevations at the end of March for Lake Powell and at the end of July for Lake Mead were selected as worst-case assumptions that have a reasonable probability of occurring. These elevations were then correlated to the reservoir surface areas (acres) and compared to the maximum elevations for Lake Powell (3,700 feet msl) and Lake Mead (1,221 feet msl) to determine the acres of exposed shoreline.

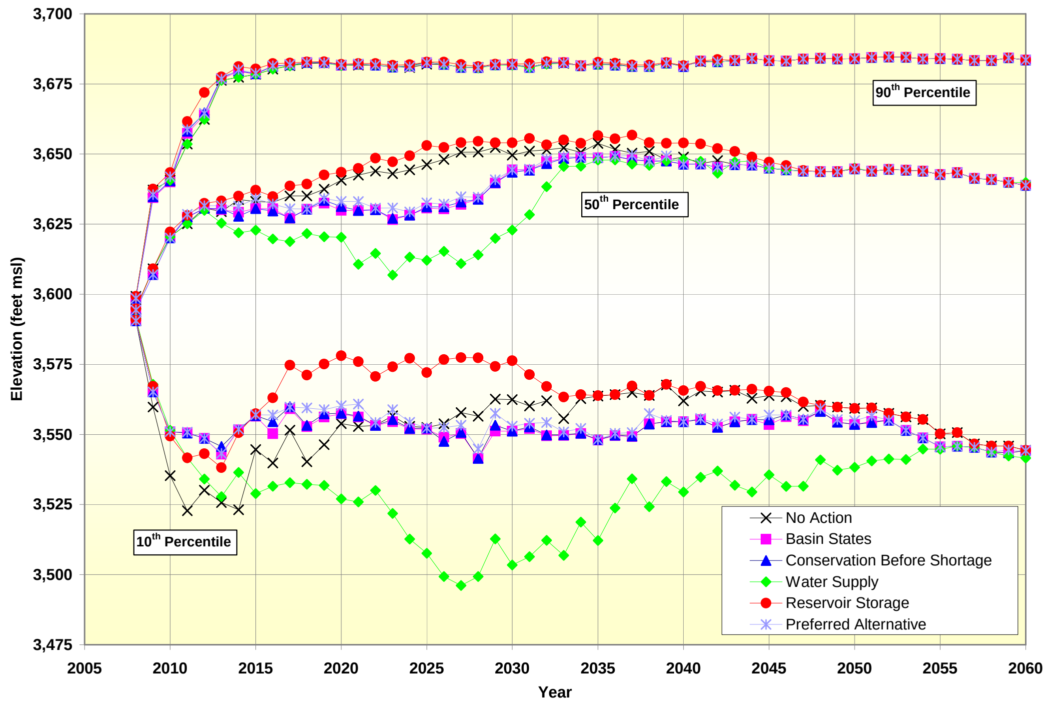
4.6.2 Lake Powell and Glen Canyon Dam

4.6.2.1 No Action Alternative

The lowest Lake Powell elevation occurs in March (Figure 4.6-1). For a comparative evaluation, the years 2008, 2016, 2025, 2040, 2050, and 2060 were examined under the No Action Alternative. The low Lake Powell elevation at the 10^{th} percentile was projected for the year 2025 with about 17,000 acres of exposed shoreline. For a comparative discussion, the action alternatives are compared to the No Action Alternative for the year 2025.

The potential for fugitive emissions is limited by the extent of the area containing fine sediment having the potential to generate dust. Areas of fine sediments at Lake Powell comprise about three percent of the 1,960 miles of shoreline (NPS 2002). The remainder of Lake Powell shoreline consists of Navajo Sandstone and other Glen Canyon Group rock formations. These rock formations are not conducive to creating significant amounts of dust.

Figure 4.6-1
Lake Powell End-of-March Elevations
Comparison of Action Alternatives to No Action Alternative
90th, 50th, and 10th Percentile Values



4.6.2.2 Basin States Alternative

At the 10th percentile, Lake Powell elevation is projected to be 3,552 feet msl in the year 2025 under the Basin States Alternative, resulting in approximately 17,000 acres of exposed shoreline. This would result in no change in exposed shoreline compared to the No Action Alternative (Table 4.6-1). With no change in shoreline acreage, there would be no increased potential to exceed the federal PSD Class II threshold or state and national Ambient Air Quality Standards (AAQS) when compared to the No Action Alternative.

Table 4.6-1
Lake Powell End-of-March 10th Percentile Elevation and Exposed Shoreline (rounded to nearest whole number)

Year	No Action	Basin States	Conservation Before Shortage	Water Supply	Reservoir Storage	Preferred Alternative

Percent Difference Compared to No Action Alternative	0	0	0	2	0	0

1 Parenthesis indicates a reduction in exposed shoreline as compared to the No Action Alternative.

4.6.2.3 Conservation Before Shortage Alternative

At the 10th percentile, Lake Powell elevation is projected to be 3,552 feet msl in the year 2025 under the Conservation Before Shortage Alternative. Drawdown of Lake Powell to this elevation could result in approximately 17,000 acres of exposed shoreline. This would result in no change in the exposed shoreline compared to the No Action Alternative (Table 4.6-1).

With no change in shoreline acreage, there would be no increased potential to exceed the PSD Class II threshold or the state or national AAQS when compared to the No Action Alternative.

4.6.2.4 Water Supply Alternative

At the 10th percentile, Lake Powell elevation is projected to be 3,508 feet msl in the year 2025 under the Water Supply Alternative, resulting in approximately 30,000 acres of exposed shoreline. This would result in a 30 percent increase in exposed shoreline compared to the No Action Alternative (Table 4.6-1).

This increase would potentially have a negative effect on air quality compared to the No Action Alternative. As sediment comprises about three percent of the 1,960 miles of shoreline, the increase in acreage susceptible to wind erosion would not result in exceedance of the PSD Class II threshold or the state or national AAQS.

4.6.2.5 Reservoir Storage Alternative

At the 10th percentile, Lake Powell elevation is projected to be 3,572 feet msl in the year 2025 under the Reservoir Storage Alternative. Drawdown of Lake Powell to this elevation would result in a decrease of approximately 14,000 acres of exposed shoreline. For the Reservoir Storage Alternative, this would result in a decrease of about 14 percent in exposed shoreline compared to the No Action Alternative (Table 4.6-1).

The Reservoir Storage Alternative would result in having the highest potential to reduce dust emissions and increased beneficial impact to air quality. Due to a decrease in exposed shoreline acreage, the potential to exceed the PSD Class II threshold or the state or national AAQS would also be decreased.

4.6.2.6 Preferred Alternative

At the 10th percentile, Lake Powell elevation is projected to be 3,552 feet msl in the year 2025 under the Preferred Alternative, resulting in approximately 17,000 acres of exposed shoreline. This would result in no change in the exposed shoreline compared to the No Action Alternative (Table 4.6-1).

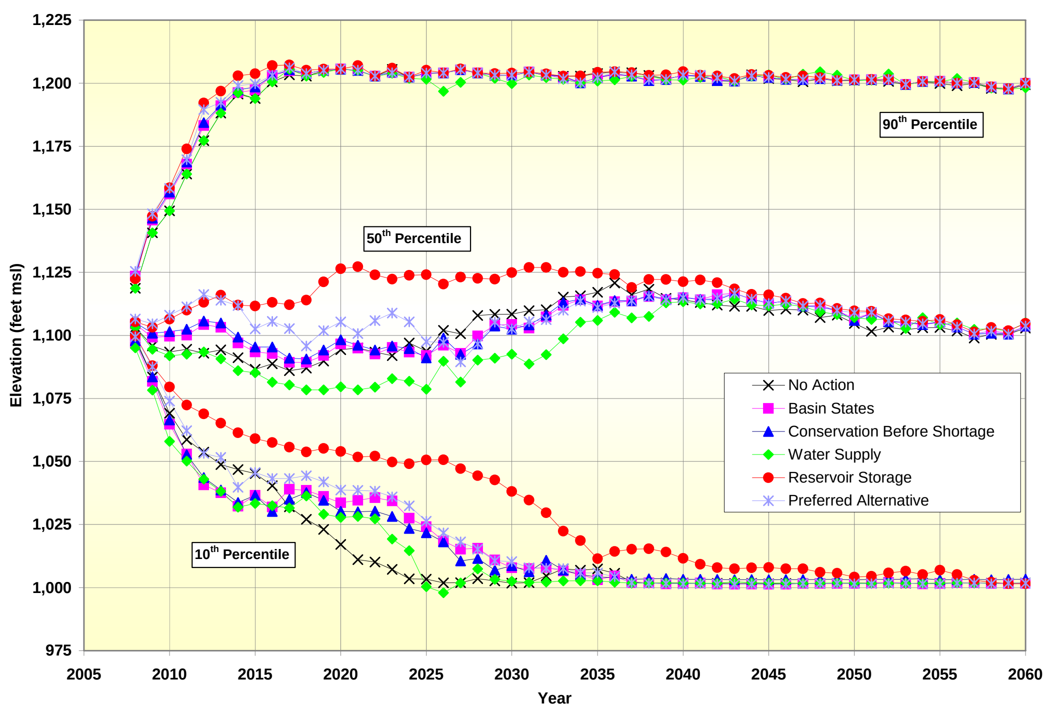
With no change in shoreline acreage, there would be no increased potential to exceed the PSD Class II threshold or the state or national AAQS when compared to the No Action Alternative. The potential to impact air quality would also be similar to that projected for the Basin States and the Conservation Before Shortage alternative.

4.6.3 Glen Canyon Dam to Lake Mead, Lake Mead and Hoover Dam

4.6.3.1 No Action Alternative

The lowest Lake Mead elevation occurs in July (Figure 4.6-2). Under the No Action Alternative, Lake Mead elevation would be drawndown to 1,003 feet msl for the year 2025, resulting in approximately 89,000 acres of exposed shoreline (Table 4.6-2). A comparative discussion of the action alternatives and the No Action Alternative for the year 2025 follows.

Figure 4.6-2
Lake Mead End-of-July Elevations
Comparison of Action Alternatives to No Action Alternative
90th, 50th, and 10th Percentile Values



4.6.3.2 Basin States Alternative

At the 10th percentile, Lake Mead elevation is projected to be 1,024 feet msl in the year 2025 under the Basin States Alternative, resulting in approximately 82,000 acres of exposed shoreline. For the Basin States Alternative, this would result in a decrease of about eight percent in exposed shoreline when compared to the No Action Alternative (Table 4.6-2). This decrease in acreage would be directly proportional to the area susceptible to wind erosion and fugitive dust emission. With a decrease in exposed shoreline acreage, the potential to exceed the PSD Class I or II thresholds or the state or national AAQS would also decrease. The eight percent decrease would result in a beneficial effect compared to the No Action Alternative.

Table 4.6-2
Lake Mead End-of-July 10th Percentile Elevation and Exposed Shoreline (Rounded to Nearest Whole Number)

Year	No Action	Basin States	Conservation Before Shortage	Water Supply	Reservoir Storage	Preferred Alternative
2008

Percent Difference Compared to No Action Alternative	0	0	(0)	0	0	0

1 Parenthesis indicates a reduction in exposed shoreline compared to the No Action Alternative.

4.6.3.3 Conservation Before Shortage Alternative

At the 10th percentile, Lake Mead elevation is projected to be 1,022 feet msl in the year 2025 under the Conservation Before Shortage Alternative, resulting in approximately 83,000 acres of exposed shoreline. For the Conservation Before Shortage Alternative, this would result in a decrease of about eight percent in exposed shoreline when compared to the No Action Alternative (Table 4.6-2).

The decrease in acreage would be directly proportional to the area susceptible to wind erosion and fugitive dust emissions. With a decrease in exposed shoreline acreage, the potential to exceed the PSD Class I or II thresholds or the state or national AAQS would also decrease. The potential decrease would result in a beneficial impact to the environment compared to the No Action Alternative.

4.6.3.4 Water Supply Alternative

At the 10th percentile, Lake Mead elevation is projected to be 1,000 feet msl in the year 2025 under the Water Supply Alternative, resulting in approximately 90,000 acres of exposed shoreline. For the Water Supply Alternative, this would result in an increase of about one percent in exposed shoreline when compared to the No Action Alternative (Table 4.6-2). The Water Supply Alternative would have potentially the same impact compared to the No Action Alternative.

Changes in shoreline acreage would be directly proportional to the area susceptible to wind erosion and fugitive dust emissions. With a less than one percent change in exposed shoreline acreage, the potential to exceed the PSD Class I or II thresholds or the state or national AAQS would be minimal compared to the No Action Alternative.

4.6.3.5 Reservoir Storage Alternative

At the 10th percentile, Lake Mead elevation is projected to be 1,051 feet msl in the year 2025 under the Reservoir Storage Alternative, resulting in approximately 73,000 acres of exposed shoreline. For the Reservoir Storage Alternative, this would result in a decrease of about 18 percent in exposed shoreline when compared to the No Action Alternative (Table 4.6-2). Compared to the No Action Alternative, the Reservoir Storage Alternative would have the most potential to reduce fugitive emissions and result in beneficial impact to air quality.

The decrease in acreage would be directly proportional to the area susceptible to wind erosion and fugitive dust emissions. With a decrease in exposed shoreline acreage, the potential to exceed the PSD Class I or II thresholds or the state or national AAQS would also be decreased. The decrease would result in a beneficial impact to the environment compared to the No Action Alternative.

4.6.3.6 Preferred Alternative

At the 10th percentile, Lake Mead elevation is projected to be 1,026 feet msl in the year 2025 under the Preferred Alternative, resulting in approximately 82,000 acres of exposed shoreline. For the Preferred Alternative, this would result in a decrease of about nine percent in exposed shoreline when compared to the No Action Alternative (Table 4.6-2).

The decrease in acreage would be directly proportional to the area susceptible to wind erosion and fugitive dust emissions. With a decrease in exposed shoreline acreage, the potential to exceed the PSD Class I or II thresholds or the state or national AAQS would also decrease. The potential decrease would result in a beneficial impact to the environment compared to the No Action Alternative.

4.6.4 Summary

The projected exposed shoreline acreage under the Basin States and Conservation Before Shortage alternatives, and the Preferred Alternative, are similar (i.e., from zero to five percent for the year 2025) to that projected under the No Action Alternative at Lake Powell. In general, the greatest increase in exposed shoreline acreage (i.e., about 30 percent for the year 2025) compared to the No Action Alternative at Lake Powell is projected under the Water Supply Alternative; the greatest reduction (i.e., about 15 percent for the year 2025) is projected under the Reservoir Storage Alternative. This trend can be observed in Figure 4.6-1.

Except for the Reservoir Storage Alternative, all of the action alternatives are projected to have similar or decreased shoreline exposure (i.e., from a less than one percent increase to a nine percent decrease) compared to the No Action Alternative for Lake Mead, and for Glen Canyon Dam to Lake Mead reach (Lake Mead delta). There is a greater potential for reduction in shoreline acreage exposure (i.e., 18 percent for the year 2025) in the Reservoir Storage Alternative and this potential is generally consistent for all years. This trend can be observed in Figure 4.6-2.

As reservoir elevations decrease and more shoreline is exposed, the potential for increased fugitive dust emission increases. However, an increase in fugitive emissions as a result of increased exposed shoreline would be limited at Lake Powell because the increased exposure of acreage would be comprised largely of sandstone, which is not conducive to generating PM10 standard fugitive emissions.

4.7 Visual Resources

This section describes the methods used in the Final EIS for analyzing the potential effects of changing reservoir elevations on visual resources at Lake Powell and Lake Mead, focusing on selected attraction features, calcium carbonate rings, and sediment deltas.

4.7.1 Methodology

To determine how changes in reservoir elevation might affect attraction features, data provided in Table 4.3-9 (Section 4.3) for end-of-September (the month of highest visitation) Lake Powell elevations were used to compare effects of the alternatives on exposure of Cathedral in the Desert. Table 4.3-9 provides percentage of values less than or equal to Lake Powell reservoir elevation of 3,550 feet msl for multiple years. Elevation 3,550 feet msl is significant because Cathedral in the Desert becomes visible at or below that elevation (Section 3.7).

For calcium carbonate rings, reservoir elevations at the 10^{th} percentile were used. Months representative of lowest reservoir elevations were used to provide a worst case analysis, or maximum extent of calcium carbonate rings; March was selected for Lake Powell and July was selected for Lake Mead, using data provided in Section 4.6 (Tables 4.6-1 and 4.6-2, respectively). The height of the calcium carbonate ring was calculated as the distance in feet from full pool elevations of Lake Powell (3,700 feet msl) and Lake Mead (1,221 feet msl) to the lowest lake elevation within the modeling time period.

The method of analysis used for projecting potential effects on calcium carbonate rings in Section 4.6 was utilized to understand relative differences between the action alternatives and the No Action Alternative for sediment deltas. The 10^{th} percentile of reservoir elevations in the months representative of lowest reservoir elevations, March for Lake Powell and July for Lake Mead, for the year 2026 are used in the Final EIS to provide a relative comparison of effects of the action alternatives on sediment deltas to the No Action Alternative.

4.7.2 Lake Powell and Glen Canyon Dam

4.7.2.1 Attraction Features

No Action Alternative. Using the modeling projections described above, there is a five percent probability of exposing the Cathedral in the Desert under the No Action Alternative. The upstream face of Glen Canyon Dam will be slightly more exposed, but this is not considered a measurable visual impact.

Basin States Alternative and Conservation Before Shortage Alternative. Under these two action alternatives, there is a seven percent chance of exposure of Cathedral in the Desert.

Water Supply Alternative. There is a 17 percent chance of exposure of Cathedral in the Desert.

Reservoir Storage Alternative. There is a three percent chance of exposure of Cathedral in the Desert.

Preferred Alternative. There is a seven percent chance of exposure of Cathedral in the Desert.

4.7.2.2 Calcium Carbonate Rings and Sediment Deltas

No Action Alternative. The 10th percentile values for March 2025 indicate a low Lake Powell reservoir elevation of 3,552 feet msl under the No Action Alternative, thus creating a potential calcium carbonate ring of 148 feet in height. Sediment deltas will continue to build up over time and be visible under the No Action Alternative. Ferrari's (2006) longitudinal profile indicates that the sediment delta is visible for at least 15 miles upstream of Hite. At 10th percentile projections, the delta may be visible from as far away as 25 miles, essentially from Hite to Gypsum Canyon.

Basin States Alternative and Conservation Before Shortage Alternative. The 10th percentile values for March 2025 indicate a low Lake Powell reservoir elevation of 3,552 feet msl under these two action alternatives, thus creating a potential calcium carbonate ring of 148 feet in height, the same as under the No Action Alternative. The sediment deltas would be exposed and visible to the same extent as under the No Action Alternative.

Water Supply Alternative. The 10th percentile values for March 2025 indicate a low Lake Powell reservoir elevation of 3,508 feet msl under the Water Supply Alternative, thus creating a potential calcium carbonate ring of 192 feet in height. Sediment deltas would be more exposed and visible than under the No Action Alternative.

Reservoir Storage Alternative. The 10th percentile values for March 2025 indicate a low Lake Powell reservoir elevation of 3,572 feet msl under the Reservoir Storage Alternative, thus creating a potential calcium carbonate ring of 128 feet in height. Potential exposure of sediment deltas would be less visible than under the No Action Alternative.

Preferred Alternative. The 10th percentile values for March 2025 indicate a low Lake Powell reservoir elevation of 3,552 feet msl under the Preferred Alternative, thus creating a potential calcium carbonate ring of 148 feet in height, the same as under the No Action Alternative. Sediment deltas would be exposed and visible to the same extent as under the No Action Alternative.

4.7.3 Glen Canyon Dam to Lake Mead

The proposed federal action would have no effects on the visual resources in this reach because daily and hourly flows would generally be similar under all alternatives.

4.7.4 Lake Mead and Hoover Dam

4.7.4.1 Attraction Features

Hoover Dam is a major destination and a national landmark. The proposed federal action would not have any visual effects on this resource.

4.7.4.2 Calcium Carbonate Rings and Sediment Deltas

No Action Alternative. The 10th percentile values for July 2025 indicate a low Lake Mead reservoir elevation of 1,003 feet msl under the No Action Alternative, thus creating a potential calcium carbonate ring of 218 feet in height. Sediment deltas are visible primarily to water-based recreationists, though they can also be viewed by visitors of the Lake Mead NRA (Section 3.7).

Basin States Alternative and Conservation Before Shortage Alternative. The 10th percentile values for July 2025 indicate a low Lake Mead reservoir elevations of 1,024 feet msl for the Basin States Alternative and 1,022 for the Conservation Before Shortage Alternative, thus creating a potential calcium carbonate ring of 197 feet and 199 feet in height, respectively. Sediment deltas would be somewhat less visible than under the No Action Alternative.

Water Supply Alternative. The 10th percentile values for July 2025 indicate a low Lake Mead reservoir elevation of 1,000 feet msl under the Water Supply Alternative, thus creating a potential calcium carbonate ring of 221 feet in height. Sediment deltas would be only slightly more exposed and therefore slightly more visible than under the No Action Alternative.

Reservoir Storage Alternative. The 10th percentile values for July 2025 indicate a low Lake Mead reservoir elevation of 1,051 feet msl under the Reservoir Storage Alternative, thus creating a potential calcium carbonate ring of 170 feet in height. Sediment deltas would be less exposed and therefore less visible than under the No Action Alternative.

Preferred Alternative. The 10th percentile values for July 2025 indicate a low Lake Mead reservoir elevation of 1,026 feet msl under the Preferred Alternative, thus creating a potential calcium carbonate ring of 195 feet in height. Sediment deltas would be somewhat less exposed and therefore less visible than under the No Action Alternative.

4.7.5 Summary

The probability of exposing Cathedral in the Desert ranged from three to 17 percent under the alternatives. The Water Supply Alternative would offer the greatest chance that visitors could see Cathedral in the Desert, while the Reservoir Storage Alternative offers the least chance. Most would agree that Cathedral in the Desert was one of the most spectacular geological features in Glen Canyon before inundation; seeing this feature would be considered a positive visual impact. There would be no visual effects on attraction features at Lake Mead.

At Lake Powell, the maximum height of calcium carbonate rings ranged from 192 feet under the Water Supply Alternative to 148 feet under the Basin States and Conservation Before Shortage alternatives, the Preferred Alternative, and the No Action Alternative, and to 128 feet under the Reservoir Storage Alternative. At Lake Mead, the maximum height of calcium carbonate rings ranged from 170 feet under the Reservoir Storage Alternative to 221 feet under the Water Supply Alternative, which is somewhat similar to the 218 foot height under the No Action Alternative. The calcium carbonate ring height under the Basin States and Conservation Before Storage alternatives, and the Preferred Alternative was around 197 feet. For both reservoirs, the presence of the calcium carbonate ring produces an effect regardless of its height. Therefore, while there are numeric differences in the projected height of the rings, the overall difference in visual impact among the alternatives is not considered significant.

At the inflow areas to both Lake Powell and Lake Mead, sediment deltas will continue to build up over time and be visible under all alternatives. Their relative exposure and visibility are directly related to reservoir elevations. The differences among all alternatives are negligible for both Lake Powell and Lake Mead.

4.8 Biological Resources

This section describes the environmental consequences related to biological resources associated with implementation of the proposed federal action, and describes the methods used to determine these effects. This section also provides descriptions of two ongoing environmental protection programs within the study area.

4.8.1 Related Environmental Programs

Reclamation is committed to compliance with environmental statutes such as the ESA and the Grand Canyon Protection Act. The following are ongoing collaborative programs intended to meet environmental compliance requirements.

4.8.1.1 Glen Canyon Dam Adaptive Management Program

Impacts to biological resources downstream of Glen Canyon Dam are considered in the Glen Canyon Dam Adaptive Management Program, which was established to monitor the effects of Glen Canyon Dam operations and other management actions on the downstream environment. This program makes recommendations to the Secretary regarding ways to fulfill the resource protection requirements of the Grand Canyon Protection Act while complying with all applicable federal laws. This program will continue to analyze the effects of varied conditions on biological resources downstream of Lake Powell.

4.8.1.2 Lower Colorado River Multi-Species Conservation Program

For a portion of the study area, Reclamation is the implementing agency for the LCR MSCP. This program mitigates potential flow-related and non-flow related impacts to biological resources along the lower Colorado River. These impacts could result from various federal and non-federal actions over the next 50 years along the lower Colorado River from Lake Mead to the SIB. This habitat-based program is being implemented to mitigate impacts to special status species, although benefits of the LCR MSCP will accrue to all species that utilize those habitats. This program covers potential impacts to the same types of habitats that may be affected by flow-related impacts of the action alternatives. For NEPA purposes, the No Action Alternative is used to represent baseline conditions. Reclamation has reviewed the effects of the Preferred Alternative in this Final EIS and has determined that all potential effects on listed species and their habitats along the Colorado River from the full pool elevation of Lake Mead to the SIB are covered by the LCR MSCP. The LCR MSCP BO addresses the effects of covered actions on reduction of Lake Mead reservoir elevations to 950 feet msl, and on flow reductions of up to 0.845 maf from Hoover Dam to Davis Dam, 0.860 maf from Davis Dam to Parker Dam, and 1.574 maf from Parker Dam to Imperial Dam. The LCR MSCP identified and it is mitigating impacts on LCR MSCP covered species and their habitats. Based on the flow reductions described above, these impacts include the potential loss of up to:

- 2,008 acres of cottonwood-willow habitats;
- 133 acres of marsh habitat; and

- 399 acres of backwater habitat.

To address these impacts, the LCR MSCP would:

- restore 5,940 acres of cottonwood-willow habitat;
- restore 512 acres of marsh habitat;
- restore 360 acres of backwater habitat;
- stock 660,000 razorback sucker over the term of the LCR MSCP; and
- stock 620,000 bonytail over the term of the LCR MSCP.

In addition, these habitats would be actively managed to provide habitat values greater than those of the impacted habitats. The quality and in most cases the quantity of restored habitat will be greater than the impacted habitats. Restoration and management of these habitats for LCR MSCP covered species would provide benefit to all flora and fauna that utilize cottonwood-willow, marsh, and backwater habitats along the lower Colorado River.

LCR MSCP flow-related covered activities include flow reductions due to potential implementation of future shortages in the Lower Basin. Reclamation is committed to enacting the conservation measures of the LCR MSCP and these measures will effectively offset any potential minor impacts identified in this Final EIS to cottonwood-willow, marsh, and backwater habitats from Lake Mead to the SIB.

4.8.2 Methodology

Two types of modeling results were used to perform the biological analysis, as follows:

- hydrologic modeling (CRSS) – reservoir elevations, dam releases, river flows; and
- water quality modeling (CE-QUAL-W2 and GEMSS) – water temperatures.

This biological analysis evaluates the relative difference between the action alternatives and the No Action Alternative. The level of available information varies with the study reaches; therefore, the methodology is adjusted according to the availability of information for a particular reach or group of reaches.

4.8.2.1 Assumptions

Desert scrub plant communities would not be affected by lowered reservoir elevations, river stage, or groundwater levels. Cottonwood-willow and marsh vegetation types could be adversely affected by lowered reservoir elevations, river stage, or groundwater levels and may be lost. Saltcedar and mesquite communities would not be adversely affected by lowered groundwater levels. For example, it has been reported that declines in groundwater levels of approximately 3.6 feet caused 92 to 100 percent of cottonwoods and willows to die, while only zero to 13 percent of saltcedar died at the sampling sites along the Bill Williams River (Shafroth et al. 2000).

Davis Dam and Parker Dam will continue to be operated to meet target reservoir elevations and these operations will not vary between alternatives, thus the proposed federal action will not impact riparian and marsh vegetation or wildlife habitats supported by these reservoirs.

The biological analyses are dependent upon the data inputs, modeling assumptions and validity of the CE-QUAL-W2 and GEMSS models for water quality. The historic data and water temperature models represent limited combinations of weather patterns, hydrology, discharge patterns, and reservoir elevations. The upper and lower temperature bounds from this analysis are the best estimates of probable discharge temperature ranges at the indicated reservoir elevations. Additional discussion and data on water temperature is provided in Section 4.5 and in Appendix P.

Inflow temperatures to Lake Mead often do not warm to equilibrium temperatures during much of the year. This is due to upstream cold releases from Lake Powell. The cool inflows restrict the depth of surface water warming and contribute to cooler discharge temperatures from Hoover Dam. If Lake Powell releases were significantly warmer, then inflow temperatures to Lake Mead could reach equilibrium and discharge temperatures would be warmer.

4.8.2.2 Vegetation Assessment Methodology

Lake Powell and Lake Mead. Reservoir elevations under the action alternatives were compared to the No Action Alternative to determine whether shoreline vegetation is more or less likely to establish and/or be inundated.

Glen Canyon Dam to NIB. Projections of average monthly releases from Glen Canyon Dam, Hoover Dam, Davis Dam, and Parker Dam under each action alternative were compared to the No Action Alternative (Figures P-BCR-6 through P-BCR-54; Figures and Tables identified with the letter P throughout this section are located in Appendix P of this Final EIS). The differences between the alternatives, primarily at the 10^{th} percentile, which has the most potential to adversely affect vegetation, were used as an indicator of potential low-flow conditions. To estimate the significance of potential impacts, the modeled releases were analyzed to determine if they would fall inside or outside the annual ranges that have historically occurred in the Colorado River (Section 3.3). Both Scott et al. (1999) and Shafroth et al. (2000) indicated that phreatophytes may develop root systems according to the hydrologic regime under which these plants have developed. Flow variations of several thousand cfs within one month and between months are considered within the range of normal conditions.

In addition to average monthly flows, annual median releases were evaluated to identify potential changes in groundwater along the Colorado River floodplain (Section 4.3, Figures 4.3-32 and 4.3-37). Changes to groundwater levels along the Colorado River may influence riparian and marsh vegetation.

Vegetation impacts from changes in river flow and groundwater levels were assumed to be restricted to those plant communities that consist of obligate phreatophytes (reliant on alluvial groundwater) and/or marsh communities. Based on the relationships used in Appendix K of the LCR MSCP BA (Reclamation 2004c), declines in groundwater levels under the action alternatives could be between 0.25 and 0.5 foot. These reductions would not impact saltcedar and mesquite land cover types because these species are facultative phreatophytes (not solely reliant on alluvial groundwater) and are more tolerant to reductions in surface water and groundwater levels than cottonwood-willow or marsh land cover types.

NIB to SIB. Potential flow changes downstream of the NIB as a result of implementation of the proposed federal action would primarily be the result of potential changes in excess flows (flood flows) arriving at the NIB. The differences in probability of these excess flows under each of the alternatives could potentially affect vegetation between the NIB and the SIB. Probabilities of these excess flows passing downstream of Morelos Diversion Dam under the action alternatives were compared to the No Action Alternative to analyze potential vegetation impacts.

4.8.2.3 Wildlife Assessment Methodology

Terrestrial wildlife was assumed to be affected only where vegetation showed substantial changes from the No Action Alternative.

Analyses of river sport fishery and aquatic food base impacts were based on release temperature modeling, surface water temperature data for Lake Powell, and review of the temperature conclusions in the SCOP FEIS (Clean Water Coalition 2006) for Lake Mead. Since sport fishery is primarily of interest to anglers, effects on this resource are discussed in Section 4.12.

4.8.2.4 Special Status Species Assessment Methodology

Lake Powell and Lake Mead. Analysis of impacts to terrestrial special status species at these two reservoirs were based primarily on the vegetation impact assessment. Potential impacts to special status fish were assessed by comparing reservoir elevations under each action alternative to those under the No Action Alternative. The potential monthly average release temperatures from Lake Powell were also used to analyze potential impacts to special status fish between Glen Canyon Dam and Lake Mead. Previous impact analysis for Lake Mead had used elevation 1,160 feet msl as a threshold for potential impact to razorback sucker spawning areas in Lake Mead. However, recent monitoring has shown that the two subpopulations of razorback sucker in Lake Mead would change their spawning locations in response to lower reservoir elevations (Albrecht and Holden 2006). Lake Mead elevation is currently below 1,160 feet msl. The elevation range of 1,120 feet msl to 1,150 feet msl was used for comparison purposes in this analysis.

Glen Canyon Dam to NIB. Analysis of impacts to terrestrial special status species along the Colorado River were based primarily on the vegetation impact assessment. Impacts to special status fish were based on comparing the modeled average monthly temperatures at Lees Ferry, Little Colorado River, and Diamond Creek to the life history temperature tolerances. There is a wide range of possible downstream temperatures when releases from Lake Powell coincide with lower Lake Powell elevation (Section 1.5; Figures P-BCR-56 through P-BCR-67). In order to provide a more meaningful comparison, the average monthly temperatures were used as the basis for evaluating impacts to special status fish (Tables P-BCR-1 through P-BCR-3). Special status fish impacts were also based on comparing the monthly Lake Mead elevations and monthly releases from Davis Dam and Parker Dam, for which water temperature data were not available. Changes in dam releases that would fall outside the range of flows that typically occur were deemed to cause impacts. Changes in release temperatures from Glen Canyon Dam under the No Action Alternative were used to determine whether impacts to the aquatic food base could in turn impact the special status fish in the Grand Canyon. This analysis used larval chironomids, larval simuliids, *Gammarus lacustris*, and *Cladophora glomerata* as indicator organisms. If a particular alternative would substantially affect non-native sport fish (Section 4.12), this was included in the special status fish assessment.

NIB to SIB. Special status fish species do not exist in this river reach so the analysis was limited to terrestrial special status species. Flows in this reach of the Colorado River are sporadic, with the river channel in the downstream portion of the reach being frequently dry.

4.8.3 Effects on Vegetation and Wildlife

This section discusses the potential impacts to vegetation and wildlife that may result from implementation of the proposed federal action.

4.8.3.1 Lake Powell and Lake Mead

No Action Alternative. Under the No Action Alternative, fluctuation of these reservoirs will continue to inhibit plant growth around the reservoirs over the long term. Lake Powell elevations trend upward at the 50th and 90th percentiles throughout the modeling period. At the 10th percentile, Lake Powell elevations trend temporarily downward (2010 through 2019 and 2041 through 2060), and temporarily upward (2027 through 2041). At the end of the interim period in 2026, Lake Powell elevation is virtually unchanged from current elevations. Figures P-WQA-6, P-BCR-1, and P-BCR-2 provide Lake Powell end-of-March, July, and September elevations, respectively.

Lake Mead elevations exhibit a pronounced downward trend at the 10th percentile. At the 50th percentile, the trend is generally unchanged at the end of the modeling period, though periodic upward and downward trends occur in both the interim and long term. Figures P-BCR-4, P-BCR-6, and P-BCR-7 provide Lake Mead end-of-month elevations for March, July, and September, respectively. To the extent that Lake Mead elevations may be lowered, these lower lake elevations may have effects on biological resources, as described in the following paragraphs.

The sediment deltas in both reservoirs are expected to continue to be colonized by weeds and saltcedar. Lake Mead sediment deltas and the downstream portion of the Grand Canyon have had riparian vegetation become established and persist over long periods of time, until inundated by rising reservoir elevations. The type of vegetation that becomes established in these delta areas is dependent on two factors. The first factor is timing. If the sediment becomes exposed during seed-fall season for cottonwood or willow, then those species are likely to become established. If the sediment becomes exposed during the fall months, then saltcedar is likely to be established and become the dominant vegetation.

A second factor that may influence the type of plant community that may become established in the delta areas is the depth to groundwater or river stage relative to these exposed sediments. As the reservoir elevation declines and the sediment becomes exposed, the level of the river as it downcuts through the newly exposed sediment delta helps determine whether cottonwoods or willows can survive, even if they become established. If the river level drops too far below the root zone of cottonwoods and willows, plant mortality would begin to occur, thus, opening gaps for saltcedar and other species to become established.

Wildlife that utilizes these reservoirs and their shorelines are affected by the fluctuating nature of these habitats to some extent. Reservoir elevation fluctuation would continue into the future, which would continue to alter habitat along the shoreline and below full pool elevation as has occurred in the past.

Quagga mussels have been detected in Lake Mead and in downstream reservoirs, and a small number of zebra and/or quagga mussel larvae were detected in Lake Powell in July 2007 (Section 3.8). Under the No Action Alternative, the potential remains for these mussels to establish in Lake Powell and continue to be present in Lake Mead and in downstream reservoirs. The adoption of guidelines for shortage and coordinated reservoir operations does not affect the potential for colonization in Lake Powell and continued presence in Lake Mead, Lake Mohave and Lake Havasu, or connected waterways. Precautionary measures of cleaning boats entering and leaving these reservoirs will continue under the No Action Alternative and the action alternatives, and the geographic locations of water delivery from the Colorado River system will not change because of this action. Since the nature of the proposed federal action will not impact the potential for spreading and/or continued presence of these invasive mussels, and since conditions related to this issue will be the same under the No Action Alternative and the action alternatives, this issue is not discussed further in this Final EIS.

Action Alternatives. While the action alternatives differ from the No Action Alternative to some degree, all action alternatives exhibit similar reservoir elevation fluctuations as compared to the No Action Alternative. Temporary establishment and loss of vegetation and wildlife habitat below the full pool elevation would occur similarly under all alternatives. In general, higher reservoir elevations such as those associated with the Reservoir Storage Alternative would decrease exposed shoreline available for plant colonization by decreasing the distance between permanent shoreline vegetation and the lake edge, and would thus provide less opportunity for temporary desirable and undesirable plant communities to develop. Lower elevations such as those associated with the Water Supply Alternative would increase the distance between permanent shoreline vegetation and aquatic habitats, which would increase shoreline available for plant colonization, but would also increase the distance wildlife would need to travel between permanent cover habitat and the lake edge. The descriptions below are limited to the 10th and 50th percentiles, as elevations at the 90th percentile under the action alternatives are virtually unchanged from those under the No Action Alternative for both Lake Powell and Lake Mead.

Preferred Alternative, Lake Powell. Compared to the No Action Alternative, the Preferred Alternative results in somewhat higher elevations during the interim period and somewhat lower elevations in the long term at the 10th percentile; and somewhat lower elevations in the interim period at the 50th percentile.

Preferred Alternative, Lake Mead. At the 10th percentile, the Preferred Alternative is generally unchanged from the No Action Alternative, with the exception of somewhat higher elevations from 2018 through 2032. At the 50th percentile, 2009 through 2025 have somewhat higher elevations. The Preferred Alternative is bracketed by the high and low reservoir elevations of the other action alternatives for all percentile scenarios, through both the interim period and the –post-interim period.

Basin States Alternative, Lake Powell. With only a few minor exceptions, the Basin States Alternative has reservoir elevations similar to the Preferred Alternative at the 10th and 50th percentiles.

Basin States Alternative, Lake Mead. From 2010 through 2017, the Basin States Alternative has somewhat lower elevations than the No Action Alternative at both the 10th and 50th percentiles. In other years, the Basin States Alternative mimics the Preferred Alternative.

Conservation Before Shortage Alternative, Lake Powell. With a few minor exceptions, the Conservation Before Shortage Alternative has reservoir elevations similar to the Preferred Alternative at the 10th and 50th percentiles.

Conservation Before Shortage Alternative, Lake Mead. The Conservation Before Shortage Alternative has reservoir elevations similar to the Basin States Alternative at the 10th and 50th percentiles.

Water Supply Alternative, Lake Powell. Through 2014, the Water Supply Alternative elevations are somewhat higher than the No Action Alternative at the 10th percentile, and significantly lower throughout the remainder of the interim period and through the modeling period. At the 50th percentile, elevations are similar through 2010, somewhat to significantly lower through approximately 2032, and similar through the remainder of the modeling period.

Water Supply Alternative, Lake Mead. At the 10th percentile, the Water Supply Alternative results in somewhat lower reservoir elevations than the No Action Alternative from 2010 through 2017, somewhat higher elevations from 2018 through 2023, and generally mimics the No Action Alternative for the remainder of the modeling period. At the 50th percentile, this alternative results in somewhat lower elevations through 2035, and unchanged elevations for the remainder of the modeling period.

The lower reservoir elevations that may occur under the Water Supply Alternative fall outside the potential range of the No Action Alternative. At these low reservoir elevations, there would be a greater potential for sediment delta headcutting at the inflow areas causing movement of sediment further into the reservoirs. The Water Supply Alternative would have the greatest potential effect on these deltas due to increased reservoir drawdown, which could potentially impact vegetation and wildlife habitat. These impacts may occur in the interim period and the post-interim period. The lower lake elevations under the Water Supply Alternative may remain lower than under the No Action Alternative until approximately 2036 for Lake Powell and until 2040 for Lake Mead at the 50th percentile, and until 2055 for Lake Powell at the 10th percentile.

Reservoir Storage Alternative, Lake Powell. Reservoir elevations under the Reservoir Storage Alternative are somewhat higher than under the No Action Alternative throughout the interim period at the 10th percentile. Beginning in 2034, there is little variation between the Reservoir Storage Alternative and the No Action Alternative throughout the remainder of the modeling period. At the 50th percentile, lake elevations under the Reservoir Storage Alternative are slightly higher than under the No Action Alternative from 2017 through 2042, and unchanged in other years.

Reservoir Storage Alternative, Lake Mead. Reservoir elevations are somewhat higher through 2045 at the 10th percentile, and through 2035 at the 50th percentile.

4.8.3.2 Glen Canyon Dam to Lake Mead

No Action Alternative. Data on modeled Glen Canyon Dam releases are provided in Figures P-BCR-8 through P-BCR-19 in Appendix P. The range of releases is similar to the range of historic annual flows observed from 2000 to the present (Section 3.3, Figure 3.3-2), though lower than the high water years between 1995 and 2000. Therefore, the release conditions which the vegetation and wildlife downstream of Glen Canyon Dam have experienced since 2000 would continue into the future at these percentiles. Vegetation and wildlife are likely adjusting or have adjusted to these lower flows. Stabilized lower flows have been observed to favor riparian vegetation development at numerous locations in the Western United States (Reclamation 1995; Gloss et al. 2005). This trend benefits species that utilize shrubby riparian vegetation. The modeled release trends indicate that the magnitude of average monthly releases under the No Action Alternative would likely be unchanged to somewhat lower in the future through the modeling period at the 10th, 50th, and 90th percentiles. The only noticeable exception to these trends occurs at the 90th percentile in June.

Action Alternatives. From the end of the interim period through the modeling period, the differences in modeled releases for the action alternatives at the 10th, 50th, and 90th percentiles are well within both daily and monthly release variations (modeled and historical), and generally mimic the modeled releases under the No Action Alternative. It is therefore anticipated that none of the action alternatives will have significant positive or negative impacts on riparian vegetation or wildlife in the Glen Canyon Dam to Lake Mead river reach in the post-interim period when compared to the No Action Alternative.

During the interim period, releases under the action alternatives at the 10th percentile are generally unchanged or lower than under the No Action Alternative, with the Reservoir Storage Alternative being the closest to the No Action Alternative. Maximum 10th percentile release reductions are typically between 700 and 2,000 cfs, though the Water Supply Alternative may be lower than the No Action Alternative by up to 3,800 cfs in July and September. Releases under the Preferred Alternative are lower by as much as 2,000 cfs between July and December at the 10th percentile. Low flows have the greatest likelihood of negatively impacting riparian and marsh vegetation and wildlife that utilize such habitats. The impacts would be minor because for the most part, these reduced releases remain within the range of annual fluctuation and would be temporary. The impacts may cause stress to phreatophytes, but would not be expected to cause significant plant die-off. These impacts would affect obligate phreatophytes such as willow more than facultative phreatophytes such as saltcedar. Thus, these minor impacts may favor continued saltcedar expansion, though saltcedar is expanding along the Colorado River under existing conditions.

Because Glen Canyon Dam releases under the action alternatives generally return to the releases under the No Action Alternative near the end of the interim period, these impacts would end after the interim period. However, the effects on phreatophytes and continued saltcedar expansion may be observable even after the releases return to those under the No Action Alternative. Minor negative impacts to riparian vegetation at the lower 10th percentile of releases under all alternatives, including the No Action Alternative, would in turn impact the habitats for herptofauna, small mammals, waterfowl, and songbirds that utilize those habitats. Snakes found downstream of Glen Canyon Dam are typically found in drier portions of the reach and should not be impacted by these alternatives. Lake Powell releases at the 50th percentile of lake elevations would have temperatures under the action alternatives similar to those under the No Action Alternative and thus would cause no temperature related impacts to amphibians along the river. Only the Water Supply Alternative may result in substantially higher temperatures in some years and may provide some thermal benefit to amphibian reproduction along the river (Tables P-BCR-1 through P-BCR-3). It would be difficult to quantitatively measure these potential impacts as the impacts to river temperatures and vegetation may be temporary and minor and thus indirect impacts to species using those habitats would be small. These potential small habitat impacts are unlikely to in turn impact large mammals in the canyon. Due to the potential for minor impacts to riparian vegetation, all the alternatives would have similar minor impacts to wildlife in the Glen Canyon Dam to Lake Mead river ranch.

At the 50th percentile, releases under the Basin States, Conservation Before Shortage, and Water Supply alternatives, and the Preferred Alternative, are generally greater than under the No Action Alternative. Differences of as much as 3,800 cfs occur during May through September under the Water Supply Alternative, with slightly smaller increases under the other action alternatives. The Reservoir Storage Alternative releases are virtually unchanged from the No Action Alternative releases at the 50th percentile. Since the 50th percentile releases are well within the range of historical annual releases, negative impacts to permanent riparian vegetation and wildlife habitat are expected to be minimal, though higher summer releases may inhibit the reestablishment of some herbaceous vegetation in riparian areas that have been exposed during recent low release years. Modestly higher seasonal flows may expand marshy areas, and benefit existing saltcedar, willow, and shrub habitat both by inundation and contributions to groundwater.

At the 90th percentile, the magnitude of flows exceeding those under the No Action Alternative that may occur under the action alternatives is relatively small, with the exception of the Reservoir Storage Alternative. Releases under the Reservoir Storage Alternative in June may be up to 6,800 cfs above releases under the No Action Alternative and approach 30,000 cfs. Unusually high flows may cause scouring of vegetation that may have developed at the lower levels on the river banks under previously lower flow conditions. These flows, however, are below the levels of historical high flows which have exceeded 40,000 cfs. Despite the potential scouring effects from these higher flows, they provide an overall benefit to vegetation and wildlife in the long term.

Releases under the Preferred Alternative at the 90th percentile are somewhat lower than under the No Action Alternative at the 90th percentile in July and September through December, and generally somewhat higher during January through May.

4.8.3.3 Hoover Dam to Davis Dam

No Action Alternative. The Hoover Dam to Davis Dam reach consists primarily of the reservoir pool of Lake Mohave, the elevation of which is controlled by operation of Davis Dam. Lake Mohave and Lake Havasu are operated on a monthly rule curve and end-of-month target elevations and therefore significant fluctuations in reservoir elevations do not occur. No change in vegetation or wildlife is expected over the interim period or the modeling period. Information on monthly Hoover Dam releases is provided in Figures P-BCR-20 through P-BCR-31.

Action Alternatives. Elevations of these two reservoirs under the action alternatives would not deviate from elevations under the No Action Alternative. Accordingly, there would be no impacts to vegetation or wildlife at these reservoirs. Because vegetation is limited in the Hoover Dam to Lake Mohave river reach, potential flow differences among alternatives in this reach of the Colorado River would not substantially impact vegetation or wildlife.

4.8.3.4 Davis Dam to Parker Dam

No Action Alternative. Fluctuations of monthly flows downstream of Davis Dam of several thousand cfs have occurred in the recent past and will continue into the future. Vegetation and wildlife habitat along the Colorado River continuously make minor adjustments as these flows fluctuate. Annual median releases from Davis Dam under the No Action Alternative show a slight downward trend through 2040 (Section 4.3, Figure 4.3-32). Accordingly, the lower releases could potentially cause a corresponding decline in groundwater levels along the 39 mile section of the Colorado River that extends from Davis Dam to Lake Havasu.

Action Alternatives. In general, both lower and higher monthly releases under the action alternatives would have similar impacts to vegetation and wildlife as discussed for the Glen Canyon Dam to Lake Mead reach. At the 10th and 50th percentiles, release rates for Davis Dam fall within a relatively narrow band for all months. Average monthly Davis Dam releases under all alternatives are provided in Figures P-BCR-32 through P-BCR-43. The differences in monthly releases under the Preferred Alternative and under the No Action Alternative are generally small, and are not expected to impact vegetation or wildlife at these percentiles in either the interim period or the post-interim period. The Reservoir Storage Alternative results in lower releases during the interim period, while the Water Supply Alternative results in higher releases. The higher releases would benefit vegetation and wildlife, but release differences are small, and these benefits would be minor. Slightly lower releases under the Reservoir Storage Alternative may have minor negative impacts on vegetation and wildlife as compared to releases under the No Action Alternative. Similarly to the Preferred Alternative, the Basin States and Conservation Before Shortage alternatives essentially follow the No Action Alternative, and where there are differences they are infrequent, small differences. Therefore, the Basin States and Conservation Before Shortage alternatives, and the Preferred Alternative, should have no measurable impacts on vegetation in the Davis Dam to Parker Dam river reach.

At the 90th percentile, the Reservoir Storage Alternative may result in higher releases due to increased flood control releases not projected under the other alternatives. These releases typically occur in winter months, outside the growing season. These flows may be up to 6,000 cfs greater than under the No Action Alternative at the 90th percentile, but would not be large enough to cause significant scouring or over-bank flooding. Thus, no substantial riparian impacts are expected. The Preferred Alternative may result in somewhat higher releases in January and February in the interim period, and somewhat lower or unchanged releases in the modeling period at the 90th percentile. The differences would be isolated and temporary, and are not expected to significantly impact vegetation or wildlife along this reach. With the exception of January, modeled releases for the No Action Alternative and the action alternatives converge relatively quickly after the end of the interim period. Releases and their effects under the action alternatives generally return to those under the No Action Alternative relatively soon after the interim period, though minor effects on vegetation may be observed beyond the interim period.

A comparison of annual median release under each action alternative to the annual median release under the No Action Alternative showed minor reductions in river stage and corresponding groundwater levels (Section 4.3). The Reservoir Storage Alternative results in the greatest reduction in annual median release from Davis Dam (Section 4.3, Figure 4.3-32) that may lower groundwater levels during the interim period by as much as 0.25 to 0.50 foot for gaining and losing reaches, respectively. Sustained decreases in groundwater levels of this magnitude might have minor negative effects on cottonwood-willow and marsh communities as compared to the No Action Alternative. The Water Supply Alternative results in annual median releases that are somewhat higher than under the No Action Alternative through the interim period, and may have minor positive impacts on cottonwood-willow and marsh vegetation during this period due to higher groundwater levels. The Basin States and Conservation Before Shortage alternatives, and the Preferred Alternative, result in annual median releases somewhat lower than but close to those under the No Action Alternative through 2012, and otherwise generally mimic the No Action Alternative in the interim and post-interim periods. These alternatives are therefore not expected to impact cottonwood-willow or marsh vegetation.

4.8.3.5 Parker Dam to Imperial Dam

No Action Alternative. Fluctuations of monthly flows downstream of Parker Dam of several thousand cfs have occurred in the recent past, and will continue into the future. Vegetation and wildlife habitat along the Colorado River continuously make minor adjustments as these flows fluctuate. Annual median releases from Parker Dam under the No Action Alternative show a slight downward trend through 2040 (Section 4.3, Figure 4.3-37), which may effect groundwater levels.

Action Alternatives. In general, both lower and higher monthly releases under the action alternatives would have similar impacts to vegetation and wildlife as discussed for the river reach between Glen Canyon Dam and Lake Mead. Release rates at the 10^{th} and 50^{th} percentiles for Parker Dam fall within a relatively narrow band for all months. Average monthly Parker Dam releases are provided in Figures P-BCR-44 through P-BCR-55. The differences in releases under the Preferred Alternative and under the No Action Alternative are generally small, and are not expected to impact vegetation or wildlife at these percentiles in either the interim or the modeling period. The Reservoir Storage Alternative results in lower releases during the interim period, while the Water Supply Alternative results in higher releases. The higher releases would benefit vegetation and wildlife, but release differences are small, and these benefits would be minor. Slightly lower releases under the Reservoir Storage Alternative may have minor negative impacts on vegetation and wildlife compared to releases under the No Action Alternative. Similarly to the Preferred Alternative, releases under the Basin States and Conservation Before Shortage alternatives essentially follow the releases under the No Action Alternative, and where there are differences they are infrequent, small differences. Therefore, changes in monthly releases from Parker Dam under the Basin States and Conservation Before Shortage alternatives, and the Preferred Alternative, should have no substantial impacts on vegetation in the river reach between Parker Dam and Imperial Dam.

At the 90th percentile, the Reservoir Storage Alternative may create higher releases due to increased flood control releases not modeled under other alternatives. These releases typically occur in winter months, outside the growing season. These flows may be up to 4,000 cfs higher than those under the No Action Alternative at the 90th percentile, but would not be large enough to cause significant scouring or over-bank flooding. Thus, no substantial riparian impacts are expected. The Preferred Alternative may result in somewhat higher releases in January and February in the interim period, and somewhat lower or unchanged releases in the modeling period at the 90th percentile. The differences would be isolated and temporary, and are not expected to significantly impact vegetation or wildlife along this river reach. With the exception of January, modeled releases under the No Action Alternative and the action alternatives converge relatively quickly after the end of the interim period. Releases and other effects under the action alternatives generally return to the those the No Action Alternative relatively soon after the interim period, though minor effects on vegetation of interim period conditions may be observed beyond the interim period.

The Reservoir Storage Alternative results in annual median releases from Parker Dam that are lower than under the No Action Alternative (Section 4.3, Figure 4.3-37), which may lower groundwater levels throughout the interim period by as much as 0.15 to 0.30 foot for gaining and losing reaches, respectively. Sustained decreases in groundwater levels of this magnitude might have minor negative effects on cottonwood-willow and marsh communities as compared to those under the No Action Alternative. The Water Supply Alternative results in annual median releases that mimic or are slightly higher than under the No Action Alternative through the interim and modeling periods, which may have minor positive impacts on cottonwood-willow and marsh vegetation from 2016 through 2026 due to higher groundwater levels. Annual median releases under the Basin States and Conservation Before Shortage alternatives, and the Preferred Alternative, are generally bracketed between the Reservoir Storage Alternative and the No Action Alternative, are all somewhat lower than under the No Action Alternative through the interim and post-interim periods. These slightly lower groundwater levels may result in minor negative impacts on marsh and riparian communities.

4.8.3.6 Imperial Dam to NIB

Most of the water delivered to Mexico is diverted at Imperial Dam, conveyed via the AAC, and then returned to the Colorado River through the Pilot Knob and Siphon Drop Powerplants and their respective wasteway channels, which discharge to the Colorado River mainstream 2.1 and 7.6 miles upstream of the NIB, respectively (Section 3.3). The proposed federal action will not alter the operation of these diversions and wasteways and therefore will not have an effect on the river reach between Imperial Dam and the NIB.

4.8.3.7 NIB to SIB

No Action Alternative. The frequency and magnitude of flows are important factors in maintaining riparian habitat and wildlife in the river reach between Morelos Diversion Dam and the SIB; however, the potential biological effects downstream of the NIB cannot be specifically determined because of the uncertainty of water use once it flows to the NIB and becomes available to Mexico.

The hydrologic models for this Final EIS (Section 4.2) have assumed that any water in excess of Mexico's scheduled normal or surplus deliveries would not be diverted by Mexico but would continue down the Colorado River channel from Morelos Diversion Dam to the SIB. This assumption results in the probability of flows passing Morelos Diversion Dam that might be somewhat higher than may actually occur. The potential impacts discussed in the following section are based on this assumption.

Under the No Action Alternative, flows downstream of Morelos Diversion Dam will continue to be primarily the result of dam leakage and agricultural return flows. Flows past Morelos Diversion Dam will continue to be relatively rare events (Figure P-BCR-56). It is expected that riparian and marsh vegetation and wildlife will continue to experience some year-round flow in the upstream part of this reach and sporadic flow in the downstream part of this reach under the No Action Alternative. Thus, historical conditions will generally continue under the No Action Alternative.

Action Alternatives. During the interim period and beyond, the Basin States and Water Supply alternatives, and the Preferred Alternative, are just as likely to result in excess flows downstream of Morelos Diversion Dam as the No Action Alternative, and would therefore have no impact on this reach as compared to the No Action Alternative. Further, the probabilities of occurrence for these excess flows are low and range between ten percent and 15 percent (Figure P-BCR-56). The magnitude of excess flows past Morelos Diversion Dam is zero for approximately 80 to 90 percent of the model traces between 2008 and 2060 (Section 4.3, Figure 4.3-39). The magnitude of these excess flows under the Reservoir Storage Alternative may be higher by as much as one mafy than under the No Action Alternative. The magnitude of these excess flows under the Conservation Before Shortage Alternative may be higher by as much as 0.35 mafy than under the No Action Alternative (Section 4.3, Figure 4.3-43).

Due to modeling assumptions under the Conservation Before Shortage and Reservoir Storage alternatives, water is also delivered to Mexico through this river reach via periodic flows of about 40 kafy to 200 kafy (Appendix M). These pulse flows[1] would

[1] These flows were modeled as part of the storage and delivery mechanism under the Conservation Before Shortage and Reservoir Storage alternatives. The modeling assumptions were utilized in this Final EIS in order to analyze the potential impacts to environmental resources of the storage and delivery mechanism, particularly with regard to reservoir elevations and river flow impacts. The use of these modeling assumptions does not represent any determination by Reclamation as to whether, or how, these releases could be made under current management of the Colorado River.

occur approximately every fifth year during the interim period only and other flows that could be used for environmental, domestic, or agricultural purposes would also be released every five years. The probability of flows past Morelos Diversion Dam under these two alternatives returns to that under the No Action Alternative after the interim period. These flows would benefit vegetation and wildlife downstream of Morelos Diversion Dam because they would increase river flow, scour and redistribute sediment, and provide opportunities for establishment of cottonwood-willow and marsh vegetation. These fluvial processes are valuable to aquatic and riparian systems in the long term, though temporary losses of riparian or marsh vegetation may occur from scouring, which could temporarily disrupt wildlife.

Table 4.8-1 summarizes impacts to vegetation and wildlife under the action alternatives relative to the No Action Alternative.

Table 4.8-1
Vegetation and Wildlife Impact Summary
Comparison of Action Alternatives to No Action Alternative

Location	Alternative	Impact	Rationale
Lake Powell and Lake Mead	Preferred Alternative	Minor - positive	Potential for higher reservoir elevations, especially at the 10th percentile in Lake Powell during the interim period.
	Conservation Before Shortage, Basin States	No impact to Minor - Positive	Elevations and fluctuation similar to those under the No Action Alternative and the Preferred Alternative.
	Water Supply	Minor – negative	Reservoir elevations tend to be lower than under the No Action Alternative, with increased opportunities for undesirable plants to colonize shoreline and for sediment delta headcutting. Lower elevations would increase distance between shoreline vegetation and the lakes.
	Reservoir Storage	Minor-positive	Elevations tend to be higher than under the No Action Alternative, with decreased opportunities for undesirable plants to colonize shoreline and for sediment delta headcutting. Elevation fluctuations inundate all vegetation below full pool elevation. Higher elevations would decrease distance between shoreline vegetation and lakes.
Glen Canyon Dam to Lake Mead	All action alternatives	Minor – negative	Decreased releases at the 10th percentile (for all alternatives there are similar reductions overall). Release differences are within the range of recent history and annual fluctuation.
Hoover Dam to Davis Dam and Lake Havasu to Parker Dam	All action alternatives	No impact	Relatively small Hoover Dam release differences and very limited vegetation upstream of Lake Mohave. Monthly rule curves at Lake Mohave and Lake Havasu prevent elevation deviations from the No Action Alternative.

Table 4.8-1
Vegetation and Wildlife Impact Summary
Comparison of Action Alternatives to No Action Alternative

Location	Alternative	Impact	Rationale
Davis Dam to Parker Dam	Conservation Before Shortage, Basin States, Preferred Alternative	No impact	Monthly releases closely follow the No Action Alternative. Annual median Davis Dam release is similar to the No Action Alternative.
	Water Supply	Minor-positive	Monthly releases higher than under the No Action Alternative at the 10th and 50th percentiles. Higher annual median release from Davis Dam.
	Reservoir Storage	Minor – Negative	Monthly releases lower than under the No Action Alternative at the 10th and 50th percentiles. Lower annual median release from Davis Dam.
Parker Dam to Imperial Dam	Water Supply	Minor - Positive	Monthly releases closely follow the No Action Alternative. Annual median Parker Dam release is similar to or higher than under the No Action Alternative.
	Basin States, Conservation Before Shortage, Reservoir Storage, Preferred Alternative	Minor – Negative	Monthly releases lower than under the No Action Alternative at the 10th and 50th percentiles (the Reservoir Storage Alternative has the greatest reduction; the Basin States Alternative has the least reduction). The Reservoir Storage Alternative higher flows in the winter are unlikely to have substantial benefits due to channel capacity. Annual median Parker Dam releases are lower than under the No Action Alternative.
	All action alternatives	No impact	Flow changes are routed through AAC and Pilot Knob/Siphon Drop Powerplants rather than the Colorado River downstream of Imperial Dam.
Imperial Dam to NIB	Basin States, Water Supply, Preferred Alternative	No impact	Probability of excess flows past Morelos Diversion Dam is very close to that of the No Action Alternative.
NIB to SIB	Reservoir Storage, Conservation Before Shortage	Moderate – positive	Relatively likely high flows expected past Morelos Diversion Dam, which would benefit the riparian corridor.

4.8.4 Special Status Species

4.8.4.1 Lake Powell

No Action Alternative. Fluctuations of Lake Powell elevations would continue into the future, precluding the development of stable vegetated terrestrial habitats below elevation 3,700 feet msl because vegetation that develops would be periodically dewatered or inundated.

Fish. The Colorado pikeminnow, bonytail chub, razorback sucker and flannelmouth sucker all occur in Lake Powell, primarily at the inflow areas of the Colorado River and the San Juan River. The flannelmouth sucker population has been decreasing since the reservoir was formed (Reclamation 2000). Low reservoir elevations increase the amount of riverine habitat available for these species in the river inflow areas, which may be a temporary benefit to these fish. In addition, when the lake elevation is below 3,660 feet msl, a waterfall becomes exposed in the San Juan River where it enters Lake Powell. This waterfall forms a barrier to upstream movement of non-native fish that can prey upon or compete with special status fish in the San Juan River (i.e., Colorado pike minnow and razorback sucker). The waterfall, however, also would prevent native fish that enter the reservoir from the river from moving back into the river. Thus, reservoir elevations below 3,660 feet msl could provide a minor benefit to special status fish in the San Juan River. The probability that Lake Powell will be at or below elevation 3,660 feet msl generally increases during the interim period but levels off at approximately 50 percent near the end of the modeling period (Figure P-BCR-57).

Birds. Special status birds that currently may be affected by elevation fluctuations of Lake Powell include California condor, bald eagle, osprey, belted kingfisher, Clark's grebe, and American peregrine falcon. California condors are scavengers, primarily on large mammals and sometimes on fish. The lower reservoir elevations projected for the future may expose additional shoreline for scavenging.

Bald eagles in this area are primarily winter residents that feed on fish, waterfowl and carrion. Though there may be effects on fisheries as reservoir elevations decline, no effects on the population of fish are anticipated. Therefore, this food source is expected to remain available for bald eagles under the No Action Alternative.

Ospreys are a rare transient in summer along the Colorado River. However, they could potentially utilize Lake Powell during migration. Fluctuating reservoir elevations would have no direct impacts to ospreys, and no substantial indirect effects on food sources (fish) are expected.

Peregrine falcons may utilize Lake Powell for hunting songbirds, bats and small mammals. Reservoir elevation fluctuations would not directly impact peregrine falcons. Nearby populations in the Grand Canyon are considered stable and the species was delisted from federal listing in 1999 (Gloss et al. 2005).

Belted kingfishers inhabit riparian areas in Arizona and mainly consume fish. Kingfishers could be affected as fish availability fluctuates over time. Given the gradual downward trend for Lake Powell elevations in the future, it is anticipated that fish populations would be able to adjust to the changing conditions. Increased inflow areas as the elevations decline may provide improved shallow-water hunting area.

Clark's grebe inhabit marshes and may be found in marsh habitat at Lake Powell inflow areas. They are common breeders in Utah and utilize lakes and shoreline vegetation for breeding habitat. The decline of reservoir elevations projected in the future under the No Action Alternative may dewater marshes at the inflow areas, causing temporary loss of marsh habitat until the marsh re-establishes at a lower elevation, or the reservoir elevations recover.

Mammals. Special status mammals that may utilize Lake Powell include spotted bat, Townsend's big-eared bat, pale Townsend's big-eared bat, Yuma myotis, Allen's big-eared bat, western red bat, and occult little brown bat. All of these species may utilize riparian habitats around the shoreline of Lake Powell. As lake elevations fluctuate, these habitats may be dewatered or inundated and localized effects on food source populations may occur. Given their wide-ranging nature, these species would not be expected to be substantially impacted under the No Action Alternative or the action alternatives. Accordingly, these species are not discussed further for this reach.

Amphibians. Northern leopard frog populations are found in side canyons of Lake Powell above the fluctuating reservoir elevations (Gloss et al. 2005). These populations in habitat areas located above elevation 3,700 feet msl and would not be impacted by declining elevations of Lake Powell. However, continued fluctuations of Lake Powell elevations would likely limit marsh and riparian vegetation at the shoreline, or only allow it to establish temporarily, thus continuing to limit the potential for leopard frogs and other amphibians to utilize areas below the full pool elevation of Lake Powell.

Action Alternatives.

Fish. Flannelmouth suckers, razorback sucker, Colorado pikeminnow and bonytail chub occur in the inflow areas of the Colorado River and the San Juan River but do not spawn in Lake Powell, and fluctuating reservoir elevations under the action alternatives would be unlikely to affect habitats within the reservoir for any individuals remaining in the reservoir. For fish in the inflow areas, however, lower reservoir elevations would increase the amount of riverine habitat while higher elevations would decrease that habitat. A waterfall would be exposed in the San Juan River when Lake Powell elevation declines to 3,660 feet msl; this waterfall would be a barrier to upstream fish movement and limit the benefits to native fish below that elevation. The changes in the extent of habitat under the action alternatives were estimated using modeling results for March, July and September at the 90th, 50th and 10th percentiles of reservoir elevations (Figures P-WQA-6, P-BCR-1 and P-BCR-2). The 90th percentile elevations are essentially the same under all alternatives and are not analyzed here. The waterfall in the San Juan River would be exposed at the 10th percentile of reservoir elevations under all alternatives, and under all but the Reservoir Storage Alternative at the 50th percentile of reservoir elevations. Thus, benefits of increased riverine habitat to native fish would be limited to the Colorado River and any other smaller tributaries that discharge to Lake Powell.

Preferred Alternative. Lake Powell elevations under the Preferred Alternative could be up to 32 feet higher than under the No Action Alternative until about 2025, and then up to 17 feet lower until about 2060 at the 10th percentile. Reservoir elevations at the 50th percentile would be up to 17 feet lower than under the No Action Alternative until about 2045 at which time reservoir elevations under the Preferred Alternative and the No Action Alternative would become equal. Thus, the Preferred Alternative could provide minor benefits to native fish during those times when Lake Powell elevations are lower than under the No Action Alternative. The probability that the San Juan River waterfall will be exposed under the Preferred Alternative is similar or higher than the probability that the waterfall will be exposed under the No Action Alternative (Figure P-BCR-57).

Basin States Alternative. Under this alternative Lake Powell elevations would be similar to those described for the Preferred Alternative, but the elevations could be slightly (up to two feet) lower. Benefits to native fish would be essentially the same as under the Preferred Alternative. The probability that the San Juan River waterfall will be exposed under the Basin States Alternative is similar or higher than the probability that the waterfall will be exposed under the No Action Alternative (Figure P-BCR-57).

Conservation Before Shortage Alternative. Lake Powell elevations would generally be within one foot of those under the Basin States Alternative, and benefits to native fish would be the same as under the Basin States Alternative. The probability that the San Juan River waterfall will be exposed under the Conservation Before Shortage Alternative is similar to or higher than the probability that the waterfall will be exposed under the No Action Alternative (Figure P-BCR-57).

Water Supply Alternative. Lake Powell elevations would remain higher than those under the No Action Alternative until about 2015 by up to about 21 feet at the 10^{th} percentile. After 2015, the elevations would be up to 65 feet lower than under the No Action Alternative to the end of the modeling period (2060). At the 50^{th} percentile, reservoir elevations would be up to 40 feet lower than under the No Action Alternative from about 2010 until 2042. This alternative would provide the most riverine habitat of all the alternatives considered. The probability that the San Juan River waterfall will be exposed under the Water Supply Alternative is similar to or higher than the probability that the waterfall will be exposed under the No Action Alternative (Figure P-BCR-57).

Reservoir Storage Alternative. Under this alternative, Lake Powell elevations would remain higher than those under the No Action Alternative at the 10^{th} and 50^{th} percentiles until about 2040 or later. Reservoir elevations would be up to 31 feet higher at the 10^{th} percentile and 10 feet higher at the 50^{th} percentile. Thus, the Reservoir Storage Alternative would provide less riverine habitat for native fish than any of the other alternatives, including the No Action Alternative, and result in a minor negative impact. The probability that the San Juan River waterfall will be exposed under the Reservoir Storage Alternative is lower than the probability that the waterfall will be exposed under the No Action Alternative (Figure P-BCR-57).

Birds. Since bald eagles, peregrine falcons, California condor and osprey are all wide-ranging species that utilize many different habitat types in the area, none of the action alternatives differ substantially enough to impact these species at Lake Powell.

Clark's grebe would be impacted predominantly by impacts to marsh habitats. The Water Supply Alternative would have a minor negative impact on vegetation, including marshes at the inflow areas, and the Reservoir Storage Alternative would have a minor-positive impact on vegetation. These impacts may occur during the interim period and the post-interim period. Clark's grebe would not be impacted under the Basin States and Conservation Before Shortage alternatives, and the Preferred Alternative.

Belted kingfishers would be most impacted by potential changes in fish food supplies. Substantial impacts to fish food supplies at Lake Powell are not anticipated under the action alternatives, thus no impacts to belted kingfishers are anticipated.

Amphibians. Northern leopard frog populations are found in side canyon areas located above elevation 3,700 feet msl, therefore, the special status amphibians at Lake Powell would not be impacted under the action alternatives.

Table 4.8-2 summarizes the impacts to special status species under the action alternatives relative to the No Action Alternative.

Table 4.8-2
Lake Powell Special Status Species Impact Summary
Comparison of Action Alternatives to No Action Alternative

Species	Alternative	Impact	Rationale
Razorback sucker, bonytail, Colorado pikeminnow, flannelmouth sucker	Water Supply, Conservation Before Shortage, Basin States, Preferred Alternative	Minor - positive	Reservoir elevations tend to be lower than under the No Action Alternative, increasing riverine conditions at the inflows. Alternatives are more likely to result in exposure of waterfall at San Juan River inflow.
	Reservoir Storage	Minor-negative	Reservoir elevations tend to be higher than under the No Action Alternative, decreasing riverine conditions at the inflows. Lower likelihood of exposure of waterfall at San Juan River inflow.
Bald eagle, peregrine falcon, osprey, California condor, belted kingfisher	All action alternatives	No impact	Wide ranging species and action alternatives do not differ substantially enough to cause indirect impacts.
Clark's grebe	Conservation Before Shortage, Basin States, Preferred Alternative	No impact	Reservoir elevations trend close to those under the No Action Alternative. Impacts to marsh not anticipated.
	Water Supply	Minor - negative	Lower reservoir elevations would have minor negative impact on marshes at the inflows, by increased likelihood of sediment delta headcutting.
	Reservoir Storage	Minor – positive	Higher reservoir elevations would have minor positive impact on marshes at the inflows, by decreased likelihood of sediment delta headcutting.
Mammals	All action alternatives	No impact	Wide-ranging species under the action alternatives do not differ substantially enough to cause indirect impacts.
Northern leopard frog	All action alternatives	No Impact	Known populations above Lake Powell elevation fluctuations.

4.8.4.2 Glen Canyon Dam to Lake Mead

No Action Alternative. Under the No Action Alternative, the magnitude of annual releases from Glen Canyon Dam would remain relatively stable during the interim period, but would be reduced over the later years of the modeling period (90th percentile) as Upper Basin depletions increase (Section 4.3, Figure 4.3-12). The magnitude of monthly releases from Glen Canyon Dam at the 90th percentile also trend downward over the later modeling period in some months (Figures P-BCR-8 through P-BCR-19). Reduced river flows have the potential to affect phreatophytes, marshes, and associated special status species.

Plants. Grand Canyon evening primrose grows on beaches along or near the mainstream Colorado River in the vicinity of Separation Canyon and downstream of Diamond Creek (Reclamation 2000). Lower releases could allow this species to colonize lower beaches exposed during reduced releases. Reduced high flows would favor encroachment of riparian vegetation towards the Colorado River, which would compete with the species. High flows and sediment, which are needed to maintain beach habitats and discourage riparian vegetation encroachment, would continue to be limited in the future. Beach habitat occupied by this species is also utilized by recreationists, which limits Grand Canyon evening primrose establishment.

Invertebrates. The Kanab ambersnail occurs in semi-aquatic habitat associated with springs and seeps. In the Grand Canyon, Kanab ambersnail were originally known to occur only at Vasey's Paradise, a large perennial spring. As part of an effort to recover the species, Kanab ambersnails were translocated from Vasey's Paradise to three other locations. One of the criteria used to select these sites was that it be above the elevation of any potential future flood flows past Glen Canyon Dam. These translocated populations would not be affected by the proposed federal action. The Vasey's Paradise population and vegetation are not flooded until flows exceed 17,000 cfs (Reclamation 2002b). Monthly releases under the No Action Alternative may exceed 17,000 cfs for more than a single year in January, February, May, June, July, August, September, and December at the 90th percentile of releases (Figures P-BCR-8 through P-BCR-19).

Niobrara ambersnail occur in wetland habitats at several locations downstream of Glen Canyon Dam. The population near Lees Ferry is subject to inundation from even moderate flows of the Colorado River (greater than 25,000 cfs), and more than 90 percent of the entire habitat is inundated at 45,000 cfs or more. The Indian Gardens population persisted through the 1996 experimental flow. The population has not been monitored since May 1998 and March 1999 at which time it was abundant. However, flows exceeded 22,000 cfs for extended periods in the summer of 1998 and in May 1999, and no snails were found during habitat searches in those periods. Flows over 20,000 cfs inundate the Indian Gardens habitat (Arizona Game and Fish 2004). Monthly releases under the No Action Alternative may exceed 20,000 cfs at the 90th percentile releases in June, July, August, September, and December, which could cause a loss of wetland vegetation and individual snails.

MacNeill's sootywing skipper is a butterfly found along the Colorado River from southern Utah and Nevada to Arizona and southeastern California (Reclamation 1996b). Communication with Mr. Larry Stevens, the Curator of Ecology at the Museum of Northern Arizona indicated that potential sootywing skipper habitat does not occur upstream of Lake Mead (Stevens 2007, personal communication). Mr. Stevens has performed surveys for various butterflies in northern Arizona. Therefore, no impacts to this species are anticipated in the Grand Canyon.

Fish. Glen Canyon Dam releases would continue to follow the guidelines provided in the 1996 Glen Canyon Dam ROD and under the No Action Alternative; the annual releases have a low probability of declining below 8.23 mafy in the future (Section 4.3, Table 4.3-11). Thus, the extent and physical characteristics of habitat available to native special status fish species (humpback chub, bluehead sucker, flannelmouth sucker) would remain about the same under the No Action Alternative. Little information is available to quantitatively assess the potential effects of monthly release trends on the habitat of these fish. In general, the daily operations and Glen Canyon Dam releases will continue to be consistent with the 1996 Glen Canyon Dam ROD; therefore, the proposed federal action is not expected to result in substantial change in the historically observed daily releases. The potential range in hourly flows of 6,000 to 8,000 cfs would continue to occur with the larger fluctuations in December, January, July, and August (Section 4.3, Tables 4.3-13 and 4.3-14). For example, a study of backwaters in the Grand Canyon (Goeking et al. 2003) found that the number and area of backwaters present varied with river discharge between years at any given site and varied among sites within one year. Given that there is little information to quantitatively correlate differences in annual or monthly releases to impacts on the physical characteristics of special status fish habitat availability, water temperature was selected as a better metric to analyze the impacts to special status fish species. Cold river temperatures and the presence of non-native fish species appear to be the key reasons for declines in populations of some native fish species (e.g., humpback chub) in this river reach.

Glen Canyon Dam release temperatures vary depending on the reservoir elevation and other factors. These release temperatures have been modeled (Section 4.5) and comparisons of the action alternatives to the No Action Alternative are shown on Figures P-BCR-58 through P-BCR-60 in Appendix P. A comparison of modeled river temperatures at selected locations downstream of Glen Canyon Dam is shown on Figures P-BCR-61 through P-BCR-69 and Tables P-BCR-1 through P-BCR-3. Native fish, such as the humpback chub, flannelmouth sucker and bluehead sucker could benefit from warmer water temperatures during their spawning season, because releases of cold water from Lake Powell generally keep water temperatures downstream of Lake Mead below that needed for mainstream spawning to occur except in the vicinity of the Diamond Creek confluence (near Lake Mead). Thus, spawning could only occur in warmer tributaries or backwaters. When Lake Powell elevations fall below about 3,600 feet msl (approximately 10th percentile of elevations), water above 15ºC (59ºF) could be released (Table P-BCR-1). This water may warm by approximately 2ºC (3.6ºF) by the time it reaches the Little Colorado

River confluence and by up to 5ºC (9ºF) near the Diamond Creek confluence (Tables P-BCR-2 and P-BCR-3). At the 10th percentile reservoir elevations, the associated release water temperatures could be warm enough for humpback chub spawning and egg incubation from approximately late May through July near Diamond Creek and in July near the Little Colorado River confluence. Growth could occur from late May through October near Diamond Creek and from July to early October near the Little Colorado River confluence.

Flannelmouth and bluehead suckers are also present in this reach of the Colorado River although they use the warmer tributaries for spawning. Only under low Lake Powell elevations (10th percentile), could suitable temperatures for spawning occur in the river for the bluehead sucker over a portion (about June through October) of their spawning season near the Little Colorado River confluence, and from about May through October near Diamond Creek. Egg incubation requires temperatures about 2ºC (3.6ºF) warmer than for spawning and thus would not occur for up to a month later in the spring, and then primarily near Diamond Creek. At the 50th percentile of reservoir elevations, water temperatures near Diamond Creek could be warm enough for their spawning from about June through October, while elevations at the 90th percentile could result in suitable spawning temperatures from about late May through September. However, temperatures may only be suitable for egg incubation in September at the 50th percentile and periodically in July and August at the 90th percentile. For flannelmouth suckers, water temperatures could be warm enough for spawning in May and June near the Little Colorado River and at Diamond Creek, and in June at Lees Ferry at the 10th percentile of reservoir elevations, while egg incubation could not occur at Lees Ferry, could occur only in June near the Little Colorado River confluence, and in May and June near Diamond Creek. Average water temperatures may be adequate to support growth of these three fish species as summarized in Table 4.8-3. Please refer to Tables P-BCR 1 through P-BCR-3 in Appendix P for further specifics on temperature.

Table 4.8-3
Months When Average Water Temperatures may be Adequate to Support Growth of Fish Under the No Action Alternative

Location	Species		
	Humpback Chub	Flannelmouth Sucker	Bluehead Sucker
Lees Ferry	August and September at the 10th percentile	August and September at the 10th percentile	July through October at the 10th percentile
Downstream of the Little Colorado River	July to early October at the 10th percentile	July to early October at the 10th percentile	Late June through October at the 10th percentile
Diamond Creek	June through October at the 10th percentile July through September at the 50th percentile July to mid September at the 90th percentile	June through October at the 10th percentile July through September at the 50th percentile July to mid September at the 90th percentile	May through October at the 10th percentile June through October at the 50th percentile Late May through September at the 90th percentile

Lake Powell elevations at the 10th percentile level pose a low potential for non-native fish to be released from Lake Powell into the Glen Canyon Dam to Lake Mead river reach. Warmer temperatures in the future under the No Action Alternative at the Diamond Creek confluence could also create conditions that would favor the upstream movement of non-native fish into the Grand Canyon from Lake Mead (e.g. striped and largemouth bass). Warmer river temperatures may also promote the movement of non-native warmwater fish from tributaries that provide inflow to this river reach. The conditions that would favor non-native warmwater species would occur infrequently and would be of short duration. Since many non-native fish prey on native fish, the potentially increased number and or higher feeding rate of non-native warmwater fish could adversely affect native species in this reach through competition or predation. However, many warmwater species of non-native fish are already present in this reach (Section 3.8, Table 3.8-4), and infrequent warmer water temperatures are unlikely to increase their numbers or change the species composition present in the long term. For cold water non-native species, such as brown trout and rainbow trout, the slight increase in water temperature at the 10th percentile would not be expected to affect their populations.

Glen Canyon Dam release temperatures have exhibited a relatively narrow seasonal variability and typically ranged from approximately 7°C to 12°C (44.6ºF to 53.6ºF) between 1990 and 2002 (Appendix F, Figure F-5). After 2002, the temperatures began to increase and the seasonal variability widened and ranged from approximately 8°C to 16°C (46.4ºF to 60.8ºF). Modeled future release temperatures under the No Action Alternative for Lake Powell elevations at the 50th percentile indicate similar potential conditions to those that began in 2002. Modeled release temperatures for Lake Powell elevations at the 10th percentile indicate the possibility of warmer release temperatures in the future (Table P-BCR-1). Warmer average river temperatures could increase the potential for expansion of the Asian tapeworm (*Bothriocephalus acheilognathi*) and anchorworm (*Lernaea cyprinacea*) in the mainstream Colorado River in some years, and could adversely affect native fish, including the humpback chub. Currently, these non-native fish parasites are found primarily in fish in the Little Colorado River and other tributaries and mostly affect native fish. Currently, and under the No Action Alternative, these parasites are less likely to infect fish in the Colorado River because water temperatures are less than optimal for these parasites.

These warmer release temperatures under the No Action Alternative also could affect the aquatic foodbase downstream of Glen Canyon Dam. However, larval chironomids, larval simuliids, *Cladophora* and *Gammarus* are key components of the aquatic foodbase downstream of Glen Canyon Dam and they are tolerant of a wide range in temperature.

The favorable temperature ranges are:

- 8°C to 25°C (46.4°F to 77°F) for larval chironomids (LeSage and Harrison 1980; Laville and Vincon 1991; Sublette et al. 1998; Stevens et al. 1998; Danks 1978; Maier et al. 1990);
- 10°C to 26°C (50°F to78.8°F) for larval simuliids (Becker 1973; Ross and Merritt 1978; Colbo and Porter 1981; Hauer and Benke 1987);
- 13°C to 17°C (55.4°F to 62.6°F) for *Cladophora* (Graham et al. 1982; Wong et al. 1978); and
- 7°C to 29°C (44.6°F to 84.2°F) for *Gammarus* (Smith 1973; Pennak and Rosine 1976; Macneil et al. 1997).

The potential future release temperatures under the No Action Alternative should be similar to or higher than historic release temperatures. The warmer releases that may occur at Lake Powell elevations at the 10th percentile may be warmer than the preference of *Cladophora* in some years, but in general, these potential warmer releases may provide some overall benefit to the aquatic foodbase. This change is anticipated to benefit special status fish that rely on these organisms as their food source. The aquatic foodbase and special status fish populations are expected to remain similar to present conditions.

Mammals. Small-footed myotis, pale Townsend's big-eared bat, Townsend's big-eared bat, spotted bat, Allen's big-eared bat, western red bat, Yuma myotis, occult little brown bat, and greater western mastiff bat all may utilize this river reach. Colorado River flows do not directly impact these species as they generally roost in caves and trees well above potential flow-related impacts. They are not obligate riparian species but may utilize such habitats for hunting. Impacts to these bat species from changes in vegetation, insect populations, from flow and water temperature changes are not likely under the No Action Alternative or the action alternatives. Accordingly, these species are not discussed further for this river reach.

Amphibians. Reduced flows in the future would not affect the spring-fed site of the leopard frog population upstream of Lees Ferry. Inundation of this site occurs at flows of approximately 21,000 cfs. Inundation of this site would potentially occur under the No Action Alternative from June through September, as releases at the 90th percentile in these months could exceed 21,000 cfs (Figures P-BCR-13 through P-BCR-16). Leopard frog reproduction has only been observed in warm (20°C or 68°F) pool and marsh areas, away from the direct influence of the Colorado River (Drost 2005). Colder pools (10°C to 15°C [50°F to 59°F]) that receive water from the Colorado River appear to be avoided. Water temperature at the spring site remains above 15°C (59°F) throughout the year and above 20°C (68°F) for several months (Spence 1996). Most of the warmer pools are located above the 21,000 cfs flow level; larvae and any remaining eggs still present during spring release peak flows would only infrequently be exposed to Colorado River flows. Average temperatures at Lees

Ferry under the No Action Alternative may be at or above 15°C (59°F) for the reservoir elevation at the 10th percentile in July, August, September and October (Table P-BCR-1). At the 50th and 90th percentiles, the average Lees Ferry temperatures are expected to remain predominantly below 15°C (59°F) under the No Action Alternative (Table P-BCR-1). Thus, temperatures would continue to remain below ideal temperatures for leopard frog under the No Action Alternative for most of the time.

Birds. Special status birds in this reach include bald eagle, California condor, southwestern willow flycatcher, Clark's grebe, osprey, belted kingfisher, snowy egret, and American peregrine falcon. For the same reasons that California condor, osprey, belted kingfisher, and American peregrine falcon would be unaffected at Lake Powell, the proposed federal action would not impact these species in the river reach between Glen Canyon Dam and Lake Mead. Steep shorelines limit the establishment of significant marshes in this river reach. It is unlikely that Clark's grebe or snowy egret would be impacted in this reach. Accordingly, only bald eagle and southwestern willow flycatcher are discussed further for this reach.

Bald eagles in this area are primarily winter residents and they feed largely on fish, waterfowl and carrion. Bald eagles feed on trout in the Lees Ferry area, and historically often congregate at Nankoweap Creek. Less than ideal river temperatures for trout may occur in the future in some years; however, despite such potential adverse effects on trout in some years, it is anticipated that trout will remain a food source for bald eagles under the No Action Alternative. Potential increases in river temperatures under the No Action Alternative or action alternatives may result in an increase in the warmwater fish population which could serve as a supplemental food source for bald eagles. The roost or nest sites are not anticipated to be effected in the future under the No Action Alternative.

Southwestern willow flycatchers nest in riparian shrub habitats of saltcedar and willow downstream of Glen Canyon Dam. Reduced flows in the future under the No Action Alternative would tend to continue favoring the establishment of riparian shrub vegetation in this reach. These conditions would benefit southwestern willow flycatchers since they inhabit willow and saltcedar plant communities and have generally benefited from post-Glen Canyon Dam conditions. This trend would continue into the future.

Action Alternatives. Releases under the action alternatives will only deviate from those under the No Action Alternative during the interim period for this river reach. Though conditions causing potential impacts would cease after the interim period, effects on vegetation communities during the interim period may be observed beyond the interim period.

Plants. At the 90th percentile for June Glen Canyon Dam releases, the Reservoir Storage Alternative may have spill avoidance releases that would exceed those under the No Action Alternative. June releases are the highest for the year at the

90th percentile and were used to gage potential impacts to Grand Canyon primrose habitat (Figure P-BCR-11 in Appendix P). These higher releases have a greater potential to adversely impact beach habitat and thus Grand Canyon evening primrose. These high flows may approach 28,000 cfs during the interim period, which is still less than recent experimental releases that have exceeded 40,000 cfs, so the impacts should be negligible. Releases under the Basin States, Conservation Before Shortage, and Water Supply alternatives, and the Preferred Alternative, sometimes exceed those under the No Action Alternative at the 90th percentile, but typically in months that are not the annual high release months, and the releases remain relatively close to those under the No Action Alternative. Therefore, these four action alternatives are not expected to result in impacts to Grand Canyon evening primrose. There could potentially be a minor negative impact on Grand Canyon primrose under the Reservoir Storage Alternative due to occasional spill avoidance releases discussed above.

Invertebrates. Kanab ambersnail habitat is impacted when flows exceed 17,000 cfs. During the interim period, flows under the Basin States and Conservation Before Shortage alternatives, and the Preferred Alternative, may exceed the flows observed under the No Action Alternative and 17,000 cfs in April and May at the 90th percentile (Figures P-BCR-11 and P-BCR-12). There are only a few isolated years under the other two action alternatives when flows are above those under the No Action Alternative and 17,000 cfs in these months. July releases at the 90th percentile under the Basin States and Conservation Before Shortage alternatives, and the Preferred Alternative, would be above 17,000 cfs, but lower than under the No Action Alternative, therefore possibly inundating less Kanab ambersnail habitat in this month. Flows under the Basin States and Conservation Before Shortage alternatives, and the Preferred Alternative, could also be above those under the No Action Alternative and 17,000 cfs at the 50th percentile in August, thus inundating more Kanab ambersnail habitat (Figure P-BCR-15). There could be flows under the Water Supply Alternative at the 50th percentile that are higher than those under the No Action Alternative and above 17,000 cfs in August, though this is the only month where this may occur under the Water Supply Alternative, and most of the time flows would be similar to those under the No Action Alternative when above 17,000 cfs (Figure P-BCR-15). In June, occasional spill avoidance releases under the Reservoir Shortage Alternative up to 4,000 cfs above those under the No Action Alternative (approaching 27,000 cfs) would flood additional Kanab ambersnail habitat (Figure P-BCR-13). The Kanab ambersnail population at Vasey's Paradise survived and recovered from innumerable similar and higher flows during the pre-Glen Canyon Dam era, and has survived six flows in excess of 45,000 cfs during the post-Glen Canyon Dam era (1965, 1980, and 1983 through 1986). Flows above 17,000 cfs could be produced under the Reservoir Storage Alternative, exceeding the flows observed under the No Action Alternative in December.

At the 10th percentile, all action alternatives may have lower releases from Glen Canyon Dam in some months. Though it is not possible to accurately project under which months those releases would occur or how many months in a row this would occur, these lower releases would allow spring vegetation at Vasey's Paradise to develop lower down on the canyon. Ambersnails could move into this lower habitat if releases are lower for long enough for such habitat to develop. When releases rise again, this habitat would be inundated and could impact ambersnails. However, this type of impact also occurs under the No Action Alternative. Accordingly, these potential impacts are expected to be minor, and the population that occurs above the zone of fluctuating releases should not be impacted under the action alternatives. Reclamation has consulted with FWS (FWS 1995; FWS 2002; Department 2004) on the effects of Glen Canyon Dam operations on the Vasey's Paradise population.

When releases under the Reservoir Storage Alternative exceed those under the No Action Alternative and 20,000 cfs in June and December at the 90th percentile, the Reservoir Storage Alternative would have a greater potential for a negative impact on Niobrara ambersnail habitat. In the months of June through September, and December, when Glen Canyon Dam releases under the No Action Alternative and the action alternatives are above 20,000 cfs at the 90th percentile, the magnitude of releases under the Basin States, Conservation Before Shortage, and Water Supply alternatives, and the Preferred Alternative, are equal to or less than those under the No Action Alternative. Thus, there is the potential for a positive impact on Niobrara ambersnail habitat during those months.

Fish. Lake Powell releases would be altered under the action alternatives, thus affecting sediment transport, water temperatures, and the potential range of hourly flows. Sediment transport is directly related to river flow, and annual releases below 8.23 mafy (as under the No Action Alternative) would transport less sediment out of the Colorado River and into Lake Mead while higher releases would transport more sediment (Section 4.5, Table 4.5-9). Temperature of the water released from Lake Powell depends on the reservoir elevation and various other conditions, with potentially warmer water being released when reservoir elevations are lower. As described for the No Action Alternative, daily fluctuations in river flows occur throughout the year. The potential range of hourly flows would be reduced, but not eliminated, in some months when annual releases are lower than 8.23 maf, and the potential range would increase in some months when annual releases are higher than 8.23 maf. Water temperatures corresponding to reservoir elevations at the 90th percentile are the same or nearly the same under the action alternatives as under the No Action Alternative; thus, no impacts would occur relative to the No Action Alternative at higher Lake Powell elevations. Temperature impacts of Lake Powell releases when lake elevations are at the 10th and 50th percentiles are described below for the action alternatives.

Preferred Alternative. Annual Glen Canyon Dam releases under the Preferred Alternative could be less than 8.23 mafy, with an approximately 9.7 percent higher probability than those under the No Action Alternative (Section 4.3, Table 4.3-11), which would reduce the transport of sediment out of the river and into Lake Mead (Section 4.5). Releases above the minimum objective release of 8.23 mafy would occur with a nearly 17 percent higher probability under the Preferred Alternative than under the No Action Alternative. These higher releases would transport more sediment out of the river. The probability of releases above nine mafy (9.01 mafy to above 16 mafy) is very similar (differ by approximately 0.5 percent) to the No Action Alternative and thus the effect on sediment transport would also be very similar to the No Action Alternative (Table 4.3-11). The impacts of these changes in sediment transport on instream habitat suitability and quantity for native fish are unknown, though higher rates of sediment transport could reduce the amount of fine sediment within the channel over time.

Average water temperatures at Lees Ferry under the Preferred Alternative would be the same as under the No Action Alternative at the 10th and 50th percentiles, resulting in no impact (Table P-BCR-1). Near the Little Colorado River confluence, average water temperatures would be up to 1ºC (1.8°F) warmer at the 10th percentile and range from 1ºC (1.8ºF) warmer to 2ºC (3.6ºF) colder than the 50th percentile of reservoir elevations (Table P-BCR-2). At Diamond Creek, the average temperatures would be less than 1.5ºC (2.7ºF) warmer at the 10th percentile and range from 1ºC (1.8ºF) warmer to 1ºC (1.8ºF) colder than the 50th percentile of reservoir elevations (Table P-BCR-3). These small changes in water temperature would have little effect on native fish spawning, egg incubation, and growth. The warmer temperatures at the 10th percentile would increase the length of time that suitable temperatures are present for spawning of native fish (humpback chub, flannelmouth sucker, and bluehead sucker) from near the Little Colorado River to Lake Mead river reach while the slightly lower temperatures from September through March at the 50th percentile would decrease the spawning season and growth in October for the bluehead sucker near Diamond Creek. The cooler water temperatures would not affect spawning or growth of the humpback chub or flannelmouth sucker.

The warmer temperatures at the 10th percentile could also increase growth of the native species and their food base organisms, which could provide a minor positive impact to special status fish. The preferred temperature for invertebrates described above would not be exceeded by the warmer temperatures at the 10th percentile of reservoir elevations, although the preferred temperature for *Cladophora* could be exceeded for a longer time relative to those under the No Action Alternative. These extensions of warm temperatures could occur in early July and late September near the Little Colorado River confluence and in early June and early October near Diamond Creek. However, *Cladophora* should remain present despite the potential for temperatures above its preferred thermal range, and invertebrates may benefit from warmer temperatures overall. The predominance of *Cladophora* downstream of Glen Canyon Dam appears to be linked to water clarity; substantial effects on river clarity trends in the reach between Glen Canyon Dam and Lake Mead are not expected under the Preferred Alternative.

The small increase in water temperatures at the 10th percentile under the Preferred Alternative relative to those under the No Action Alternative also could benefit the non-native fish species present in the Colorado River by allowing earlier reproduction and increased growth in those years when such temperature increases occur. Furthermore, the small increase in temperature in some years has a low potential to increase movement of nonnative species into the river from Lake Mead (e.g., striped and largemouth bass) and from tributaries that provide inflow to the river in the years that such temperature increases occur, as discussed for the No Action Alternative. Since many non-native fish prey on native fish, the potentially increased number or feeding activity of non-native fish could adversely impact the native fish in this reach. However, many species of non-native fish are already present in this reach and the infrequent, slightly warmer temperatures are unlikely to significantly increase their abundance or species composition in the long term. Passage of non-native fish from Lake Powell to the Colorado River in releases under low reservoir elevations would have a slightly higher probability of occurring at the 10^{th} percentile under the Preferred Alternative as compared to the No Action Alternative because lake elevations would generally be up to 13 feet lower under the Preferred Alternative from about 2025 to 2060 (Figures P-WQA-6, P-BCR-1, and P-BCR-2). Only some of these fish would survive this passage, resulting in few additional fish in the river to interact with native fish, which could result in a minor negative impact to special status fish.

Warmer river temperatures could increase the potential for expansion of the Asian tapeworm and anchorworm in the mainstream Colorado River in years when Lake Powell elevations are at the 10^{th} percentile level (Table P-BCR-3). Water temperatures could be above 20ºC (53.8°F) for the same three months as under the No Action Alternative near Diamond Creek in those years. The level of effect is unknown but expected to be negligible considering the low frequency of warmer water occurrences and the small increase in temperature that could occur under the Preferred Alternative. Glen Canyon Dam releases made when Lake Powell elevations are at the 50^{th} percentile of elevations result in approximately the same to cooler downstream temperatures that are always below 20°C (53.8°F) (Table P-BCR-3).

Releases from Glen Canyon Dam of less than 8.23 mafy could also result in a reduction in the potential range of hourly flows in the Colorado River (Section 4.3, Tables 4.3-13 and 4.3-14). The reduction in this potential range at a release rate of 7.48 mafy could be as much as 1,000 to 2,000 cfs in April, and October through December. This level of reduction would be unlikely to occur under the No Action Alternative and would have about an eight percent chance of occurring under the Preferred Alternative (Section 4.3, Table 4.3-11). For release rates of nine mafy, the potential range of hourly flows could be 2,000 cfs greater in June and September, and this annual release volume would have a higher probability of occurring under the Preferred Alternative than under the No Action Alternative (Section 4.3, Tables 4.3-11, 4.3-13 and 4.3-14). Because the range of hourly flows would change and the probability of this level of annual release is higher than under the No Action Alternative, an increased range of flows could impact habitat conditions for native fish.

Basin States Alternative. The probability of annual Glen Canyon Dam releases above nine maf and below 8.23 maf would be essentially the same as described for the Preferred Alternative (Section 4.3, Table 4.3-11), and the alteration of sediment transport would be the same. Average water temperatures in the Colorado River at Lees Ferry under the Basin States Alternative would be up to 1.9ºC (3.4ºF) warmer from March through August and up to 1.1ºC (2ºF) colder from October through February than under the No Action Alternative at the 10th percentile (Table P-BCR-1). At the 50th percentile, the average water temperatures would be up to 0.8ºC (1.4ºF) warmer from March through October and up to 1.4ºC (2.7ºF) colder in January and February than under the No Action Alternative. Average water temperatures at the 90th percentile would be within 0.5ºC (0.9ºF) of those under the No Action Alternative. These small changes in water temperature would not affect bluehead sucker and flannelmouth sucker spawning, egg incubation, and growth (humpback chubs are not in this reach). Average water temperatures would be the same at the Little Colorado River confluence and Diamond Creek as under the Preferred Alternative, and the impacts would also be the same (Tables P-BCR-2 and P-BCR-3). The probability of annual releases less than 8.23 maf would be approximately the same under the Basin States Alternative as under the Preferred Alternative with negligible impacts on native fish habitat (Section 4.3, Table 4.3-11).

Conservation Before Shortage Alternative. The probability of annual Glen Canyon Dam releases above nine maf and below 8.23 maf would be essentially the same as described for the Preferred Alternative (Section 4.3, Table 4.3-11), and the alteration of sediment transport would be the same. Average water temperatures would be the same as under the Basin States Alternative, and thus, impacts would also be the same. The probability of annual releases less than 8.23 maf would be approximately the same under the Conservation Before Shortage Alternative as under the Preferred Alternative and the Basin States Alternative, with negligible impacts on native fish habitat.

Water Supply Alternative. Annual Glen Canyon Dam releases of less than 8.23 mafy could result approximately 9.5 percent more frequently under the Water Supply Alternative than under the No Action Alternative (Section 4.3, Table 4.3-11), similar to the Preferred Alternative. During those times, sediment transport out of the Colorado River and into Lake Mead would be reduced. Higher annual release rates (between 9.01 and greater than 16 mafy) could occur with a frequency of about 24 percent higher under the Water Supply Alternative than under the No Action Alternative. These higher releases would transport more sediment into Lake Mead. The effects of these changes in release rates on habitat suitability and quantity for native fish are unknown.

Under the Water Supply Alternative, the Colorado River could be up to 2ºC (3.6ºF) warmer than under the No Action Alternative at the 10th percentile of elevations in the river reach extending to Lake Mead (Tables P-BCR-1 through P-BCR-3). Temperature changes throughout the river at the 50th percentile would range from about 1ºC (1.8ºF) warmer to 2ºC (3.6ºF) colder as described for the Preferred

Alternative. These changes in temperature at the 50th percentile are about the same for those under the Preferred Alternative, and impacts to native fish would be the same as described for the Preferred Alternative. At Lees Ferry, suitable spawning and egg incubation temperatures at the 10th percentile could be present in July for humpback chub and in June for flannelmouth sucker. The bluehead sucker could spawn in August and September compared to no spawning under the No Action Alternative. Near the Little Colorado River confluence, all three species could spawn a month earlier plus a month later for the bluehead sucker. Near Diamond Creek, humpback chubs could spawn a month earlier (May) than under the No Action Alternative while the other two species could spawn a few weeks earlier.

Under the Water Supply Alternative, water temperatures may support growth of all three species for one to two months longer in the Glen Canyon Dam to Lake Mead river reach than under the No Action Alternative at the 10th percentile of reservoir elevations. The cooler water temperatures in the fall and winter at the 50th percentile of elevation releases would not impact growth of the humpback chub or flannelmouth sucker but would not support growth of bluehead sucker in October near Diamond Creek.

The warmer water temperatures under the Water Supply Alternative would also benefit existing populations of non-native, non-game warmwater species such as carp, fathead minnows, catfish, and red shiner. This could increase competition for resources or predation on the native species which would have a negative impact on the native species, thereby at least partially offsetting the benefits of the warmer temperatures on the native species. Increasing water temperatures by up to about 2ºC (3.6°F), primarily during the spring and summer, could benefit non-native species as described for the Preferred Alternative, but a long-term increase in their population size and species composition is unlikely to occur due to the small, infrequent temperature increases. There is also a greater probability of providing favorable conditions for the migration of the Asian tapeworm and anchorworm into the mainstream of the Colorado River under the Water Supply Alternative than under the No Action Alternative because the Water Supply Alternative results in the lowest Lake Powell elevations, and thereby potentially warmer Glen Canyon Dam release temperatures. Based on the temperature modeling, however, average monthly water temperatures above 20ºC (68°F) could occur only near Diamond Creek from late June through September. These temperatures would be less than 2ºC (3.6°F) warmer than under the No Action Alternative and the duration would be about one month longer. Thus, increased parasitism of native fish in the Colorado River would have a low probability of occurring.

The passage of non-native fish through Glen Canyon Dam may occur as the lake elevations drop, and the greatest potential for this to occur is under the Water Supply Alternative, which tends to have lake elevations that are considerably lower than under the No Action Alternative after 2015 (Section 4.6, Figure 4.6-1; Figures P-BCR-1 and P-BCR-2).

Reservoir Storage Alternative. Annual Glen Canyon Dam releases of less than 8.23 mafy could result approximately 17 percent more frequently under the Reservoir Storage Alternative than under the No Action Alternative (Section 4.3, Table 4.3-11). When releases are below 8.23 mafy, sediment transport out of the Colorado River and into Lake Mead would be reduced. The probability of releases higher than nine mafy is similar to the No Action Alternative but about 1.5 percent more likely (Section 4.3, Table 4.3-11). The lower release rates would remove less sediment from the river system in those years when they occur. The effects of reduced sediment transport on habitat suitability and quantity of native fish habitat is unknown.

Under the Reservoir Storage Alternative, average monthly water temperatures in the Colorado River would be up to 0.8 ºC (1.4 ºF) warmer in some months and up to 2.8 ºC (5.0 ºF) colder in some months at the 10^{th} and 50^{th} percentiles relative to the No Action Alternative. At the 10^{th} percentile, the water could be too cold for growth of the humpback chub and flannelmouth sucker at Lees Ferry (Table P-BCR-1), and the number of months with adequate growth temperatures for the bluehead sucker would be reduced by one month (July) compared to the No Action Alternative. Near the Little Colorado River confluence, water temperatures would be too cold for humpback chub spawning during July, the only month when water would be warm enough for spawning under the No Action Alternative (Table P-BCR-2). The flannelmouth sucker growing season would be about one month shorter as would the bluehead sucker spawning season. Changes in water temperature near Diamond Creek at the 10^{th} percentile would not affect spawning or growth of the humpback chub, flannelmouth sucker, or bluehead sucker (Table P-BCR-3). At the 50^{th} percentile, the changes in water temperature compared to the No Action Alternative would not affect spawning or the growing season of these three species at Lees Ferry or near the Little Colorado River confluence. Near Diamond Creek, however, bluehead sucker growing season would be reduced by about one month due to the colder temperatures in October.

Average monthly water temperatures would be colder beginning in June or July at the 10^{th} percentile and would generally be less than 0.5ºC (0.9 ºF) warmer in the spring and fall (except at Lees Ferry where temperatures would be colder) compared to the No Action Alternative. At the 50^{th} percentile, average monthly water temperatures would be up to 0.5 ºC (0.9ºF) warmer in the spring to early summer (three to four months) and colder in the other months under the Reservoir Storage Alternative relative to the No Action Alternative. Because consistently warmer temperatures would not occur under the Reservoir Storage Alternative, changes in warmwater non-native fish populations would not be expected to occur. The cooler summer temperatures would provide less favorable conditions for migration of Asian tapeworm and anchorworm the into mainstream Colorado River than under the No Action Alternative. Based on the temperature modeling, average monthly water temperatures above 20 ºC (68 ºF) could occur only near Diamond Creek in July under the Reservoir Storage Alternative.

There is also a low potential for non-native fish passage from Lake Powell under the Reservoir Storage Alternative because the lake elevations are generally higher than those under the No Action Alternative (Section 4.6, Figure 4.6-1; Figures P-BCR-1 and P-BCR-2). Reductions in the potential range of hourly flows would also occur as described for the Preferred Alternative, and these reductions could occur a little more frequently because reduced releases could occur more frequently under the Reservoir Storage Alternative.

Amphibians. Because leopard frogs preferentially select warmer water for breeding, as such, the occasional introduction of warmer water would presumably benefit them. Lake Powell releases and average temperatures at Lees Ferry at the 50th percentile of reservoir elevations would always be colder than 15°C (59°F) under the alternatives, so there would be no temperature impact to leopard frogs at the 50th percentile of Lake Powell elevation releases (Table P-BCR-1). Average Lees Ferry temperatures of 15°C (59°F) or above may result under the No Action Alternative and the action alternatives, except under the Reservoir Storage Alternative, starting in July at the 10th percentile of Lake Powell elevations and continuing through October, which would provide a thermal benefit from less thermal shock to eggs and larvae (Table P-BCR-1). Under the Reservoir Storage Alternative average water temperatures would not reach 15ºC (59°F) until July, a minor negative impact compared to the No Action Alternative. Following Atkinson (1996), it is possible that the warmer water would increase the rate of metamorphosis but result in a smaller size class of metamorphs.

Flows under the action alternatives may inundate the Lees Ferry leopard frog habitat from June through September at the 90th percentile of Glen Canyon Dam releases (Figures P-BCR-11 through P-BCR-15). During the interim period, these high releases may differ from those under the No Action Alternative. There are no differences relative to the No Action Alternative beyond the interim period at these higher-end releases. Occasional June spill avoidance releases under the Reservoir Storage Alternative, when above 21,000 cfs, may exceed the releases that occur under the No Action Alternative by up to 4,000 cfs (Figure P-BCR-11). Though these higher flows would presumably have a greater impact on the Lees Ferry leopard frog habitat, they would occur in years when flows under the No Action Alternative may also exceed 21,000 cfs, so the inundation impacts would be similar, though the habitat may be under deeper water than under the No Action Alternative. The Basin States, Conservation Before Shortage, and Water Supply alternatives, and the Preferred Alternative, may have lower flows at the 90th percentile in July and September, but still above 21,000 cfs, so the inundation impacts would be similar to those under the No Action Alternative, though the habitat may be under shallower water (Figures P-BCR-13 and P-BCR-15).

Birds. Bald eagles may be indirectly impacted by alterations to the trout fishery. At the 10th percentile, the greatest potential temperature related impact to the trout fishery would occur under the Water Supply Alternative (Table P-BCR-1). However, these potential temperature effects are mitigated by the trout’s ability to move to thermal refugia at different Colorado River stages and because warmer temperatures will only occur in some years. Accordingly, despite these potential occasional changes in temperature, population-level impacts to the Lees Ferry trout fishery are not anticipated as a result of the proposed federal action. Warmer river flow temperatures may affect trout in some years and may benefit warmwater fish which could provide an alternative food source for bald eagles. The levels of potential flow impacts to vegetation communities anticipated under some alternatives are not likely to cause a significant impact to bald eagles. Given their mobility, varied diet, and lack of impacts to roost or nest sites, none of the action alternatives would substantially impact bald eagles that inhabit areas downstream of Glen Canyon Dam.

Though higher flows, particularly under the Reservoir Storage Alternative in June (Figure P-BCR-11), may flood riparian habitats, these flows would not be expected to impact southwestern willow flycatcher populations. Nests are typically above the 45,000 cfs stage. Reclamation concluded that long term effects of the 42,000 to 45,000 cfs test flow in 2002 on southwestern willow flycatcher habitat are expected to be beneficial (Reclamation 2002b). Saltcedar are expected to withstand potential increased flows that may occur under the Reservoir Storage Alternative peaks in June. Flows under the Basin States, Conservation Before Shortage, and Water Supply alternatives, and the Preferred Alternative, are higher than flows under the No Action Alternative by up to a few thousand cfs in some months, though these higher flows would not inundate southwestern willow flycatcher nests. When flows under the action alternatives (all at least in some months) are lower than those under the No Action Alternative (typically at the 10^{th} percentile), these flows would not be expected to kill saltcedar, which is what southwestern willow flycatcher typically nest in downstream of Glen Canyon Dam.

Under the Basin States, Conservation Before Shortage, and Water Supply alternatives, and the Preferred Alternative, releases at the 10^{th} percentile would be lower from April through September (Figures P-BCR-9 through P-BCR-15), and under the Reservoir Storage Alternative, releases at the 10^{th} percentile would be lower from June through September (Figures P-BCR-11 through P-BCR-15). These lower releases may reduce moist soil conditions below nesting sites, which is a preference of southwestern willow flycatcher. Lack of moist soil below nest sites may degrade the habitat for this species, at least temporarily. A lack of moist soil conditions is more likely under the action alternatives than under the No Action Alternative at the 10^{th} percentile of monthly releases, because there could be an annual release less than 8.23 maf under the action alternatives under certain conditions. Releases at the 50^{th} percentile under the action alternatives would be at or above those under the No Action Alternative during the southwestern willow flycatcher nesting season. Therefore, potential impacts to southwestern willow flycatcher are only expected to occur coincident with lower releases which may occur in a few years.

Table 4.8-4 displays impacts to special status species in the Glen Canyon Dam to Lake Mead reach under the action alternatives relative to the No Action Alternative.

Table 4.8-4
Glen Canyon Dam to Lake Mead Reach Special Status Species Impact Summary
Comparison of Action Alternatives to No Action Alternative

Species	Alternative	Impact	Rationale
Mammals	All action alternatives	No impact	Flow differences not expected to rise to the level of indirectly impacting special status mammals.
Grand Canyon evening primrose	Conservation Before Shortage, Basin States, Water Supply, Preferred Alternative	No impact	Similar to 90th percentile releases under the No Action Alternative.
	Reservoir Storage	Minor-negative	Higher 90th percentile releases than under the No Action Alternative may affect beach habitat more than the No Action Alternative. Interim period only. High flows still less than experimental releases.
Kanab ambersnail	All action alternatives	Minor-negative	90th percentile releases exceed the No Action Alternative and 17,000 cfs. Interim period only. High flows still less than past high flows from which Kanab ambersnail has recovered.
Niobrara ambersnail	Reservoir Storage	Minor-negative	90th percentile releases exceed the No Action Alternative and 20,000 cfs. Interim period only. High flows still less than past high flows.
	Conservation Before Shortage, Basin States, Water Supply, Preferred Alternative	Minor-positive	When above 20,000 cfs at the 90th percentile of releases, impacts under the action alternatives are equal or less than those under the No Action Alternative.
Humpback chub, bluehead sucker, flannelmouth sucker	Conservation Before Shortage, Basin States, Preferred Alternative	Minor-positive to negative No impact No impact	Release temperatures similar to or slightly higher than those under the No Action Alternative with warming a little earlier in the year, resulting in small benefit to native fish, non-native fish, and fish parasites. Slightly less sediment loss due to reduced annual releases in some years and greater loss in some years due to higher annual releases. Reduction in range of hourly flows in some months during reduced releases and increased range during higher releases.
	Reservoir Storage	Minor-negative No impact No impact	Release temperatures slightly higher to or lower than those under the No Action Alternative with warmer temperatures primarily in the spring to early summer and cooler temperatures the remainder of the year, resulting in a shorter growing season for native fish and no benefit to non-native fish and fish parasites. Slightly less sediment loss due to reduced annual releases in some years and greater loss in some years due to higher annual releases. Reduction in range of hourly flows in some months during reduced releases and increased range during higher releases.

Table 4.8-4
Glen Canyon Dam to Lake Mead Reach Special Status Species Impact Summary
Comparison of Action Alternatives to No Action Alternative

Species	Alternative	Impact	Rationale
	Water Supply	Minor-positive to negative No impact No impact	Release temperatures similar to or slightly higher than those under the No Action Alternative with warming a little earlier in the year, resulting in small benefit to native fish, non-native fish, and fish parasites. Slightly less sediment loss due to reduced annual releases in some years and greater loss in some years due to higher annual releases. Reduction in range of hourly flows in some months during reduced releases and increased range during higher releases.
Northern leopard frog	Conservation Before Shortage, Basin States, Water Supply, Preferred Alternative	No Impact	Average river temperatures higher than 15°C (59°F) at the 10th percentile of releases would occur in the same months as under the No Action Alternative. High flows would inundate Lees Ferry frog habitat, but the habitat is inundated also under the No Action Alternative.
	Reservoir Storage	Minor-negative	Average river temperatures higher than 15°C (59°F) at the 10th percentile of releases would occur one month later than under the No Action Alternative. High flows inundate Lees Ferry frog habitat; the habitat is inundated also under the No Action Alternative.
Bald eagle	All action alternatives	No impact	Substantial indirect impacts through impacts to food sources not anticipated. Wide ranging species with the varied diet. Impacts to roost or nest sites are not anticipated.
Southwestern willow flycatcher	All action alternatives	Minor-negative	Lower flows at the 10th percentile may impact southwestern willow flycatcher but not saltcedar. Lower flows at the 10th percentile may reduce moist soil conditions below nest sites and degrade habitat value. Occurs under all action alternatives at the 10th percentile of releases.

4.8.4.3 Lake Mead

No Action Alternative.

Birds. Lake Mead elevations may exhibit a slight downward trend into the future under the No Action Alternative (Figures P-BCR-3 and P-BCR-4). This trend would have effects on the riparian and marsh habitats at the inflow areas and on the special status bird species that utilize such habitats for breeding, roosting or foraging. The downward trend of Lake Mead elevations would increase the potential for dewatering and sediment delta headcutting, which would adversely affect riparian and marsh vegetation that has developed on the sediment deltas. This adverse effect on the sediment delta in turn has the greatest potential to adversely affect special status birds that utilize cottonwood-willow and marsh habitats such as bald eagle, southwestern willow flycatcher, yellow-billed cuckoo, long-eared owl, American kestrel, osprey, Cooper's hawk, American peregrine falcon, northern harrier, Clark's grebe, snowy egret, Yuma clapper rail, California black rail, American bittern, western least bittern, great egret, white-faced ibis, belted kingfisher, and American white pelican.

Mammals. Townsend's big-eared bat, pale Townsend's big-eared bat, occult little brown bat, spotted bat, Allen's big-eared bat, western red bat, Yuma myotis, western yellow bat, cave myotis, greater western mastiff bat, and small-footed myotis may utilize the riparian and marsh habitats at Lake Mead for foraging and roosting. These bat species utilize a variety of habitats for roosting, including dead trees, so potential vegetation effects should not substantially impact roosting opportunities for these bats. Substantial effects to insect food sources for special status bats are not expected because Lake Mead elevations will continue to experience annual fluctuations and the downward trend will be gradual over time. The Yuma hispid cotton rat or Colorado River cotton rat would not be impacted under the No Action Alternative as these species are found further south along the lower Colorado River.

Amphibians. Relict leopard frog populations at Lake Mead would not be affected under the No Action Alternative because the known populations are at springs located above the influence of Lake Mead's elevation fluctuations. Colorado River toads are not known to exist at Lake Mead. Special status amphibians at Lake Mead are not expected to be affected under the No Action Alternative.

Plants. Sticky buckwheat, Geyer's milkvetch and Las Vegas bear poppy all occur at the shorelines of Lake Mead. These species typically benefit from lower reservoir elevations that expose additional shoreline habitat. Lake Mead would continue to experience elevation fluctuations under the No Action Alternative, which would result in varied levels of exposed shoreline through the year. The general downward trend of Lake Mead elevations that may occur under the No Action Alternative would generally result in increased shoreline exposure which would benefit these species while this trend continues.

Invertebrates. MacNeill's sooty-winged skipper is not known to exist at Lake Mead and would thus not be affected under the No Action Alternative. Potential vegetated habitats below the full pool elevation of Lake Mead are ephemeral and change over time as the lake elevation fluctuates.

Fish. Under the No Action Alternative, special status fish would experience Lake Mead elevations less than 1,120 feet msl all year at the 50^{th} and 10^{th} percentiles. The 90^{th} percentile of reservoir elevations is generally projected to be near or above 1,200 feet msl all year. Modeled Lake Mead elevations for end of February, March, April, July, and September are provided in Figures P-BCR-3 through P-BCR-7. Razorback sucker spawning is known to occur between elevations 1,120 feet msl and 1,150 feet msl from January through June, and as elevations have dropped within this range and exposed areas used for spawning in earlier years, the fish have moved their spawning to nearby suitable areas (Albrecht and Holden 2006). Based on the modeled reservoir elevations under the No Action Alternative, the preferred spawning sites would be out of the water over 50 percent of the time during the spawning season. Razorback sucker would have to move to suitable spawning habitat at lower reservoir elevations, where such habitat is available.

Action Alternatives. Lake Mead elevations will deviate from those under the No Action Alternative during the interim period and the post-interim period.

Birds. No impacts to riparian or marsh habitats are anticipated at Lake Mead under the Basin States and Conservation Before Shortage alternatives, and the Preferred Alternative, because Lake Mead elevations under these action alternatives trend close to those under the No Action Alternative. Therefore, special status bird species at Lake Mead would not be impacted under these action alternatives.

Minor negative impact to cottonwood-willow, saltcedar and marsh vegetation at Lake Mead inflow areas and sediment deltas would result under the Water Supply Alternative. These negative impacts would be caused by lower reservoir elevations, increased dewatering of sediment deltas, and delta erosion. However, depending on duration of the lower elevations, the impact may be offset by new vegetation growing on the newly exposed sediments. These impacts to vegetation would cause minor negative impact to those special status bird species that forage, breed or roost in cottonwood-willow, saltcedar and marsh habitats. Potentially impacted species include: southwestern willow flycatcher, Clark's grebe, snowy egret, Yuma clapper rail, yellow-billed cuckoo, California black rail, American bittern, western least bittern, great egret, white faced ibis, long-eared owl, American kestrel, osprey, northern harrier, Cooper's hawk, bald eagle, belted kingfisher, American peregrine falcon, and American white pelican.

Minor positive impact to vegetation at Lake Mead would result under the Reservoir Storage Alternative, primarily at the inflow areas and sediment deltas. These positive impacts would be caused by higher reservoir elevations than under the No Action Alternative, and thus result in less potential for dewatering or sediment delta headcutting than under the No Action Alternative. Positive impacts are anticipated for the southwestern willow flycatcher, Clark's grebe, snowy egret, Yuma clapper rail, yellow-billed cuckoo, California black rail, American bittern, western least bittern, great egret, white faced ibis, long-eared owl, American kestrel, osprey, northern harrier, Cooper's hawk, bald eagle, belted kingfisher, American peregrine falcon, and American white pelican.

Mammals. Impacts to special status mammals at Lake Mead are not expected to occur for the same reasons provided for the No Action Alternative discussion.

Amphibians. Impacts to special status amphibians at Lake Mead are not expected for the reasons described for the No Action Alternative.

Plants. Sticky buckwheat, Geyer's milkvetch and Las Vegas bear poppy all occur at the shorelines of Lake Mead. These species typically benefit from lower reservoir elevations that expose additional shoreline habitat. These species would not be impacted under the Basin States and Conservation Before Shortage alternatives, and the Preferred Alternative, since reservoir elevations trend close to the elevations under the No Action Alternative. A minor beneficial impact would be provided to these species under the Water Supply Alternative through lowered elevations.

A minor negative impact to these species would be caused under the Reservoir Storage Alternative through raised elevations and inundation of shoreline habitats.

Invertebrates. MacNeill's sooty winged skipper is not known at Lake Mead, and would thus not be impacted under any action alternative. Habitats below the full pool elevation of Lake Mead are ephemeral and are periodically inundated and desiccated as the reservoir elevation changes.

Fish. Effects on razorback sucker spawning is the primary issue to be addressed for the alternatives. Since their spawning season is from January through June, modeling results for February, March, and April were used in the analysis. Lowered reservoir elevations are known to allow vegetation to grow on the exposed lake bed, and these areas are then inundated at higher reservoir elevations. These submerged vegetated areas can provide cover for juvenile razorback suckers and enhance their survival. Thus, periodic lower reservoir elevations may have some benefits (minor positive impact) to razorback sucker spawning success and recruitment after the reservoir elevations rise and inundate the vegetation growing on the edge under all alternatives. In addition, reservoir elevations would be nearly the same under all alternatives at the 90^{th} percentile, resulting in no impacts relative to the No Action Alternative.

Preferred Alternative. Lake Mead elevations at the 50^{th} percentile would be above those under the No Action Alternative through 2026 and then below until 2038 when the elevations become the same as those under the No Action Alternative (Figures P-BCR-3, P-BCR-4 and P-BCR-5). The maximum elevation would be 1,122 feet msl in February and the minimum would be 1,090 feet msl in April. Reservoir elevations may vary from 25 feet above to 13 feet below those under the No Action Alternative. The Preferred Alternative would have minor positive impacts when elevations are above those under the No Action Alternative (to 2026) to minor negative impacts when elevations are below those under the No Action Alternative. Reservoir elevations at the 10^{th} percentile would vary from a little above to a little below those under the No Action Alternative until 2017 when the elevations would be above those under the No Action Alternative until after 2035. Because the elevations would be below the current elevations used by razorback suckers for spawning, no impacts would likely occur.

Reservoir elevations below those under the No Action Alternative would extend the riverine habitat where the Colorado River enters Lake Mead, which in turn would increase habitat for the humpback chub, razorback sucker, flannelmouth sucker, and bluehead sucker that could move downstream from Grand Canyon. At the 50^{th} percentile of reservoir elevations, this minor benefit would occur from about 2026 through 2037, and at the 10^{th} percentile this minor benefit would occur only in one to two years and thus would provide no benefit to those species.

Basin States Alternative. Under the Basin States Alternative, reservoir elevations may vary from ten feet above to ten feet below at the 50^{th} percentile of reservoir elevations as compared to the No Action Alternative in February (Figure P-BCR-3), the month with the highest reservoir elevations. The maximum elevation may be 1,122 feet msl and the minimum 1,093 feet msl. In April, the maximum elevation may be 1,118 feet msl and the minimum 1,093 feet msl (Figure P-BCR-5). Minor positive impacts could occur under the Basin States Alternative when elevations are above those under the No Action Alternative (before 2020), to minor negative impacts when elevations are below those under the No Action Alternative (after about 2020). These impacts would trend to no impact. Reservoir elevations at the 10th percentile would be less than under the No Action Alternative until 2018 and then higher until 2033. Because the projected elevations would be below the current elevations used by razorback suckers for spawning, no impacts would likely occur.

There would be elevations at the 50th percentile under the Basin States Alternative above or only slightly below those under the No Action Alternative which would provide essentially no benefit to species in the Colorado River inflow. At the 10th percentile of reservoir elevations, there could be a minor positive impact prior to 2018 under this alternative.

Conservation Before Shortage Alternative. This alternative would be essentially the same as the Basin States Alternative at the 50th percentile of reservoir elevations with maximum and minimum elevations differing by one foot (Figures P-BCR-3, P-BCR-4, and P-BCR-5). At the 10th percentile of reservoir elevations, the Conservation Before Shortage Alternative would be similar to the Basin States Alternative in most years but not as high as, or above the No Action Alternative in 2021 through 2025.

Water Supply Alternative. Reservoir elevations at the 50th percentile under the Water Supply Alternative would be near or below those under the No Action Alternative until 2045 when they would become slightly higher, resulting in a minor negative impact compared to the No Action Alternative (Figures P-BCR-3, P-BCR-4, and P-BCR-5). At the 10th percentile, elevations under the Water Supply Alternative would be below and then above those under the No Action Alternative elevations, with no impact.

At the 50th percentile of reservoir elevations, the Water Supply Alternative would provide the greatest benefit, relative to the No Action Alternative, of any of the action alternatives to those species using riverine habitat at the Colorado River inflow to the reservoir, resulting in a minor positive impact.

Reservoir Storage Alternative. Under the Reservoir Storage Alternative, reservoir elevations at the 50th percentile would be above those under the No Action Alternative by up to 35 feet with occurrences of elevations above 1,125 feet msl from 2020 through 2037 with the maximum elevation at 1,135 feet msl (Figures P-BCR-3, P-BCR-4, and P-BCR-5). Thus, the Reservoir Storage Alternative would maintain reservoir elevations within the range currently used by razorback suckers for spawning more than 50 percent of the time in about half of the years modeled, a moderate positive impact. Reservoir elevations at the 10th percentile under the

Reservoir Storage Alternative would be above those under the No Action Alternative but none would be near the current elevations used for razorback spawning. Impacts could range from no effect to a minor positive impact but would likely result in no impact.

The Reservoir Storage Alternative would provide no riverine habitat increase relative to the No Action Alternative, a minor negative impact.

Table 4.8-5 compares potential special status species impacts under the action alternatives at Lake Mead relative to the No Action Alternative.

4.8.4.4 Hoover Dam to Davis Dam and Lake Havasu to Parker Dam

Due to lack of differences among the alternatives in these reaches, and the lack of change in vegetation or habitat, there would be no impacts to special status species at these locations.

4.8.4.5 Davis Dam to Lake Havasu

No Action Alternative. Monthly releases from Davis Dam exhibit a downward trend in the future at the 90th percentile (Figures P-BCR-32 through P-BCR-43). While special status species along the Colorado River are constantly making minor adjustments as flows fluctuate, downward trending releases could result in special status species habitat impacts.

Birds. Downward trending Davis Dam releases in the future under the No Action Alternative may have gradual adverse effects on cottonwood-willow and marsh habitats, which are utilized by many special status bird species. These species include: bald eagle, osprey, belted kingfisher, peregrine falcon, southwestern willow flycatcher, vermillion flycatcher, Clark's grebe, snowy egret, Yuma clapper rail, western yellow-billed cuckoo, California black rail, elf owl, gilded flicker, Gila woodpecker, Arizona Bell's vireo, Sonoran yellow warbler, summer tanager, American white pelican, double crested cormorant, American least bittern, Western bittern, great egret, black-crowned night heron, white faced ibis, black tern, long-eared owl, brown crested flycatcher, Lucy's warbler, yellow-breasted chat, northern cardinal, northern harrier, Cooper's hawk, and American kestrel. Since lower flows are more likely to affect cottonwood-willow than saltcedar, continued saltcedar expansion along the lower Colorado River is expected to be favored under the No Action Alternative.

Table 4.8-5
Lake Mead Special Status Species Impact Summary
Comparison of Action Alternatives to No Action Alternative

Species	Alternative	Impact	Rationale
Birds	Conservation Before Shortage, Basin States, Preferred Alternative	No impact	Reservoir elevations trend close to the No Action Alternative.
	Reservoir Storage	Minor-positive	Reservoir elevations trend higher than the No Action Alternative.
	Water Supply	Minor-negative	Reservoir elevations trend lower than the No Action Alternative.
Mammals	All action alternatives	No Impact	Substantial impacts to insect food sources for bats not anticipated.
Relict leopard frog	All action alternatives	No impact	Overton Arm population is located at a spring above Lake Mead's influence.
MacNeill's sooty-winged skipper	All action alternatives	No impact	Species not known at Lake Mead. LCR MSCP indicates zero acres of *atriplex* habitat at Lake Mead. Habitats below the full pool elevation are ephemeral under all alternatives.
Sticky buckwheat, Geyer's milkvetch, and Las Vegas bearpoppy	Conservation Before Shortage, Basin States, Preferred Alternative	No impact	Reservoir elevations trend close to the No Action Alternative.
	Reservoir Storage	Minor-negative	Reservoir elevations trend higher than the No Action Alternative, inundating shoreline habitat. Habitats below full pool elevation considered temporary due to reservoir, elevation fluctuation.
	Water Supply	Minor-positive	Reservoir elevations trend lower than the No Action Alternative, exposing additional shoreline habitat. Habitats below full pool elevation considered temporary due to reservoir elevation fluctuation.
Fish	Preferred Alternative	Minor-positive No impact Minor-positive	Elevations would be higher than the No Action Alternative in some years but seldom above the current razorback spawning areas at the 50th percentile of reservoir elevations. Elevations at the 10th percentile would be well below current razorback spawning areas. Lower elevations would extend riverine habitat at the inflow areas for species status fish at the 50th percentile of reservoir elevations.
	Conservation Before Shortage, Basin States	No impact Minor-positive	Elevations above 1,120 feet msl could have a slight benefit to razorback sucker spawning while lower elevations could be less valuable; at the 10th percentile, elevations under these alternatives would be above and below those under the No Action Alternative and below the current razorback spawning level. Increased amount of riverine habitat at the 10th percentile of reservoir elevations prior to 2018.
	Water Supply	Minor negative Minor positive	Reservoir elevations would be near to or less than those under the No Action Alternative at the 50th percentile of reservoir elevations. Lower reservoir elevations would provide more riverine habitat for fish from Separation Canyon at the 50th percentile of reservoir elevations.
	Reservoir Storage	Moderate positive Minor negative	Reservoir elevations would be above 1,120 feet msl over 50 percent of the time in about half the modeled years; at the 10th percentile of elevations, no impact. Higher reservoir elevations would provide less riverine habitat for fish from Separation Canyon than under the No Action Alternative at the 10th and 50th percentiles of reservoir elevations.

Mammals. Townsend's big-eared bat, Pale Townsend's big-eared bat, spotted bat, Allen's big-eared bat, Western red bat, occult little brown bat, Yuma myotis, Western Yellow bat, cave myotis, greater western mastiff bat, and small-footed myotis utilize riparian and marsh habitats in this reach for foraging and roosting. Downward trending Davis Dam releases under the No Action Alternative are expected to be gradual, though they may affect the composition of riparian habitats. Such gradual changes are not expected to substantially affect insect food sources for special status bats. Since these bats typically utilize a variety of roost sites, including live and dead trees, substantial impacts to these species' roost sites are not anticipated under the No Action Alternative.

The Yuma hispid cotton rat is only known to exist from Yuma south. This species will not be affected under the No Action Alternative in this reach. The Colorado River cotton rat inhabits this reach, and particularly grassy riparian areas along the Colorado River. Downward trending Davis Dam releases under the No Action Alternative are expected to be gradual, though they may impact the habitat for the Colorado River cotton rat in this reach. The lower monthly releases and lower annual median releases from Davis Dam under the Reservoir Storage Alternative could have a minor negative impact on the Colorado River cotton rat. The higher monthly and annual median releases from Davis Dam under the Water Supply Alternative could have minor positive impact on the Colorado River cotton rat. Monthly and annual median releases from Davis Dam under the Basin States and Conservation Before Shortage alternatives, and the Preferred Alternative, are similar to those under the No Action Alternative and therefore should not impact the Colorado River cotton rat.

Amphibians. Relict leopard frogs are known downstream of Hoover Dam at several springs to the north of this reach and are above the influence of the Colorado River. The Lowland leopard frog is known along the Bill Williams River, but not in this reach. The Colorado River toad is not known to occur in this reach. The special status amphibians in this reach would not be affected under the No Action Alternative.

Invertebrates. MacNeill's sooty-winged skipper is known at scattered sites along the lower Colorado River and is associated with quailbrush (*Atriplex*) and mesquite communities. The *Atriplex* land cover type is present in this reach (Section 3.8, Table 3.8-2). However, quailbrush typically grows on alluvial floodplains and flow-related impacts under the No Action Alternative are not anticipated to affect alluvial floodplains. Downward trending releases may affect groundwater levels. However, because the declines will likely be gradual and that mesquite and quailbrush are not obligate phreatophytes, groundwater-related effects under No Action Alternative are not anticipated. MacNeill's sooty-winged skipper in this reach is not expected to be affected under the No Action Alternative.

Fish. In the Colorado River reach between Davis Dam and Lake Havasu, some backwaters are present that could be used by razorback suckers, bonytail, and flannelmouth suckers, the only special status fish species present. Reduced flows in the future in this reach may result in more frequent dewatering of backwaters, resulting in a reduction of habitat for these special status fish species. Backwaters may become vegetated with marsh plants under reduced flow conditions. Non-native fish would continue to be present in this reach and compete with native fish.

Action Alternatives. Special status species in this reach would not be impacted under the Basin States and Conservation Before Shortage alternatives, and the Preferred Alternative, because Davis Dam monthly and annual median releases trend close to those under the No Action Alternative (Section 4.3, Figure 4.3-32; Figures P-BCR-32 through P-BCR-43), therefore, these three action alternatives are not discussed further for this reach. Flow deviations under the Water Supply and Reservoir Storage alternatives from those under the No Action Alternative generally return to those under the No Action Alternative at the end of the interim period, though the vegetation and associated special status species effects of interim period conditions may be observed beyond the interim period.

Birds. The Reservoir Storage and Water Supply alternatives may result in lower and higher monthly and annual median releases, respectively. Lower and higher annual median releases would have corresponding effects on groundwater levels and could impact riparian and marsh vegetation (Section 4.8). Respective impacts to special status birds would be similar to impacts at Lake Mead. However, a higher number of species may be impacted in this river reach since this reach includes California special status birds not considered at Lake Mead. There would be a minor negative impact on the following special status birds under the Reservoir Storage Alternative through flow-related and groundwater-related negative impacts to their habitats: bald eagle, osprey, belted kingfisher, peregrine falcon, southwestern willow flycatcher, vermillion flycatcher, Clark’s grebe, snowy egret, Yuma clapper rail, western yellow-billed cuckoo, California black rail, elf owl, gilded flicker, Gila woodpecker, Arizona Bell’s vireo, Sonoran yellow warbler, summer tanager, American white pelican, double crested cormorant, American least bittern, Western bittern, great egret, black-crowned night heron, white faced ibis, black tern, long-eared owl, brown crested flycatcher, Lucy’s yellow warbler, yellow-breasted chat, northern cardinal, northern harrier, Cooper’s hawk, and American kestrel. The Water Supply Alternative is expected to have a minor positive impact on these same species since monthly and annual median flows will be higher than under the No Action Alternative. Fluctuations of groundwater levels anticipated for this reach may be on the order of 0.5 foot or less (Section 4.3), which contributes to these impacts being minor.

Mammals. Though there may be higher and lower Davis Dam releases under the Water Supply and Reservoir Storage alternatives, respectively, these differences are not expected to substantially impact foraging or roosting conditions for special status bats. Impacts under the action alternatives on special status mammals are expected to be similar to those expected under the No Action Alternative.

The Yuma hispid cotton rat is only known to exist along the Colorado River from Yuma south. Therefore, the proposed federal action would not impact this species in this reach. The Colorado River cotton rat is present in this reach and its habitat could be adversely impacted by the lower monthly and annual median releases from Davis Dam and potentially lower groundwater levels associated with the Reservoir Storage Alternative. The Water Supply Alternative could have a small positive impact on this species' habitat because the higher monthly and annual median releases from Davis Dam under this alternative would benefit riparian and marsh vegetation in this reach.

Amphibians. There would be no impacts under the Water Supply and Reservoir Storage alternatives to the Colorado River toad, relict leopard frog or lowland leopard frog in this reach for the same reasons as described for the No Action Alternative.

Invertebrates. There would be no impacts under the Water Supply and Reservoir Storage alternatives to MacNeill's sooty-winged skipper in this reach for the same reasons as described for the No Action Alternative.

Fish.

Water Supply Alternative. There may be slightly more flows under the Water Supply Alternative than under the No Action Alternative in most months of the year at the 10^{th} and 50^{th} percentiles of reservoir elevations. The slightly higher flows could have a minor positive impact on the razorback sucker, bonytail, and flannelmouth sucker.

Reservoir Storage Alternative. There may be slightly lower flows under the Reservoir Storage Alternative than under the No action Alternative in most months of the year at the 10^{th} and 50^{th} percentiles of reservoir elevations. Reductions in Colorado River flows downstream of Davis Dam could affect the flannelmouth sucker through loss of spawning habitat in the riverine sections and rearing habitat in backwaters. This would be a minor negative impact for this species. Reduced flows could also have a minor negative impact on razorback sucker and bonytail through loss of rearing habitat. At the 90^{th} percentile, higher releases in the winter under the Reservoir Storage Alternative could have potential benefits or detriments to backwater habitats depending on the amount of sediment scour or deposition. Overall, however, no impact would be expected from higher winter releases.

Table 4.8-6 provides a summary of potential impacts that may occur under the action alternatives to special status species in the Davis Dam to Lake Havasu reach as compared to the No Action Alternative.

Table 4.8-6
Davis Dam to Lake Havasu Reach Special Status Species Impact Summary
Comparison of Action Alternatives to No Action Alternative

Species	Alternative	Impact	Rationale
Birds	Conservation Before Shortage, Basin States, Preferred Alternative	No Impact	Monthly and annual median releases are similar to the No Action Alternative.
	Water Supply	Minor-positive	Monthly and annual median releases higher than under the No Action Alternative at the 10th and 50th percentiles.
	Reservoir Storage	Minor-negative	Monthly and annual median releases lower than under the No Action Alternative at the 10th and 50th percentiles.
Mammals	Conservation Before Shortage, Basin States, Preferred Alternative	No impact	Conservation Before Shortage and Basin States alternatives monthly and annual median releases are similar to those under the No Action Alternative.
	Reservoir Storage	Minor-negative	Lower monthly and annual median releases from Davis Dam could degrade riparian habitats of the Colorado cotton rat. Flow differences not expected to impact special status bats.
	Water Supply	Minor – positive	Higher monthly and annual median releases from Davis Dam could benefit riparian habitats of the Colorado River cotton rat. Flow differences not expected to impact special status bats.
Amphibians	All action alternatives	No Impact	Species not known in this reach.
Invertebrates	All action alternatives	No impact	Action alternatives not expected to adversely impact quailbrush or mesquite communities on alluvial floodplains.
Fish	Conservation Before Shortage, Basin States, Preferred Alternative	No impact	Davis Dam releases trend close to those under the No Action Alternative.
	Water Supply	Minor- positive	Increased releases at the 10th and 50th percentiles of reservoir elevations could benefit razorback sucker, bonytail, and flannelmouth sucker.
	Reservoir Storage	Minor- negative	Decreased releases at the 10th and 50th percentiles of reservoir elevations could result in habitat reduction for razorback sucker, bonytail, and flannelmouth sucker.

4.8.4.6 Parker Dam to NIB

No Action Alternative. Monthly flows from Parker Dam to Imperial Dam may be sightly lower in future years because of a reduction in the 90th percentile releases in some months (Figures P-BCR-44 through P-BCR-55). Annual median releases from Parker Dam also indicate a slight downward trend into the future (Section 4.3, Figure 4.3-37). While special status species along the Colorado River are constantly adjusting as flows fluctuate, the slight downward trend in the future could adversely affect cottonwood and marsh communities and the special status species that rely on such habitats. Under the No Action Alternative, shortage conditions would occur without specific operating criteria.

The gradual nature of this slight downward trend is such that terrestrial special status species and habitat conditions would not change abruptly or substantially. The Colorado River downstream of Imperial Dam would not be affected under the No Action Alternative because flows between Imperial Dam and the NIB consist primarily of leakage from Imperial Dam and return flows from water diverted at Imperial Dam. Accordingly, there will be no effects under the proposed federal action on special status species downstream of Imperial Dam. The following discussion applies only to the Colorado River reach between Parker Dam and Imperial Dam.

Birds. The gradual and slight downward trend of monthly and annual median flows in this reach in the future may adversely affect cottonwood-willow and marsh habitats and thus the special status birds that utilize such habitats. These species include: bald eagle, osprey, belted kingfisher, peregrine falcon, southwestern willow flycatcher, vermillion flycatcher, Clark's grebe, snowy egret, Yuma clapper rail, western yellow-billed cuckoo, California black rail, elf owl, gilded flicker, Gila woodpecker, Arizona Bell's vireo, Sonoran yellow warbler, summer tanager, American white pelican, double crested cormorant, American bittern, Western least bittern, great egret, black-crowned night heron, white faced ibis, black tern, long-eared owl, brown crested flycatcher, Lucy's warbler, yellow-breasted chat, northern cardinal, northern harrier, Cooper's hawk, and American kestrel. Lower flows would continue to favor expansion of saltcedar along this reach, which tends to reduce the value of the habitats the species invades.

Mammals. The gradual and slight downward trend of monthly and annual median flows in this reach in the future under the No Action Alternative would have similar effects on special status bats as described for the No Action Alternative for the Davis Dam to Lake Havasu reach.

The Yuma hispid cotton rat and Colorado River cotton rat do occur in this reach and they inhabit moist grassy areas along the lower Colorado River, including wetlands. The downward trend of monthly and annual median releases from Parker Dam under the No Action Alternative may have minor effects on the moist riparian habitats these two species prefer. However, since these species also utilize agricultural fields and the downward release trend is gradual and small, effects under the No Action Alternative on these two rat species is expected to be small.

Amphibians. Special status amphibians do not occur in this reach, thus, effects under the No Action Alternative are not anticipated.

Invertebrates. MacNeill's sooty-winged skipper may occur in the quailbrush and mesquite communities that are present in this reach. However, the alluvial floodplains or *Atriplex* communities are not expected to be affected or impacted under the No Action Alternative through groundwater effects. MacNeill's sooty-winged skipper in this reach would not be affected under the No Action Alternative.

Fish. The only listed fish species present in the Colorado River or in-stream reservoirs from Parker Dam to the NIB are the razorback sucker and bonytail chub. Reduced flows under the No Action Alternative would alter habitat for these fish downstream of Parker Dam as described for downstream of Davis Dam.

Action Alternatives. Flow deviations under the action alternatives from those under the No Action Alternative generally return close to those under the No Action Alternative at the end of the interim period, though the vegetation and associated special status species effects of the interim period may be observed beyond the interim period.

Birds. In the river reach between Parker Dam and Imperial Dam, monthly and annual median flows under the Basin States, Conservation Before Shortage, and Reservoir Storage alternatives, and the Preferred Alternative, would be lower than under the No Action Alternative at the 10th and 50th percentiles. The Reservoir Storage Alternative results in the greatest reduction of flows as compared to the No Action Alternative, while the Basin States Alternative results in the least reduction (Section 4.3, Figure 4.3-37; Figures P-BCR-44 through P-BCR-55). Departures under the action alternatives from the No Action Alternative may cause a decline in groundwater levels adjacent to the Colorado River of 0.15 to 0.30 foot. These lower releases and groundwater levels would have a minor negative impact on cottonwood-willow and marsh habitats and thus a correspondingly minor negative impact to special status birds that rely on those habitats. Potentially impacted species include the following: bald eagle, osprey, belted kingfisher, peregrine falcon, southwestern willow flycatcher, vermillion flycatcher, Clark's grebe, snowy egret, Yuma clapper rail, western yellow-billed cuckoo, California black rail, elf owl, gilded flicker, Gila woodpecker, Arizona Bell's vireo, Sonoran yellow warbler, summer tanager, American white pelican, double crested cormorant, American bittern, Western least bittern, great egret, black-crowned night heron, white faced ibis, black tern, long-eared owl, brown crested flycatcher, Lucy's yellow warbler, yellow-breasted chat, northern cardinal, northern harrier, Cooper's hawk, and American kestrel. The annual median flows under the Water Supply Alternative are somewhat higher than under No Action Alternative and therefore would have a minor positive impact on cottonwood-willow and marsh habitats, and on these same special status species.

Mammals. The special status bat species would not be impacted in this reach for the same reasons as described for the Davis Dam to Lake Havasu reach.

The lower flows, declines in groundwater levels adjacent to the river of 0.15 to 0.30 foot, and resultant impacts to riparian vegetation associated with the Basin States, Conservation Before Shortage, and Reservoir Storage alternatives, and the Preferred Alternative, could have a minor negative impact on the Colorado River cotton rat upstream of Imperial Dam. The higher flows, groundwater levels, and small positive impacts to riparian vegetation under the Water Supply Alternative could have a minor positive impact on the Colorado River cotton rat upstream of Imperial Dam. The action alternatives would not alter the historic operational methodology or range of flow volumes in the river channel downstream of Imperial Dam. Therefore, none of the action alternatives would impact the Yuma hispid cotton rat or Colorado River cotton rat downstream of Imperial Dam.

Amphibians. Special status amphibians do not occur in this reach.

Invertebrates. MacNeill's sooty-winged skipper would not be impacted in this reach because alluvial floodplains with quailbrush and mesquite are not expected to be substantially impacted under any alternative.

Fish. The Basin States, Conservation Before Shortage, and Reservoir Storage alternatives, and the Preferred Alternative, have monthly releases that would be less than those under the No Action Alternative at the 10th and 50th percentiles. These lower flows could have impacts on razorback sucker and bonytail chub similar to those described for the Reservoir Storage Alternative in the Davis Dam to Lake Havasu reach. The use of High Levee Pond on the Cibola NWR for native fish would not be affected by changes in releases from Parker Dam.

Table 4.8-7 summarizes the potential impacts to special status species in the Parker Dam to the NIB reach for the action alternatives relative to the No Action Alternative.

Table 4.8-7
Parker Dam to NIB Special Status Species Impact Summary
Comparison of Action Alternatives to No Action Alternative

Species	Alternative	Impact	Rationale
Birds	Water Supply	Minor - Positive	Monthly releases closely follow the No Action Alternative. No flow-related impacts anticipated downstream of Imperial Dam. Annual median releases from Parker Dam are higher than under the No Action Alternative, which provides a minor benefit to riparian habitats and associated birds.
	Conservation Before Shortage, Basin States, Reservoir Storage, Preferred Alternative	Minor-negative	Monthly releases lower than under the No Action Alternative at the 10th and 50th percentiles. Small anticipated groundwater level impacts. No flow-related impacts anticipated downstream of Imperial Dam. Annual median releases from Parker Dam are lower than under the No Action Alternative, which results in a minor negative impact to riparian habitats and associated birds.
Mammals	Water Supply	Minor - Positive	Monthly flows under the Water Supply Alternative are similar to those under the No Action Alternative. Flows are not substantially different than those under No Action Alternative to cause indirect impacts to special status bats. Higher annual median releases from Parker Dam could benefit Colorado River cotton rat upstream of Imperial Dam. Two cotton rat species occur downstream of Imperial Dam, where flow impacts are not anticipated.
	Conservation Before Shortage, Basin States, Reservoir Storage, Preferred Alternative	Minor - Negative	Monthly flows are similar to those under the No Action Alternative. Flows are not substantially different than those under the No Action Alternative to cause indirect impacts to special status bats. Lower annual median releases from Parker Dam could benefit Colorado River cotton rat upstream of Imperial Dam. Two cotton rat species occur downstream of Imperial Dam, where flow impacts are not anticipated.
Amphibians	All action alternatives	No Impact	Species not known in this reach.
Invertebrates	All action alternatives	No impact	Action alternatives not expected to adversely impact quailbrush or mesquite communities on alluvial floodplains.
Razorback sucker and bonytail chub	Water Supply	No Impact	Monthly flows closely follow those under the No Action Alternative.
	Conservation Before Shortage, Basin States, Reservoir Storage, Preferred Alternative	Minor-negative	Monthly flows are lower than those under the No Action Alternative at the 10th and 50th percentiles and could result in habitat reduction.

4.8.4.7 NIB to SIB

No Action Alternative. The lack of flows precludes the presence of a significant river fishery in the Colorado River reach between Morelos Diversion Dam and the SIB (Limitrophe Division); the riparian and marsh habitats, and the special status species that rely on those habitats are adversely affected by this condition. Flows past Morelos Diversion Dam tend to benefit downstream vegetated habitats and associated special status species. The probability of these excess flows occurring in the future under the No Action Alternative is relatively low, typically less than 20 percent (Figure P-BCR-56). The infrequency of flows under the No Action Alternative would continue to maintain less than ideal conditions for cottonwood-willow and marsh habitats and the species that rely on such habitats. The special status bird and mammal species identified in the Parker Dam to the NIB reach will continue to experience these adverse effects on their habitat downstream of Morelos Diversion Dam under the No Action Alternative. Special status amphibians, plants or fish will not be affected under the No Action Alternative because none are present in this reach. Infrequent flows in this reach under the No Action Alternative will continue to favor the expansion of saltcedar which may compete with mesquite and quailbrush communities, thus limiting the habitat potential for MacNeill's sooty-winged skipper in this reach.

Action Alternatives. The likelihood of excess flows passing Morelos Diversion Dam under the Basin States and Water Supply alternatives, and the Preferred Alternative, is approximately the same as under the No Action Alternative. Therefore, these action alternatives would have no impact on special status species in this reach. The Reservoir Storage and Conservation Before Shortage alternatives have a higher likelihood of excess flows passing Morelos Diversion Dam than the No Action Alternative (Figure P-BCR-56). In addition, due to modeling assumptions for the Reservoir Storage and Conservation Before Shortage alternatives, water is assumed to be delivered to Mexico and assumed to allow to pass the Morelos Diversion Dam via periodic flows[2] of about 40 kafy to 200 kafy (Section 2.4). These pulse flows would occur approximately every other year during the interim period only. The probability of flows past Morelos Diversion Dam under these two action alternatives returns to the probability of flows under the No Action Alternative after the interim period. These flows would have overall benefits to river flow, riparian and marsh vegetation and special status species that utilize these habitats since substantial flow in this reach is relatively rare. There would be a moderate, positive impact on special status species between Morelos Diversion Dam and the SIB under the Reservoir Storage and Conservation Before Shortage alternatives.

---

[2] These flows were modeled as part of the storage and delivery mechanism under the Conservation Before Shortage and Reservoir Storage alternatives. The modeling assumptions were utilized in this Final EIS in order to analyze the potential impacts to environmental resources of the storage and delivery mechanism, particularly with regard to reservoir elevations and river flow impacts. The use of these modeling assumptions does not represent any determination by Reclamation as to whether, or how, these releases could be made under current management of the Colorado River.

Birds. The species identified as impacted in the Parker Dam to the NIB reach would be positively impacted by the increased likelihood of flows past Morelos Diversion Dam under the Reservoir Storage and Conservation Before Shortage alternatives. Special status birds would not be impacted under the Basin States and Water Supply alternatives, and the Preferred Alternative, since under these action alternatives flows past Morelos Diversion Dam are just as likely to occur as under the No Action Alternative.

Amphibians, Plants and Fish. There are no special status amphibians, plants or fish in this reach.

Mammals. The increased likelihood of flows past Morelos Diversion Dam under the Reservoir Storage and Conservation Before Shortage alternatives would provide a moderate benefit to riparian and marsh habitats downstream of Morelos Diversion Dam, which would potentially benefit special status bats, the Yuma hispid cotton rat, and Colorado River cotton rat in this reach.

Invertebrates. The *Atriplex* land cover type is present in this reach, which may provide habitat for MacNeill's sooty-winged skipper. Though not specifically known in this reach, the species has been documented in Yuma County, Arizona. Flows past Morelos Diversion Dam under the Basin States and Water Supply alternatives, and the Preferred Alternative, are as likely to occur as under the No Action Alternative. Flows past Morelos Diversion Dam under the Reservoir Storage and Conservation Before Shortage alternatives are more likely to occur. Though an overall benefit to habitat conditions, flows past Morelos Diversion Dam could scour riparian vegetation, potentially including *Atriplex*, which serves as potential habitat for MacNeill's sooty-winged skipper. Thus, these alternatives would potentially have a minor negative impact on this species, despite overall benefits to the conditions in this reach.

Table 4.8-8 summarizes the impacts to special status species in the NIB to the SIB reach for the action alternatives relative to the No Action Alternative.

4.8.5 Summary

4.8.5.1 Vegetation and Wildlife

Lake Powell and Lake Mead. Under the Water Supply Alternative there may be a minor negative impact on obligate phreatophytes, and marsh and the wildlife that use such habitats because lake elevations tend to be lower than under the No Action Alternative. Under the Basin States, Conservation Before Shortage, and Reservoir Storage alternatives, and the Preferred Alternative, there may be a minor positive impact on obligate phreatophytes, and marsh and associated wildlife because lake elevations tend to be higher than under the No Action Alternative.

Table 4.8-8
NIB to SIB Reach Special Status Species Impact Summary
Comparison of Action Alternatives to No Action Alternative

Species	Alternative	Impact	Rationale
Birds	Basin States, Water Supply, Preferred Alternative	No Impact	Flows past Morelos Diversion Dam just as likely under the No Action Alternative.
	Reservoir Storage, Conservation Before Shortage	Moderate – positive	Flows past Morelos Diversion Dam more likely than under the No Action Alternative. Flows are rare in this reach, so increased likelihood would benefit the riparian corridor and associated special status species.
Mammals	Basin States, Water Supply, Preferred Alternative	No impact	Flows past Morelos Diversion Dam just as likely under the No Action Alternative.
	Reservoir Storage, Conservation Before Shortage	Moderate-positive	Flows past Morelos Diversion Dam more likely than under the No Action Alternative. Flows are rare in this reach, so increased likelihood would benefit the riparian corridor and associated special status species.
Amphibians, Plants and Fish	All action alternatives	No Impact	Fish occurrence is problematic due to lack of steady flows. No special status plants or amphibians are known in this reach.
MacNeill's sooty-winged skipper	Basin States, Water Supply, Preferred Alternative	No impact	Flows past Morelos Diversion Dam just as likely under the No Action Alternative.
	Reservoir Storage, Conservation Before Shortage	Minor-negative	*Atriplex* vegetation occurs in this reach and could be impacted by scouring by increased likelihood of flow past Morelos Diversion Dam.

Glen Canyon Dam to Lake Mead. All five action alternatives tend to have lower 10th percentile releases from Glen Canyon Dam than the No Action Alternative. These lowered releases may negatively impact obligate phreatophytes, and marsh and associated wildlife downstream of Lake Powell. The impacts are expected to be minor because though lower, they are within the range of recent history and are anticipated for the interim period only.

Hoover Dam to Davis Dam and Lake Havasu to Parker Dam. Under all five action alternatives there would be no impacts to vegetation or wildlife in these river reaches because there may be only small differences in Lake Mead releases and these reaches are dominated by Lake Mohave and its backwater, and Lake Havasu. Vegetated habitats potentially affected by flow changes between Hoover Dam and Lake Mohave are limited. Lake Mohave and Lake Havasu are operated on monthly rule curves so vegetation and wildlife effects at the lakes under the action alternatives are identical to those under the No Action Alternative.

Davis Dam to Parker Dam. Under the Water Supply Alternative there may be higher 10th and 50th percentile monthly releases and a higher annual median release from Davis Dam; this may cause a minor positive impact to obligate phreatophytes, and marsh and associated wildlife as compared to the No Action Alternative. Under the Reservoir Storage Alternative, there may be lower 10th and 50th percentile monthly releases and a lower annual median release from Davis Dam; this may cause a minor negative impact to obligate phreatophytes, and marsh and associated wildlife as compared to the No Action Alternative. These differences remain within the range of annual fluctuations that have historically occurred, and are expected to occur during the interim period only.

Parker Dam to Imperial Dam. Under the Basin States, Conservation Before Shortage, and Reservoir Storage alternatives, and the Preferred Alternative, there are lower 10th and 50th percentile monthly releases and a lower annual median release from Parker Dam; these lower releases may have a minor negative impact on obligate phreatophytes, and marsh and associated wildlife. Under the Water Supply Alternative there is a higher annual median release from Parker Dam, which may provide a minor benefit to obligate phreatophytes, and marsh and associated wildlife.

Imperial Dam to NIB. There are no impacts to vegetation or wildlife under any of the action alternatives in this reach. Flow changes in this reach would be limited to the AAC rather than to the Colorado River downstream of Imperial Dam. No impacts to vegetation or wildlife are anticipated from differences in flows within the AAC.

NIB to SIB. Mexico diverts its water at Morelos Diversion Dam (at the NIB) and flows downstream of this dam are rare. There is a higher probability of excess flows passing Morelos Diversion Dam under the Conservation Before Shortage and Reservoir Storage alternatives than under the No Action Alternative, which is expected to cause a moderate positive benefit to river flows, obligate phreatophytes, and marsh and associated wildlife downstream of Morelos Diversion Dam. These benefits were deemed moderate because flows in this reach are currently rare and any additional flow in this reach is assumed to be beneficial.

4.8.5.2 Special Status Species

Lake Powell. Lower Lake Powell elevations under the Basin States, Conservation Before Shortage, and Water Supply alternatives, and the Preferred Alternative, at the 10th and 50th percentile of reservoir elevations may increase the amount of riverine habitat available at the inflow areas to Lake Powell. This may provide a minor positive impact to razorback sucker, bonytail, Colorado pikeminnow, and flannelmouth sucker found in the riverine areas at the inflows. The higher lake elevations under the Reservoir Storage Alternative may decrease the amount of riverine habitat at the inflow areas, which may result in a minor negative impact.

Clark’s grebe that may inhabit Lake Powell could be impacted by elevation changes in Lake Powell that affect marsh habitat at the inflow areas. Under the Reservoir Storage and Water Supply alternatives, there may be higher and lower lake elevations, respectively, which would mean a minor positive and a minor negative impact, respectively, to Clark’s grebe.

Glen Canyon Dam to Lake Mead. Under the action alternatives, except for the Reservoir Storage Alternative, there may result higher river temperatures downstream of Glen Canyon Dam at the 10th percentile of elevations and higher to lower temperatures at the 50th percentile of elevations than under the No Action Alternative. Under the Reservoir Storage Alternative there may result higher to lower river temperatures at the 10th and 50th percentiles of elevations, respectively. Higher temperatures may provide a minor positive impact to humpback chub, bluehead sucker and flannelmouth sucker spawning and growth. However, these warmer temperatures also benefit non-native fish species which compete with native fish, and parasites that affect native fish, resulting in a minor negative impact. The lower average temperatures in the summer and winter at the 10th percentile of elevations under the Reservoir Storage Alternative could reduce the growing season for humpback chub, bluehead sucker, and flannelmouth sucker but would not affect spawning, resulting in a minor negative impact. The short duration of warmer average temperatures in the spring followed by cooler temperatures are unlikely to provide any benefit to non-native fish and native fish parasites. Lower annual releases in some years could reduce sediment loss from the Colorado River while higher releases in some years could increase sediment losses. How these changes in sediment transport could affect native fish habitat is unknown. The range in hourly flows could be reduced during lower annual releases and increased during higher annual releases. Lower temperatures may provide a minor negative impact to these native fish species. Under the Reservoir Storage Alternative, average water temperatures above 15ºC (59°F) may occur one month later than under the No Action Alternative and may have a minor negative impact on leopard frogs due to increased potential for thermal shock in July. Under the other action alternatives impacts to the leopard frog are not expected as compared to the No Action Alternative.

Higher 90th percentile releases under the Reservoir Storage Alternative have a potential for increased impact to beach habitat in the lower Grand Canyon, which could adversely impact vegetation and Grand Canyon evening primrose on those beaches. Under the five action alternatives, flows may exceed those under the No Action Alternative and 17,000 cfs in some months, which may cause additional impact to Kanab ambersnail habitat at Vasey’s Paradise. Under the Reservoir Storage Alternative, flows in June could exceed those under the No Action Alternative and exceed 20,000 cfs, thus causing greater impact to Niobrara ambersnail habitat. Under the Basin States, Conservation Before Shortage, and Water Supply alternatives, and the Preferred Alternative at the 90th percentile there may be flows that when above 20,000 cfs are equal to or less than those under No Action Alternative, which would provide a minor positive benefit to the Niobrara ambersnail. Under the five action alternatives there may be a minor negative impact on the southwestern willow flycatcher because of the 10th percentile release flows trend lower than those under the No Action Alternative. These lower potential flows could adversely impact southwestern willow flycatcher habitat in the Grand Canyon.

Lake Mead. The lower and higher Lake Mead elevations that may occur under the Water Supply and Reservoir Storage alternatives, respectively, could cause minor negative and minor positive impacts, respectively, to special status bird species. Impacts on bird species may be caused by increased or decreased potential for dewatering of riparian habitats and headcutting at the Lake Mead inflow areas. Higher lake elevations under the Reservoir Storage Alternative may inundate additional shoreline habitat for the sticky buckwheat, Geyer’s milkvetch and Las Vegas Bearpoppy and be a minor negative impact. Lower Lake Mead elevations under the Water Supply Alternative may expose additional shoreline habitat for these plants and be a minor positive impact. These impacts were deemed minor because all habitats below the full pool elevation of Lake Mead are subject to periodic inundation and exposure as the lake elevation fluctuates in the future. Under the Preferred Alternative, there could be minor positive impacts to special status fish when elevations are above the current razorback spawning areas at the 50^{th} percentile of elevations and when lower elevations would extend riverine habitat in the inflow area for special status fish. Elevations higher than under the No Action Alternative at the 10^{th} percentile would have no impacts on razorback sucker spawning. Lake elevations under both the Basin States and Conservation Before Shortage alternatives could be both above and below those under the No Action Alternative and would have no impact to razorback suckers. The increased amount of riverine habitat at the 10^{th} percentile of elevations could provide a minor positive impact to special status fish in the Colorado River inflow. Under the Water Supply Alternative there may be both minor positive and negative impacts to special status fish species due to providing more riverine habitat and lower elevations relative to razorback spawning areas, respectively, at the 50^{th} percentile. Under the Reservoir Storage Alternative, elevations could be above current razorback sucker spawning areas over 50 percent of the time in about half the modeled years, a moderate positive impact. Higher reservoir elevations would provide less riverine habitat for special status fish in the Colorado River inflow at the10^{th} and 50^{th} percentile elevations for a minor negative impact.

Hoover Dam to Davis Dam and Lake Havasu to Parker Dam. There is no substantial difference between the No Action Alternative and any of the action alternatives in this reach.

Davis Dam to Lake Havasu. Lower monthly and annual median releases from Davis Dam under the Reservoir Storage Alternative may have a minor negative impact on obligate phreatophytes, and marsh and associated special status bird species, and Colorado River cotton rat. Impacts to these species may occur through adverse effects to their habitats from reduced dam releases. Razorback sucker, flannelmouth sucker, and bonytail may experience a minor negative impact because lower potential releases could have adverse impacts to riverine spawning habitat and backwater rearing habitats that these species utilize. Higher monthly and annual median releases from Davis Dam under the Water Supply Alternative may have a minor positive impact on obligate phreatophytes, and marsh and associated special status bird species, and Colorado river cotton rat. razorback sucker, flannelmouth sucker, and bonytail may also benefit from these higher flows because they could maintain more of the spawning and rearing habitats present in this reach.

Parker Dam to Imperial Dam. Lower monthly and annual median flows under the Basin States, Conservation Before Shortage, and Reservoir Storage alternatives, and the Preferred Alternative, may have minor negative impacts to the habitats of the special status bird species and Colorado river cotton rat. Obligate phreatophytes, and marsh and associated special status species would be negatively impacted by lower releases. Razorback sucker and bonytail chub may be negatively impacted by lower flows under the Basin States, Conservation Before Shortage, and Reservoir Storage alternatives, and the Preferred Alternative. Lower flows may negatively impact spawning and rearing habitats for these species. Higher annual median flows under the Water Supply Alternative would benefit the habitats of special status birds, mammals and fish and may have a minor positive impact.

Imperial Dam to NIB. Under the No Action Alternative and the action alternatives there would be no impact to special status species in this reach. Flow changes in this reach would be limited to flows in the AAC rather than to the Colorado River downstream of Imperial Dam. No impacts to special status species are anticipated from flow differences in the AAC.

NIB to SIB. Flows past Morelos Diversion Dam are more probable under the Reservoir Storage and Conservation Before Shortage alternatives. The increased probability of flows may have a moderate positive impact on the special status bird species through positive impacts to riparian and marsh habitats these species utilize. These higher probabilities of flows may also positively impact the special status bat species listed in this section, Yuma hispid cotton rat, and Colorado river cotton rat through positive impacts to their riparian and marsh habitats. Though these flows are an overall benefit to the riparian corridor downstream of the NIB, the increased probability of high flows could increase the likelihood of scouring *Atriplex* vegetation in this reach, which would be a minor negative impact to MacNeill's sooty-winged skipper.

4.9 Cultural Resources

This section describes the methods used in the analysis of potential effects to cultural resources, including historic properties, Indian sacred sites, and issues of Tribal concern as a result of implementing the alternatives developed under the proposed federal action.

4.9.1 Methodology

This section provides a general analysis that considers how cultural sites might be exposed and affected by implementation of the proposed federal action. However, the specifics about current integrity of submerged sites and the impacts that might occur to these sites once they are exposed are mostly unknown. Because of this, Reclamation and NPS will work together to develop an agreement acceptable to the consulting parties that implements an appropriate strategy to identify, analyze, and address potential effects to cultural sites as they are exposed in the future as a consequence of implementing the proposed federal action.

For Lake Powell, the 10th percentile was selected as the basis for effect determination because it represents the "worst case" that still has a reasonable probability of occurring. At Lake Mead, elevation 1,080 feet msl was selected as the basis for effect determination.[1] Processes that might result in a loss of integrity vary by reach and property type; consequently, methods of assessing effects differ by reach.

4.9.2 Lake Powell and Glen Canyon Dam

4.9.2.1 No Action Alternative

Under the No Action Alternative, the lowest projected elevation of Lake Powell under the 10th percentile modeled Lake Powell elevations is 3,522 feet msl (Figure P-WAQ-6 in Appendix P). Some 194 unexcavated archaeological sites are at or above this elevation and would therefore be subject to erosion or visitor impacts.

4.9.2.2 Basin States Alternative and Conservation Before Shortage Alternative

Under the Basin States and Conservation Before Shortage alternatives, the lowest projected elevation of Lake Powell at the 10th percentile of modeled Lake Powell elevations is 3,541 feet msl. Some 190 unexcavated archaeological sites are at or above this elevation and would therefore be subject to erosion or visitor impacts. This is essentially the same effect as under the No Action Alternative.

[1] Elevation 1,083 feet msl is the lowest elevation observed since Lake Mead filled.

4.9.2.3 Water Supply Alternative

Under the Water Supply Alternative, the lowest projected elevation of Lake Powell at the 10th percentile of modeled Lake Powell elevations is 3,496 feet msl. Some 227 unexcavated archaeological sites are at or above this elevation and would therefore be subject to erosion or visitor impacts. This is a greater number of affected sites than under the No Action Alternative.

4.9.2.4 Reservoir Storage Alternative

Under the Reservoir Storage Alternative, the lowest projected elevation of Lake Powell at the 10th percentile of modeled Lake Powell elevations is 3,538 feet msl. Some 193 unexcavated archaeological sites are at or above this elevation and would therefore be subject to erosion or visitor impacts. This is essentially the same effect as under the No Action Alternative.

4.9.2.5 Preferred Alternative

Under the Preferred Alternative, the lowest projected elevation of Lake Powell at the 10th percentile of modeled Lake Powell elevations is 3,543 feet msl. Some 190 unexcavated archaeological sites are at or above this elevation and would therefore be subject to potential erosion or visitor impacts. This is essentially the same effect as identified under the No Action Alternative.

4.9.3 Glen Canyon Dam To Lake Mead

The Colorado River reach between Glen Canyon Dam and Separation Canyon contains 336 NRHP-eligible properties. These are actively managed by the NPS, Navajo Nation and Hualapai Indian Tribe. In addition, Reclamation's NHPA Section 106 responsibilities for effects of Glen Canyon Dam operations are managed through a programmatic agreement. A treatment plan for mitigation of adverse impacts to historic properties is in development and will be implemented in 2008. The Grand Canyon Protection Act of 1992 ensures long-term mitigation of effects. Thus, the alternatives currently under analysis pose no additional threat to historic properties not already considered by existing programs.

4.9.4 Lake Mead and Hoover Dam

Some 32 previously recorded cultural resources are located at or below elevation 1,080 feet msl at Lake Mead, although many more undocumented cultural resources are probably submerged in Lake Mead at or below this elevation. If these cultural resources were to emerge, additional impacts would be anticipated as a result of invasion by invasive species of plants and animals (specifically as seen at St. Thomas by tamarisk and Asiatic freshwater clams), cracking and fissuring of sediments as a result of repeated wetting and drying and freeze/thaw cycles (Wyskup 2006), and as a result of visitor impacts. Resources like the B-29 Bomber aircraft, and the aggregate classification plant are currently at depths where they cannot be reached without specialized breathing-gas mixture and diving equipment, but a lowering of the reservoir elevation would bring these resources into the range of recreational divers.

4.9.4.1 No Action Alternative

The probability of Lake Mead elevation falling below 1,080 feet msl was analyzed in Section 4.3 and Table 4.3-22. Figure 4.3-22 present the probabilities of Lake Mead elevation falling below 1,080 feet msl over the period of analysis for all alternatives. Under the No Action Alternative, the probability begins at zero percent in 2008 and increases to 41 percent in 2060. From 2016 through 2040, the probability fluctuates between 39 percent and 45 percent.

4.9.4.2 Basin States Alternative and Conservation Before Shortage Alternative

In 2008, the probability of Lake Mead elevation falling below elevation 1,080 feet msl is zero under these action alternatives. In years 2016 through 2040, the probability is slightly higher (one to five percent) than under the No Action Alternative for several years and ranges between 40 percent and 46 percent. Given these small differences compared to the No Action Alternative, the differential effect on cultural resources would be negligible.

4.9.4.3 Water Supply Alternative

In 2008, the probability of Lake Mead elevation falling below 1,080 feet msl is zero. From 2016 through 2040, the probability fluctuates between 40 percent and 49 percent, a relative difference of about one to nine percent under the Water Supply Alternative compared to the No Action Alternative. Consequently, there is a higher probability that cultural resources submerged at or below elevation 1,080 feet msl would emerge under the Water Supply Alternative.

4.9.4.4 Reservoir Storage Alternative

In 2008, the probability of Lake Mead elevation falling below 1,080 feet msl is zero. The probability of the Lake Mead elevation falling below 1,080 feet msl is substantially lower (one percent to 13 percent) under this alternative compared to the No Action Alternative. Consequently, there is a lower probability that cultural resources submerged at or below elevation 1,080 feet msl would emerge under the Reservoir Storage Alternative.

4.9.4.5 Preferred Alternative

In 2008, the probability of Lake Mead elevation falling below 1,080 feet msl is zero. In 2016 the probability of Lake Mead elevation falling below elevation 1,080 feet msl is slightly lower (five percent) than under the No Action Alternative; and in 2017 through 2040, the probability is slightly higher (one to three percent) than under the No Action Alternative. Given these small differences compared to the No Action Alternative, the differential effect on cultural resources would be negligible.

4.9.5 Hoover Dam to Davis Dam

Under all alternatives, Lake Mohave would continue to be operated to meet monthly target elevations. Because there would be no change in reservoir operations, there is no potential for adverse effects to occur to cultural resources submerged in Lake Mohave as a result of the proposed federal action.

4.9.6 Davis Dam to Parker Dam

Geomorphic processes in lacustrine and fluvial environments differ, therefore, the Davis Dam to Parker Dam reach has been subdivided into sub-reaches for this analysis, a river reach and Lake Havasu.

4.9.6.1 Davis Dam to Upper Lake Havasu

There are ten previously recorded cultural resources located along the reach of the Colorado River from Davis Dam to the upstream end of Lake Havasu. Three of these cultural resources span the Colorado River with their end-points anchored in positions well above the river surface. A lowering of the elevation of the river in the area of these sites would have no direct or indirect effect on these resources. Examination of the site forms and map plots for two other previously recorded cultural resources, both being segments of railroads indicate that these sites are located in elevated positions back from the riverbank. No direct or indirect effects to these resources are anticipated as a result of the proposed federal action due to their elevated locations.

Of the five additional cultural resources in this reach, only two would be directly affected by a drop in river elevation. These two sites represent the remnants of two bridges used by contractors during the construction of Davis Dam.

Although the proposed federal action may result in reductions in the annual volume of water released from Davis Dam and the corresponding mean daily releases, the hourly releases will continue to fluctuate between the historical minimum and maximum ranges due to operational considerations and constraints. The corresponding river flows and associated elevations would also continue to fluctuate between the historical minimum and maximum ranges and therefore it is unlikely that there would be any changes in depositional or erosional processes along tributary streams or washes, or the Colorado River itself. Furthermore, it is highly unlikely that daily or hourly changes in elevation would result in conditions that would allow for more ready access to cultural resources located immediately adjacent to or in the river.

4.9.6.2 Lake Havasu and Parker Dam

Under the alternatives, Lake Havasu will continue to be operated to meet monthly target elevations. Because there will be no change in the manner in which the reservoir has been operated historically, there is no potential for effects to occur to cultural resources submerged in Lake Havasu.

4.9.7 Parker Dam to Imperial Dam

The Implementation Agreement FEIS (Reclamation 2002a) identified several cultural resource sites within or proximal to the Parker Dam to Imperial Dam reach. However, most of the historic resources that may be present in the APE, as suggested from plats and site records, have been destroyed by meandering and relocation of the mainstream channel of the Colorado River and agricultural development. Further, the proposed federal action will have no effect on Parker Dam, Imperial Dam or the Old Parker Road.

Although the proposed federal action may result in reductions in the annual volume released from Parker Dam and the corresponding mean daily releases, the hourly releases will continue to fluctuate between the historical ranges due to operational considerations and constraints. The corresponding river flows and associated elevations would also continue to fluctuate between the historical minimum and maximum ranges and therefore it is unlikely that there would be any changes in depositional or erosional processes along tributary streams or washes, or the Colorado River. Eleven of the twelve sites located proximate to the APE are situated in locations above the river channel, its connected lakes and backwaters, and floodplain. The anticipated changes in river elevations would therefore not impact these sites. Also, the prehistoric habitation site listed on the National Register would not be directly impacted by a drop in river elevation. It is conceivable that it could be indirectly impacted by better accessibility if the river drops in elevation more frequently or for longer periods of time. The probability of this occurring is small and would be countered by the emergence of impenetrable vegetation behind the retreating water line. Furthermore, it is highly unlikely that daily or hourly changes in elevation would result in conditions that would allow for more ready access to cultural resources located immediately adjacent to or in the river.

4.9.8 Sacred Sites and Other Issues of Tribal Concern

As a result of prior government-to-government consultations, several tribes had identified Indian sacred sites located on federal lands within the affected environment. During consultations regarding this proposed federal action, the Hualapai Indian Tribe was the only tribe who specifically raised a concern regarding how the alternatives might adversely affect the physical integrity of sacred sites. The Hualapai Indian Tribe also raised concerns regarding biological resources located in Grand Canyon and on Hualapai Tribal land.

Reclamation, NPS, and FWS (federal agencies who manage lands within the affected environment) remain committed to accommodating access to and ceremonial use of Indian sacred sites by Indian religious practitioners. The agencies also remain committed to avoiding any adverse effects to the physical integrity of such sites in compliance with Exec. Order No. 13007. None of the alternatives are anticipated to adversely affect any identified Indian sacred site or alter access to such a site.

During consultation for this proposed federal action, several tribes expressed concern that the alternatives might result in inadvertent discoveries of Native American human remains or cultural items as defined under the Native American Graves Protection and Repatriation Act of 1990 (NAGPRA). Reclamation and the federal land-managing agencies remain committed to compliance with both the inadvertent discovery and museum inventory sections of this law and its implementing regulations.

With respect to museum inventories from the original Glen Canyon archaeological project, Reclamation is working on cultural affiliation determinations on behalf of tribes seeking repatriation of inventory items from the Glen Canyon archaeological project.

4.9.9 Summary

For Lake Powell, under the Water Supply Alternative at the 10th percentile, there are at least 227 unexcavated sites subject to effect, as compared to about 193 sites under the other alternatives. Consultation is underway regarding eligibility and effect.

For the reach from Glen Canyon to Lake Mead, the alternatives pose no additional threat to cultural resources because of the programs already underway.

For Lake Mead, there are at least 32 cultural resources located below elevation 1,080 feet msl. The probability of exposing sites below this elevation vary by alternative, with the Reservoir Storage Alternative having the lowest probability (up to 13 percent lower compared to the No Action Alternative) and the Water Supply Alternative having the highest probability (up to nine percent higher compared to the No Action Alternative). The Basin States and Conservation Before Shortage alternatives and the Preferred Alternative have probabilities similar to those of the No Action Alternative.

For reaches downstream of Lake Mead, no adverse effects are anticipated from any of the alternatives. However, consultation regarding eligibility and effect will be undertaken.

For Indian sacred sites and other issues of Tribal concern (not including ITAs), none of the alternatives are expected to restrict access or result in loss of physical integrity to sacred sites. Consultations with Indian tribes are ongoing with respect to these issues and other issues and concerns.

4.10 Indian Trust Assets

4.10.1 Water Rights and Trust Lands

No vested water right of any kind, quantified or unquantified, including federally reserved Indian rights to Colorado River water, rights pursuant to the Consolidated Decree or Congressionally-approved water right settlements utilizing CAP water, will be altered as a result of any of the alternatives under consideration.

To the extent that additional Tribal water rights are developed, established or quantified during the interim period of the proposed federal action, the United States will manage Colorado River facilities to deliver water consistent with such additional water rights, if any, pursuant to federal law. Thus, modifications to system operations, in accordance with pertinent legal requirements, will consider Tribal water rights, and will be exercised in accordance with applicable law.

Water deliveries to the Fort Mojave, Chemehuevi, CRIT, and Fort Yuma Indian Reservations will not be affected by the proposed federal action due to their early priority dates. For the Cocopah Indian Reservation, its 1915 and 1917 PPRs would also not be affected. However, the 1974 priority date of 2,026 afy of the Cocopah Indian Reservation may be reduced during certain shortage conditions, as summarized in Section 4.4 (Water Deliveries). Similarly, the CAP Settlement tribes, with their post-1968 CAP Priority, would also be subject to shortages. However, even when water deliveries are reduced to these Indian Reservations, the underlying water rights would not be affected.

Water delivery reductions may result in fallowing of some Indian lands; however, these changes in land-use are expected to be temporary and no permanent changes in land-use would occur. In terms of effects to the shorelines of reservations that abut to the affected reservoirs or river reaches, the fluctuations that might occur as a result of this action downstream of Lake Mead are projected to be within historic levels.

For the action alternatives, the distribution of average daily releases may change (Table 4.3-13) from those under the No Action Alternative, but the operations would still be within the parameters of the 1996 Glen Canyon Dam ROD (Section 3.3). These occasional flow reductions and the concomitant sediment transport difference past the boundaries of the Navajo Nation and the Hualapai Indian Reservation would not affect Indian trust lands.

4.10.2 Hydroelectric Power Generation and Distribution

The energy generated at Headgate Rock Powerplant under the Basin States, Conservation Before Shortage, and Reservoir Storage alternatives, and the Preferred Alternative could potentially be less than the energy generated under the No Action Alternative (Section 4.11). These reductions in energy generation range from 1.3 percent to 2.8 percent (Table 4.11-23). However, Reclamation has determined that water appropriated to non-CRIT entities that flows through Headgate Rock Dam and generates electricity is not an ITA.

4.10.3 Cultural Resources

Reclamation is currently in the process of identifying cultural resources and evaluating potential effects of implementing the proposed federal action (Section 4.9). However, based on what is currently known of Tribal historic and traditional cultural properties, there would be no effect on cultural resources of concern to the tribes. Furthermore, under Exec. Order No. 13007, there would be no change in access to Tribal sacred sites as a result of the proposed federal action.

4.10.4 Biological Resources

While not necessarily ITAs, the Navajo Nation and the Hualapai Indian Tribe have expressed concern over biological resources located on their reservations and in the intervening Grand Canyon. The action alternatives would result in occasional changes of flows past the Navajo Nation and the Hualapai Indian Reservation, compared with the No Action Alternative (Section 4.8). These flows would have some potential to affect phreatophytes such as willow (a plant of concern to many tribes); however, the effects are likely to be short-term, especially in comparison to the long-term trends favoring tamarisk expansion.

The Navajo Nation and the Hualapai Indian Tribe also expressed concern over native fish. The Hualapai Indian Tribe is particularly concerned with razorback sucker in the upper end of Lake Mead. The modeling of Lake Mead elevations indicates that the minimum Lake Mead elevations under the action alternatives would be similar to those under the No Action Alternative (Section 4.8). Therefore, the proposed federal action is expected to have either no effects or only minor effects on razorback sucker and other fish of Tribal concern.

4.10.5 Summary

After analyzing each resource, it is concluded that Tribal trust assets identified in the study area would not be adversely affected by any of the anticipated environmental impacts stemming from the proposed federal action.

4.11 Electrical Power Resources

This section analyzes the potential effects of the proposed federal action on electrical power (or hydropower) resources. The following issues are addressed:

- change in electrical power generated and the associated change in economic value;
- effect on Upper and Lower Colorado Basin funds that pay for operation, maintenance, replacements of power facilities, and other programs supported by these funds;
- financial implications associated with implementation of surcharges;
- potential impact to ancillary services; and
- change in annual cost of electrical power for pumping water associated with the Navajo Generating Station, City of Page water supply system, SNWA water supply system, and CAP pumping load.

4.11.1 Methodology

Reclamation conducted a study of the potential effects of the action alternatives on electrical power resources of the Colorado River system that included all major facilities with the exception of generation capacity at the Glen Canyon Powerplant. Western conducted a parallel analysis of the potential effects of the action alternatives only on Glen Canyon Powerplant (Appendix O). The two studies show very similar trends among the alternatives and the relative findings of each study are comparable. Western's analytical methodology includes a more detailed hourly analysis of the capacity of the Glen Canyon Powerplant because of operational limitations of hydropower facilities resulting from the 1996 Glen Canyon Dam ROD. The results of Reclamation's analysis are used throughout this section with the exception of the analysis of generation capacity and the economic value of generation capacity of the Glen Canyon Powerplant, which uses the results of the hourly analysis conducted by Western.

4.11.1.1 Electrical Energy Generated

The basis for the electrical power analysis is the CRSS model described in Section 4.2 and Appendix A of this final EIS. Among other variables, the model simulates monthly turbine release (af) and end-of-month reservoir elevation (feet msl) and calculates monthly generation (MWh) and monthly capacity (MW). The monthly generation data were then aggregated to produce estimates of annual generation. Using the resulting annual data, the mean, median, 90th percentile, and 10th percentile annual energy generation statistics were calculated for each year for the Glen Canyon, Hoover, Parker, and Davis Powerplants.

Since the reservoir behind Headgate Rock Dam is maintained at a relatively constant elevation, electrical power generation at the Headgate Rock Powerplant was calculated based on modeling changes in river flows provided by the CRSS model for the

No Action Alternative and the action alternatives. The modeled flows available to pass through the Headgate Rock Powerplant were first reduced by a factor of 5.96 percent to account for water that is likely to be bypassed through the Colorado River gates. This factor was derived from actual 2001 through 2005 data. Energy was then calculated using a conversion factor of 12.97 kWh/af, derived by averaging the monthly kWh/af values for the Headgate Rock Powerplant from 1996 through 1998.

In general, mean values provide an assessment of the overall impact to hydropower. The mean is the average of all modeled traces, which includes all hydrologic extremes, while the median is the midpoint of all values. Mean energy values higher than median values reflect water released from Glen Canyon Dam for equalization and the existence of the minimum objective release. Mean energy values lower than median values at the Hoover Powerplant are likely due to extreme dry conditions when Hoover Powerplant may not be generating power.

4.11.1.2 Generation Capacity

Using the capacity relationships for each powerplant, their respective monthly availability factors and the monthly forebay elevations simulated by the CRSS model, the monthly generation capacity for each powerplant was computed. The mean, median, 90^{th} percentile and 10^{th} percentile capacity values were then computed for the No Action Alternative and the action alternatives for the Glen Canyon, Hoover, Parker, and Davis Powerplants. For the Glen Canyon Powerplant, the analysis was conducted by Western (Appendix O). Capacity was not calculated for the Headgate Rock Powerplant because no changes in capacity are anticipated due to the constant elevation that is maintained in the upstream impoundment.

4.11.1.3 Economic Values

The economic value of operating an existing hydroelectric powerplant varies considerably with time of day. The cost of meeting demand varies on a second-by-second basis depending on the load, the mix of powerplants being operated to meet load, and their output levels. During off-peak periods, demand is typically satisfied with lower-cost coal, run-of-river hydropower, and nuclear units. During on-peak periods, the additional load is met with more expensive sources such as gas turbine units. Consequently, the economic value of hydropower is greatest during the hours when the demand for electricity, and the variable cost of meeting demand, is the highest.

The electrical energy prices used in this analysis were developed from both an hourly price forecast keyed to the Palo Verde Interchange and mean monthly reported price indices for the Palo Verde Interchange obtained from Dow Jones, Inc. The hourly forecast of 2004 electricity prices at the Palo Verde Interchange was developed using the AURORA model (Electric Power Information Solutions, Inc. 2005).

AURORA model simulations used in this analysis were developed for and used in the Northwest Power and Conservation Council's (NWPCC) Fifth Northwest Electric Power and Conservation Plan (NWPCC 2005). The NWPCC is primarily interested in Northwestern electricity markets. Relatively less attention is devoted to characterizing market conditions in other areas. Consequently, the forecast described in this analysis primarily reflects the default data supplied with the AURORA model.

For purposes of this analysis, the hourly prices developed using the AURORA model were scaled to match the mean monthly reported prices purchased from Dow Jones, Inc. The resulting (scaled) hourly prices exhibit the expected daily, weekly and monthly patterns of price behavior and reflect the mean values actually observed in each month.

The underlying hourly prices yielded by this process are for 2004. These prices were escalated by 2.2 percent per year to estimate 2008 prices. For this analysis, estimates of the economic value for the No Action Alternative and each of the action alternatives were analyzed using monthly generation data simulated by the CRSS model. The monthly generation values were then analyzed using the escalated mean price of electricity for that month. The monthly economic value was then aggregated to produce estimates of annual economic value.

The costs and benefits associated with electrical power generation are incurred at different times over a long period of time. Because the timing of these costs and benefits differ across the alternatives, the present value of the future stream of costs and benefits for each alternative was computed as a means of assessing the economic value of electrical power for each alternative.

All economic value estimates reported in this Final EIS are measured in present value 2008 dollars (PV 2008 $). All annual costs and benefits subsequent to 2008 were escalated by 2.2 percent per year and discounted back to the 2008 base year using a discount rate of 4.875 percent.

Similar to the process used in the economic analysis of electrical energy generation, the present value of generation capacity was analyzed. In this instance, the capacity was valued at $6.32/kW-month based upon the alternative market cost of capacity.

4.11.2 Electrical Power Generation Facilities

4.11.2.1 Glen Canyon Powerplant

No Action Alternative. The No Action Alternative values for annual energy generation, monthly generation capacity, and economic value at Glen Canyon Powerplant for the mean, median, 90th percentile, and 10th percentile values are presented in Table 4.11-1.

Table 4.11-1
No Action Alternative Values at Glen Canyon Powerplant

Measure	Mean	Median	90th Percentile	10th Percentile
Annual Energy Generation (MWh)	4,247,880	3,748,420	6,312,730	3,130,880
Monthly Capacity (MW)	606	546	839	451
Economic Value of Electrical Power Generation - Total (PV 2008 $ million)	7,350	6,523	10,663	5,436

Comparison of Action Alternatives to No Action Alternative. Table 4.11-2 presents the change in annual electrical energy generation for each alternative in MWh in comparison to the No Action Alternative, for the mean, median, 90th percentile, and 10th percentile values.

Table 4.11-2
Change in Glen Canyon Powerplant Annual Energy Generation (MWh)

Action Alternative	Mean	Median	90th Percentile	10th Percentile
Basin States	(3,610)	51,210	(38,020)	(92,680)
Conservation Before Shortage	(2,990)	50,570	(36,450)	(92,910)
Water Supply	(109,120)	34,830	(98,710)	(226,660)
Reservoir Storage	33,170	20,360	61,490	3,600
Preferred Alternative	3,460	46,250	(26,610)	(75,130)

Table 4.11-3 presents the percent change in annual energy generation for each alternative, in comparison to the No Action Alternative, for the mean, median, 90th percentile, and 10th percentile values.

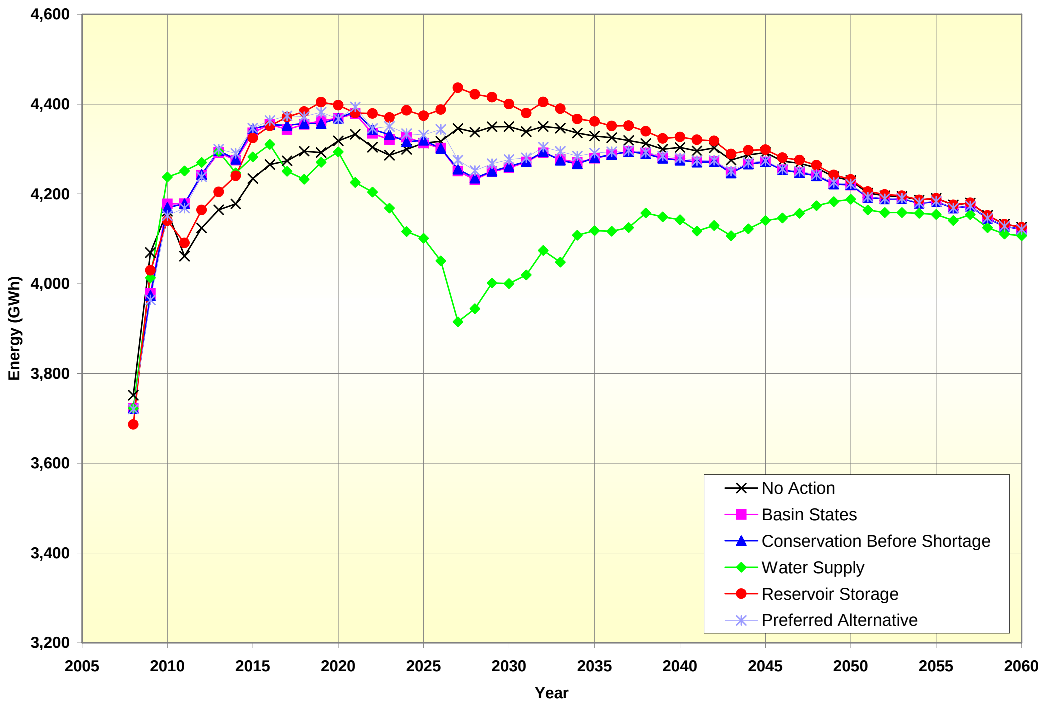
Table 4.11-3
Change in Glen Canyon Powerplant Annual Generation (percent)

Action Alternative	Mean	Median	90th Percentile	10th Percentile
Basin States	(0.08)	1.37	(0.60)	(2.96)
Conservation Before Shortage	(0.07)	1.35	(0.58)	(2.97)
Water Supply	(2.57)	0.93	(1.56)	(7.24)
Reservoir Storage	0.78	0.54	0.97	0.11
Preferred Alternative	0.08	1.23	(0.43)	(2.40)

Figure 4.11-1 shows average values of annual electrical energy production in gigawatt-hours (GWh) for the Glen Canyon Powerplant, over the period of study, for the action alternatives, and the No Action Alternative. Differences in mean generation values between the No Action Alternative and the action alternatives are the greatest from 2020 through 2050.

Western conducted a complementary study of energy generation and associated economic value using an hourly time-step to simulate hourly Glen Canyon Powerplant generation levels. Western's model was used to determine the hourly operation schedule that maximized the economic value of the hydropower resource. Hourly pricing data, inflation and discount rates used in Western's study were the same as those used by Reclamation.

Figure 4.11-1
Glen Canyon Powerplant
Average Annual Electrical Energy Production



The Western study also included an analysis of the impacts to generation capacity at the Glen Canyon Powerplant. Table 4.11-4 presents the change in generation capacity for each alternative, as compared to the No Action Alternative, for the mean, median, 90th percentile, and 10th percentile values. The corresponding percentage changes are identified in Table 4.11-5.

Table 4.11-4
Change in Glen Canyon Powerplant Generation Capacity (MW)

Action Alternative	Mean	Median	90th Percentile	10th Percentile
Basin States	(0.88)	6.04	(0.79)	(15.12)
Conservation Before Shortage	(0.79)	6.09	(0.74)	(15.01)
Water Supply	(16.50)	3.71	(9.65)	(33.91)
Reservoir Storage	4.81	2.87	6.75	(2.55)
Preferred Alternative	0.18	5.49	0.24	(12.41)

Table 4.11-5
Change in Glen Canyon Powerplant Generation Capacity (percent)

Action Alternative	Mean	Median	90th Percentile	10th Percentile
Basin States	(0.15)	1.11	(0.09)	(3.35)
Conservation Before Shortage	(0.13)	1.12	(0.09)	(3.33)
Water Supply	(2.72)	0.68	(1.15)	(7.52)
Reservoir Storage	0.79	0.53	0.80	(0.57)
Preferred Alternative	0.03	1.01	0.03	(2.75)

Table 4.11-6 presents the change in total economic value of electrical power generation for each alternative, as compared to the No Action Alternative for the mean, median, 90th percentile, and 10th percentile values. Table 4.11-7 presents the corresponding percentage change in net present value for each alternative as compared to the No Action Alternative for the mean, median, 90th percentile, and 10th percentile values.

Table 4.11-6
Change in Glen Canyon Powerplant Total Economic Value of Electrical Power Generation (PV 2008 $ million)

Action Alternative	Mean	Median	90th Percentile	10th Percentile
Basin States	1.70	126.57	(60.55)	(212.78)
Conservation Before Shortage	2.86	125.07	(57.90)	(212.17)
Water Supply	(165.72)	112.08	(151.39)	(426.17)
Reservoir Storage	64.72	41.70	108.40	(35.31)
Preferred Alternative	14.26	111.43	(40.61)	(178.60)

Table 4.11-7
Change in Glen Canyon Powerplant Total Economic Value of Electrical Power Generation (percent)

Action Alternative	Mean	Median	90th Percentile	10th Percentile
Basin States	0.02	1.94	(0.57)	(3.91)
Conservation Before Shortage	0.04	1.92	(0.54)	(3.90)
Water Supply	(2.25)	1.72	(1.42)	(7.84)
Reservoir Storage	0.88	0.64	1.02	(0.65)
Preferred Alternative	0.19	1.71	(0.38)	(3.29)

Under all the action alternatives, the greatest impact to power would occur in the dry years. The Reservoir Storage Alternative provides an increased electrical power generation value, as a result of higher reservoir elevations, while the other action alternatives show generally decreased electrical power generation values.

4.11.2.2 Hoover Powerplant

No Action Alternative. The No Action Alternative values for annual energy generation, monthly generation capacity, and economic value at the Hoover Powerplant for the mean, median, 90th percentile, and 10th percentile values are presented in Table 4.11-8.

Table 4.11-8
No Action Alternative Values at Hoover Powerplant

Measure	Mean	Median	90th Percentile	10th Percentile[1]
Annual Energy Generation (MWh)	3,127,523	3,675,298	5,188,960	0.0
Monthly Capacity (MW)	1,191	1,424	2,069	0.0
Economic Value of Electrical Power Generation - Total (PV 2008 $ million)	7,223	8,395	10,453	3,185

1 *The 10th percentile value for capacity and energy is zero on cumulative distribution function graphs of end-of-December capacity and energy, a result of Lake Mead elevation being less than 1,050 feet msl (the assumed minimum power head). This result cascades in calculating total generation and percentage changes in Tables 4.11-9 through 4.11-14.*

Comparison of Action Alternatives to No Action Alternative. Table 4.11-9 presents the change in annual electrical energy generation in MWh for each action alternative, in comparison to the No Action Alternative, for the mean, median, 90th percentile, and 10th percentile values.

Table 4.11-9
Change in Hoover Powerplant Annual Electrical Energy Generation (MWh)

Action Alternative	Mean	Median	90th Percentile	10th Percentile
Basin States	(6,960)	(46,952)	(15,193)	0.0
Conservation Before Shortage	(1,544)	(51,927)	(10,080)	0.0
Water Supply	(74,646)	(22,550)	(70,747)	0.0
Reservoir Storage	283,813	(55,065)	96,443	0.0
Preferred Alternative	43,772	(71,765)	6,843	0.0

Table 4.11-10 presents the percent change in annual electrical energy generation for each action alternative, in comparison to the No Action Alternative, for the mean, median, 90th percentile, and 10th percentile values.

Table 4.11-10
Change in Hoover Powerplant Annual Electrical Energy Generation (percent)

Action Alternative	Mean	Median	90th Percentile	10th Percentile
Basin States	(0.22)	(1.28)	(0.29)	0.0
Conservation Before Shortage	(0.05)	(1.41)	(0.19)	0.0
Water Supply	(2.39)	(0.61)	(1.36)	0.0
Reservoir Storage	9.07	(1.50)	1.86	0.0
Preferred Alternative	1.40	(1.95)	0.13	0.0

Figure 4.11-2 depicts average values of annual electrical energy production for Hoover Powerplant over the period of study for each alternative, including the No Action Alternative. Differences in mean generation values between the No Action Alternative and the action alternatives are the greatest from 2020 through 2050.

Figure 4.11-2
Hoover Powerplant
Average Annual Electrical Energy Production

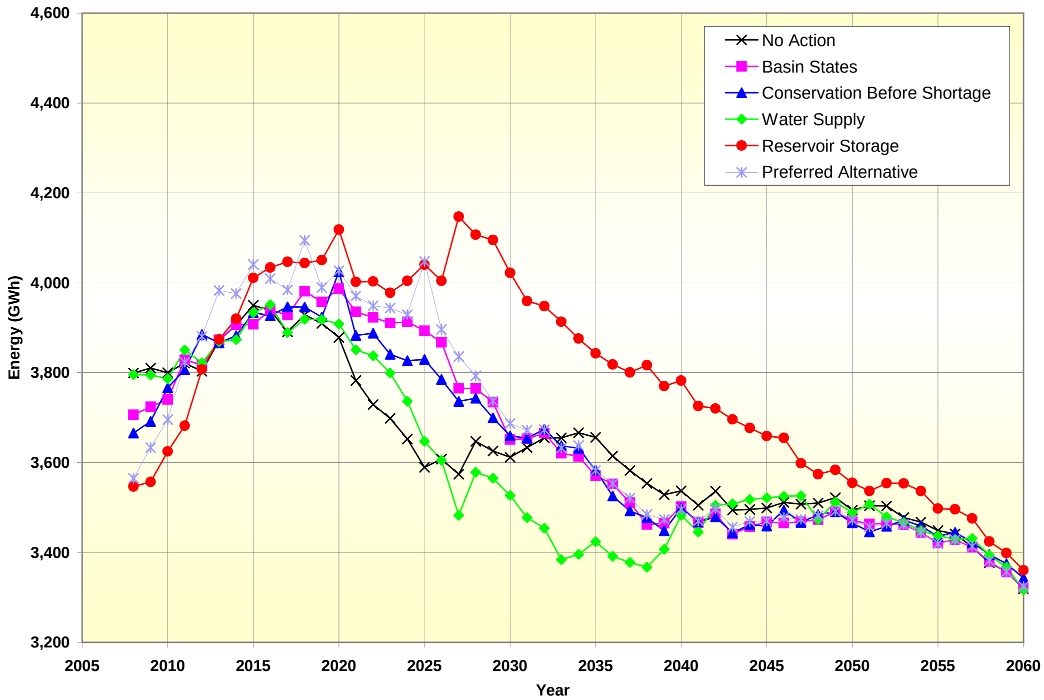


Table 4.11-11 presents the change in Hoover Powerplant monthly generation capacity (MW) for the action alternatives compared to the No Action Alternative for the mean, median, 90th percentile, and 10th percentile values.

Table 4.11-11
Change in Hoover Powerplant Monthly Generation Capacity (MW)

Action Alternative	Mean	Median	90th Percentile	10th Percentile
Basin States	3.7	2.2	0.6	0.0
Conservation Before Shortage	6.9	5.1	0.9	0.0
Water Supply	(30.5)	(13.0)	(0.5)	0.0
Reservoir Storage	137.2	56.6	4.9	0.0
Preferred Alternative	27.6	16.1	1.3	0.0

Table 4.11-12 presents the percentage change in the Hoover Powerplant monthly capacity for each of the action alternatives as compared to the No Action Alternative for the mean, median, 90th percentile, and 10th percentile values.

Table 4.11-12
Change in Hoover Powerplant Monthly Generation Capacity (percent)

Action Alternative	Mean	Median	90th Percentile	10th Percentile
Basin States	0.31	0.15	0.03	0.0
Conservation Before Shortage	0.58	0.36	0.04	0.0
Water Supply	(2.56)	(0.91)	(0.03)	0.0
Reservoir Storage	11.52	3.97	0.24	0.0
Preferred Alternative	2.31	1.13	0.06	0.0

Table 4.11-13 presents the change in each of the action alternatives as compared to the net present value of the total electrical power generation under the No Action Alternative for the mean, median, 90th percentile, and 10th percentile values.

Table 4.11-13
Change in Hoover Powerplant Total Economic Value of Electrical Power Generated (PV 2008 $ million)

Action Alternative	Mean	Median	90th Percentile	10th Percentile
Basin States	5.86	(269.01)	(16.1)	(87.19)
Conservation Before Shortage	24.34	(265.45)	(8.7)	(82.9)
Water Supply	(181.0)	(479.69)	(30.34)	(270.47)
Reservoir Storage	768.15	307.14	49.13	1,551.99
Preferred Alternative	172.13	(163.23)	25.62	163.95

Table 4.11-14 presents the corresponding percentage change in net present value for each alternative as compared to the No Action Alternative for the mean, median, 90th percentile, and 10th percentile values.

Table 4.11-14
Change in Hoover Powerplant Total Economic Value of Electrical Power Generated (percent)

Action Alternative	Mean	Median	90th Percentile	10th Percentile
Basin States	0.08	(3.20)	(0.15)	(2.74)
Conservation Before Shortage	0.34	(3.16)	(0.08)	(2.60)
Water Supply	(2.51)	(5.71)	(0.29)	(8.49)
Reservoir Storage	10.63	3.66	0.47	48.73
Preferred Alternative	2.38	(1.94)	0.25	5.15

In general, the Reservoir Storage Alternative and the Preferred Alternative provide the greatest increase in electrical power generation value at the Hoover Powerplant, while the Water Supply Alternative proves most adverse to power generation. The Basin States and Conservation Before Shortage alternatives show similar results and they are ranked between the Reservoir Storage Alternative and the Water Supply Alternative in their effect on power resources at the Hoover Powerplant.

4.11.2.3 Parker and Davis Powerplants

No Action Alternative. The No Action Alternative values for annual energy generation, monthly generation capacity, and total economic value for the Parker and Davis Powerplants for the mean, median, 90th percentile, and 10th percentile values are presented in Table 4.11-15.

Table 4.11-15
No Action Alternative Values at Parker and Davis Powerplants

Measure	Mean	Median	90th Percentile	10th Percentile
Annual Energy Generation (MWh)	1,639,687	1,581,530	1,820,271	1,506,057
Monthly Capacity (MW)	331.4	364.0	364.0	285.8
Economic Value of Electrical Power Generation - Total (PV (2008 $ million)	2,268	2,288	2,380	2,156

Comparison of Action Alternatives to No Action Alternative. Table 4.11-16 presents the change in annual electrical energy generation in MWh for each action alternative, in comparison to the No Action Alternative, for the mean, median, 90th percentile, and 10th percentile values.

Table 4.11-16
Change in Parker and Davis Powerplants Annual Electrical Energy Generation (MWh)

Action Alternative	Mean	Median	90th Percentile	10th Percentile
Basin States	(9,188)	(9,406)	(574)	(9,325)
Conservation Before Shortage	(11,363)	(12,380)	(176)	(11,029)
Water Supply	1,737	14,057	(12,449)	2,976
Reservoir Storage	(17,478)	(24,259)	(29,860)	(22,397)
Preferred Alternative	(11,214)	(14,561)	3,039	(13,763)

Table 4.11-17 presents the percent change in generation between the No Action Alternative and the action alternatives for the Parker and Davis Powerplants for the mean, median, 90th percentile, and 10th percentile values.

Table 4.11-17
Change in Parker and Davis Powerplants Annual Electrical Energy Generation (percent)

Action Alternative	Mean	Median	90th Percentile	10th Percentile
Basin States	(0.56)	(0.59)	(0.03)	(0.62)
Conservation Before Shortage	(0.69)	(0.78)	(0.01)	(0.73)
Water Supply	0.11	0.89	(0.68)	0.20
Reservoir Storage	(1.07)	(1.53)	(1.64)	(1.49)
Preferred Alternative	(0.68)	(0.92)	0.17	(0.91)

Table 4.11-18 shows that no changes are anticipated in monthly generation capacity under the action alternatives for the mean, median, 90th percentile, and 10th percentile values.

Table 4.11-18
Change in Parker and Davis Powerplants Monthly Generation Capacity (MW)

Action Alternative	Mean	Median	90th Percentile	10th Percentile
Basin States	0.0	0.0	0.0	0.0
Conservation Before Shortage	0.0	0.0	0.0	0.0
Water Supply	0.0	0.0	0.0	0.0
Reservoir Storage	0.0	0.0	0.0	0.0
Preferred Alternative	0.0	0.0	0.0	0.0

Figure 4.11-3 and Figure 4.11-4 depict average values of annual electrical energy production for the Parker Powerplant and Davis Powerplant, respectively, comparing the action alternatives to the No Action Alternative.

An observation from Figures 4.11-3 and 4.11-4 is a spike in energy production in 2025. This spike is due to a modeling assumption with regard to the storage and delivery mechanism and the modeled depletion schedules which withdraw a large volume of the storage credits in 2025.

Figure 4.11-3
Parker Powerplant
Average Annual Electrical Energy Production

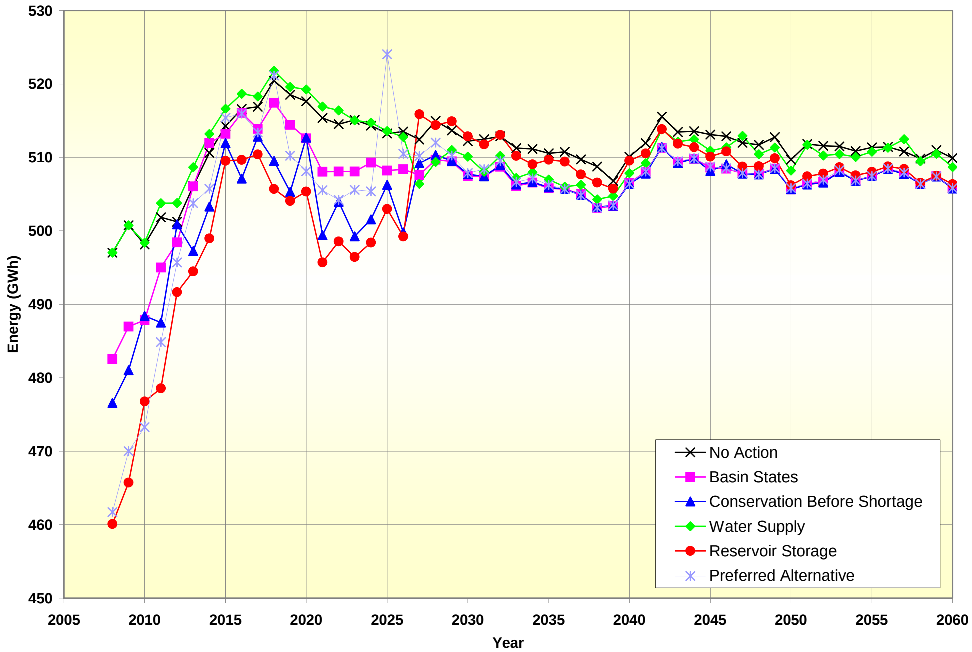

Figure 4.11-4
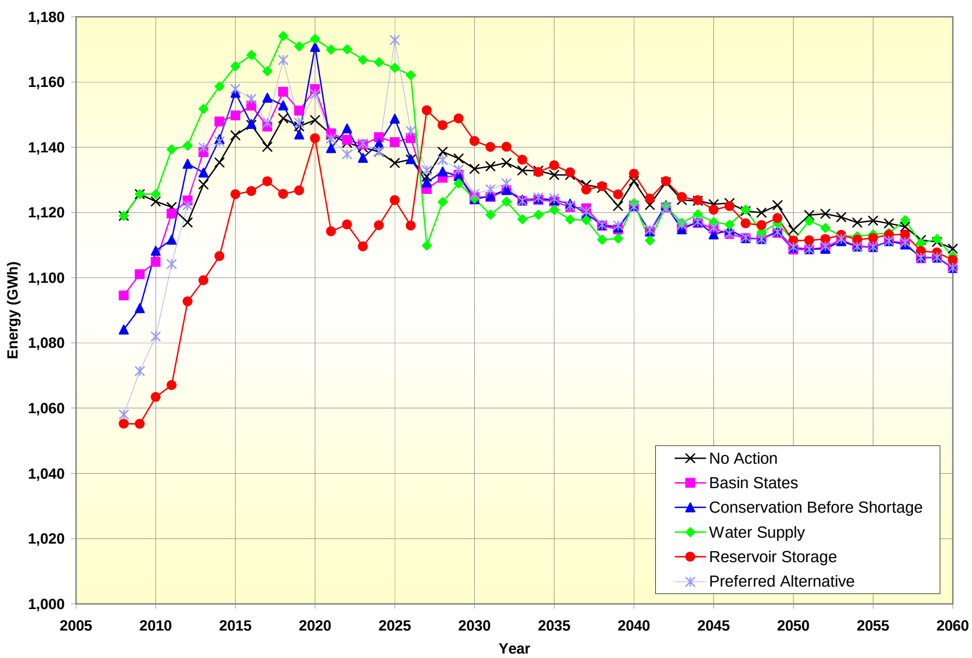
Davis Powerplant
Average Annual Electrical Energy Production



Economic value comparisons between the No Action Alternative and the action alternatives are presented in Table 4.11-19 for the mean, median, 90th percentile, and 10th percentile values.

Table 4.11-19
Change in Parker and Davis Powerplants Total Economic Value of Electrical Power Generation (PV 2008 $ million)

Action Alternative	Mean	Median	90th Percentile	10th Percentile
Basin States	(12.02)	(10.95)	(11.31)	(12.99)
Conservation Before Shortage	(16.66)	(16.50)	(12.09)	(19.16)
Water Supply	7.05	7.32	3.68	8.70
Reservoir Storage	(34.94)	(30.61)	(27.38)	(49.61)
Preferred Alternative	(18.32)	(17.57)	(14.23)	(20.08)

Table 4.11-20 presents the percent change in economic value between the No Action Alternative and each of the action alternatives for the mean, median, 90th percentile, and 10th percentile values.

Table 4.11-20
Change in Parker and Davis Powerplants Total Economic Value of Electrical Power Generated (percent)

Action Alternative	Mean	Median	90th Percentile	10th Percentile
Basin States	(0.53)	(0.48)	(0.48)	(0.60)
Conservation Before Shortage	(0.73)	(0.72)	(0.51)	(0.89)
Water Supply	0.31	0.32	0.15	0.40
Reservoir Storage	(1.54)	(1.34)	(1.15)	(2.30)
Preferred Alternative	(0.81)	(0.77)	(0.60)	(0.93)

In general, the Basin States and Conservation Before Shortage alternatives, and the Preferred Alternative could potentially provide a slight decline in the economic value of electrical power generated at Parker and Davis Powerplants. The Reservoir Storage Alternative is expected to result in a greater decline in economic values. The Water Supply Alternative results in slight increases in economic value for the Parker and Davis Powerplants.

Because of downstream requirements (i.e., environmental, plant operations, water requirements) the forebay elevations at Parker and Davis Powerplants remain relatively constant and electrical power generation is proportional to inflow. Consequently, the maximum generation capacity at Parker and Davis Powerplants will not be affected by the any of the action alternatives.

4.11.2.4 Headgate Rock Powerplant

No Action Alternative. The No Action Alternative values for annual generation and economic value at the Headgate Rock Powerplant for the mean, median, 90th percentile, and 10th percentile values are presented in Table 4.11-21.

Table 4.11-21
No Action Alternative Values at Headgate Rock Power Plant

Measure	Mean	Median	90th Percentile	10th Percentile
Annual Energy Generation (MWh)	77,482	73,698	85,069	69,611
Economic Value of Electrical Power Generation (PV 2008 $ million)	103	98	113	93

Comparison of Action Alternatives to No Action Alternative. Table 4.11-22 presents the change in annual generation in MWh for each action alternative relative to the No Action Alternative. The Water Supply Alternative provides higher median electrical energy generation due to the higher observed flows as compared to the No Action Alternative. The Basin States, Conservation Before Shortage, and Reservoir Storage alternatives, and the Preferred Alternative provided lower electrical energy generation as compared to the No Action Alternative for the mean, median, 90th percentile, and 10th percentile values.

Table 4.11-22
Change in Headgate Rock Powerplant Annual Electrical Energy Generation (MWh)

Action Alternative	Mean	Median	90th Percentile	10th Percentile
Basin States	(934)	(972)	(444)	(1,168)
Conservation Before Shortage	(1,322)	(1,252)	(509)	(1,946)
Water Supply	(216)	168	(716)	83
Reservoir Storage	(1,319)	(2,078)	1,164	(2,233)
Preferred Alternative	(1,164)	(1,283)	(437)	(1,817)

Table 4.11-23 presents the percent change in annual electrical energy generation for each action alternative relative to the No Action Alternative for the mean, median, 90th percentile, and 10th percentile values.

Table 4.11-23
Change in Headgate Rock Powerplant Annual Electrical Energy Generation (percent)

Action Alternative	Mean	Median	90th Percentile	10th Percentile
Basin States	(1.21)	(1.32)	(0.52)	(1.68)
Conservation Before Shortage	(1.71)	(1.70)	(0.60)	(2.80)
Water Supply	(0.28)	0.23	(0.84)	0.12
Reservoir Storage	(1.70)	(2.82)	1.37	(3.21)
Preferred Alternative	(1.50)	(1.74)	(0.51)	(2.61)

Figure 4.11-5 depicts average values of annual electrical energy production for Headgate Rock Powerplant, comparing the No Action Alternative and the action alternatives.

Figure 4.11-5
Headgate Rock Powerplant
Average Annual Electrical Energy Production

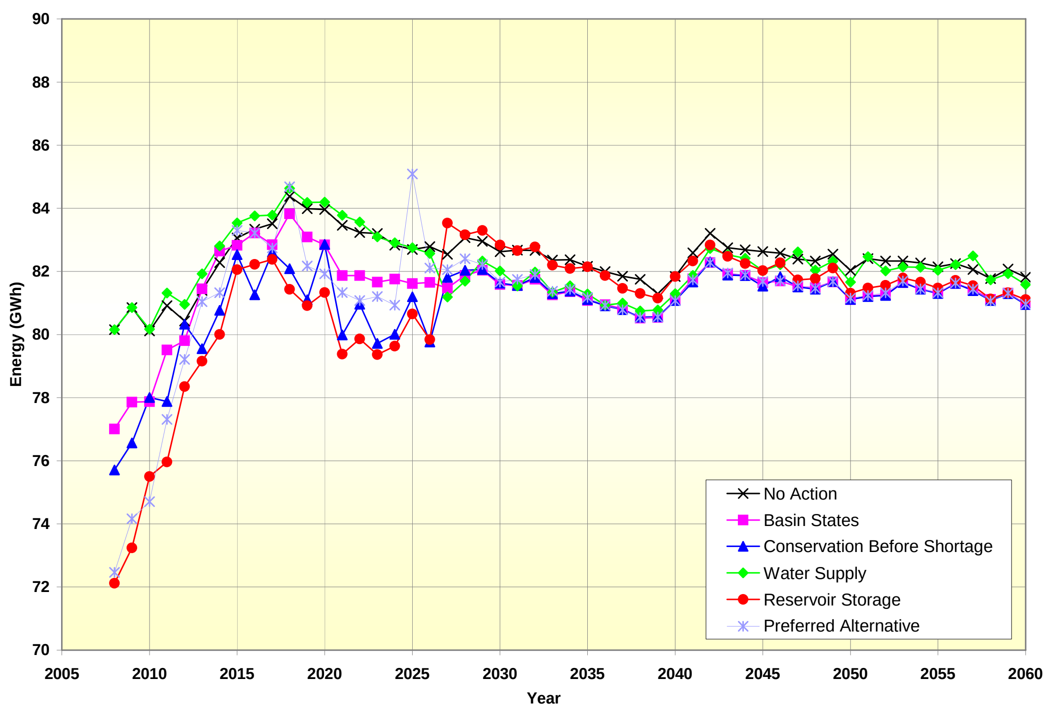


Table 4.11-24 provides an overview of the potential change in economic value of electrical power generated for each action alternative relative to the No Action Alternative for the mean, median, 90th percentile, and 10th percentile values.

Table 4.11-24
Change in Headgate Rock Powerplant Total Economic Value of Electrical Power Generated (PV 2008 $ million)

Action Alternative	Mean	Median	90th Percentile	10th Percentile
Basin States	(1.33)	(1.43)	(0.43)	(1.89)
Conservation Before Shortage	(2.08)	(2.08)	(0.52)	(3.52)
Water Supply	(0.18)	0.30	(0.86)	0.23
Reservoir Storage	(2.38)	(3.73)	1.46	(4.32)
Preferred Alternative	(1.89)	(2.19)	(0.54)	(3.41)

Table 4.11-25 provides an overview of the potential percent change in economic value of electrical power generated for each action alternative relative to the No Action Alternative for the mean, median, 90th percentile, and 10th percentile values.

Table 4.11-25
Change in Headgate Rock Powerplant Total Economic Value of Electrical Power Generated (percent)

Action Alternative	Mean	Median	90th Percentile	10th Percentile
Basin States	(1.29)	(1.46)	(0.38)	(2.03)
Conservation Before Shortage	(2.02)	(2.12)	(0.46)	(3.78)
Water Supply	(0.17)	0.31	(0.76)	0.25
Reservoir Storage	(2.31)	(3.81)	1.29	(4.65)
Preferred Alternative	(1.83)	(2.23)	(0.48)	(3.67)

In general, the value of electrical power generated under the Water Supply Alternative could potentially be slightly higher than under the No Action Alternative. The value of electrical power generated under the Basin States, Conservation Before Shortage, and Reservoir Storage alternatives, and the Preferred Alternative could potentially be less than under the No Action Alternative.

Currently Headgate Rock Powerplant generates more electrical power than is needed by CRIT. Implementation of any of the action alternatives is not expected to impact Headgate Rock Powerplant's ability to meet CRIT's current electrical power demands. However, a reduction in Headgate Rock Powerplant generation could impact BIA's ability to meet new Tribal energy demands.

4.11.2.5 Basin Power Funds

Upper Colorado River Basin Fund. Approximately $175 million is needed each year to fund Reclamation and Western operating needs. Western is responsible for transmission and marketing of CRSP power, collecting payment for the power, and the transfer of revenues for repayment to the General Treasury.

Implementation of the various alternatives will likely result in more variation in the Basin Fund, and could lead to additional actions such as power rate adjustments, rate surcharges, or reductions to customer allocations to respond to shortfalls in revenue under dry conditions. Western and its power customers need to quickly respond to changing hydrological conditions to forestall possible financial problems.

In addition, if an alternative were to increase or decrease Glen Canyon Powerplant electrical power generation over an extended period of time, Western and its power customers might decide to increase or decrease allocations in response, which could, in turn, affect the rate Western charges for the power and its financial reserves in the Basin Fund. A rate increase could affect customers' generation and power purchase decisions as well as their overall financial condition.

An important aspect associated with power delivery is whether and how much one or more of the alternatives alters the probability of a total loss of generation from Glen Canyon Powerplant. Loss of Glen Canyon Powerplant generation would result in a loss of revenue to Western, Reclamation, and various environmental programs in the Upper Basin; loss of generation and replacement costs for power customers; and degradation to power system reliability.

In the cases of such a loss of power, potential mitigation measures may need to be evaluated to offset or replace power revenue reductions and impacts to the Basin Fund and programs supported by this fund. A significant portion of the annual funding of the Endangered Fish Recovery Implementation Program is provided by power revenues. As such, any significant reduction in the power revenues would require that funds be secured from other sources.

Figure 4.11-6 shows the percentage of Lake Powell end-of-March elevations from Reclamation's CRSS modeling output that are less than or equal to elevation 3,490 feet msl. March typically has the lowest Lake Powell reservoir elevation of the year and elevation 3,490 feet msl is the point at which electrical power can no longer be produced at the Glen Canyon Powerplant. Using this measure, the Water Supply Alternative is more likely to provide conditions that would result in Lake Powell elevations falling below the minimum power pool elevation of 3,490 feet msl, as compared to the No Action Alternative. The Reservoir Storage, Basin States, and Conservation Before Shortage alternatives, and the Preferred Alternative have equal or slightly lower probabilities than the No Action Alternative. An analysis of end-of-July elevations indicated that these values are less pronounced than the end-of-March elevations, but similar.

Lower Colorado River Basin Development Fund. The functions of the Development Fund are to collect revenues and repayment associated with CAP, and to fund expenses related to the Colorado River Basin Salinity Control Program and projects as directed by the Arizona Water Rights Settlements Act (Public Law 108-451).

An important aspect associated with power delivery is whether and how much one or more of the alternatives alters the probability of a total loss of generation from Hoover Powerplant. Loss of Hoover Powerplant generation would result in a loss of revenue to Western, Reclamation and various environmental programs in the Lower Basin; loss of generation and replacement costs for power customers; and, degradation to power system reliability.

Figure 4.11-7 shows the percentage of end-of-July elevations from Reclamation's CRSS modeling output that are less than or equal to elevation 1,050 feet msl. This elevation is the point at which it is currently assumed that power can no longer be produced at the Hoover Powerplant.

Figure 4.11-6
Lake Powell End-of-March Elevations
Comparison of Action Alternatives to No Action Alternative
Percent of Values Less Than or Equal to Elevation 3,490 feet msl

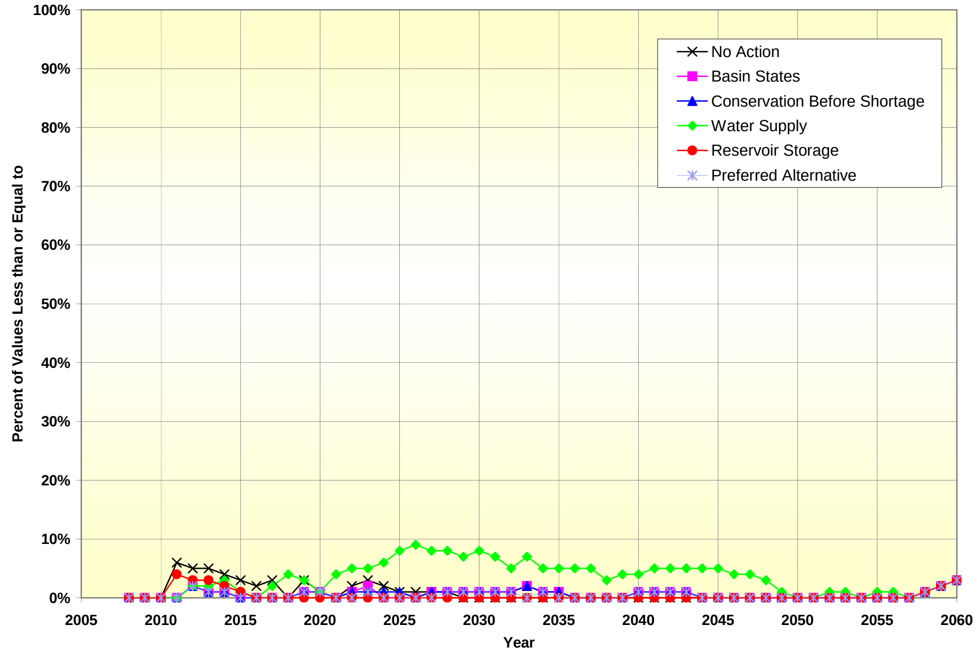

Figure 4.11-7
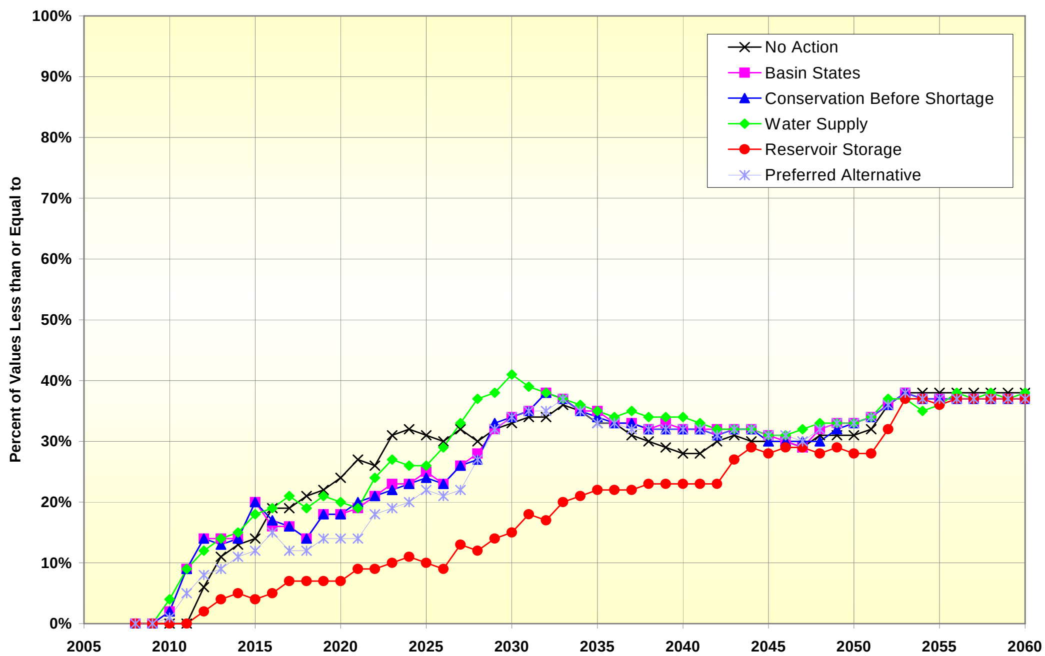
Lake Mead End-of-July Elevations
Comparison of Action Alternatives to No Action Alternative
Percent of Values Less than or Equal to Elevation 1,050 feet msl



Using this measure, the Water Supply Alternative is slightly more likely to produce conditions that would result in Lake mead elevations falling below the minimum power pool elevation of 1,050 feet msl than the No Action Alternative, while the Basin States and Conservation Before Shortage alternatives have equal or slightly lower probabilities than the No Action Alternative. The Preferred Alternative has slightly lower probability of having elevations below the power pool elevation through 2028, while the Reservoir Storage Alternative has much lower probability of having elevations below the power pool elevation. Values for end-of-July Lake Mead elevations are less pronounced, but similar.

Any of the alternatives that reduce electrical power production would reduce the surcharge revenues available to defray costs associated with the Colorado River Basin Salinity Control Act (Title II) and the CAP repayment.

Colorado River Dam Fund. The Dam Fund is utilized to fund operation and maintenance payments to states, visitor services, up-rating program, replacements, investment repayment, and interest expenses of the Boulder Canyon Project. The annual revenue requirement is typically approximately $60 to $70 million per fiscal year.

Since implementation of the various alternatives could result in more variation in the Dam Fund cash reserves, this could lead to additional actions such as power rate adjustments, or reductions to contractors allocations to respond to shortfalls in capacity, energy and revenues under dry conditions.

4.11.2.6 System-Wide Electrical Power Issues

Conservation Before Shortage Surcharge. The Conservation Before Shortage proposal submitted to Reclamation (Appendix K) suggests that a portion of the funding for the proposed voluntary conservation program could be derived from a conditional surcharge on power rates under existing or renewed contracts for hydropower produced at Hoover Dam. It is suggested that this surcharge could be imposed in years when Reclamation’s August 24-month study projects that storage in Lake Mead falls below 50 percent of its active capacity. The revenues generated by this surcharge could be collected in a power pool protection fund, to be maintained by Reclamation for expenditure when and if lake elevations reach a conservation trigger.

This surcharge is not included in the current economic analysis at any of the Upper or Lower Basin facilities or Basin Funds. Surcharges imposed are typically not included within Western's or Reclamation's electrical power rate structure. For example, the current 4.5 mil and the 2.5 mil rate imposed on Hoover Powerplant, and Parker and Davis Powerplant power contractors to help repay Reclamation’s CAP project construction costs and to provide funding for salinity projects are a separate part of the contractor’s bill.

Imposing a surcharge on power revenues would require separate legislation. Rate-making authority, except for Reclamation's project use power, lies with Western, therefore such changes would be under the purview of the Secretary of the Department of Energy and the United States Congress.

Ancillary Service Impacts. In addition to generating electrical power, each of the power generation facilities in the study area provides other electrical products and services referred to as ancillary services. Ancillary services are those services necessary to keep the power grid functioning continuously, safely, and reliably.

Western, as an operator of multiple control areas (referred to also as balancing authorities), is required by the Federal Energy Regulatory Commission to offer ancillary services to entities purchasing transmission services in its control areas. Entities purchasing transmission are required to self-supply ancillary services or purchase ancillary services from third parties. Hoover Powerplant capacity and energy is dynamically scheduled and made available to the contractors which allows certain ancillary services to be utilized in other control areas. The Hoover Powerplant is also a significant source of reserves, regulation and frequency control for non-Western control areas in Arizona, California, and Nevada.

Reserves. Because of low load factors at the Glen Canyon Powerplant and Hoover Powerplant, at any given time there are hundreds of megawatts of spinning or supplemental reserves that can be called on to respond to generating unit outages and power system emergencies. The available unscheduled capacity at the Parker and Davis Powerplants is used primarily for reserves. In addition, the generation units at Davis Powerplant have a portion of their capacity used exclusively for reserves.

Action alternatives that reduce or eliminate capacity at the Glen Canyon Powerplant and Hoover Powerplant will reduce or eliminate reserve capacity as well, impacting reliability of the power system, and impacting revenue to Western or to specific projects. None of the alternatives are expected to have a significant impact on reserves at the Parker and Davis Powerplants since the associated reservoir elevations are not affected. A reduction in electrical power production at these powerplants would create a slight increase in the average reserve capacity available.

Regulation and Frequency Control. Regulation and frequency control is needed to maintain power system stability and the moment-to-moment balance between load and generation. Reductions in electrical power generation from the Glen Canyon Powerplant and Hoover Powerplant would impact the ability of these powerplants to provide regulation services. Although the generating units are able to regulate throughout most of their operating range, the amount of regulation available decreases as generating capability decreases.

The Hoover Powerplant is primarily used to provide regulation for the control area. However, the Davis Powerplant has some capability for regulation and frequency control, but the available unscheduled capacity at the Davis Powerplant is used almost exclusively for reserves.

Any of the alternatives that cause the Glen Canyon Powerplant or Hoover Powerplant to stop generating completely due to low reservoir elevation (below the minimum power pool elevation), could potentially eliminate regulation as well. As shown on Figures 4.11-6 and 4.11-7, the Water Supply Alternative poses the greatest risk to regulation and frequency control at the Glen Canyon Powerplant and Hoover Powerplant, respectively.

Reactive Supply and Voltage Control. Reactive power is power required to charge the transmission lines and associated electrical equipment that comprise the power grid. Unlike other ancillary services that can assist the power system over large geographical areas, reactive supply and voltage control are limited to small areas. The Glen Canyon Powerplant supplies reactive power to northern Arizona and southern Utah, and the Hoover Powerplant supplies reactive power to northwestern Arizona, Southern Nevada, and southeastern California. Without an adequate supply of reactive power and constant monitoring, power system voltages can increase or decrease beyond acceptable limits, leading to system instability, cascading outages, and damage to electrical equipment.

Black Start Capability. Black Start Service, also referred to as Startup Service consists of providing the electrical power needed to start up a generating plant, usually after a system emergency (e.g., large scale blackout) that causes loss of electricity from the generating station.

The Glen Canyon Powerplant is relied upon to provide Black Start Service capability to the power system. The Hoover Powerplant is relied upon to provide the same capability to the power system and also for Palo Verde Nuclear Generating Station located outside Phoenix, Arizona. Similar to regulation and frequency control, the Water Supply Alternative is most prone to cause Glen Canyon Powerplant and Hoover Powerplant to stop generating completely due to low reservoir elevation conditions. The Parker and Davis Powerplants do not provide Black Start Service.

Contract Commitments. Western contracts with preference power customers to supply firm energy and capacity. Currently, about 243 municipalities, rural electric cooperatives, Indian tribes, irrigation districts, and state and federal facilities in Arizona, Nevada, New Mexico, Colorado, Utah, and Wyoming are served from SLCA/IP power facilities, which includes the Glen Canyon Powerplant. The Hoover Powerplant contractors have an allocation from Western for a specific quantity of contingent capacity and associated firm energy.

At the Glen Canyon Powerplant, the current contracts went into effect in October 2004 and extend through September 2024. At the Hoover Powerplant, the current contracts went into effect in June 1987 and extend through September 2017. For the Parker and Davis Powerplants, current contracts went into effect in October 1988 and extend through September 2008.

Each contractor has an allocation from Western for a specific quantity of energy and capacity each month. Western guarantees that the minimum quantity of energy will be available for contractors, and purchases power to meet that level whenever hydropower generation is insufficient to supply the required amount (referred to as firming purchases). Hydropower generation above the minimum level is also allocated to contractors on an as-available basis as operational and hydrological conditions allow.

An alternative may increase or decrease energy generation and capacity at the Glen Canyon Powerplant or Hoover Powerplant. Western has the ability to modify its contract commitments to its electrical power customers when a change in the volume of water released at these dams results in changes in electrical generation and capacity. For example, if an alternative reduces energy generation and capacity at the Glen Canyon Powerplant over the long-term average, Western would have the ability to lower its contract commitments to those customers who have contracts that include Glen Canyon Powerplant electrical power. The lower commitments would cause these customers (electrical utilities) to add new generating facilities, speed up planned construction of new generating facilities or take other action to make up for the reduction in Western's contract commitment. The estimated values of these actions by customers are what is portrayed in the tables in this section.

Energy and capacity allocations to contractors can be revised when the contracts are renewed. Allocations to contractors after contract terms expire will depend upon projections of future capacity and energy.

4.11.2.7 Electrical Power Use Associated with Water Supply Systems

This section discusses potential changes in pumping costs for the following entities that pump water from reservoirs: the NGS which obtains cooling water from Lake Powell; the City of Page which obtains municipal water from Lake Powell; SNWA which obtains water from Lake Mead; and CAP and MWD which pump water from Lake Havasu. Incremental differences in pumping costs are associated with differences in modeled average Lake Powell, Lake Mead, and Lake Havasu elevations between the No Action Alternative and the action alternatives.

River system modeling provided the average elevations for Lake Powell, Lake Mead, and Lake Havasu under the No Action Alternative and the action alternatives. Increases or decreases in net effective pumping head correspond with decreases or increases in average reservoir elevations. Estimates of the differences in pumping costs were calculated using these changes in pumping head, as well as estimates of annual pumping volumes, unit electrical power costs and pump efficiency.

Navajo Generating Station. The SRP estimates that water use at NGS will be approximately 29,000 afy in the future. Power for the intake pumps is obtained from auxiliary power units at NGS at a cost of $0.0104 per kWh. Table 4.11-26 identifies changes in electrical power requirements for the alternatives and the associated increase or decrease in cost.

Table 4.11-26
Change in Navajo Generating Station Intake Electrical Power Requirements at Lake Powell [1]

Action Alternative	Change in Annual Electrical Power Requirement (kWh)[2]	Change in Associated Annual Cost ($)
Basin States	122,484	1,170
Conservation Before Shortage	107,701	1,120
Water Supply	307,748	3,201
Reservoir Storage	(102,580)	(1,067)
Preferred Alternative	84,684	881

1. *Assumes 29,000 afy of pumping; Cost = E (kWh) = $0.0104*
2. *E (kWh) = 1.024 * V (afy) * H (ft) / E (%)*

City of Page Water Supply. The average annual water demand by the City of Page in recent years has been around 2,650 af (Section 3.12). Annual electrical power demand to deliver the water has averaged around 3,900,000 kWh per year over the past 10 years. Under the No Action Alternative, using the current rate of $.03286 per kWh (includes overhead), the annual cost of electrical power for pumping the water is around $130,000 per year.

Table 4.11-27 summarizes the differences in pumping costs for the Reclamation-operated raw water intake serving the City of Page. The greatest increase would occur under the Water Supply Alternative, an average increase of about $919 per year, in comparison to the No Action Alternative total annual cost of $130,000, an approximate increase of less than one percent. In general the effect on City of Page pumping costs would be minor under all alternatives.

Table 4.11-27
Change in City of Page Intake Electrical Power Requirements at Lake Powell [1]

Action Alternative	Change in Annual Electrical Power Requirement (kWh)[2]	Change in Associated Annual Cost ($)
Basin States	10,280	336
Conservation Before Shortage	9,842	322
Water Supply	28,122	919
Reservoir Storage	(9,374)	(306)
Preferred Alternative	7,738	253

1. *Assumes 2,650 afy of Pumping; Cost = E (kWh) = $0.03286*
2. *E (kWh) = 1.024 * V (afy) * H (ft) / E(%)*

SNWA Water Supply. Under the No Action Alternative, the average Lake Mead elevation declines from 2007 through 2060. The chance that lake elevations could drop below the minimum power pool elevation of 1,050 feet msl increases for all alternatives, with the Reservoir Storage Alternative resulting in the smallest increase in probability. These results also suggest that under the No Action Alternative, SNWA can expect pumping costs to increase due to the increase in net effective pumping head. The cost of pumping varies with each of the action alternatives as an increase or decrease compared to the No Action Alternative. Table 4.11-28 shows the potential differences between pumping costs under the action alternatives to those under the No Action Alternative.

Table 4.11-28
Change in Estimated SNWA Pumping Costs

Action Alternative	Change in Cost ($)
Basin States	(22,780)
Conservation Before Shortage	(38,726)
Water Supply	227,803
Reservoir Storage	(2,144,115)
Preferred Alternative	(501,720)

The change in pumping costs shown in Table 4.11-28 considers the difference in the average of the 50th percentile (median) Lake Mead annual elevation values from 2008 to 2060 under each action alternative to that of the No Action Alternative. The differences in the average of the median elevations (between each action alternative and the No Action Alternative) was multiplied by the estimated annual SNWA combined pumping costs for the two SNWA intake pump stations (Levy 2006 personal communication) corresponding to the respective Lake Mead elevations. A positive number in Table 4.11-28 indicates an increase in annual SNWA pumping costs and a negative number (in parenthesis) indicates a potential savings in annual SNWA pumping costs when compared to pumping costs required under the No Action Alternative.

CAP Pumping Load. Under all alternatives, when shortages are imposed on the CAP, there is an associated reduction in electrical power requirements to pump water, and more of CAP's share of NGS generation is available to be marketed (after 2011). For a 500,000 af shortage (at $48/MWh), the annual market value of the electrical power available to be marketed is approximately $41 million.

This revenue would benefit all CAP users to the extent it would be used to offset CAWCD's repayment obligation, as well as Indian tribes that benefit from the AWSA. The Reservoir Storage Alternative would result in the greatest overall shortages, and therefore the greatest reduction in CAP pumping load. Increased power revenues on the CAP water would likely be offset by increased delivery charges to CAP water users when CAP deliveries are reduced because of shortages.

4.11.2.8 Summary Comparison of Alternatives

Tables 4.11-29, 4.11-30, 4.11-31, and 4.11-32 summarize effects of each of the action alternatives compared to the No Action Alternative for electrical energy generation, generation capacity, and associated economic effects for the Glen Canyon, Hoover, Parker and Davis, and Headgate Rock Powerplants.

Table 4.11-29
Glen Canyon Powerplant
Summary Comparison of Action Alternatives to No Action Alternative
Mean Values for Electrical Energy Generation, Generation Capacity, and Economic Value

	Action Alternative					
	No Action	Basin States	Conservation Before Shortage	Water Supply	Reservoir Storage	Preferred Alternative
Annual Energy Generation (MWh)	4,247,880	4,244,270	4,244,890	4,138,760	4,281,050	4,251,340
Change in Annual Energy Generation (MWh)	0.0	(3,610)	(2,990)	(109,120)	33,170	3,460
Change in Annual Energy Generation (percent)	0.0	(0.08)	(0.07)	(2.57)	0.78	0.08
Monthly capacity (MW)	606	605	605	589	611	606
Change in Monthly Capacity (MW)	0.0	(1)	(1)	(17)	5	0
Change in Monthly Capacity (percent)	0.0	(0.15)	(0.13)	(2.72)	0.79	0.0
Economic Value of Electrical Power Generation – Total (PV 2008 $ million)	7,350	7,352	7,353	7,184	7,415	7,364

Glen Canyon and Hoover Powerplants. Tables 4.11-29 and 4.11-30 presents potential changes in generation, capacity, and economic value of electrical power. The Basin States, Conservation Before Shortage, and Water Supply alternatives, and the Preferred Alternative result in minor variations for each of these parameters. The Water Supply Alternative would have the greatest adverse effect on electrical power production and value because of generally lower elevations. Most of these changes are less than one percent, however, and these alternatives result in both positive and negative variations. Therefore, these impacts are considered minor. The Reservoir Storage Alternative generally results in greater positive changes with respect to electrical power production and value because of higher reservoir elevations and would result in moderate beneficial effects, particularly in the case of the Hoover Powerplant.

Parker, Davis, and Headgate Rock Powerplants. These facilities are generally considered to be "run of the river" electrical power generation facilities and are affected primarily by release volumes from Hoover Dam. As presented in Tables 4.11-31 and 4.11-32, the Basin States, Conservation Before Shortage, and Reservoir Storage alternatives, and the Preferred Alternative, all generally result in minor decreases in electrical power production and value at these facilities as compared to the No Action Alternative because they result in lower release volumes downstream of Hoover Dam, with the Reservoir Storage Alternative having the greatest adverse effects. Again, these changes are relatively minor (most less than one percent). The Water Supply Alternative results in greater release volumes downstream and therefore slight increases in electrical power production and value as compared to the No Action Alternative. These increases are considered beneficial but also minor as compared to overall electrical power production at these facilities.

Water Supply Systems. As presented in Table 4.11-29, the Basin States, Conservation Before Shortage, and Water Supply alternatives, and the Preferred Alternative would generally result in lower elevations at Lake Powell, as compared to the No Action Alternative, and therefore could potentially result in increased pumping costs for NGS and City of Page, with the Water Supply Alternative resulting in approximately twice the increase in costs as compared to the other action alternatives.

At Lake Mead, all of the action alternatives, with the exception of the Water Supply Alternative, provide higher reservoir elevations as compared to the No Action Alternative and therefore could potentially provide a decrease in pumping costs. As presented in Table 4.11-28 the Water Supply Alternative could potentially increase pumping costs.

The Reservoir Storage Alternative would result in generally higher reservoir elevations and therefore reduced pumping costs as compared to the No Action Alternative. This beneficial effect is also considered minor.

Basin Power Funds. Reductions in power revenues could reduce the amount of money available to meet the intended uses of these funds, possibly leading to reductions in allocations to power contractors or power rate adjustments. The action alternatives generally have a minor impact on the economic value of electrical power generation at the Glen Canyon and Hoover Powerplants. However, total loss of electrical power generation capabilities would have a substantial effect on the basin power funds. At the Glen Canyon Powerplant, the probability of this type of loss in electrical power generation capability is very small (less than five percent) except under the Water Supply Alternative, which would result in as much as a nine percent probability. At Hoover Powerplant, the probability of total loss of generation is higher, increasing from the current negligible probability to about 30 percent in 2026. However, as shown in Figure 4.11-7, the Reservoir Storage Alternative is the exception to this, while the remaining alternatives are very similar to the No Action Alternative.

4.12 Recreation

This section discusses the recreational resources within the study area that may be affected by the proposed federal action. The potentially affected recreational resources include:

- shoreline public use facilities;
- reservoir boating;
- river and whitewater boating; and
- sport fishing.

4.12.1 Methodology

The following methods were used to determine the effects of the alternatives on recreational resources.

4.12.1.1 Method Used to Assess Shoreline Public Use Facilities

These sections examine the probabilities that reservoir elevations would decrease below critical thresholds for use of selected marinas, boat docks, and boat launch ramps. These sections also assess whether impacts would occur in access to or use of attraction features. Threshold reservoir elevations were determined by reviewing published sources and through personal communication with Reclamation, NPS, and resource specialists, and from public comments provided during scoping for this EIS. The threshold elevations were used as indicators of recreational facilities that might be rendered inoperable or require relocation or modification to maintain their operation. Projections of reservoir elevations for 2008, 2016, 2026, 2030, 2040, 2050, and 2060 are provided in Section 4.3. The narrative of effects of the alternatives is provided below for selected facilities in July or September, representing relatively high visitation months for both Lake Powell and Lake Mead. These facilities are representative of potential effects of the alternatives on shoreline recreation opportunities at each reservoir. Results are presented for 2026, representing the end of the interim period. For Lake Powell, Wahweap Marina was selected for description in the narrative due to its popularity with boaters. For Lake Mead, Pearce Ferry at the inflow area to the reservoir is described. Effects on Echo Bay public launch ramp are also described in the narrative because it represents a facility that closes at the relatively low reservoir elevation of 1,050 feet msl.

4.12.1.2 Method Used to Assess Reservoir Boating

This analysis assesses the probabilities of reservoir elevations decreasing below critical thresholds, resulting in boating navigation hazards, changing navigable areas, and passage ways, and assesses whether corresponding decreases in reservoir surface areas might affect safe boating capacities. Threshold pool elevations were determined by reviewing published sources and through personal communication with Reclamation, NPS, and resource specialists, and from public comments.

In general, the surface area of the reservoirs available for boating is reduced when the reservoir elevation drops, which may affect the number of boats that can safely operate at one time, referred to as safe boating density. The safe boating density value can be used to assess the effects of each alternative on boating safety if levels of daily boating use were available. However, recent and consistent information on the level of daily or peak boating use, such as whether the current boating densities on the reservoirs have approached or exceeded the safe boating density is not available. Without information on current reservoir boating densities, it cannot be determined whether any reductions in pool elevations at Lake Powell and Lake Mead associated with the alternatives would result in unsafe boating conditions due to a corresponding increase in boating density. Personal communications with boaters and NPS managers suggest that Lake Mead and Lake Powell have not exceeded safe boating densities.

Navigation hazards and shallow waters require boaters to take detours around inaccessible areas. This may add mileage to trips and may influence recreational boaters to remain in specific areas, which can result in congestion in those areas. Additionally, as reservoir elevations drop and surface area decreases, congestion may become more noticeable in popular areas that receive high-use or where narrow travel corridors exist.

4.12.1.3 Method Used to Assess River and Whitewater Boating

This analysis uses river flow data from Section 4.3 to analyze whether there would be increased exposures to boating navigation hazards, changes in access or use of rest areas and take-outs, or changes in trip durations resulting under the action alternatives as compared to the No Action Alternative. Whitewater boating is the key recreational activity in Grand Canyon downstream of Lees Ferry and upstream of Lake Mead. Other river reaches do not provide whitewater boating opportunities and, therefore, are not addressed in this EIS.

Threshold river flows were determined by reviewing published sources and through personal communication with river managers and from comments received during scoping. These representative river flows were chosen as indicators for whitewater boating safety and the availability of rest areas and take-out points.

This analysis also includes a discussion of areas on the Colorado River that could become unsafe for whitewater boating at certain flows due to hazards such as exposed rocks, changes in navigation patterns caused by obstructions, and increased or decreased flow velocities. These flows were also analyzed to determine elevations at or below which various whitewater boating facilities (rest areas and take-out points) might be rendered inoperable or require modification to maintain their operation.

4.12.1.4 Method Used to Assess Sport Fishing

This analysis evaluates changes in sport fishing opportunities by river reach under the action alternatives as compared to the No Action Alternative. The assessment of sport fishing was based on literature review to determine the current status of fish assemblages in the study area. No specific reservoir elevation thresholds related to sport fishing were found. A general discussion about changes in flow and salinity and possible effects on sport fish is also provided.

A more detailed analysis of effects to rainbow trout based on changes in water temperature is used for the Colorado River reach between Glen Canyon Dam and Lake Mead. Water temperature changes may affect sport fish. Rainbow trout were chosen for the analysis based on the importance of its recreational fishery in the Colorado River reach below Glen Canyon Dam.

Striped bass and threadfin shad in Lake Powell and Lake Mead were selected to represent the reservoir sport fishery; striped bass are a sports fish and threadfin shad are their food source. Striped bass feed on threadfin shad, and when shad are abundant, striped bass are able to reproduce and grow quickly. The resulting increased bass population continues feeding on the threadfin shad, and they deplete the shad populations. As striped bass decline in numbers predation on threadfin shad decreases. This causes the threadfin shad population to increase again. This cycle has been occurring since the first introduction of striped bass into Lake Powell in 1974 and is expected to continue in the future (Gustaveson 1999).

Rainbow trout and its water temperature thresholds were used to analyze potential differences in impacts between the alternatives downstream of Glen Canyon Dam. Minimum, maximum, and lethal water temperatures for various life history stages were determined and the months during which spawning, incubation, and growth occur were established. The 10^{th} percentile data were used to analyze potential effects because the 50^{th} and 90^{th} percentile data are essentially identical between the alternatives and no meaningful differences exist. It is important to note that the 10^{th} percentile elevations are unlikely to occur in any given year or consistently over time (Section 4.2). Modeled temperature data at Glen Canyon Dam and Lees Ferry, the Little Colorado River confluence, and at Diamond Creek were used in the trout fishery analysis. A qualitative analysis of potential water temperature changes and effects on rainbow trout were made by comparing the differences between water temperatures under the No Action Alternative and the action alternatives.

Water Temperature Assessment. Minimum and maximum monthly surface water temperature data (up to ten feet below the surface) for Lake Powell were provided and compared to striped bass and threadfin shad thresholds to determine whether potential surface water temperatures would exceed the lethal tolerances of striped bass or threadfin. The lower lethal limit for striped bass is 5°C and the upper lethal limit is 33°C. The lower lethal limit for threadfin shad is 5°C and the upper lethal limit is 37°C.

Modeled river water temperatures (Section 4.5 and Appendix P) were used to assess the possible effects on rainbow trout in the river reach from Glen Canyon Dam to Diamond Creek (Tables 4.5-4 to 4.5-9 and Appendix P). Conditions supporting rainbow trout spawning and incubation were assumed to deteriorate as temperature of river water warms beyond 15ºC (Table 4.12-1). Trout eggs that are subjected to temperatures warmer than 15ºC are prone to increased mortality (Table 4.12-1). Juvenile rearing success is assumed to deteriorate at water temperatures ranging from 17ºC to 25ºC. Rainbow trout can be expected to show significant mortality at temperatures exceeding 25ºC (Myrick and Cech 2001; Raleigh et al. 1984) (Table 4.12-1).

Table 4.12-1
Water Temperature Tolerances of Rainbow Trout (ºC)

Species	Species Code	Spawning			Incubation			Growth			Lethal	
		Minimum	Maximum	Optimum	Minimum	Maximum	Optimum	Minimum	Maximum	Optimum	Low	High
Rainbow Trout	RBT	8	13	10	7	15	10	12	21	16	0	25

In the Colorado River, rainbow trout are year-round residents. Spawning typically begins in January and continues into May, with peak spawning occurring in March and April (Korman et al. 2005) (Table 4.12-2). During spawning, the female digs a redd (i.e., gravel nest) where the eggs are deposited, and they are then fertilized by the male. The optimal water temperature for trout spawning and incubation has been reported to fall between 7ºC and 15ºC (Table 4.12-1). Incubation lasts from 1.5 months to 4 months, depending on water temperature (Table 4.12-2).

Newly emerged fry move to shallow, protected areas along stream banks, but as they grow, they move to faster, deeper areas of the river. Shallow riffles are the most important channel type for trout during their first year (Barnhart 1986). Juvenile trout generally use riffles and runs in the main and secondary channels, along with the head and tail of pools. Juvenile rearing success is assumed to deteriorate at water temperatures ranging from 17ºC to 25ºC. Juvenile trout feed on a variety of aquatic and terrestrial insects and other small invertebrates.

Salinity Assessment. Salinity levels were assessed downstream of Hoover Dam and it was determined that future salinity levels would not affect rainbow trout (Section 4.5). Striped bass are naturally a brackish to salt water species, so any slight increase in salinity should have no effect on striped bass or threadfin shad. Therefore this issue is not discussed further.

Flow Assessment. Flow reductions that occur outside of spawning periods of fish are expected to have minimal impacts on fish species because habitat is likely not a factor limiting their populations. Extreme reductions, however, could result in the loss of fish through stranding and reduction in water quality (e.g., dissolved oxygen, temperature). The abundance of sports fishes, however, would be expected to recover following flow reduction periods through natural reproduction and through augmentations under fish stocking programs.

Flow reductions during the spawning period could desiccate eggs or strand juvenile fish. Impacts on sport fishes are expected to be minimal because their populations are relatively large and would be expected to recover following reduced flow conditions through natural reproduction and through augmentations under fish stocking programs.

Given that releases from Glen Canyon Dam would remain within their historic range, it was concluded that changes in flow would not be a useful tool to analyze effects on sport fish in this reach of the river. The reaches downstream of Hoover Dam are also expected to continue with operations similar to historic conditions. Therefore, flow assessment was not used in this analysis.

4.12.2 Recreation at Lake Powell

Threshold elevations below which shoreline recreational facilities at Lake Powell could be affected are identified in Section 3.12, Table 3.12-3. Below these elevations, facility adjustments or capital improvements would be required, creating potential impacts on recreation at Lake Powell. The percentages of values less than or equal to these threshold elevations during the study period are presented in Section 4.3, Figures 4.3-3 through 4.3-11 and Tables 4.3-2 through 4.3-10.

4.12.2.1 Access or Use of Lake Powell Boating Facilities

No Action Alternative. In September 2026, there is a 16 percent chance that the boat launch ramp at Antelope Point marina, located at elevation 3,588 feet msl, would close or need to be modified. In September 2026, there is a seven percent chance that elevations will be less than 3,560 feet msl, resulting in the closure or modification of Wahweap and lower Bullfrog launch ramps. Section 4.3, Table 4.3-7 and Figure 4.3-8 provide data for all years and all alternatives.

Basin States and Conservation Before Shortage Alternatives. In September 2026, there is a 20 percent chance of Closing Antelope Point and a nine percent chance of closing Wahweap launch ramps and a 10 percent chance of closing lower Bullfrog launch ramp under these two alternatives, respectively.

Water Supply Alternative. In September 2026, there is a 35 percent chance of closing Antelope Point launch ramp and a 23 percent chance of closing Wahweap and lower Bullfrog launch ramps under this alternative.

Reservoir Storage Alternative. In September 2026, there is an eight percent chance of closing Antelope Point launch ramp or modifying it, and a three percent chance of closing Wahweap and lower Bullfrog launch ramps under this alternative.

Preferred Alternative. In September 2026, there is a 19 percent chance of closing Antelope Point launch ramp and an eight percent chance of closing Wahweap and lower Bullfrog launch ramps under this alternative.

4.12.2.2 Safe Boating Capacities and Exposure to Navigation Hazards

In general, as reservoir elevations drop, hazards such as submerged snags and boulders can become exposed or become closer to the surface, increasing the likelihood that boats can come in contact with such hazards. The elevations of such hazards are often unknown until the hazards become exposed. At Lake Powell elevation of 3,620 feet msl, hazardous obstructions result in NPS prohibiting boating around Castle Rock and Gregory Butte; data for all years and all alternatives are provided in Section 4.3, Table 4.3-5 and Figure 4.3-6.

No Action Alternative. In September 2026, there is a 28 percent chance NPS would have to prohibit boating around Castle Rock and Gregory Butte due to navigational hazards.

Basin States and Conservation Before Shortage Alternatives. In September 2026, there is a 36 percent and 35 percent chance of boating restrictions around Castle Rock and Gregory Butte under these two alternatives, respectively.

Water Supply Alternative. In September 2026, there is a 52 percent chance of boating restrictions around Castle Rock and Gregory Butte.

Reservoir Storage Alternative. In September 2026, there is a 24 percent chance of boating restrictions around Castle Rock and Gregory Butte.

Preferred Alternative. In September 2026, there is a 32 percent chance of boating restrictions around Castle Rock and Gregory Butte.

4.12.2.3 Lake Powell Sport Fish Populations

The maximum lethal limits of 37°C and 33°C for threadfin shad and striped bass, respectively, would not be exceeded under any of the alternatives. Further, these water temperatures are for the upper ten feet of the reservoir, and lower depths provide cooler water. It is assumed that striped bass and threadfin shad would be able to move into the cooler thermocline during the summer months (Gustaveson 1999). Water temperatures would not drop below the lower lethal limit of 5°C for striped bass or threadfin shad under any alternative. The coldest winter temperature could be 7°C. Because surface temperatures would not exceed the lethal tolerances of either species, and it is assumed that both species would have adequate thermal refugia; substantial temperature-related impacts to the reservoir sport fishery are not anticipated to occur under any of the alternatives.

The general trend for the alternatives indicates that Lake Powell elevations under the Basin States and Conservation Before Shortages alternatives, and the Preferred Alternative, do not differ substantially from the No Action Alternative. Therefore, Lake Powell sport fishing populations are expected to be similar to those under the No Action Alternative for lake sport fish under these three action alternatives. The Water Supply Alternative tends to have lower reservoir elevations, which makes the lake more susceptible to atmospheric temperature influence. The Reservoir Storage Alternative has generally higher Lake Powell elevations as compared to the No Action Alternative, which makes the lake less susceptible to atmospheric temperature influence. However, threadfin shad and striped bass should still be able to survive potential winter and summer temperature variations.

4.12.2.4 Access or Use of Rainbow Bridge

Above Lake Powell elevation of 3,650 feet msl, Rainbow Bridge is visible from the floating walkway and interpretive platforms at Rainbow Bridge National Monument. If Lake Powell elevations fall below 3,650 feet msl, Rainbow Bridge is no longer visible from the lake and the floating walkway and interpretive platforms are removed and stored. Under this circumstance, dock facilities would be moved to a lower elevation and connected to the land trail with a short walkway, and the old land trail through Bridge Canyon (submerged at full pool elevation) would be used. Reservoir elevation data for all years and all alternatives are provided in Section 4.3, Table 4.3-3 and Figure 4.3-4.

No Action Alternative. In September 2026, there is a 43 percent chance that NPS would have to close or modify facilities at Rainbow Bridge.

Basin States and Conservation Before Shortage Alternatives. In September 2026, there is a 58 percent and 57 percent chance that NPS would have to close or modify facilities at Rainbow Bridge under these two alternatives, respectively.

Water Supply Alternative. In September 2026, there is a 61 percent chance that NPS would have to close or modify facilities at Rainbow Bridge.

Reservoir Storage Alternative. In September 2026, there is a 39 percent chance that NPS would have to close or modify facilities at Rainbow Bridge.

Preferred Alternative. In September 2026, there is a 56 percent chance that NPS would have to close or modify facilities at Rainbow Bridge.

4.12.3 Recreation from Glen Canyon Dam to Lake Mead

4.12.3.1 Boating

Current operation of Glen Canyon Dam requires a minimum flow release of 8,000 cfs between 7 a.m. and 7 p.m., and 5,000 cfs at night. Therefore, daytime flows will not drop lower than the safe whitewater boating threshold flow of 5,000 cfs. In addition, flow releases from Glen Canyon Dam will be within the historical operating range. Releases from Glen Canyon Dam would generally be much higher than these minimum flows under all alternatives and hydrological conditions (Section 4.3, Tables 4.3-12 through 4.3-14). Therefore, there would be no change in exposure to unsafe boating conditions caused by change in river levels. Minor changes in exposure to boating navigation hazards caused by change in river velocity; changes in access or use of rest areas and take-out points; changes in trip duration caused by changes in river velocity; or ability to use sport fishing sites caused by change in flows, may occur under all alternatives. These changes would not be substantial and would not affect recreation use or opportunities.

4.12.3.2 Sport Fish Populations

Water temperature data from Lees Ferry, Little Colorado River confluence, and downstream of Diamond Creek gage were used for the Glen Canyon Dam to Lake Mead river reach to compare the No Action Alternative to the action alternatives (Tables P-BCR-1 to P-BCR-3 in Appendix P). Rainbow trout are the major sport fish in this Colorado River reach and they are therefore used for this assessment.

Glen Canyon Dam to Lees Ferry Reach:

- **No Action Alternative.** The historical range of release temperatures from Glen Canyon Dam was relatively stable between 1990 and 2002 and typically ranged from 7°C to 12°C (Section 4.8). These relatively stable cold temperatures were favorable for rainbow trout. Beginning in 2002, the range of release temperatures increased and the higher end of the range approached 16°C (Figure F-5 in Appendix F). Whirling disease was recently discovered in Lees Ferry trout. Research on whirling disease in other states indicates that water temperatures between approximately 10°C and 16°C appear to result in the highest prevalence of whirling disease infection (Montana Fish, Wildlife and Parks 1998). The intermediate host of the parasite that causes whirling disease is the tubifex worm. Water temperatures above and below the optimal range have been observed to reduce infection in trout. Under the No Action Alternative at the 10^{th} percentile, water temperatures have the highest potential to affect spawning, incubation, growth, and mortality of rainbow trout. Average temperatures at Lees Ferry will remain colder than the low end of the preference range for trout growth (less than 12°C) and within the historic range most of the time at Lees Ferry. In summer and fall months at the 10^{th} percentile release, average temperatures may exceed 12°C (Table P-BCR-1 in Appendix P). Average temperatures at Lees Ferry (Table P-BCR-1 in Appendix P) are always above the minimum suitable spawning temperature of 8°C (Table 4.12-1). The coldest months tend to be February, March, and April and average temperatures approach 8°C in these months, particularly at Lees Ferry. During potential egg incubation months of January through August, average temperatures may exceed the maximum temperature preference for incubation in August. Average temperatures at Lees Ferry are not expected to exceed 25°C but will be the warmest in summer and fall months at 10^{th} percentile releases. Temperatures under the No Action Alternative will continue to correspond with the optimal range for whirling disease in some months in the future, as has been occurring more frequently since 2002. However, temperatures could be both above and below the optimal range at certain times (Table P-BCR-1 in Appendix P). Since the parasite can persist in river sediments for a long time, temporary deviations from the ideal temperature range are not likely to result in eradication of this fish parasite once it is established in a particular river. Therefore, temperatures will continue to favor whirling disease downstream of Glen Canyon Dam into the future under the No Action Alternative. Overall, rainbow trout are expected to continue to persist downstream of Glen Canyon Dam under the No Action Alternative, though occasionally temperatures may be less than ideal for certain life history stages and parasites, as has occurred more often since 2002. Substantial impacts to the aquatic foodbase are not anticipated (Section 4.8).

- **Action Alternatives.** While the action alternatives as compared to the No Action Alternative are similar, the 10th percentile water temperatures show a potential slight warming trend for all of the alternatives except the Reservoir Storage Alternative. Under the Reservoir Storage Alternative, the 10th percentile average temperatures are above the minimum for growth (12°C) from July through November, which is similar to the No Action Alternative, though temperatures in these months remain lower than the No Action Alternative. The Water Supply Alternative shows the most potential warming but average water temperatures do not exceed the preferred growth temperature. Growth temperatures under the Basin States and Conservation Before Shortage alternatives, and the Preferred Alternative, are similar to those under the No Action Alternative. During the potential egg incubation period of January through August, the high end of the egg incubation temperature preference range (15°C) may be exceeded in July and August under the Basin States, Conservation Before Shortage, and Water Supply alternatives (Table P-BCR-1 in Appendix P). The Reservoir Storage Alternative, and the Preferred Alternative may exceeded incubation preferences in August. These higher average temperatures during the potential incubation period could cause egg mortality to a similar degree as under the No Action Alternative. The severity of egg mortality would depend on the duration of water temperatures above the limits for incubation, which is not known. Lethal limits for rainbow trout are not exceeded in any month for any action alternative. The Water Supply Alternative has the highest potential temperatures and thus may result in a shorter spawning season. Potential temperature effects on whirling disease under the Basin States and Conservation Before Shortage alternatives, and the Preferred Alternative, are similar to those under the No Action Alternative. The Water Supply Alternative has the warmest potential temperatures and could result in more often favorable conditions for whirling disease infection, though also a higher likelihood of temperatures too warm to favor whirling disease. The Reservoir Storage Alternative has the coldest temperatures and thus could be less likely to favor whirling disease infection. Substantial impacts to the aquatic foodbase are not anticipated (Section 4.8).

Little Colorado River Confluence:

- **No Action Alternative.** Under the No Action Alternative, the 10th percentile water temperatures were compared against the preferred water temperatures for spawning, incubation, growth and mortality of rainbow trout. From December through April average temperatures may be below the preferred ranges for growth (Table P-BCR-2 in Appendix P). Average temperatures are within the tolerance ranges for spawning during the spawning season and mortality for all months (Table P-BCR-2 in Appendix P). Average temperatures during the egg incubation period may exceed the temperature tolerance in July and August. Temperatures are within the ideal range for whirling disease in many months, though both warmer and colder than the ideal range sometimes. Conditions for whirling disease will be similar to those under the No Action Alternative for Lees Ferry.

- **Action Alternatives.** While the action alternatives as compared to the No Action Alternative are similar, the 10th percentile water temperatures show a slight potential warming trend for all of the alternatives except the Reservoir Storage Alternative, which is slightly cooler. The Water Supply Alternative shows the most potential warming and may exceed spawning temperatures in May (Table P-BCR-2 in Appendix P). Therefore, the Water Supply Alternative could potentially provide the shortest spawning season. Average temperatures under the remaining action alternatives remain suitable for spawning and are similar to those under the No Action Alternative, though the spawning season could be shortened in some years due to the warming trend of the remaining action alternatives. Warmer temperatures under the Water Supply Alternative would benefit trout growth, while the colder temperatures under the Reservoir Storage Alternative would reduce trout growth. The remaining action alternatives would result in growth conditions similar to those under the No Action Alternative. During the egg incubation period, the Basin States, Conservation Before Shortage, and Water Supply alternatives, and the Preferred Alternative, may exceed the egg incubation tolerance in June through August. The colder temperatures under the Reservoir Storage Alternative would only exceed this threshold in July and August. The severity of egg mortality would depend on the duration of water temperatures above the limits for incubation, which is not known. Lethal limits for rainbow trout are not exceeded in any month under any action alternative. Under all the action alternatives, temperatures are projected to be both within, above and below the ideal range for whirling disease. Temperature conditions for whirling disease under the Basin States and Conservation Before Shortage Alternatives, and the Preferred Alternative, are similar to those under the No Action Alternative. Temperature conditions for whirling disease under the Water Supply and Reservoir Storage Alternatives relative to the No Action Alternative are similar to the description for Lees Ferry, though the Reservoir Storage Alternative is above the ideal whirling disease range more often than others at Lees Ferry.

Diamond Creek:

- **No Action Alternative.** Under the No Action Alternative for Diamond Creek, the 10th percentile water temperatures show that from December through March average temperatures may be below the suitable range for growth. Higher average temperatures in May could exceed the temperature tolerance for spawning of 13°C (Table P-BCR-3 in Appendix P). Egg incubation temperatures may be exceeded in May through August and reduce reproductive success. Lethal water temperatures may be reached in the summer under the No Action Alternative though average temperatures remain below 25°C and it is anticipated that fish would be able to find thermal refugia.

- **Action Alternatives.** While the action alternatives as compared to the No Action Alternative are similar, the 10th percentile water temperatures show a potential warming trend for all of the alternatives, except for the Reservoir Storage Alternative. All of the action alternatives may meet or exceed spawning temperatures in April and May and exceed the egg incubation temperatures from May through August (Table P-BCR-3 in Appendix P). The Water Supply and Reservoir Storage Alternatives may potentially provide the shortest and longest spawning seasons, respectively, of the alternatives. The severity of egg mortality due to warmer temperatures would depend on the duration of water temperatures above the limit for incubation, which is not known. All of the action alternatives result in average temperatures from December through March that are below the threshold for trout growth, though similar to those under the No Action Alternative. The Basin States, Conservation Before Shortage, and Water Supply alternatives, and the Preferred Alternative, could result in average temperatures above the growth threshold (21°C) for trout in some months (Table P-BCR-3 in Appendix P). Overall, the Water Supply Alternative would result in the least favorable conditions for trout, while the Reservoir Storage Alternative would result in the best conditions. Lethal water temperatures above 25°C may be reached in July, August and September, though the average temperatures would remain below this threshold. These summer high temperatures would be greater than those under the No Action Alternative for these months except for the Reservoir Storage Alternative. However, juvenile and adult fish are able to find thermal refugia by moving upstream into cooler water habitats such as pools and may not be substantially affected by warmer water temperatures. Further, Diamond Creek is not as important for trout as Lees Ferry is.

4.12.4 Recreation at Lake Mead

Threshold elevations below which shoreline recreational facilities at Lake Mead could be affected are identified in Section 3.12, Table 3.12-7. Facility adjustments or capital improvements would be required below these elevations, creating potential impacts on recreation at Lake Mead. The percentages of values less than or equal to these thresholds during the study period are provided in Section 4.3, Figures 4.3-18 through 4.3-23 and Tables 4.3-18 through 4.3-23.

4.12.4.1 Access or Use of Lake Mead Boating Facilities

No Action Alternative. In July 2026, there is a 74 percent probability that Lake Mead elevations may be lower than 1,175 feet msl, resulting in the closure of the Pearce Bay launch ramp and the addition of another 16 miles that boaters would have to travel downstream to take-out (Section 4.3, Table 4.3-18 and Figure 4.3-18). The Echo Bay public launch ramp would close at elevation 1,050 feet msl (Section 4.3, Figure 4.3-22 and Table 4.3-22). In July 2026, there is a 30 percent chance that this facility would close under the No Action Alternative.

Basin States and Conservation Before Shortage Alternatives. In July 2026, there is a 76 and 75 percent chance of closing the Pearce Bay launch ramp under these two alternatives, respectively. In July 2026, there is a 23 percent chance under both of these alternatives that the Echo Bay public launch ramp would close due to low reservoir elevations.

Water Supply Alternative. In July 2026, there is a 78 percent chance of closing the Pearce Bay launch ramp. In July 2026, there is a 29 percent chance that the Echo Bay public launch ramp would close due to low reservoir elevations.

Reservoir Storage Alternative. In July 2026, there is a 66 percent chance of closing the Pearce Bay launch ramp and adding 16 miles to river trips. In July 2026, there is a nine percent chance that the Echo Bay public launch ramp would close.

Preferred Alternative. In July 2026, there is a 74 percent chance of closing the Pearce Bay launch ramp. In July 2026, there is a 21 percent chance that the Echo Bay public launch ramp would close.

4.12.4.2 Safe Boating and Navigation Hazards

Over the years, sediment has built up in the section of the reservoir between Grand Wash Cliffs and Pearce Ferry. When Lake Mead elevation drops below 1,170 feet msl, there is no well-defined river channel in this upper portion of Lake Mead, making it dangerous for boaters (NPS 2005a).

No Action Alternative. In July 2026, there is a 73 percent probability that boaters may encounter navigational hazards in upper Lake Mead (Section 4.3, Figure 4.3-19 and Table 4.3-19).

Basin States and Conservation Before Shortage Alternatives. In July 2026, there is a 73 percent probability that boaters may encounter navigational hazards in upper Lake Mead.

Water Supply Alternative. In July 2026, there is a 76 percent probability that boaters may encounter navigational hazards in upper Lake Mead.

Reservoir Storage Alternative. In July 2026, there is a 64 percent probability that boaters may encounter navigational hazards in upper Lake Mead.

Preferred Alternative. In July 2026, there is a 72 percent probability that boaters may encounter navigational hazards in upper Lake Mead.

4.12.4.3 Sport Fish Populations

No Action Alternative. Rainbow trout and razorback suckers are raised in the Lake Mead Fish Hatchery by Nevada Department of Wildlife (NDOW). NDOW obtains its water supply for the fish hatchery from Lake Mead. This water comes from the Basic Management, Inc. (BMI) intake at reservoir elevation of 1,060 feet msl. Under recent conditions, the hatchery has experienced problems with water temperature and total dissolved solids in its water from the intake (Parke 2006). Water temperature taken at the intake is approximately 24°C, which is too warm for trout. NDOW has noticed that the increase in water temperatures start when Lake Mead's elevation is less than 100 feet above the BMI intake (elevation 1,160 feet msl and less). The 50th and 10th percentile monthly elevations are never above 1,160 feet msl so temperature problems are likely to persist for future hatchery operations. The 90th percentile elevations are identical for all alternatives and would alleviate the hatchery's temperature problems. The 50th percentile elevations are always above 1,060 feet msl, but the 10th percentile elevations for all alternatives fall below 1,060 feet msl in the future. Thus, the hatchery may have water supply problems at the 10th percentile elevation values.

The situation for striped bass and threadfin shad in Lake Powell is expected to be similar at Lake Mead. However, threadfin shad are near the northern limit of their range at Lake Powell. Threadfin shad are less likely to be affected by cold winter temperatures at Lake Mead.

Action Alternatives. The Basin States and Conservation Before Shortage Alternatives, and the Preferred Alternative, would be similar to the No Action Alternative. The Reservoir Storage Alternative is the most beneficial to the hatchery's water supply and the Water Supply Alternative would have the most adverse effects on water temperature. Effects on threadfin shad and striped bass are expected to be similar to the effects at Lake Powell, and substantial temperature-related impacts to the reservoir sport fishery are not anticipated to occur under any of the alternatives.

4.12.5 Recreation from Hoover Dam to SIB

Flow releases from Hoover Dam, Davis Dam, Parker Dam, and Imperial Dam will all be within historical operating range. Therefore, there would be minimal changes in exposure to boating navigation hazards caused by changes in river elevation; changes in exposure to boating navigation hazards caused by changes in river velocity; changes in access or use of rest areas and take-out points; changes in trip duration caused by changes in river velocity; or decrease in access or use of sport fishing sites caused by changes in flows. The sport fishery in this reach is primarily in warm water. The minor changes in water temperatures that may occur downstream of Hoover Dam are not expected to affect warm water sport fish.

4.12.6 Summary

4.12.6.1 Shoreline Facilities

For shoreline public use facilities at Lake Powell, there is a 16 percent chance that the launch ramp at Antelope Point marina would close or need to be modified under the No Action Alternative. Under the Preferred Alternative, the chance is 19 percent. There is a three to 10 percent probability that the Wahweap and lower Bullfrog launch ramps may close in 2026 under the No Action Alternative, the Basin States, Conservation Before Shortage, and Reservoir Storage Alternatives, and the Preferred Alternative, while under the Water Supply Alternative there is a 23 percent probability of this occurrence. Other marinas and launch ramps are similarly affected under the different alternatives.

There is a 43 percent probability under the No Action Alternative that in 2026 NPS would have to close or modify recreational facilities at the Rainbow Bridge National Monument. The probability of facility closures under the action alternatives would be 39 to 61 percent.

At Lake Mead, under all of the alternatives there is a 74 to 78 percent probability that the Pearce Bay launch ramp would be closed to boaters, except under the Reservoir Storage Alternative this probability is 66 percent. Similarly, there is a 21 to 30 percent probability of closure of the Echo Bay public launch ramp (in the north end of the reservoir) under all of the alternatives, except under the Reservoir Storage Alternative this probability is nine percent.

4.12.6.2 Safe Boating and Navigation

For safe boating at Lake Powell, probabilities range from 24 to 28 percent that NPS would have to prohibit boating around Castle Rock and Gregory Butte under the No Action Alternative and the Reservoir Storage Alternative. Under the Basin States Alternative there is a 36 percent probability and under the Conservation Before Shortage Alternative there is a 35 percent probability that boating prohibitions would need to be put in place. Under the Water Supply Alternative the probability of this occurrence is 52 percent. Under the Preferred Alternative there is a 32 percent probability that prohibitions would be put in place. For Lake Mead, all the alternatives except the Reservoir Storage Alternative in July 2026 provide a 72 to 76 percent probability that boaters may encounter navigational hazards upstream end of Lake Mead due to reservoir elevations being drawn down to below 1,170 feet msl. Under the Reservoir Storage Alternative there is a 69 percent probability of a similar recreational impact. Similar effects would occur in the Overton Arm of Lake Mead.

For whitewater boating through Grand Canyon, the Glen Canyon Dam ROD flows will be maintained. Even in a 7.0 maf Glen Canyon Dam release year, the minimum daily flow will remain at or above 5,000 cfs, a safe boating threshold.

4.12.6.3 Sport Fish Populations

Sport fish populations would not be adversely affected at Lake Powell under any of the alternatives. Although surface water temperatures may approach lethal levels in the upper 10 feet of the reservoir under any alternative, lethal levels for striped bass and threadfin shad are not expected to be exceeded by any alternative. Moreover, cooler temperatures below the lake surface would serve as a refuge for the fish. The situation for striped bass and threadfin shad in Lake Mead is similar to Lake Powell. Higher water temperatures could impair the Lake Mead Fish Hatchery, particularly under the Water Supply Alternative.

Under the No Action Alternative, 10^{th} percentile temperatures are suitable for growth, spawning, and incubation in the months presented in Table 4.12-2. Higher water temperatures under the Basin States, Conservation Before Shortage, and Water Supply alternatives, and the Preferred Alternative, could affect various life history stages of rainbow trout downstream of Glen Canyon Dam. Under the action alternatives, 10^{th} percentile modeling results indicate that there could be minor impacts to rainbow trout due to warmer temperatures. The Water Supply Alternative shows the most warming and potential to negatively impact trout. The Reservoir Storage Alternative shows the least warming and will often result in colder temperatures than the No Action Alternative. Conditions for trout under the Basin States, Conservation Before Shortage, and Water Supply alternatives, and the Preferred Alternative, will be similar to slightly worse than under the No Action Alternative.

This page intentionally left blank.

4.13 Transportation

This section describes the methods of analysis and potential effects on transportation, focusing on ferry services and river taxis.

4.13.1 Methodology

4.13.1.1 Effects on Lake Powell Ferry Service

The John Atlantic Burr Ferry becomes inoperable when Lake Powell elevation falls below 3,550 feet msl, requiring additional driving of approximately 130 miles between the Bullfrog and Halls Crossing marinas. Consequently, for each action alternative, the analysis evaluates the probability of the ferry becoming inoperable and compares that to the probability under the No Action Alternative. These comparisons were based on Lake Powell end-of-September elevations between 2008 through 2060 (Table 4.13-1, Figure 4.3-10, and Table 4.3-9).

4.13.1.2 Effects on Laughlin River Taxis and Tour Boats

Changes in releases from Davis Dam have the potential to impact the operations of river taxi services and tour boats in Laughlin, Nevada. The projected discharges or flows were compared to the flows required by the river taxis and the tour boats.

4.13.1.3 Effects on Lake Havasu Ferry Service

Changes in Lake Havasu elevations could affect the existing ferry service and recreational uses. Effects of changes in Lake Havasu elevations on recreational uses are discussed in the recreational impacts discussion (Section 4.12). The discussion presented below is limited to the potential effects on ferry service provided on Lake Havasu.

4.13.2 Lake Powell Ferry Service

Table 4.13-1 lists the range of probabilities of Lake Powell elevations being less than or equal to 3,550 feet msl for each alternative. An analysis for each alternative is provided below.

Table 4.13-1
Range of Probabilities (percent) of Lake Powell Elevations Less Than or Equal 3,550 feet msl

Alternative	2008 through 2026	2026 through 2060
No Action	0 to 5	4 to 7
Basin States	0 to 7	5 to 7
Conservation Before Shortage	0 to 7	5 to 7
Water Supply	0 to 17	8 to 17
Reservoir Storage	0 to 3	1 to 7
Preferred Alternative	0 to 7	5 to 7

4.13.2.1 No Action Alternative

The likelihood that Lake Powell elevations would fall below 3,550 feet msl under the No Action Alternative is not greater than seven percent for all years (zero to seven percent; Table 4.13-1, Figure 4.3-10, and Table 4.3-9). Consequently, the Lake Powell ferry service would be able to operate 93 percent or more of the time under the No Action Alternative.

4.13.2.2 Basin States Alternative

The Basin States Alternative would result in very similar or slightly higher probabilities (zero to seven percent) of Lake Powell elevations being less than 3,550 feet msl when compared to the No Action Alternative for the period 2008 through 2026 (Table 4.13-1, Figure 4.3-10, and Table 4.3-9). For the period 2026 through 2060, the Basin States Alternative would result in similar or slightly higher probabilities (five to seven percent) as compared to the No Action Alternative. The net effect under this alternative is minor.

4.13.2.3 Conservation Before Shortage Alternative

The Conservation Before Shortage Alternative would result in very similar or slightly higher probabilities (zero to seven percent) of Lake Powell elevations being less than 3,550 feet msl when compared to the No Action Alternative for the period 2008 through 2026 (Table 4.13-1, Figure 4.3-10, and Table 4.3-9). For the period 2026 through 2060, the Conservation Before Shortage Alternative would result in similar or slightly higher probabilities (five to seven percent) as compared to the No Action Alternative. The net effect under this alternative is minor.

4.13.2.4 Water Supply Alternative

The Water Supply Alternative would result in similar or higher probabilities (zero to 17 percent) of Lake Powell elevations being less than 3,550 feet msl when compared to the No Action Alternative for the period 2008 through 2026 (Table 4.13-1, Figure 4.3-10, and Table 4.3-9). For the period 2026 through 2060, the Water Supply Alternative would result in higher probabilities (eight to 17 percent) as compared to the No Action Alternative. The net effect under this alternative is moderately adverse.

4.13.2.5 Reservoir Storage Alternative

The Reservoir Storage Alternative would result in similar or slightly lower probabilities (zero to three percent) of Lake Powell elevations being less than 3,550 feet msl compared to the No Action Alternative for the period 2008 through 2026 (Table 4.13-1, Figure 4.3-10, and Table 4.3-9). For the period 2026 through 2060, the Reservoir Storage Alternative would result in similar or slightly lower probabilities (one to seven percent) as compared to the No Action Alternative. The net effect under this alternative is beneficial.

4.13.2.6 Preferred Alternative

The Preferred Alternative would result in similar or slightly higher probabilities (zero to seven percent) of Lake Powell elevations being less than 3,550 feet msl compared to the No Action Alternative for the period 2008 through 2026 (Table 4.13-1, Figure 4.3-10, and Table 4.3-9). For the period 2026 through 2060, the Preferred Alternative would result in similar or slightly higher probabilities (five to seven percent) as compared to the No Action Alternative. The net effect under the Preferred Alternative is minor.

4.13.3 Laughlin River Taxis and Tour Boats

The minimum future flow under the No Action Alternative and under the action alternatives will continue to be 2,300 cfs, the minimum flow needed to run one turbine of the Davis Powerplant at about one-half capacity. The duration of flows in the 2,300 to 4,600 cfs range would not be affected by the proposed federal action. However, the duration of flows in the 4,600 cfs to 9,200 cfs range may be affected by the proposed federal action. For example, due to changes in annual releases, the duration of hourly flows in the 4,600 to 9,200 cfs range may increase during some days under the Water Supply Alternative and decrease during some days under the Reservoir Storage Alternative. These changes have a minor effect on transportation. The duration of hourly flows in the 4,600 cfs to 9,200 cfs range under the Basin States and Conservation Before Shortage alternatives, and the Preferred Alternative are expected to be nearly the same as those under the No Action Alternative.

4.13.4 Lake Havasu Ferry Service

Lake Havasu will continue to be operated to meet monthly elevation targets; therefore, adoption of any of the alternatives would not affect the operation of the Lake Havasu ferry service.

4.13.5 Summary

For the Lake Powell ferry, the Basin States and Conservation Before Shortage alternatives, and the Preferred Alternative would have minor effects on ferry service; the Water Supply Alternative could result in potential moderate adverse effects; and the Reservoir Storage Alternative could have beneficial effects. The probability varies from year to year, but there is up to a 17 percent probability that the Lake Powell ferry may become inoperable under the Water Supply Alternative for some period of time. Conversely, the ferry would remain operable with the highest probabilities and greatest durations of time under the Reservoir Storage Alternative.

For the Colorado River ferry service downstream of Davis Dam, only under the Reservoir Storage Alternative are there any measurable effects and these potential effects would be minor. The other action alternatives show no difference from the No Action Alternative.

The Lake Havasu ferry service would be unaffected under all of the action alternatives.

This page intentionally left blank.

4.14 Socioeconomics

This section describes the potential impacts of the proposed federal action with respect to socioeconomics and describes the methods used to determine and analyze those impacts. Included in this analysis are the potential impacts to employment, income and tax revenue due to changes in agricultural production. Also included are the potential socioeconomic impacts to M&I and recreation uses. The study area and issues associated with these resources are described in Section 3.14. Additional details on the assessment of the socioeconomic effects is provided in Appendix H. Cumulative impacts related to socioeconomics use are discussed in Chapter 5.

4.14.1 Methodology

This section describes the methods used to estimate the effects on socioeconomics resulting from the proposed federal action. The assessment focused on estimating the socioeconomic effects that might occur as a result of potential changes in agricultural production, reservoir-related and river-related recreation, and the change in M&I water availability.

4.14.1.1 Agriculture

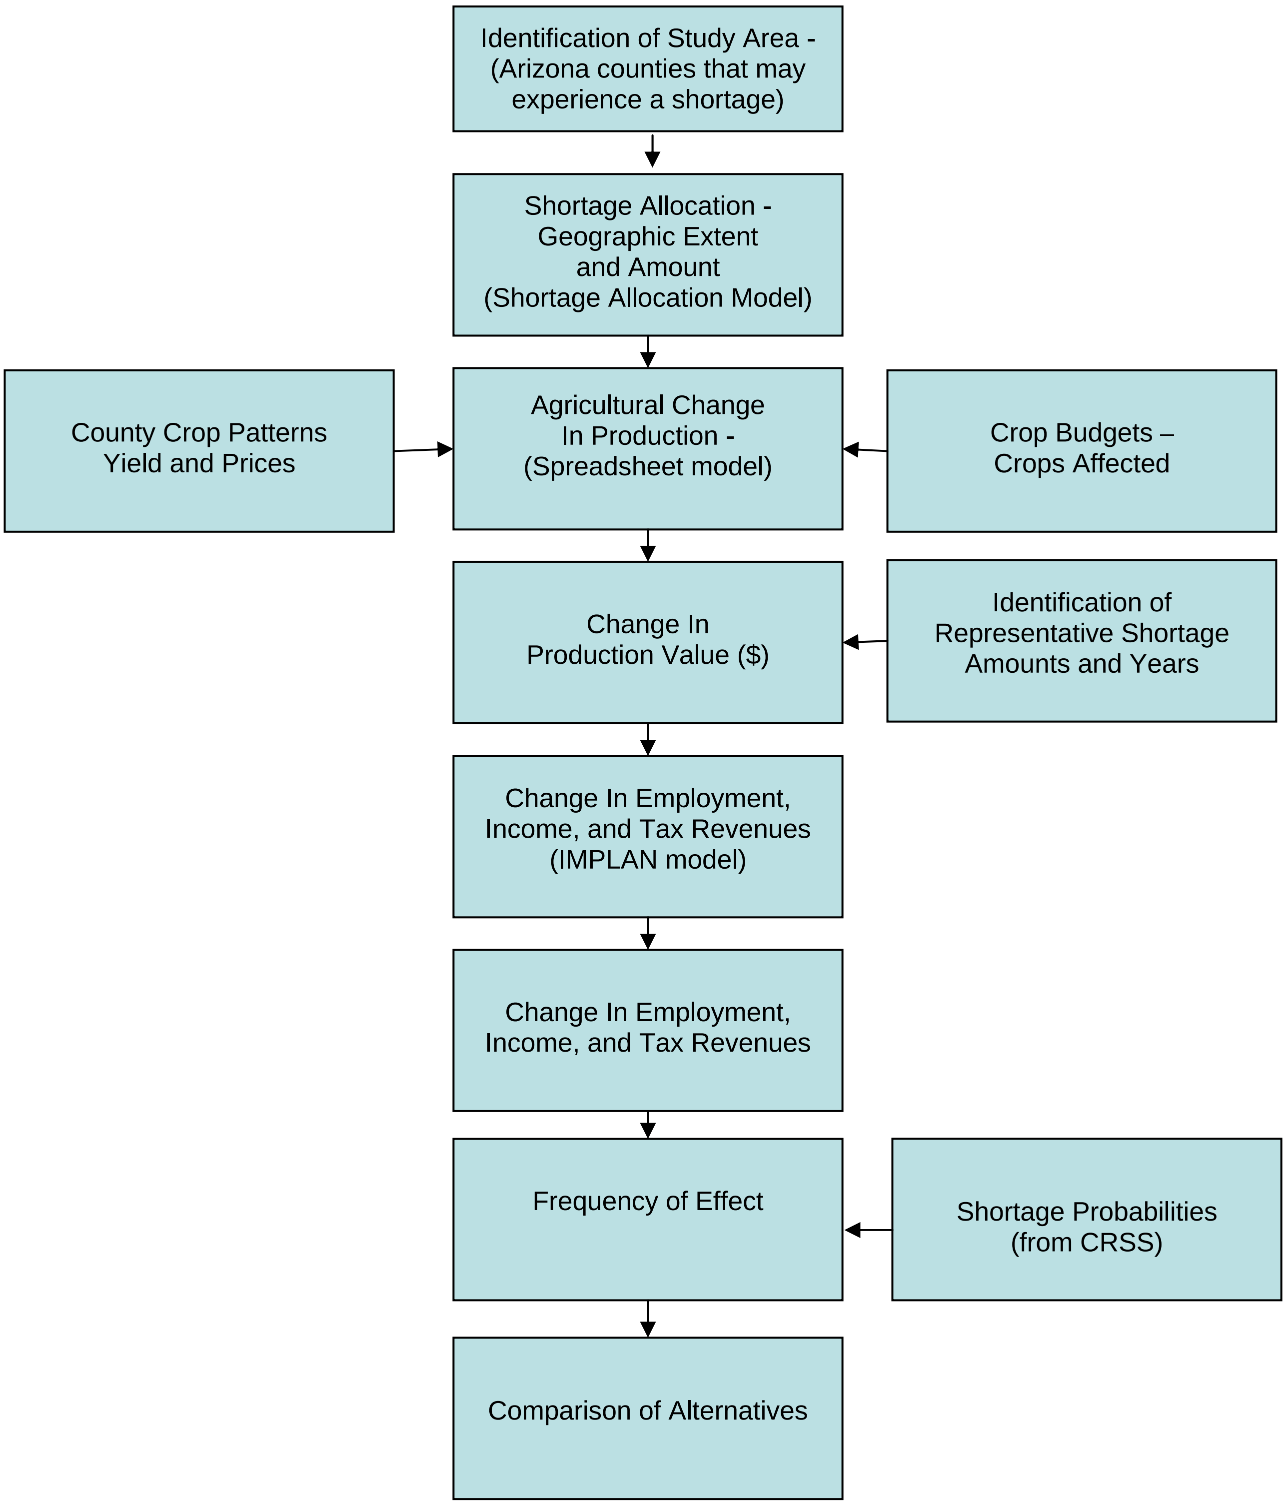
The potential socioeconomic effects due to changes in agricultural production were quantitatively assessed for Arizona agricultural districts and the corresponding counties that would likely experience shortages (i.e., within the CAP service area and the 4th priority agricultural use along the river). An assessment of potential socioeconomic effects due to changes in agricultural production in Nevada was not necessary since shortages of the magnitudes generated by the alternatives would only affect the M&I sector. An assessment of potential socioeconomic effects in California was also not necessary since shortages of the magnitudes generated by the alternatives would primarily affect the M&I sector. Shortages of significant magnitude that would affect agricultural users in California were observed to be very unlikely to occur, and if shortages of this nature occurred, the result would be limited to insignificant reductions in water use relative to California agricultural entitlements.

The quantitative assessment was conducted in three major steps:

- ♦ estimating changes in agricultural production as the result of reduced water deliveries;
- ♦ estimating the potential changes in employment, income, and tax revenue as a result of reduced water deliveries; and
- ♦ applying the shortage probabilities for a particular shortage amount and year to assess the likelihood that the potential changes would occur.

Figure 4.14-1 provides an overview of the steps followed in conducting the assessment of changes in agricultural production and resulting changes in employment, income, and tax revenues.

Figure 4.14-1
Steps in Analyzing Changes in Agricultural Production
and Resulting Changes in Employment, Income, and Tax Revenue



Estimating Changes in Agricultural Production Value:

Involuntary Shortages. The purpose of the impact assessment for agriculture is to estimate the change in agricultural production values as a result of the proposed federal action. Specifically, this section focuses on the incidence of these impacts on non-Indian and Indian agricultural production in Pinal, Maricopa, Pima, Mohave, La Paz, and Yuma counties for 2008, 2017, 2026, 2027, 2040, and 2060. The six counties were selected because the agricultural districts that may experience shortages are located within these counties. Impacts to agriculture in the six-county area were examined by observing modeled changes in industry output and acreage of fallowed lands for agriculture. The years 2008, 2017, and 2026, were selected because they represent the beginning, midpoint, and end of the interim period. The years 2027, 2040, and 2060 were selected because they represent the beginning, midpoint, and end of the remaining period of analysis.

The objectives of this study were to quantify potential:

- changes in agricultural production for various levels of shortage; and
- amounts of fallowed land for various levels of shortage.

Key to this impact analysis is the assumption that the most conservative way to estimate impacts is to assume that, if a shortage occurs, farmers would react by fallowing irrigated lands. The decision to fallow lands would rest on the ability of the farmer to cover the variable costs of production for crops grown in the study area. These assumptions are discussed in more detail later in this section.

While fallowing of lands may occur during shortages, there are other sources of water that may be used by farmers in order to offset shortages. For example, a farmer may have a groundwater well available and may be able to mitigate shortages in surface water supply by pumping additional groundwater. Other farmers may be able to take delivery of groundwater that is recovered from a groundwater bank. It is difficult to project exactly how individual farmers, irrigation districts, or each of the Lower Division states may mitigate potential, future agricultural impacts from shortages. Therefore, for the purposes of this analysis, the projected change in agricultural production was based on the conservative assumption that other sources of water would not be available.

The potentially affected crops considered included cotton, wheat, alfalfa, vegetables and melons, and trees and vines. The primary focus is on cotton, wheat, and alfalfa because these crops have lower earnings per acre-foot of water than fruit, vegetable, and nut crops and, therefore, are more vulnerable to changes in water costs and shortages. Farm budgets were developed for cotton, wheat, and alfalfa to determine the maximum water cost a farmer can pay and still produce a particular crop. These budgets represent a generalization of the variable production costs for a particular crop exclusive of water costs. When the cost of water exceeds the maximum water cost a farmer can pay or if water is not available, a crop is taken out of production and the land is fallowed for the year in which a shortage occurs. The data from all of the model runs for the action alternatives were compared to those of the No Action Alternative.

General Assumptions and Data Sources:

Crop Patterns, Yields, and Prices. Crop patterns, yield per acre, and prices were assumed to remain constant for non-Indian and Indian agricultural output for all alternatives during the study period. Crop patterns for the CAP and other irrigation districts in this study are based on historical crop patterns that were reported by irrigation districts to Reclamation for the years 1999 through 2004. These data were averaged and aggregated at the county level for the impact analysis. Cropping patterns for Indian agriculture come from a variety of sources and may be incomplete. Accordingly, it was assumed that cropping patterns on Indian lands were similar to that of nearby irrigation districts. Appendix H includes information on cropping patterns for CAP and other irrigation districts.

Yield data was based on five-year average county-level yields for the period 2000 through 2005. Prices are based on five-year average statewide prices for Arizona for the period 2000 to 2005. The yield and price data are published by the USDA's National Agricultural Statistics Service (NASS) for Arizona. Information on county-level yield and price data is provided in Appendix H.

Water Costs. The cost of water used in the analysis of agricultural impacts is a blended cost that reflects the price of CAWCD excess water pools, groundwater pumping, and other water. The price of CAWCD excess water was obtained directly from the CAWCD. Cost estimates for groundwater pumping and other water were obtained from various irrigation districts. These data were aggregated to a county-level basis for use in the agricultural impacts analysis. The blended cost of water data for each county is included in Appendix H.

Crop Budgeting and Impacts upon Crop Selection due to Water Cost and Water Shortages. Crop budgets were developed to determine the crop types that would be affected as a result of water shortages. A detailed description of how the crop budgets were developed is included in Appendix H.

Assessment of Changes in Agricultural Production. It is assumed that the agricultural impacts for involuntary shortages are the same for various levels of shortage for each alternative. As an example, a 600,000 af shortage occurring under the Reservoir Storage Alternative would result in the same change in agricultural production as a 600,000 af shortage occurring under the Basin States Alternative. Shortages may occur more or less frequently under various alternatives, but the change in agricultural production during a particular volume of shortage was assumed to be the same across the alternatives. This is due to the modeling assumptions made with regard to how shortages might be distributed to various water users (Section 4.2, Appendix A, and Appendix G). These assumptions are the same across all alternatives. Changes in agricultural production and resulting changes in production value due to voluntary shortages would likely be different than the changes due to involuntary shortages, discussed in additional detail below.

Output from Reclamation's Shortage Allocation Model (Section 4.2 and Appendix G) was used as input for assessing changes in agricultural production during the involuntary fallowing of agricultural lands. The various levels of shortage were input into the model and the amount of shortage that would be allocated to various agricultural users was generated. These results were aggregated on a county-level basis for use in the agricultural impacts analysis.

Impacts for both non-Indian and Indian agriculture were analyzed independently. For both analyses, the shortage allocated to non-Indian and Indian water users in each county for various levels of overall shortage were input into a spreadsheet model developed by Reclamation that estimates changes in agricultural production and production value. Model input includes output from the partial crop budgets, the amount of available surface water in each county, county-wide shortage amounts from the water allocation model, the amount of water applied per acre for each crop, and county-wide water distribution patterns with respect to cotton, wheat, and alfalfa production. Based on the amount of shortage realized in each county, the model estimates the amount of land that would be fallowed using the relative profitability of each crop. The model assumes that the least profitable crops are fallowed first. Once all of the irrigated land associated with the least profitable crop is fallowed, the model assumes that fallowing of the next-least profitable crop would commence. The irrigated acreage associated with fallowing is estimated based on the amount of water allocated to various crops and the crop water use per acre associated with those crops. The resulting direct economic impacts are calculated by multiplying the number of acres fallowed for various crops by the gross output for those crops.

The federal government has reserved a volume of CAP water in the range of 47,000 to 67,000 af for future water settlements. At some time, this water may be allocated to tribes in Arizona for agricultural or M&I use. Once allocated, this water would potentially be vulnerable to shortages. However, it is not known where or when this water may be allocated. Because of this uncertainty, the reserved federal government water has not been included in the analysis.

Shortages. The partial farm budgets used in the analysis of involuntary shortages are a potential means to estimate the minimum amount of compensation a farmer would accept to fallow agricultural ground. However, compensation rates included in recently established fallowing programs do not reflect these minimum amounts. It appears that market forces have contributed significantly to the compensation rates paid in fallowing programs for conserved water. As a result, available data from several fallowing programs were used to estimate a range of costs for conserved water and to estimate potential amounts of land that would be fallowed under various levels of shortage.

Data from several sources suggest that fallowing agricultural lands would result in a reduction in the consumptive use of water ranging between 4.2 and 6.9 af per acre (Colby et al. 2006). The amount of acreage that would be fallowed would be dependent on the crops grown and the consumptive use of those crops. However, again, it is difficult to project which irrigators or districts would fallow their land and what crops would not be grown. In lieu of attempting to project the crops that would not be grown, for the purposes of this study, it was assumed that the amount of fallowed land per acre-foot of conserved water would be similar to the range shown above. It was assumed that all of the potentially conserved water results from agricultural water conservation.

Voluntary shortages may result in a beneficial effect on farmers rather than a detriment. The minimum amount of water a farmer would likely accept would be at a break-even price. However, given the demand for water conservation under voluntary shortages, a farmer would be less likely to accept a minimum payment and would be more likely to attempt to maximize economic gain.

Implementation of voluntary shortages is the focus of the Conservation Before Shortage Alternative. The water conservation (voluntary shortage) prior to involuntary shortage included in this alternative assumes that farmers would be compensated to initiate voluntary water conservation measures. These conservation measures could be implemented in a variety of ways such as on-farm efficiency improvements, canal lining, etc. It is, however, difficult to project what actions individual farmers or irrigation districts might take in the future to conserve water. Land fallowing programs have frequently been used as a means to voluntarily conserve water and fallowing would likely result in the most significant impacts with regard to land use. For the purposes of this study, it is assumed that land fallowing would be the means of conserving water for the Conservation Before Shortage Alternative.

Estimating Changes in Employment, Income, and Tax Revenue. The socioeconomic effects of changes in agricultural production in Arizona were analyzed using the IMPLAN model. IMPLAN is a regional economic model that describes the flows from producers to intermediate and final consumers using a series of economic multipliers. The IMPLAN model describes for each county the transfers of money between all industries and institutions. This model of county-level economic interactions is used to project, using the input-output multipliers, total regional economic activity based on a change in expenditures.

In addition to the direct loss in agricultural output, reduced expenditures occur from a drop in business-to-business purchases and in reduced household expenditures. These changes, known as indirect and induced economic effects were also estimated using IMPLAN. The resulting socioeconomic effects were quantified as changes in employment, income, and tax revenue.

The qualitative assessment for changes in agricultural production and resulting changes in employment, income, and tax revenues was based on the probability of shortages occurring in the agricultural sector in California and Nevada.

4.14.1.2 Municipal and Industrial Water Uses

The potential socioeconomic consequences of shortages occurring in the M&I sector were qualitatively assessed for Arizona, California, and Nevada. The effects were qualitatively assessed because it was not known to what degree a specific economic sector considered an M&I use would be affected. The analysis was based on the shortage amounts and shortage allocations reported in Section 4.4.

The analysis first examined the probability of a range of water shortages occurring in different years. The shortages analyzed included 400,000 af, 500,000 af, 600,000 af, 800,000 af, 1 maf, 1.2 maf, 1.8 maf, and 2.5 maf. Consistent with the assessment of the effects to agriculture, the M&I analysis examined years 2008, 2017, 2026, 2027, 2040, and 2060 for each of the shortage amounts.

The analysis focused on those years and shortage levels having the highest probability of occurrence and where the probability was substantially different under the action alterative compared to the No Action Alternative. The analysis then examined whether a particular shortage event would affect the M&I sector as compared to the No Action Alternative. For example, a shortage in Arizona would affect the agricultural sector first. In contrast, a shortage in Nevada would affect M&I, primarily because Nevada has a small agricultural sector that is dependant on Colorado River water.

For situations likely to have an effect on the M&I sector, the ability of each state to manage shortages to the M&I sector were analyzed. The M&I shortages allocated to each state were compared to the drought plans or actions that state or local agencies could institute during a shortage. The analysis then qualitatively discussed whether such drought planning mechanisms are adequate to address shortages to the M&I sector.

4.14.1.3 Recreation

The recreation-related socioeconomic effects resulting from changes in Lake Powell and Lake Mead elevations and flows in the Colorado River downstream of Lake Powell and Lake Mead were qualitatively assessed. The conclusions regarding the extent of changes in reservoir elevations and river flows reported in Section 4.3 and recreation opportunities reported in Section 4.12 were used to help determine the magnitude of socioeconomic effects.

Lake Powell and Lake Mead. The assessment of changes in recreation-related economic activity was based on changes in Lake Powell and Lake Mead elevations. Particular months representative of the primary recreational season were selected for each lake to analyze the potential elevation changes (September for Lake Powell; July for Lake Mead).

Figure 4.14-2 depicts the end-of-September Lake Powell elevations and Figure 4.14-3 depicts the end-of-July Lake Mead elevations used in this analysis. The years considered in the assessment are 2008, 2016, 2026, and 2060. For each year, lake elevations for each alternative were compared to the No Action Alternative. This comparison was conducted for the 90th, 50th, and 10th percentiles as shown in Figures 4.14-2 and 4.14-3.

Colorado River Downstream of Lake Powell and Lake Mead. The assessment of socioeconomic effects as a result of changes in recreation-related economic activity was based on the results of the recreation assessment. The results of this assessment are provided in Section 4.12.

4.14.2 Potential Impacts to Agriculture

This section provides the assessment of potential effects on agricultural production and resulting changes in employment, income, and taxes. The potential socioeconomic effects due to changes in agricultural production were only assessed for Arizona agricultural districts and the corresponding counties that would likely experience shortages (i.e., within the CAP service area and the 4th priority agricultural use along the Colorado River). Table 4.14-1 provides estimates of involuntary fallowed agricultural land for each shortage amount. Table 4.14-2 provides estimates of changes in agricultural production value for each shortage amount. The change in production value was used as input to IMPLAN to estimate changes in employment, income, and tax revenue.

Table 4.14-1 provides the total estimated fallowed acreage for each shortage amount for 2008, 2017, 2026, 2027, 2040, and 2060. No change in production would occur in 2008 because no shortages are projected to occur in that year. In general, for each shortage amount, the amount of fallowed non-Indian agricultural land decreases between 2017 and 2060 reflecting the trend of fewer acres of agricultural land being in production in the future. No permanent change in land uses would occur under any of the alternatives because shortages would be of a temporary nature and agricultural lands would likely not be permanently removed from production.

The changes in agricultural production values are shown in Table 4.14-2. These changes are a direct result of the amount of land fallowed for each shortage amount. Similar to the acreages of fallowed land, the changes in production value is expected to decrease as a result of less land being fallowed in the future for non-Indian agriculture.

Table 4.14-1
Estimate of Involuntarily Fallowed Acres in Arizona under Various Levels of Shortage for Various Years

Shortage Amount (af)	Non-Indian Agriculture					
	2008	2017	2026	2027	2040	2060
400,000	-	75,923	32,849	-	-	-

Note: a dash indicates that a shortage of the given magnitude did not occur in that particular year and therefore there is no change in production value.

4.14.2.1 Changes in Agricultural Production and Resulting Changes in Employment and Income in Arizona

This section describes the potential changes in employment and income for each alternative as a result of changes in agricultural production. The discussion is a summary of the impact analysis conducted for the Arizona counties that may experience a shortage resulting in changes in agricultural production. The results of this county-level assessment of changes in employment and income for each shortage amount, year, and county are provided in Appendix H. The counties analyzed are Maricopa, Pinal, Pima, Mohave, La Paz, and Yuma. A summary comparison of the effects on employment and income among the alternatives is provided at the end of this subsection.

Table 4.14-3 presents a comparison of the shortage amounts with the estimated changes in employment and income and lists the probabilities of occurrence for each alternative, based on Tables 4.4-5 through 4.4-9. Shortages generated by the alternatives that were not exactly equal to the amounts shown in Table 4.14-3 were counted at the next highest value for the probabilities listed in Table 4.14-3.

Table 4.14-3
Estimated Reduction in Employment as a Result of Shortages to Agricultural Lands for the Action Alternatives and the No Action Alternative
by Selected Years and Shortage Amounts

Shortage Amount (af)	2017

Note:
NA = No Action Alternative
WS = Water Supply Alternative
CBS = Conservation Before Shortage Alternative
BS = Basin States Alternative
RS = Reservoir Storage Alternative
PA = Preferred Alternative
- = No shortage occurring

No Action Alternative. Potential decreases in employment attributable to a shortage occurring under the No Action Alternative for the period 2008 through 2026 would range from a low of 561 jobs during a 500,000 af shortage in 2026 to a high of 1,161 jobs during a 1.2 maf shortage in 2017. Resulting losses in personal income range from a low of approximately $18.0 million to a high of approximately $43.1 million (Table 4.14-3).

For the period 2008 through 2026, a shortage of approximately 500,000 af would have the greatest probability of occurring, estimated at 34 percent in 2026 and 45 percent in 2017. This shortage amount would result in an estimated loss of up to 627 jobs and resulting reduction in personal income of approximately $23.8 million (Table 4.14-3). Even if considered to be permanent, these potential changes in jobs and personal income are not considered substantial because the changes represent less than one percent of total employment and personal income generated within the six-county study area in Arizona.

Potential decreases in employment attributable to a shortage occurring under the No Action Alternative for the period 2027 through 2060 would range from a low of 397 jobs during a 500,000 af shortage in 2060 to high of 1,271 jobs during a 1.8 maf shortage in 2027. Resulting losses in personal income over the same period would range from a low of approximately $12.3 million to a high of approximately $46.4 million (Table 4.14-3).

For the period 2027 through 2060, a shortage of approximately 500,000 af would have the greatest probability of occurring, ranging from 37 percent in 2040 to 54 percent in 2060. In 2060, a 500,000 af shortage would result in an estimated loss of 397 jobs and reduction in personal income of approximately $12.3 million (Table 4.14-3). Even if considered to be permanent, these potential changes in jobs and personal income are not considered substantial because the changes represent less than one percent of total employment and personal income within the six-county study area in Arizona.

Basin States Alternative. Potential decreases in employment attributable to a shortage occurring under the Basin States Alternative for the period 2008 through 2026 would range from a low of 561 jobs during a 500,000 af shortage in 2026 to a high of 860 jobs during an 800,000 af shortage in 2017 resulting in a loss in personal income ranging from approximately $18 million to $30.8 million (Table 4.14-3).

For the period 2008 through 2026, a shortage of 500,000 af would have the greatest probability of occurring at 15 percent in 2017 and 2026 with corresponding job losses of 561 in 2026 and 627 in 2017. Reductions in personal income would range form $18 million in 2026 to $23.8 million in 2017. Even if considered to be permanent, these potential changes in jobs and personal income are not considered substantial because the changes represent less than one percent of total employment and personal income within the six-county study area in Arizona. Potential decreases in employment attributable to a shortage occurring under the Basin States Alternative between 2027 and 2060 would range from a low of 397 jobs during a 500,000 af shortage in 2060 to a high of 1,693 jobs during a 2.5 maf shortage in 2027. Resulting losses in personal income would range from a low of approximately $12.3 million to a high of approximately $56.5 million (Table 4.14-3).

For the period 2027 through 2060, a shortage of 500,000 af would have the greatest probability of occurring, ranging from 35 to 54 percent. Corresponding losses in jobs would range from 397 in 2060 to 522 in 2027. Losses in personal income would range from $12.3 million to $17.3 million. (Table 4.14-3). Even if considered to be permanent, these changes in jobs and personal income are not considered substantial because the changes represent less than one percent of total employment and personal income within the six-county study area in Arizona.

Conservation Before Shortage Alternative. The results of the analysis reported in this discussion may underestimate the socioeconomic effects of particular shortages occurring under the Conservation Before Shortage Alternative. This analysis assumes that the voluntary conservation targets (400 kaf, 500 kaf, and 600 kaf at Lake Mead elevations 1,075 feet msl, 1,050 feet msl, and 1,025 feet msl, respectively) would be met, assuming that farmers would participate voluntarily in the program and that losses resulting from voluntary shortages would be offset by payments made to farmers to forgo raising crops. With these assumptions, only the potential impacts of involuntary shortages were analyzed in this section.

Potential decreases in employment attributable to an involuntary shortage occurring under the Conservation Before Shortage Alternative for the period 2008 through 2026 would range from a low of 561 jobs during a 500,000 af shortage in 2026 to a high of 937 jobs during a 1 maf shortage in 2017. Estimated losses in personal income would range from a low of approximately $18 million to a high of approximately $25 million (Table 4.14-3).

Shortages have a much greater probability of occurring under the No Action Alternative than under the Conservation Before Shortage Alternative. This suggests for the period 2008 through 2026 the probability of adverse socioeconomic effects occurring under the Conservation Before Shortage Alternative would be much less when compared to the No Action Alternative.

Potential decreases in employment attributable to a shortage occurring under the Conservation Before Shortage Alternative for the period 2027 through 2060 would range from a low of 397 jobs during a 500,000 af shortage in 2060 to a high of 1,181 jobs during a 1.8 maf shortage in 2040. Similarly, estimated losses in personal income over the same period would range from a low of approximately $12.3 million to a high of approximately $43.5 million (Table 4.14-3).

For the period 2027 through 2060, a shortage of 500,000 af would have the greatest probability of occurring, ranging from 33 percent to 50 percent. Estimated losses in jobs would range from 387 in 2060 to 522 in 2017. Corresponding losses in personal income would range from $12.3 million to $17.3 million (Table 4.14-3). Even if considered permanent, these job losses and reductions in personal income are not considered substantial because the changes represent less than one percent of total employment and personal income within the six-county study area in Arizona.

When compared to the No Action Alternative, the probabilities of shortages in 2027 under the Conservation Before Shortage Alternative are higher for shortages of 500,000 af and similar for greater shortages. However, in 2060 shortages of 500,000 af have a slightly lower probability of occurring under the Conservation Before Shortage Alternative and similar probabilities for higher shortage levels.

Water Supply Alternative. For the period 2008 through 2026, potential decreases in employment attributable to a shortage under the Water Supply Alternative would occur only during a 400,000 af shortage in 2017 and 2026. This would result in an estimated loss of 425 jobs in 2026 and 577 jobs in 2017. Losses in personal income would range from $13.5 million and $22.6 million (Table 4.14-3). This lack of shortages is a result of this alternative’s strategy to provide full water deliveries until no water remains in Lake Mead, a reservoir draw down situation which has a low probability of occurring during the interim period.

Potential decreases in employment attributable to a shortage occurring under the Water Supply Alternative for the period 2027 through 2060 would range from a low of 397 jobs during a 500,000 af shortage in 2060 to a high of 1,693 jobs during a 2.5 maf shortage in 2060. Resulting losses in personal income over the same period would range from a low of approximately $12.3 million to a high of approximately $56.5 million (Table 4.14-3).

For the period 2040 through 2060, the probability of shortages under the Water Supply Alternative are very similar to those of the other alternatives, and shortages of 500,000 af would have the greatest probability of occurring, ranging from 37 percent to 51 percent. A 500,000 af shortage would result in an estimated loss of up to 527 jobs and reduction in personal income of up to $17.3 million. Even if considered to be permanent, these changes in jobs and personal income are not considered substantial because the changes represent less than one percent of total employment and personal income within the six-county study area in Arizona.

Reservoir Storage Alternative. Potential decreases in employment attributable to a shortage occurring under the Reservoir Storage Alternative for the period 2008 through 2026 would range from a low of 683 jobs during an 800,000 af shortage in 2026 to a high of 1,161 jobs during a 1.2 maf shortage in 2017. Resulting losses in personal income over the same period would range from a low of approximately $21.6 million to a high of approximately $43.1 million (Table 4.14-3).

For the period 2008 through 2026, a shortage of 800,000 af would have the greatest probability of occurring at 18 percent. Job losses during an 800,000 af shortage would range from 600 in 2026 to 860 in 2017 (Table 4.14-3). Losses in personal income would range from $18.8 million to $30.8 million. Even if considered to be permanent, these changes in jobs and personal income are not considered substantial because the changes represent less than one percent of total employment and personal income within the six-county study area in Arizona.

Shortages of 400,000 to 600,00 af have a much greater potential of occurring under the No Action Alternative whereas shortages of 800,000 af to 1.2 maf have a greater probability of occurring under the Reservoir Storage Alternative. This suggests that for the period 2008 through 2026 the probability of adverse socioeconomic effects occurring under the Reservoir Storage Alternative may be slightly less than under the No Action Alternative, but when shortages of greater than 800,000 af do occur, they are greater in magnitude with increased socioeconomic effects.

Potential decreases in employment attributable to a shortage occurring under the Reservoir Storage Alternative for the period 2027 through 2060 would range from a low of 397 jobs during a 500,000 af shortage in 2060 to a high of 1,181 jobs during a 1.8 maf shortage in 2040 (Table 4.14-3). Losses in personal income would range from a low of approximately $12.3 million to a high of approximately $43,5 million (Table 4.14-3).

For the period 2027 through 2060, a shortage of 500,000 af would have the greatest probability of occurring, ranging from 38 percent to 53 percent. Job losses during a 500,000 af shortage would range from 397 jobs in 2060 to 552 jobs in 2027. Losses in personal income would range from $12.3 million to $17.3 million (Table 4.14-3). Even if considered to be permanent, these changes in jobs and personal income are not considered substantial because the changes represent less than one percent of total employment and personal income within the six-county study area and Arizona.

The probabilities of shortages occurring under the Reservoir Storage Alternative during a 500,000 af shortage would be similar to the probabilities under the No Action Alternative.

Preferred Alternative. Potential decreases in employment attributable to a shortage occurring under the Preferred Alternative for the period 2008 through 2026 would range from a low of 561 jobs during a 500,000 af shortage in 2026 to a high of 860 jobs during an 800,000 af shortage in 2017. Resulting losses in personal income over the same period would range from a low of approximately $18 million to a high of approximately $30.8 million (Table 4.14-3).

For the period 2008 through 2026, a shortage of 500,000 af would have the greatest probability of occurring at 16 percent in 2017 and 24 percent in 2026. Job losses during an 500,000 af shortage would range from 561 in 2017 to 627 in 2017 (Table 4.14-3). Corresponding losses in personal income would range from $18 million to $23.8 million. Even if considered to be permanent, these changes in jobs and personal income are not considered substantial because the changes represent less than one percent of total employment and personal income within the six-county study area in Arizona.

Shortages of 500,000 af have a lower probability of occurring under the Preferred Alternative compared to the No Action Alternative whereas shortages of 600,000 and 800,000 af have a greater probability of occurring under the Preferred Alternative. This suggests that for the period 2008 through 2026 the probability of adverse socioeconomic effects occurring under the Preferred Alternative may be slightly lower during a 500,000 af shortage but greater for shortages between 600,000 and 800,000 af.

Potential decreases in employment attributable to a shortage occurring under the Preferred Alternative for the period 2027 through 2060 would range from a low of 397 jobs during a 500,000 af shortage in 2060 to a high of 1,181 jobs during a 1.8 maf shortage in 2040 (Table 4.14-3). Losses in personal income would range from a low of approximately $12.3 million to a high of approximately $43.5 million (Table 4.14-3).

For the period 2027 through 2060, a shortage of 500,000 af would have the greatest probability of occurring, ranging from 36 percent to 52 percent. Job losses during a 500,000 af shortage would range from 397 jobs in 2060 to 552 jobs in 2027. Losses in personal income would range from $12.3 million to $17.3 million (Table 4.14-3). Even if considered to be permanent, these changes in jobs and personal income are not considered substantial because the changes represent less than one percent of total employment and personal income within the six-county study area and Arizona.

The probabilities of shortages occurring under the Preferred Alternative in 2040 and 2060 are similar to the probabilities under the No Action Alternative. The probability of a 500,000 af shortage occurring under the Preferred Alternative in 2027 is greater when compared to the No Action Alternative.

4.14.2.2 Changes in Tax Revenues in Arizona

This section describes the potential changes in tax revenue for each alternative as a result of changes in agricultural production. Changes in tax revenue would result from the direct reduction in agricultural production, from reduced business-to-business activity, and from reductions in personal income. The tax revenue discussion summarizes the impacts for those Arizona counties that may experience a water shortage resulting in changes in agricultural production. The results of the county-level assessment on tax revenues for each shortage amount, year, and county are provided in Appendix H. The counties analyzed are Maricopa, Pinal, Pima, Mohave, La Paz, and Yuma. A summary comparison of the effects on tax revenue is provided at the end of this subsection.

Table 4.14-4 presents a comparison of the shortage amounts with the estimated changes in tax revenues and lists the probabilities of occurrence for each alternative. Shortages generated by the alternatives that were not exactly equal to the amounts shown in Table 4.14-4 were counted at the next highest value for the probabilities listed in Table 4.14-4.

Table 4.14-4
Estimated Reduction in Tax Revenues as a Result of Shortages to Agricultural Lands Under the Action Alternatives and the No Action Alternative by Selected Year and Shortages

Shortage Amount (af)	2017						
	Shortage Probabilities for Each Alternative (percent)						Changes in Tax Revenues ($ million)

Note:
NA = No Action Alternative
WS = Water Supply Alternative
CBS = Conservation Before Shortage Alternative
BS = Basin States Alternative
RS = Reservoir Storage Alternative
PA = Preferred Alternative
- = No Shortage Occurring

Arizona reported a total of $8.477 billion in state taxes collected and $5.943 billion in local government taxes collected for 2001 through 2002 (http://ftp2.census.gov/govs/estimate/02slsstab1a.xls). These values are compared to the tax impacts associated with the action alternatives and the No Action Alternative, discussed in the following paragraphs, as referred to in Table 4.14-4 and in Appendix H.

No Action Alternative. Potential decreases in tax revenue occurring under the No Action Alternative for the period 2008 through 2026 would range from a low of $5.9 million during a 500,000 af shortage in 2026 to a high of $14.8 million during a 1.2 maf shortage in 2017. For the period 2008 through 2026, a shortage of approximately 500,000 af would have the greatest probability of occurring, estimated at 45 percent in 2017 and 34 percent in 2026.

Potential decreases in tax revenue for the period 2027 through 2060 would range from a low of $4.2 million during a 500,000 af shortage in 2060 to a high of $18.9 million during a 2.5 maf shortage in 2027. For the period 2027 through 2060, a shortage of 500,000 af would have the greatest probability of occurring, estimated at between 37 percent in 2040 to 54 percent in 2060. These changes in tax revenues represent less than 0.2 percent total state taxes collected and less than 0.3 percent of local taxes collected.

Basin States Alternative. Potential decreases in tax revenue occurring under the Basin States Alternative for the period 2008 through 2026 would range from a low of $5.9 million during a 500,000 af shortage in 2026 to a high of $10.6 million during an 800,000 af shortage in 2017. For the period 2008 through 2026, a shortage of 500,000 af would have the greatest probability of occurring, estimated at 15 percent.

Potential decreases in tax revenue attributable to a shortage occurring under the Basin States Alternative during the period 2027 through 2060 would range from a low of $4.2 million during a 500,000 af shortage in 2060 to a high of $18.9 million during a 2.5 maf shortage in 2027. For the period 2027 through 2060, a shortage of 500,000 af would have the greatest probability of occurring, estimated at between 35 percent in 2040 to 52 percent in 2060. These changes in tax revenues represent less than 0.3 percent of total state taxes collected and less than 0.4 percent of local taxes collected.

Conservation Before Shortage Alternative. This analysis assumes that the voluntary conservation targets (400 kaf, 500 kaf, and 600 kaf at Lake Mead elevations 1,075 feet msl, 1,050 feet msl, and 1,025 feet msl, respectively) would be met and therefore only the potential impacts of involuntary shortages were analyzed. Potential decreases in tax revenue due to an involuntary shortage occurring under the Conservation Before Shortage Alternative during the period 2008 through 2026 would range from a low of $5.9 million during a 500,000 af shortage in 2026 to a high of $11.6 million during a 1 maf shortage in 2017. For the period 2008 through 2026, a shortage of 800,000 af would have the greatest probability of occurring, estimated at only three percent.

Potential decreases in tax revenue attributable to a shortage occurring under the Conservation Before Shortage Alternative during the period 2027 through 2060 would range from a low of $4.2 million during a 500,000 af shortage in 2060 to a high of $1.6 million during a 1.8 maf shortage in 2040. For the period 2027 through 2060, a shortage of 500,000 af would have the greatest probability of occurring, estimated at between 33 percent in 2040 to 50 percent in 2060. These changes in tax revenues represent less than 0.2 percent of total state taxes collected and less than 0.3 percent of local taxes collected.

Water Supply Alternative. Potential decreases in tax revenue occurring under the Water Supply Alternative during the period 2008 through 2026 would range from a low of $4.6 million during a 400,000 af shortage in 2026 to a high of $7.7 million during a 400,000 af shortage in 2017. For the period 2008 to 2026, only shortages of 400,000 af would occur, ranging from two percent in 2017 to 12 percent in 2026. This lack of shortages is a result of this alternative's strategy to provide full water deliveries until no water remains in Lake Mead, a reservoir draw down situation which has a low probability of occurring during the interim period.

Potential decreases in tax revenue attributable to a shortage occurring under the Water Supply Alternative during the period 2027 through 2060 would range from a low of $4.2 million during a 500,000 af shortage in 2060 to a high of $18.9 million during a 2.5 maf shortage in 2060. For the period 2027 through 2060, a shortage of 500,000 af would have the greatest probability of occurring, estimated at between 37 percent in 2027 to 51 percent in 2060. These changes in tax revenues represent less than 0.3 percent of total state taxes collected and less than 0.4 percent of local taxes collected.

Reservoir Storage Alternative. Potential decreases in tax revenue attributable to a shortage occurring under the Reservoir Storage Alternative during the period 2008 through 2026 would range from a low of $7.4 million during an 800,000 af shortage in 2026 to a high of $14.8 million during a 1.2 maf shortage in 2017. For the period 2008 through 2026, a shortage of 800,000 would have the greatest probability of occurring, estimated at 18 percent in 2017 and 2026.

Potential decreases in tax revenue attributable to a shortage occurring under the Reservoir Storage Alternative during the period 2027 through 2060 would range from a low of $4.2 million during a 500,000 af shortage in 2060 to a high of $14.6 million during a 1.8 maf shortage in 2040. For the period 2027 through 2060, a shortage of 500,000 af would have the greatest probability of occurring, estimated at between 38 percent in 2027 to 53 percent in 2060. These changes in tax revenues represent less than 0.2 percent of total state taxes collected and less than 0.3 percent of local taxes collected.

Preferred Alternative. Potential decreases in tax revenue attributable to a shortage occurring under the Preferred Alternative during the period 2008 through 2026 would range from a low of $5.9 million during 500,000 af shortage in 2026 to a high of $10.6 million during an 800,000 af shortage in 2017. For the period 2008 through 2026, a shortage of 500,000 af would have the greatest probability of occurring, estimated at 16 percent in 2017 and 24 percent in 2026.

Potential decreases in tax revenue attributable to a shortage occurring under the Preferred Alternative during the 2027 through 2060 would range from a low of $4.2 million during a 500,000 in 2060 to a high of $14.6 million during a 1.8 maf shortage in 2040. For the period 2027 through 2060, a shortage of 500,000 af would have the greatest probability of occurring, estimated at between 36 percent in 2040 to 52 percent in 2060. These changes in tax revenues represent less than 0.2 percent of total state taxes collected and less than 0.3 percent of local taxes collected.

4.14.2.3 Changes in Agricultural Production in California and Resulting Changes in Employment and Income in California

The results of the water allocation modeling indicate that although a portion of the shortages may be shared by California, agricultural users and production would only be affected by a very large shortage. However, agricultural production in California would not be adversely affected because any shortage amount would be very small. None of the alternatives are expected to result in a substantial change in California’s agricultural production.

4.14.2.4 Changes in Agricultural Production in Nevada and Resulting Changes in Employment and Income in Nevada

The results of the water allocation modeling indicate that although a portion of the shortages may be shared by Nevada, agricultural users would not be affected in the event a shortage occurs. There are very few agricultural users that receive part of Nevada’s Colorado River water allocation. None of the alternatives are expected to result in a change in Nevada’s agricultural production.

Shortages occurring in Nevada are expected to be limited to the M&I sector. No changes in employment and income as a result of changes in agricultural production in Nevada are expected under any of the alternatives.

4.14.3 Potential Impacts to Municipal and Industrial Water Users

This section provides the results of the assessment of potential changes in M&I water use and resulting socioeconomic effects. The analysis is a qualitative discussion supported by the assessment of the shortage probabilities and volumes described in Section 4.4, Tables 4.4-5 through 4.4-8, Table 4.4-15, and in Appendix G.

For the period 2008 through 2060 the probability of a shortage occurring is highest for shortages ranging from 400,000 to 800,000 af and the probabilities of shortages occurring greater than 800,000 af are very similar among all the alternatives, including the No Action Alternative. Accordingly, the focus of the M&I analysis is to describe the effects of shortages that range from 400,000 af to 800,000 af.

For the period 2008 through 2026, the shortages under the No Action Alternative, the Basin States, Conservation Before Shortage, and Reservoir Storage Alternatives, and the Preferred Alternative would have the highest probability of occurring. In 2017, a 500,000 af shortage would have a 45 percent chance of occurring under the No Action Alternative compared to a 16 percent chance under the Preferred Alternative; the alternative with the highest probability of a shortage occurring among the action alternatives. Conversely, a 600,000 af shortage would have a greater likelihood of occurring under the Basin States, Conservation Before Shortage, and Reservoir Storage Alternatives as compared to the No Action Alternative and the Water Supply Alternative.

For the period 2027 through 2060, the probability of a shortage occurring under each alternative is highest at the 500,000 af shortage level. When compared to the No Action Alternative, shortages of 500,000 af in 2060 have a greater probability of occurring under all the action alternatives. Conversely, in 2027 and in 2040 shortages of 500,000 af have a similar probability of occurring under all the alternatives.

4.14.3.1 Changes in Municipal and Industrial Water Uses In Arizona

This section describes the potential socioeconomic effects that would result from changes in deliveries to M&I users in Arizona. The analysis is based on an analysis of shortage amounts in the range of 400,000 af to 800,000 af.

Arizona's Drought Management Plan serves as an umbrella that provides direction to Arizona state agencies and guidance to regional and local agencies regarding responses to drought conditions (Arizona Drought Task Force 2004). Shortages to the Arizona M&I sector would be addressed through the state's and each local jurisdiction's drought responses and plans. These responses include supply-side and demand-side actions. Supply-side actions may include groundwater recharge, water purchase agreements, and alternative water supplies such as brackish water and reclaimed water. Demand-side strategies focus on implementing different stages of water conservation measures as a drought progresses. Shortages to the Arizona M&I sector would be addressed through each entity's supply-side and demand-side drought response actions and programs.

In 2017, Arizona M&I shortages would range from approximately 9,200 af during a 400,000 af shortage to 176,000 af during an 800,000 af shortage. In 2026, Arizona M&I shortages would range from approximately 99,000 af during a 400,000 af shortage to 176,000 af during an 800,000 af shortage. Implementing statewide and local demand-side and supply-side strategies are expected to minimize adverse socioeconomic effects occurring during the maximum M&I shortage.

4.14.3.2 Changes in Municipal and Industrial Water Uses In California

The section provides the results of the analysis of changes of potential socioeconomic effects as a result of changes in deliveries to M&I users. The conclusions are based on information provided in Section 4.4 of this Final EIS. In summary, deliveries to MWD are not anticipated to be adversely affected for Lower Basin shortages up to 1.8 maf because of California's higher Colorado River water supply priority relative to Arizona's and Nevada's Colorado River water supply priorities. In addition, shortages of 1.8 maf or greater have a low probability of occurring. MWD has or is working on putting in place storage and transfer programs that are expected to provide full supplies when needed even when Colorado River surplus supplies are not available. Examples of MWD actions include agreements with irrigation districts and individual landowners to reduce water use by fallowing lands, funding water efficiency improvements, and banking and exchange programs.

MWD is not expected to experience a substantial reduction in deliveries to M&I users during a shortage because of the priority of California's water rights in combination with the availability of alternative water supplies. The action alternatives are not expected to result in a substantial change in economic activities dependent on M&I deliveries.

4.14.3.3 Changes in Municipal and Industrial Water Uses in Nevada

This section describes the potential socioeconomic effects that would result from changes in deliveries to M&I users in Nevada. The analysis is based on a comparison of the action alternatives to the No Action Alternative.

Shortages to the M&I sector of Southern Nevada would mostly be borne by the SNWA, which has prepared a drought plan (SNWA 2005) to address water shortages. That plan includes two levels; a drought watch, and a drought alert and calls for landscape watering restrictions to private lawns, community use recreational turf areas, and golf courses. The plan also includes restrictions on surface, building, equipment, and vehicle washing.

Between 2008 and 2027, action alternatives would result in shortage allocations that are both less than or greater than those under the No Action Alternative. Although the largest differential would occur under the Water Supply Alternative in 2027, where the maximum shortage would equal approximately 279,000 af as compared to 60,548 af under the No Action Alternative, this shortage amount is the result of the unlikely event that Lake Mead elevation would fall below the SNWA intake. Under the Preferred Alternative, maximum shortages would decrease by 15,000 af in 2017 and increase to approximately 45,000 af in 2026. For each shortage scenario, the probability of shortages in southern Nevada would not be substantially different than under the No Action Alternative, with the exception of the 500,000 af shortage. The probability of a 500,000 af shortage occurring under any of the action alternatives would be substantially lower when compared to the No Action Alternative (Tables 4.4-5 and 4.4-6). In addition, with Nevada's drought plan in place, shortages to the M&I sector (under the No Action Alternative or under either of the action alternatives) would be managed. Socioeconomic effects on southern Nevada's M&I sector would vary depending on the size of the shortage, but the probability of larger shortages (greater than 600 kaf) which have the potential for more impacts, is not substantially different between the No Action Alternative and the Preferred Alternative.

4.14.4 Potential Impacts to Recreation

This section describes the changes in reservoir-related and river-related economic activity attributable to implementing the action alternatives. The assessment is based, in part, on the conclusions provided in Section 4.3 and Section 4.12.

4.14.4.1 Change in Economic Activity as a Result of Changes in Recreation Occurring at Lake Powell

The following qualitative assessment of changes in recreation-related economic activity is based on a comparison of Lake Powell elevations modeled for the No Action Alternative and for each action alternative.

As shown in Figure 4.14-2, at the 90th percentile there are no differences in Lake Powell end-of-September elevations between the alternatives. This suggests that at higher lake elevations there would be no differences in recreation opportunities and associated economic activity among the alternatives.

At the 50th percentile, end-of-September reservoir elevations under the Reservoir Storage Alternative would be nearly the same as those under the No Action Alternative. This suggests that recreation opportunities and resulting economic activity would not change. Reservoir elevations would be lower under the Conservation Before Shortage, Basin States, and Water Supply Alternatives, and the Preferred Alternative when compared to the No Action Alternative, with the Water Supply Alternative showing the lowest 50th percentile elevations. Because the reservoir would have substantial storage under all alternatives at the 50th percentile, these lower elevations are not expected to result in substantial change in recreation opportunities at Lake Powell and would not result in a substantial change in recreation-related economic activity.

The greatest differences in Lake Powell elevations would occur at the 10th percentile. Lake Powell elevations would be higher under the Reservoir Storage Alternative when compared to the No Action Alternative. These higher elevations would benefit recreation opportunities at Lake Powell and resulting economic activity. Reservoir levels would be nearly the same under the Basin States and Conservation Before Shortage Alternatives, the Preferred Alternative, and the No Action Alternative. This suggests that recreation-related economic activity would be the same among these four alternatives. Reservoir elevations would be lowest under the Water Supply Alternative and would result in the greatest adverse effect on recreation opportunities and associated reduction in economic activity.

4.14.4.2 Change in Economic Activity as a Result of Changes in Recreation Occurring in the Colorado River Downstream of Lake Powell

Recreation opportunities and use would not be adversely affected on the Colorado River reach downstream of Lake Powell because flows would not drop below safe boating thresholds for all of the alternatives. There would be no resulting changes in recreation-related economic activity among the alternatives because recreation use is not expected to change.

4.14.4.3 Change in Economic Activity as a Result of Changes in Recreation Occurring at Lake Mead

The following qualitative assessment of changes in recreation-related economic activity is based on a comparison of Lake Mead elevations modeled for the No Action Alternative and each action alternative.

As illustrated in Figure 4.14-3, at the 90th percentile there are essentially no differences in Lake Mead end-of-July elevations among the alternatives. This suggests that at the higher lake elevations there would no differences in recreation opportunities and associated economic activity.

At the 50th percentile, end-of-July reservoir elevations under the Reservoir Storage Alternative would be higher when compared to the No Action Alternative. This suggests that recreation opportunities and resulting economic activity would be greater under the Reservoir Storage Alternative. Reservoir levels for the Basin States and Conservation Before Shortage Alternatives, the Preferred Alternative, and the No Action Alternative would be nearly the same. No substantial differences in economic activity would occur under the Conservation Before Shortage, Basin States, and Water Supply alternatives, and the Preferred Alternative.

The greatest differences in Lake Mead elevations would occur at the 10th percentile. Lake Mead elevations under the Basin States, Conservation Before Shortage, and Water Supply alternatives, and the Preferred Alternative would be slightly higher during the interim period when compared to the No Action Alternative. This suggests that there would be only a small, if any, increase in economic activity when compared to the No Action Alternative. The Reservoir Storage Alternative would result in the greatest increase in Lake Mead elevations compared to the No Action Alternative. These higher elevations would benefit recreation opportunities and resulting economic activity.

4.14.4.4 Changes in Economic Activity as a Result of Changes in Recreation Occurring in the Colorado River Downstream of Lake Mead

Recreation opportunities and use would not be adversely affected on the reach of the Colorado River downstream of Lake Mead because daily and hourly releases from Hoover Dam, Davis Dam, Parker Dam, and Imperial Dam would remain within historical ranges. As a result, there would be no change in recreation-related economic activity among the alternatives because recreation opportunities and use are not expected to change.

4.14.5 Potential Impacts of Multi-Year Shortages

An analysis was conducted to estimate the magnitude and probability of shortages occurring during two or more consecutive years (Section 4.4 and Appendix P). The analysis suggests that during the interim period, there is a high probability that multi-year shortages for volumes greater than or equal to 400,000 af may occur. The No Action Alternative has the highest probability of multi-year shortages and the Water Supply Alternative has the lowest probability (zero percent) during the interim period. Of the five action alternatives, the Reservoir Storage Alternative has the highest probability of multi-year shortages. After the end of the interim period, the probability of a multi-year shortages occurring would be very similar among all the alternatives.

A multi-year shortage could result in a higher probability of a permanent loss in employment, income, and tax revenue if the same agricultural operations or M&I uses experience a shortage over consecutive years. Because it is not known how a multi-year shortage would be allocated over a specific water delivery area, the potential magnitude of longer-term socioeconomic effects cannot be estimated. However, as indicated in the multi-year shortage graphs provided in Section 4.4 and in Appendix P, the probabilities of multi-year shortages occurring would typically be less than under the No Action Alternative. This suggests that the probability of longer-term adverse socioeconomic effects occurring under the action alternatives would be less when compared to the No Action Alternative.

4.14.6 Potential Impacts of a Voluntary Conservation Program

An assessment was performed of the positive and negative impacts of implementing a voluntary conservation program (Appendix H) as postulated in the Conservation Before Shortage Alternative. The compensation to farmers under a voluntary fallowing program could potentially offset some of the adverse socioeconomic effects of reducing agricultural production. The degree to which these payments would offset the adverse socioeconomic effects of fallowing agricultural lands would depend on the payment schemes and amounts associated with a particular program. Instituting a voluntary fallowing program could result in positive economic effects. However, as suggested by the results of the two scenarios described in Appendix H, estimating the socioeconomic effects of implementing a program with a reasonable degree of certainty is difficult without additional detail regarding payment amounts, geographic location, and timing. There are many variables that need to be considered and these will vary widely by region, programs size, length of program, and participating entities.

4.14.7 Summary

4.14.7.1 Employment, Income, and Tax Revenues

Although a loss in employment and income could potentially occur under any of the action alternatives, the probability of any shortage occurring would be greater under the No Action Alternative. This suggests that the potential loss in employment, income, and tax revenues estimated for the No Action Alternative would be reduced under each of the action alternatives. The probabilities of any shortage amount occurring would be similar under all the action alternatives during the interim period with the exception of the Water Supply Alternative. When compared to the other action alternatives, the probabilities of any shortage amount occurring would be lower under the Water Supply Alternative. This indicates that, with the exception of the Water Supply Alternative, the potential losses in employment, income, and tax revenues would be similar among the action alternatives during the interim period. However, none of the changes in employment and income are considered substantial when compared to total employment and income generated within the study area.

For the period 2027 through 2060, the change in employment and income would be similar between the No Action Alternative and the action alternatives. The greatest difference would be in 2027 in which the probabilities would be slightly higher when compared to those under the No Action Alternative. However, by 2040, the probabilities of shortages occurring under all of the alternatives are very similar.

4.14.7.2 Municipal and Industrial Water Uses
Adverse effects on employment and income in Arizona and Nevada during shortages would be minimized as a result of drought plans being in place. No adverse effects are expected in California because of priority of apportionment and the availability of alternative water supplies.

4.14.7.3 Recreation
Recreation opportunities and associated economic activity at Lake Powell are not expected to be substantially different under the No Action Alternative, the Basin States and Conservation Before Shortage Alternatives, and the Preferred Alternative. Recreation opportunities and associated economic activity could potentially be adversely affected under the Water Supply Alternative due to the potentially lower Lake Powell elevations that may occur under this alternative. Conversely, recreation opportunities and associated economic activity would benefit under the Reservoir Storage Alternative as a result of potentially higher Lake Powell elevations under this alternative.

Recreation opportunities and associated economic activity at Lake Mead are not expected to be substantially different under the No Action Alternative, the Basin States, Conservation Before Shortage, and Water Supply alternatives, and the Preferred Alternative. Recreation opportunities and associated economic activity could potentially benefit under the Reservoir Storage Alternative due to the potentially higher Lake Mead elevations that may occur under this alternative.

Because daily and hourly flows in the Lake Powell to Lake Mead reach and in the Colorado River reaches downstream of Lake Mead would likely remain within ranges suitable for boating, there would be no change in river-related economic activity.

This page intentionally left blank.

4.15 Environmental Justice

This section describes the methods of analysis, and potential effects on environmental justice communities at the county level. The twelve environmental justice counties that were identified in Section 3.15 are: Coconino, La Paz, Mohave, Pima, Pinal, and Yuma counties in Arizona; Imperial, Los Angeles, Orange, Riverside, and San Bernardino counties in California; and San Juan County in Utah.

4.15.1 Methodology

The twelve environmental justice counties were examined by resource to identify whether any of the alternatives are likely to have disproportionate and adverse human health or environmental impacts.

4.15.2 Hydrology, Water Deliveries, and Socioeconomics

Potential water shortages will not impact water deliveries in Utah (Section 4.4) and would only rarely affect water deliveries in California (Table 4.4-21 and Table 4.4-22). Six of the eight Arizona counties are environmental justice communities. Two of the three counties served by the CAP are environmental justice communities (Pinal and Pima). Under all alternatives, a Lower Basin shortage would cause the reduction of water deliveries first to the CAP and other post-1968 Colorado River contractors in Arizona. While some would consider this a disproportionate impact on these Arizona counties as compared to other Colorado River contractors, this water entitlement priority is mandated under the CRBPA, and would occur under all of the action alternatives as well as under the No Action Alternative.

As an example of the magnitude of potential socioeconomic impacts, in 2026 a 500,000 af shortage has a 34 percent chance of occurring under the No Action Alternative. This would potentially result in a loss of about 561 jobs in Arizona (Table 4.14-3). In comparison, under the Preferred Alternative, the probability of occurrence is approximately 24 percent and would result in a loss of the same number of jobs. Under the Basin States Alternative, the probability of this shortage volume in 2026 is approximately 15 percent. Under the Conservation Before Shortage and the Water Supply alternative, there would be a one percent and zero percent probability of this occurrence, respectively. Under the Reservoir Storage Alternative, there is a zero percent probability of this shortage volume in 2026. The biggest difference in the probability of shortage occurs in 2017 with an 18 percent probability of occurrence of an 800,000 af shortage under the Reservoir Storage Alternative and a zero percent probability of occurrence under the No Action Alternative. Even so, this effect is projected to only result in the loss of approximately 860 jobs in Arizona. The loss in the number of jobs is so small compared to the total number of jobs in the environmental justice counties that the effects of the alternatives are negligible.

Accordingly, there is no substantive difference among the alternatives with respect to environmental justice impacts from water deliveries and socioeconomics.

4.15.3 Water Quality

Potential changes to water quality were evaluated for salinity, temperature, metals, and perchlorate. Effects on these parameters would be minor and would not disproportionately affect any environmental justice communities in the study area. For example, in Imperial County, California, the predicted salinity values would range from 732 mg/L to 783 mg/L. All values are below the 879 mg/L numeric criterion established by the Colorado River Basin Salinity Control Forum (Section 4.5).

4.15.4 Air Quality

Potential changes to fugitive dust emissions due to exposed shoreline are minor at Lake Powell and there would be no disproportionate effect on the health of residents of San Juan County compared to the other counties. Likewise, there would be no significant difference among alternatives at Lake Mead or downstream. Therefore, the proposed federal action would not result in any disproportionate effects to environmental justice communities.

4.15.5 Visual Resources

Potential impacts to visual resources were considered for attraction features, calcium carbonate rings, and sediment deltas. While some of these features are located within San Juan County, Utah, (e.g., Rainbow Bridge) an environmental justice community, effects are not disproportionate or unique to any environmental justice community.

4.15.6 Biological Resources

Potential impacts to biological resources would not disproportionately impact any environmental justice community identified within the study area. Potential impacts to vegetation, wildlife, and fish due to the action alternatives would be minor.

Scoping and subsequent consultation did not result in the identification of any environmental justice community for whom indigenous fish, vegetation, or wildlife constituted a significant portion of their diet. There will be no difference in rates or patterns of subsistence consumption by environmental justice communities, including Indian tribes, in comparison to the general population in the study area.

4.15.7 Cultural Resources

Potential impacts or access to cultural resources are not expected to be unique to the environmental justice communities identified in the study area. Reclamation and the cooperating agencies are committed to compliance with all laws and regulations associated with historic properties, sacred sites, and cultural resources. Consultations are ongoing with concerned Indian tribes.

4.15.8 Indian Trust Assets

Reclamation has concluded that the proposed federal action will have no significant impacts on ITAs. Reclamation is committed to protecting and maintaining ITAs and rights reserved by or granted to Indian tribes or individual Indians by treaties, statutes, and executive orders.

4.15.9 Electrical Power Resources

Changes to electrical power production among the alternatives have the potential to affect environmental justice communities disproportionately through possible minor increases in electricity rates resulting from decreased electrical power generation under some of the action alternatives. However, these changes in electrical power production are generally very minor (less than one percent) and the facilities potentially affected produce less than four percent of the total power produced in the region. Therefore no substantial environmental justice effects are anticipated.

4.15.10 Recreation

Potential recreational impacts are primarily associated with reduced reservoir elevations affecting access or necessitating capital alterations to shoreline facilities around Lake Powell and Lake Mead. Individuals and businesses within San Juan County, Utah, which is greater than 50 percent minority, could be affected by these recreational impacts. However, the effect would not be disproportionate to the recreational impacts experienced by other counties adjacent to Lake Powell and Lake Mead.

4.15.11 Transportation

Potential transportation impacts are associated with ferry services on Lake Powell and on the Colorado River downstream of Davis Dam. At Lake Powell, both San Juan County and Kane County would be equally affected by any disruption to the ferry service due to low reservoir elevations. San Juan County would not be disproportionately affected. Downstream of Davis Dam, the ferry service across the river serves two non-environmental justice counties.

4.15.12 Summary

After evaluating each resource, it is concluded that the environmental justice communities identified in the study area would not be disproportionately affected by any of the anticipated environmental impacts stemming from the proposed federal action. Nor would the proposed federal action result in adverse disproportionate impacts on human health within these environmental justice communities.

This page intentionally left blank.

4.16 Indirect Effects of Intentionally Created Surplus Mechanism

Indirect effects are reasonably foreseeable environmental impacts which are caused by the proposed federal action, but may occur later in time or farther removed in distance. This section describes the potential indirect effects from Reclamation's proposed creation of the ICS mechanism as part of the proposed federal action. Potential cumulative effects of other related non-ICS projects are described in Chapter 5.

Several Colorado River water users have expressed preliminary interest in proposing ICS projects in the future, but the projects are not sufficiently formulated to include in this indirect effect analysis. The types of proposed projects that are being contemplated include: (1) fallowing, (2) tail-water recovery systems, (3) seepage interception, (4) ground-water desalination, (5) canal lining, (6) crop rotation, (7) importation of non-system water, (8) integrated information systems, and (9) scientific irrigation scheduling. Such future ICS proposals will be proposed and considered for approval in accordance with the operational guidelines to be adopted in the ROD[1].

SNWA proposes three ICS projects which were specifically formulated to utilize the ICS mechanism. It is anticipated that creation of ICS and subsequent delivery of water from Lake Mead for these currently proposed projects will be approved as part of the ROD. While the proposed SNWA ICS projects are not federal projects, they will rely on Reclamation's approval for creation, accounting, and delivery of water from Lake Mead. The effects of these projects within the geographic scope of the proposed federal action have been included in the modeling assumptions and are therefore included in the various resource analyses in the Final EIS. The localized impacts of these ICS projects (outside the geographic scope of the proposed federal action) are described here as indirect effects of Reclamation's establishment of the ICS mechanism.

The currently proposed ICS projects addressed in this section include:

- SNWA Virgin River and Muddy River Tributary Conservation;
- SNWA Coyote Spring Well and Moapa Transmission System Project; and
- Lower Colorado River Drop 2 Storage Reservoir Project.

Each of these currently proposed projects is described below.

[1] Reclamation has included draft guidelines in the Final EIS (Appendix S) that discuss the administration of ICS.

4.16.1 ICS Projects Directly Related to Creation of ICS Mechanism

4.16.1.1 SNWA Virgin River and Muddy River Tributary Conservation

As part of an ongoing initiative to protect southern Nevada from drought and augment future water supplies, SNWA proposed a project in 2004 to develop surface flows from the Virgin River and Muddy River for which it holds water rights. The SNWA currently holds water right Permit 58591 (priority date 1989) and Permit 57643 (priority date 1993) for a total not to exceed annual diversion from the Virgin River of 190 kaf, and also owns pre-BCPA water rights in the form of shares which were purchased from irrigation companies on the Virgin River and Muddy River.

SNWA would utilize pre-BCPA Virgin River and Muddy River water rights by retiring the rights from their current use and allowing them to flow into Lake Mead for recovery for municipal and industrial purposes, also known as Tributary Conservation ICS. Tributary Conservation is a form of ICS where water rights on Colorado River tributaries within the Lower Basin states that have been used for a significant period of years and were perfected prior to June 25, 1929 (the effective date of the BCPA) could be retired and allowed to flow into the Colorado River mainstream. Under the proposed federal action, the Lower Basin state that provides such Tributary Conservation could then recover the amount of water contributed through Tributary Conservation for municipal or industrial purposes only.

Pre-BCPA water rights on the Virgin River have a priority date of pre-1905 and were decreed by the Nevada Supreme Court in 1927. The decree allocated 17,785 afy to the Bunkerville and Mesquite Irrigation Companies. SNWA currently owns shares in the Bunkerville Irrigation Company representing approximately 3,700 afy of surface water rights, but does not currently own any shares in the Mesquite Irrigation Company. On the Muddy River, water rights were decreed in 1920 and that decree allocated the entire flow of the Muddy River. On the lower Muddy River, the entire flow is diverted by the Muddy Valley Irrigation Company for agricultural use. SNWA currently owns shares in the Muddy Valley Irrigation Company representing approximately 7,000 afy of pre-BCPA surface water rights. On the upper Muddy River, SNWA leases approximately 1,000 afy from the Church of Jesus Christ of Latter-Day Saints (LDS Church). The LDS Church lease is for a term of 20 years, with an option to renew the lease for an additional 20 years.

SNWA has been purchasing pre-BCPA water rights on the Virgin River and Muddy River since 1997 in an effort to reduce SNWA's dependence on the Colorado River and to develop additional water supplies for Southern Nevada. SNWA's purchase and retirement of pre-BCPA water rights will allow for assured flows within the entire Muddy River and the portion of the Virgin River downstream of the Bunkerville and Mesquite Irrigation Companies by using flows that were historically consumptively used off channel by agriculture for the creation of Tributary Conservation ICS.

4.16.1.2 SNWA Coyote Spring Well and Moapa Transmission System Project

This project involves the development of groundwater production and conveyance facilities for groundwater from Coyote Spring Valley in Clark County, Nevada. The purpose of the Coyote Spring Well and Moapa Transmission System Project is to develop and convey SNWA's existing 9,000 afy of Coyote Spring Valley water rights in an efficient and practical manner to locations where such water can be placed to a beneficial use by SNWA and/or Moapa Valley Water District. This project would increase diversification of SNWA's current water resources to include non-Colorado River water resources.

SNWA applied to BLM for a Right of Way for the project facilities in November 2002. The application required BLM to prepare an EA which was initiated in July 2003. The Final EA and FONSI for the project were issued in June 2007.

4.16.1.3 Lower Colorado River Drop 2 Storage Reservoir Project

The lower Colorado River Drop 2 Storage Reservoir Project is one of many potential actions that will be taken to maximize beneficial use of Colorado River water in the United States. Reclamation issued a draft EA on November 30, 2006 for public review. The specific objectives of the proposed Drop 2 Storage Reservoir Project include:

- providing additional storage capacity to reduce non-storable flows of the Colorado River below Parker Dam; and
- providing additional operational flexibility in the lower Colorado River system for the Imperial Irrigation District, Coachella Valley Water District, and other Colorado River system users.

The Drop 2 Storage Reservoir Project has three primary physical components: 1) the reservoir itself; 2) an inlet canal; and 3) an outlet canal:

- **Reservoir.** Two 4,000 af capacity reservoir cells would be formed by excavating below the existing ground surface. The approximate depth of the reservoir would be 20 feet. The reservoir would occupy approximately 621 acres.
- **Inlet Canal.** The inlet canal would be from five to seven miles in length depending on alignment. Inlet canal capacity would be 1,700 cfs.
- **Outlet Canal.** The outlet canal would be approximately 3,500 feet in length, connecting the reservoir to the AAC near Drop 2 Reservoir Project. Outlet canal capacity would be 1,700 cfs.

The Drop 2 Storage Reservoir Project operations would be relatively simple: a new inlet canal would convey water from the existing Coachella Canal Turnout on the AAC to a new storage reservoir, and as needed, water would be returned to the AAC via a new outlet canal. Both the inlet and outlet canals would be designed to use gravity flow.

Recent legislation passed by Congress in late 2006[2] requires that the Secretary proceed "without delay" with the "construction, operation and maintenance" of the Drop 2 Storage Reservoir Project. Reclamation published a Final EA on the project and made it available to the public on June 20, 2007. Construction is scheduled to begin in 2008.

4.16.2 Impacts by Resource

4.16.2.1 Hydrologic Resources and Water Delivery

The SNWA Virgin River and Muddy River Tributary Conservation are projected to result in up to 30,000 af of additional water being delivered to Lake Mead annually from the Virgin River and the Muddy River. Approximately one-third of this amount is expected to come from the Virgin River and two-thirds from the Muddy River. This is consistent with the flow volumes that were analyzed in the Final EIS and the additional flow volumes from the Virgin River and Muddy River analyzed in the LCR MSCP for effects to Lake Mead.

The retired agricultural water rights will be conveyed to Lake Mead via the Overton Arm in one of two fashions. Water will be diverted from the Colorado River through its historic point of diversion, flow through irrigation company ditches, and return to the mainstream Colorado River further downstream if the flow is necessary in the irrigation company ditches to avoid impacts to the irrigation company's operations or wildlife. This is the proposed operation for waters thus far acquired in the Bunkerville Irrigation Company and Muddy Valley Irrigation Company. Alternatively, if the water is not associated with an irrigation company or not required for the purposes described above, it will not be diverted and instead will remain in the channel and allowed to flow to the mainstream Colorado River. Additional information on the hydrology of the Lower Virgin River and Muddy River is provided in Appendix R.

The effects to lower Virgin River and Muddy River hydrology are detailed in Appendix R. In the Virgin River, the 10,000 afy of Tributary Conservation represents less than 7 percent of the historic annual flow in the Virgin River at Halfway Wash. Given the relative magnitudes of flow, and the complex geology and underflow that occur in the floodplains along the entire Virgin River, it is questionable whether there would be any noticeable change in surface flows on the Virgin River from this project. Upper Muddy River surface water flow is measured at the Moapa and Glendale gages, which average

---

[2] The full text of the legislation, contained in Public Law 109-432 provides:
: "SEC. 396. REGULATED STORAGE WATER FACILITY.
(a) CONSTRUCTION, OPERATION, AND MAINTENANCE OF FACILITY.—
Notwithstanding any other provision of law, upon the date of enactment of this Act, the Secretary shall, without delay, pursuant to the Act of January 1, 1927 (44 Stat. 1010, chapter 47) (commonly known as the ''River and Harbor Act of 1927''), as amended, design and provide for the construction, operation, and maintenance of a regulated water storage facility (including all incidental works that are reasonably necessary to operate the storage facility) to provide additional storage capacity to reduce nonstorable flows on the Colorado River below Parker Dam.
(b) LOCATION OF FACILITY.—
The storage facility (including all incidental works) described in subsection (a) shall be located at or near the All American Canal."

approximately 30,000 afy. The current leased SNWA water rights in the upper Muddy River (1,000 afy) represent approximately 3 percent of the gages' flow, well within a typical gage margin of error of 10 percent and virtually undetectable. In the lower Muddy River, the surface flows are measured at the Overton Gage which averages approximately 9,000 afy. This gage reflects surface water flows reaching Lake Mead. While there have been no studies confirming irrigation system losses to the alluvium, it is believed that there is water bypassing the Overton Gage as underflow. Because of irrigation system losses and substantial underflow bypassing the gage, simply subtracting the Moapa-Glendale Gage readings from the Overton Gage readings will not provide an accurate accounting of the volume of Tributary Conservation flow reaching Lake Mead. Like the Virgin River and upper Muddy River, the complex geology, gaging accuracies and historic use of this water will make it difficult to see a marked increase in the Overton Gage from Tributary Conservation flows. Due to all the factors mentioned above, 20,000 afy of Tributary Conservation is not likely to result in a noticeable change to flows on the Muddy River from the current conditions. Additional information on the effects to river hydrology is provided in Appendix R.

The hydrologic impacts on Lake Mead from additional inflows from the Virgin River and Muddy River, and additional water deliveries to SNWA, were included in the modeling assumptions and are described in Chapter 4.3 of the Final EIS. Impacts of the Virgin River and Muddy River tributary conservation projects are described in this section.

The development of Coyote Spring Well and the Moapa Transmission System would similarly result in increased flows into Lake Mead. The project would develop and convey SNWA's existing 9,000 afy of Coyote Spring Valley water rights for delivery into the mainstream of the Colorado River. These hydrologic effects were also included in the modeling conducted for this EIS. For the reasons described above, the positive effect on river flow would be subtle, if noticeable at all.

The Drop 2 Storage Reservoir Project would result in a reduction in the non-storable flows that are delivered to Mexico. The Drop 2 Storage Reservoir Project was included in the hydrologic modeling for Lake Mead and the Colorado River conducted for this EIS, and any resulting impacts are included in the analysis in Sections 4.3 and 4.4. The EA for the Drop 2 Storage Reservoir Project included a specific analysis of the hydrologic impacts of the project on smaller (non-flood release) flows in the limitrophe division of the Colorado River. The EA concluded decreases in surface water flows passing Morelos Diversion Dam would not conflict with 1944 Treaty delivery obligations, or substantially alter the existing drainage pattern or flows of the limitrophe reach. The slight decrease in flows could potentially adversely affect groundwater levels, but the change does not represent a significant impact to groundwater supplies.

4.16.2.2 Water Quality

No significant impacts on water quality in the Virgin River and the Muddy River are anticipated from the SNWA Tributary Conservation. For the reasons described immediately above, the changes in river flow, while positive, would be within a typical gage margin of error of ten percent and virtually undetectable. Potential water quality impacts of the Drop 2 Storage Reservoir Project on the Colorado River were included in the modeling assumptions, and are included in the analysis in Section 4.5. The localized short-term and long-term water quality impacts of the Drop 2 Storage Reservoir Project were considered in the Reclamation EA and determined not to be significant, with implementation of mitigation measures, such as construction of sediment traps (e.g., hay bales, silt fences, straw wattles) and temporary desilting basins for onsite erosion control.

4.16.2.3 Air Quality

Any effect from SNWA's development of pre-BCPA water rights on the Virgin River and the Muddy River, the development of the Coyote Spring Well and the Moapa Transmission System, and the Drop 2 Storage Reservoir Project on Lake Mead was taken into account in the modeling performed for this project, and any impacts of wind blown dust from exposed reservoir shoreline is included in the analysis in Section 4.6. SNWA's Virgin River and Muddy River Tributary Conservation project has the potential to contribute to air quality concerns through the retirement of agricultural lands. However, this concern is mitigated by the gradual implementation of the full project. Moreover, some of the water rights that SNWA purchased may have already been regularly fallowed or out of production at the time they were acquired by SNWA. The air quality effects of the Coyote Spring Well and the Moapa Transmission System were considered in the BLM EA and determined not to be significant because construction emissions would cease at the completion of construction and will be mitigated by implementation of an approved dust control plan. Air emissions from the Drop 2 Storage Reservoir Project were estimated in the Reclamation EA for the project and determined not to be significant. Project air emissions from both construction and operation and maintenance activities would remain below all emission significance thresholds would produce no significant air quality impacts.

4.16.2.4 Visual Resources

The potential impact of SNWA's development of pre-BCPA water rights on the Virgin River and the Muddy River, the development of the Coyote Spring Well and the Moapa Transmission System, and the Drop 2 Storage Reservoir Project related to the exposure of the calcium carbonate ring around Lake Mead was included in the modeling for Lake Mead elevations, as described in Section 4.7. SNWA's Virgin River and Muddy River Tributary Conservation would not result in visual impacts because, as described above, the increased flows in the two rivers would likely not be noticeable. Visual impacts from the Coyote Spring Well and the Moapa Transmission System were considered in the BLM EA and determined not to be significant because SNWA will mitigate visual effects by restoring the pipeline right-of-way and using best management practices to reduce the line and form contrast of the regulating tank by application of color, reduction of height, reduction of size, and addition of architectural features. Construction emissions from the Drop 2 Storage Reservoir Project were considered in the Reclamation EA and determined not to be significant. The location for the Drop 2 Storage Reservoir Project is a former working farm and the location has no visually unique characteristics. As this site is presently void of any significant visual feature, and as the nearby open space areas would remain unchanged from existing conditions, construction and operation under the Drop 2

Storage Reservoir River Project would not degrade the existing visual character or quality of the site and its surroundings.

4.16.2.5 Biological Resources

In general, increased flow from the SNWA Virgin River and Muddy River Tributary Conservation is expected to have a beneficial, albeit minor, effect on any marsh or riparian habitat along the Muddy River or within the Mormon Mesa area on the Virgin River. No effect is anticipated on the Virgin River above the Bunkerville Irrigation Company service area, as acquisition of surface water rights will take place below this area.

Drought has been identified as one type of event that could create conditions that can impact sensitive fish species on the Lower Virgin River and the Muddy River. The assured flows in the Virgin River and the Muddy River proposed by the SNWA Tributary Conservation Program are expected to have a beneficial effect on fish and bird species because they may help lessen the effects of drought (Bio-West Inc. 2007). While drought tends to decrease river flows, the Tributary Conservation flows are expected to act as an assured baseflow for sensitive fish and bird species on the Muddy River and below the Bunkerville Irrigation Company service area on the Virgin River. Potential effects to species within Lake Mead from increased flows from the Virgin River and the Muddy River are described in Section 4.8 and were addressed in the LCR MSCP. More detailed information on the existing biological resources along the Virgin River and the Muddy River and potential project impacts is provided in Appendix R. The Coyote Spring Well and the Moapa Transmission System would have similar, but proportionately smaller benefits to biological resources. Other biological impacts from the Coyote Spring Well and the Moapa Transmission System were considered in the BLM EA and determined not to be significant because any impacts to species will be mitigated through the Clark County Multiple Species Habitat Conservation Program and conservation measures implemented through the Biological Opinion for the project. Restoration of the right-of-way will minimize impacts to vegetation.

The Drop 2 Storage Reservoir Project will reduce the amount of non-storable flows that arrive at Morelos Diversion Dam, resulting in reduced frequency of a portion of these flows in the limitrophe reach of the Colorado River. These and other impacts to biological resources from the Drop 2 Storage Reservoir Project were described in the Reclamation EA for the project and determined not to be significant. Because the habitat where the storage reservoir would be constructed is already relatively disturbed, the development would not result in a significant adverse effect on vegetation and wildlife habitat.

Reductions in non-storable flows to Morelos Diversion Dam would not significantly affect riparian communities and associated wildlife of the limitrophe. Based on results of groundwater modeling, the potential impacts on marsh habitats from potential changes in minimum groundwater levels are considered not significant. Potential impacts on occupied southwestern willow flycatcher habitat are considered not significant. The implementation of the proposed compensation and the conservation of habitat will fully mitigate impacts to the flat-tailed horned lizard.

4.16.2.6 Cultural Resources

SNWA's Virgin River and Muddy River Tributary Conservation would not result in impacts to cultural resources because, as described above, the increased flows in the two rivers would not cause effects outside their normal channels. Further, because the surface water rights acquired are not appurtenant to specific land parcels, there would be no way to associate the water rights acquisition to specific land use changes. Cultural resource impacts from the Coyote Spring Well and the Moapa Transmission System were considered in the BLM EA and determined not to be significant because no impacts to historic properties or paleontological resources are proposed and impacts to one cultural resource site has been mitigated by implementation of an archeological site treatment plan. Reclamation considered cultural resources for the Drop 2 Storage Reservoir Project as part of its EA. Mitigation or avoidance will be implemented for the four historic properties which may be either directly or indirectly affected by the proposed project. There would be no significant residual impacts to cultural resources.

4.16.2.7 Indian Trust Assets

SNWA's Virgin River and Muddy River Tributary Conservation would not result in impacts to ITAs because, as described above, the increased flows in the two rivers would not cause effects outside their normal channels. Further, because the surface water rights acquired are not appurtenant to specific land parcels, there would be no way to associate the water rights acquisition to specific land use changes. No ITAs were identified by BLM in the area affected by the Coyote Spring Well and the Moapa Transmission System. No Indian tribes, groups, or individuals have identified any specific ITAs during the public notification or scoping process. Therefore, no impacts to ITAs are anticipated from implementation of the project. Reclamation considered ITAs for the Drop 2 Storage Reservoir Project as part of its EA and determined that none would be affected. The Drop 2 Storage Reservoir Project would augment Reclamation's ability to meet its obligations to Colorado River water users, including the Quechan Tribe.

4.16.2.8 Electrical Power

SNWA's development of pre-BCPA water rights on the Virgin River and the Muddy River, the development of the Coyote Spring Well and the Moapa Transmission System, and the Drop 2 Storage Reservoir Project would result in limited impacts to power production. These projects were included in the hydrologic modeling for the EIS, and the potential impacts of these changes on power production are included in Section 4.11. None of the projects would have significant effects on electrical power resources in the local project areas.

4.16.2.9 Recreation

SNWA's Virgin River and Muddy River Tributary Conservation would not result in impacts to recreational activities because the increased flows in the two rivers would be small. Potential impacts to recreational activities from the Coyote Spring Well and the Moapa Transmission System were considered in the BLM EA and determined not to be significant. Reclamation considered potential recreation impacts for the Drop 2 Storage

Reservoir Project as part of its EA and determined that the Drop 2 Storage Reservoir Project would have impacts during the construction period through temporary closure of BLM trails, and some access roads to recreation areas. These temporary closures were determined not to be a significant impact on recreation.

4.16.2.10 Transportation

SNWA's Virgin River and Muddy River Tributary Conservation would not result in impacts to transportation because the two rivers are not used for transportation. Potential impacts to transportation from the Coyote Spring Well and the Moapa Transmission System were considered in the BLM EA and determined not to be significant because there are currently low levels of traffic in the vicinity and construction traffic impacts would cease at the end of construction activity. Reclamation considered potential transportation impacts for the Drop 2 Storage Reservoir Project as part of its EA and determined that the Drop 2 Storage Reservoir Project would have temporary, insignificant impacts to area roadways during its construction period. Impacts would be mitigated by implementation of traffic management plan and other measures. The outlet canal would be installed as a pipe underneath Interstate 8 (I-8). This construction has the potential to require temporary closure of some travel lanes of I-8. During the Drop 2 Storage Reservoir Project construction Reclamation will direct the contractor to maintain at least one eastbound travel lane and one westbound travel lane on I-8 (or the functional equivalent using detours).

4.16.2.11 Socioeconomics

SNWA has been purchasing pre-BCPA water rights on the Virgin River and the Muddy River since 1997, in an effort to reduce SNWA's dependence on the Colorado River and to develop additional water supplies for Southern Nevada. As of July 1, 2007, SNWA has acquired water rights from Virgin River and Muddy River sources that will yield an average annual water supply of approximately 11,700 af. SNWA anticipates acquiring a total of approximately 30,000 afy of pre-BCPA water rights from entities with rights on the Virgin River and the Muddy River. Water rights historically used for agriculture along these two rivers are being voluntarily sold or leased to willing buyers, including buyers not associated with SNWA. Sometimes the water rights are leased back for agricultural use with a provision that at the end of the lease term, the water rights will be retired and allowed to return to the river system. Socioeconomic impacts on the local communities are reduced by the gradual nature of the acquisition program. The gradual conversion of these agricultural water rights to other uses is ongoing and will continue regardless of the establishment of the ICS mechanism, and this particular project. The Coyote Spring Well, the Moapa Transmission System, and the Drop 2 Storage Reservoir Project will result in short-term economic benefits from the creation of jobs and purchases of materials, supplies, and services. These effects were considered in the two EA's for these projects. The Drop 2 Storage Reservoir Project would have no effect on agricultural production and related revenues within Imperial County.

4.16.2.12 Environmental Justice

SNWA's Virgin River and Muddy River Tributary Conservation would not result in disproportionately high and adverse human health and environmental impacts to low-income or minority populations. The acquisition of surface water rights is from willing sellers and provides an economic benefit to the sellers. No environmental justice impacts were identified in the BLM EA for the Coyote Spring Well and the Moapa Transmission System. Reclamation considered environmental justice impacts for the Drop 2 Storage Reservoir Project as part of its EA and determined there would be no disproportionate impacts to low-income or minority populations.

Chapter Five

5.1 Federal Statutes and Policies

In compliance with NEPA, this Final EIS is intended to provide decision makers and the public with information regarding compliance with other environmental laws, rules, and regulations that are applicable to the proposed federal action as well as the environmental impacts of the proposed federal action, as presented below.

5.1.1 Endangered Species Act of 1973, as Amended (16 U.S.C. Sections (§§) 1531-1544)

Section 7 of the ESA requires federal agencies to consult with FWS to ensure that undertaking, funding, permitting, or authorizing an action is not likely to jeopardize the continued existence of listed species or destroy or adversely modify designated critical habitat, as defined under the law.

Adoption of the proposed federal action by the Secretary is a discretionary federal action and it is, therefore, subject to compliance with ESA. Reclamation has prepared a biological assessment to address the potential effects of the proposed federal action on listed species and has initiated formal consultation with FWS (Appendix R). It is anticipated that consultation will be completed prior to Reclamation's execution of a Record of Decision.

5.1.2 Fish and Wildlife Coordination Act of 1934, as Amended (16 U.S.C. §§ 661-667d)

The Fish and Wildlife Coordination Act of 1934, as amended, requires consultation and coordination with federal and state wildlife agencies to ensure that fish and wildlife are given equal consideration when developing water resources projects. This Act applies "whenever the waters of any stream or other body of water are proposed or authorized to be impounded, diverted, the channel deepened, or the stream or other body of water otherwise controlled or modified…" and requires that the responsible federal agency "shall consult with the United States Fish and Wildlife Service, Department of the Interior, and with the head of the agency exercising administration over the wildlife resources of the particular State wherein the impoundment, diversion, or other control facility is to be constructed". The proposed federal action is not a construction project. Nevertheless, FWS is a cooperating agency and has been involved in the preparation of the Draft EIS and the Final EIS. In addition, FWS reviewed and provided comments on the Draft EIS and the Final EIS. The close coordination with FWS on this project meets the intent and provisions of the Fish and Wildlife Coordination Act.

5.1.3 National Wildlife Refuge System Administration Act of 1966 (16 U.S.C. § 668dd)

The National Wildlife Refuge System Administration Act of 1966 provides for the administration and management of the national wildlife refuge system, including wildlife refuges, areas for the protection and conservation of fish and wildlife threatened with extinction, wildlife ranges, game ranges, wildlife management areas and waterfowl production areas. The study area includes the following four national wildlife refuges on the Colorado River downstream of Hoover Dam: Havasu NWR, Bill Williams NWR, Cibola NWR, and Imperial NWR. Only minor changes in Colorado River flow through these refuges would occur under the action alternatives. No adverse impacts to refuges would result from the proposed federal action; thus, it would be consistent with the National Wildlife Refuge System Administration Act.

5.1.4 Wild and Scenic Rivers Act of 1968 (16 U.S.C. §§ 1271-1287)

The Wild and Scenic Rivers Act of 1968 establishes a National Wild and Scenic Rivers System for the protection of rivers with important scenic, recreational, fish and wildlife, and other values. Rivers are classified as wild, scenic or recreational. The Congressional policy behind the National Wild and Scenic Rivers System is not to halt use of a river; instead, the goal is to preserve the character of a river. Uses compatible with the management goals of a particular river are allowed; however, development must ensure the river's free flow and protect its "outstandingly remarkable resources." The Wild and Scenic Rivers Act of 1968 designates specific rivers for inclusion in the National Wild and Scenic Rivers System and prescribes the methods and standards by which additional rivers may be added. There are no designated wild and scenic rivers within the study area.

However, pursuant to Section 5(d) of the Wild and Scenic Rivers Act, NPS has compiled and maintains a Nationwide Rivers Inventory (NRI), a register of river segments that potentially qualify as national wild, scenic, or recreational river areas. The NRI is a listing of more than 3,400 free-flowing river segments in the United States that are believed to possess one or more "outstandingly remarkable" natural or cultural values judged to be of more than local or regional significance. Under a 1979 Presidential directive, and related Council on Environmental Quality procedures, all federal agencies must seek to avoid or mitigate actions that would adversely affect one or more NRI segments. Within the study area, NPS has identified four river segments (with segment lengths provided in parentheses) on the NRI:

- Colorado River from Paria Riffle (RM 1) to 237-Mile Rapid in Grand Canyon National Park (236 miles);
- Colorado River from Glen Canyon Dam to Lake Mead (278 miles);
- Colorado River from upper end of Lake Havasu (Blankenship Bend) to Interstate Highway 40 bridge crossing in Topock (11 miles); and
- Colorado River from gaging station below Cibola Lake to Martinez Lake (Fishers Landing) (31 miles).

The relatively minor changes in flow associated with the proposed federal action would not adversely affect the values for which these Colorado River segments were identified.

5.1.5 Migratory Bird Treaty Act of 1918 (16 U.S.C. §§ 703-712)

The Migratory Bird Treaty Act of 1918 protects migratory birds by limiting the hunting, capturing, selling, purchasing, transporting, importing, exporting, killing, or possession of these birds or their nests or eggs. The specific migratory birds covered are identified in separate agreements between the United States and Great Britain, Mexico, and Japan. No significant adverse impacts to migratory birds would result from the proposed federal action; thus, it would be consistent with the Migratory Bird Treaty Act.

5.1.6 Migratory Bird Conservation Act of 1929 (16 U.S.C. § 715)

The Migratory Bird Conservation Act of 1929 protects migratory birds by creating the Migratory Bird Conservation Commission. This commission's purpose is to consider and approve the purchase, rental, or other acquisition of any areas of land or water that may be recommended by the Secretary for the purpose of establishing sanctuaries for migratory birds. No significant adverse impacts on migratory birds would result from the proposed federal action; thus, it would be consistent with the Migratory Bird Conservation Act.

5.1.7 Bald Eagle Protection Act of 1940 (16 U.S.C. § 668)

The Bald Eagle Protection Act of 1940 imposes criminal and civil penalties on anyone in the United States or within its jurisdiction who, unless excepted, takes, possesses, sells, purchases, barters, offers to sell or purchase or barter, transports, exports or imports at any time or in any manner a bald or golden eagle, alive or dead; or any part, nest or egg of these eagles; or violates any permit or regulations issued under the Bald Eagle Protection Act. No adverse impacts to bald eagles would result from the proposed federal action; thus, it would be consistent with the Bald Eagle Protection Act.

5.1.8 Clean Air Act of 1963, as Amended (42 U.S.C. § 7506)

The primary objective of the Clean Air Act of 1963, as amended, is to establish federal standards for air pollutants from stationary and mobile sources and to work with the states to regulate polluting emissions. The Clean Air Act is designed to improve air quality in areas of the country that do not meet federal standards and to prevent significant deterioration in areas where air quality exceeds those standards. The proposed federal action would not result in any emissions from stationary or mobile sources or violate air quality standards. Therefore the proposed federal action is consistent with the Clean Air Act.

5.1.9 Federal Water Pollution Control Act (Clean Water Act) of 1972, as Amended (33 U.S.C. Chapter 26)

Section 404 of the Clean Water Act of 1972, as amended, identifies conditions under which a permit is required for construction projects that result in the discharge of fill or dredged materials into waters of the United States. Section 402 of the Clean Water Act requires a permit for the discharge of pollutants into waters of the United States. No construction activities are associated with implementation of the proposed federal action. Therefore, it is consistent with the Clean Water Act.

5.1.10 River and Harbors Act of 1899 (33 U.S.C. §§ 401-403)

The River and Harbors Act of 1899 protects the public's right to free navigation in navigable waters of the United States as described by the USACE Section 10/404 implementing regulations at 33 C.F.R. pt. 329. The River and Harbors Act also prohibits unauthorized construction in navigable waters of the United States. No construction activities are associated with implementation of the proposed federal action. Therefore, it is consistent with the River and Harbors Act.

5.1.11 National Historic Preservation Act of 1966, as Amended (16 U.S.C. § 470)

Federally funded undertakings that have the potential to impact historic properties are subject to Section 106 of the NHPA and its implementing regulations under 36 C.F.R. pt. 800. Under the National Historic Preservation Act of 1966, as amended, federal agencies are responsible for the identification, management, and nomination to the NRHP of cultural resources; if a proposed undertaking would affect historic properties, the agency must afford the Advisory Council on Historic Preservation the opportunity to comment. Reclamation's compliance with the National Historic Preservation Act, as amended, is described in Section 4.9.

5.1.12 Native American Graves Protection and Repatriation Act of 1990 (25 U.S.C. §§ 3001-3013)

Native American Graves Protection and Repatriation Act of 1990 assigns ownership to Indians of human burials and associated grave goods, which are excavated or discovered on federal or Tribal lands. Implementation of the proposed federal action has no potential to disturb Indian human remains or associated funerary objects; however, Reclamation and the other Department agencies with compliance responsibilities under this Act or its implementing regulations are committed to compliance with the inadvertent discovery process in pertinent laws and regulations.

5.1.13 Archaeological Resources Protection Act of 1979 (16 U.S.C. § 470)

The Archaeological Resources Protection Act (ARPA) of 1979 provides for the protection of archaeological resources on public and Indian lands. Protection of archaeological resources, under the guidelines of ARPA, includes consideration of excavation and removal of resources, enforcement of ARPA, and confidentiality of information concerning the nature and location of archaeological resources. It also provides substantial criminal and civil penalties for those who violate the terms of ARPA. Should any data recovery be proposed as a result of cultural resources compliance and consultation, Reclamation or its contractors shall seek the appropriate ARPA permits.

5.1.14 Farmland Protection Policy Act of 1981 (7 U.S.C. §§ 4201-4209)

The purpose of the Farmland Protection Policy Act of 1981 is to minimize the extent to which federal programs contribute to the unnecessary conversion of farmland to nonagricultural uses. The proposed federal action will not permanently convert any farmland, prime or otherwise. The Farmland Protection Policy Act also stipulates that federal programs be compatible with state, local, and private efforts to protect farmland. While there is a potential for increased temporary land following during droughts under some of the action alternatives, the proposed federal action would not likely result in the conversion of farmland to nonagricultural uses. Any impact from the storage and delivery mechanism would not result in the permanent conversion of any prime farmland. Therefore, the proposed federal action is consistent with the Farmland Protection Policy Act.

5.1.15 Executive Order No. 11988, Floodplain Management, May 24, 1977

This executive order requires avoiding or minimizing harm associated with the occupancy or modification of a floodplain. The proposed federal action would not involve modifications or occupancy of any floodplain, therefore the proposed federal action is consistent with Exec. Order No. 11988.

5.1.16 Executive Order No. 11990, Protection of Wetlands, May 24, 1977

This executive order provides for protection of wetlands through avoidance or minimization of adverse impacts. The proposed federal action would not involve modifications of or construction within jurisdictional wetlands, therefore, the proposed federal action is consistent with Exec. Order No. 11990. Minor changes in river flow and its potential effect on backwaters and marsh habitat is discussed in Section 4.8.

5.1.17 Executive Order No. 12898, Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations, February 11, 1994

This executive order directs agencies to identify and address, as appropriate, disproportionately high and adverse human health and environmental impacts of their programs, policies, and activities on minority and low-income populations. An analysis of the effects of the proposed federal action on minority and low-income populations is included in Section 4.15 of this Final EIS. No significant disproportionate impacts on minority or low income populations were identified.

5.1.18 Executive Order No. 13007, Indian Sacred Sites, May 24, 1996

This executive order requires that all Executive Branch agencies that have responsibility for the management of federal lands will, where practicable, permitted by law, and not clearly inconsistent with essential agency functions, provide access to Indian sacred sites for ceremonial use by Indian religious practitioners, and will avoid adversely impacting the integrity of these sites. When possible, federal agencies must also maintain the confidentiality of sacred sites. Implementation of the proposed federal action would not conflict with the requirements of Exec. Order No. 13007.

5.1.19 Executive Order No. 12114, Environmental Impacts Abroad of Major Federal Actions, January 4, 1979

The 1944 Treaty between the United States and Mexico (including its implementing Minutes) establishes the obligations of the United States regarding the delivery of Colorado River water to Mexico. In addition, Section 397 of Public Law 109-432 states: "The Treaty between the United States of America and Mexico relating to the utilization of waters of the Colorado and Tijuana Rivers and of the Rio Grande, and supplementary protocol signed November 14, 1944, signed at Washington February 3, 1944 (59 Stat. 1219) is the exclusive authority for identifying, considering, analyzing, or addressing impacts occurring outside the boundary of the United States of works constructed, acquired, or used within the territorial limits of the United States."

Exec. Order No. 12114 provides among other things that: (1) federal agencies involved in actions with potential significant environmental impacts outside of the United States must provide information to federal decision makers so that the potential effects may be analyzed with other pertinent considerations of national policy; (2) activities involving foreign governments be coordinated through the Department of State; and (3) pertinent information may be withheld from other agencies and nations when necessary to avoid adverse impacts to foreign relations and ensure appropriate reflection of diplomatic factors. Section 1 of Exec. Order No. 12114 provides that it is the United States' "exclusive and complete determination of the procedural and other actions to be taken by the federal agencies to further the purpose of the National Environmental Policy Act, with respect to the environment outside the United States, its territories and possessions."

Reclamation has complied with Exec. Order No. 12114 and Public Law 109-432 by informing the Department of State of the proposed federal action and by providing technical support to the USIBWC for its consultation with Mexico. This Final EIS incorporates appropriate information regarding potential hydrologic and water quality impacts to Mexico at the border with Mexico that have been prepared after coordination with the USIBWC, as well as with representatives of the Department of State.

5.1.20 Secretarial Order No. 3206, American Indian Tribal Rights, Federal-Tribal Trust Responsibility, and the Endangered Species Act, June 7, 1997

This Secretarial Order directs that the Department and it's sub-bureaus carry out their responsibilities under ESA in a manner "that harmonizes the Federal trust responsibility to tribes, tribal sovereignty, and statutory missions of the Departments, and that strives to ensure that Indian tribes do not bear a disproportionate burden for the conservation of listed species, so as to avoid or minimize the potential for conflict and confrontation." Implementation of the proposed federal action will be undertaken consistent with the requirements of this Secretarial Order.

5.2 Cumulative Impacts

The CEQ's regulations (40 C.F.R. pt. 1500 through 1508) implementing the procedural provisions of NEPA defines cumulative impacts as the following:

> "…the impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency (Federal or non-Federal) or person undertakes such other actions. Cumulative impacts can result from individually minor but collectively significant actions taking place over a period of time (40 C.F.R. pt. 1508.7)."

Cumulative impacts refer to two or more individual impacts that, when considered together, are significant or that compound or increase other environmental impacts. Cumulative impacts can be categorized as additive and interactive. An additive impact results from additions from one kind of source either through time or space. An interactive impact results from more than one kind of source.

Generally, other actions that could result in cumulative impacts when considered in tandem with the effects of the proposed federal action (as identified in Chapter 4) have been incorporated into modeling of future system conditions. Such actions include future increases in consumptive use of Colorado River water in the Upper Division states, intrastate water transfers in the Lower Division states (e.g., QSA water transfers), implementation of the LCR MSCP, and various requirements and constraints applied to the operation of the Colorado River system.

This section addresses the cumulative impacts of the proposed federal action combined with other regional water supply or closely related projects in the region. Closely related projects that could result in significant cumulative impacts are briefly described below.

5.2.1 SNWA Clark, Lincoln, and White Pine Counties Groundwater Development Project

This project includes groundwater production, conveyance and treatment facilities, and power conveyance facilities located in central and eastern Nevada. The project as proposed would develop and convey up to 167 kafy of groundwater from Clark, Lincoln, and White Pine Counties to the Las Vegas Valley for use in the SNWA service area to supplement the SNWA water supplies. This project will assist SNWA in meeting southern Nevada's projected future water demands and increase the diversification of SNWA's current water resources to include non-Colorado River groundwater resources.

SNWA applied to BLM for the Rights of Way for the pipelines and other facilities. BLM is the lead federal agency preparing SNWA's groundwater EIS to analyze the environmental issues associated with SNWA's request for Rights of Way. It is not currently anticipated that this project will be completed prior to 2014. Water from this project will be fully consumptively used in southern Nevada.

5.2.2 SNWA Lake Mead Intake No. 3 Project

SNWA presently operates two water intakes at Saddle Island on the west shore of Lake Mead, approximately five miles northwest of Hoover Dam and approximately 20 miles east of the center of Las Vegas, within the LMNRA. Drought has caused declining Lake Mead elevations during recent years. Long-term water supply modeling indicates that the lake elevation is expected to decline even further in future years, even under normal hydrologic conditions in the Colorado River Basin, until the system recovers from the recent drought conditions.

SNWA proposes to construct a third deep-water intake, Intake No. 3, in Lake Mead, and other associated project components to protect the existing water system capacity against the potential loss of pumping capability of Intake No. 1 should the lake elevations fall below 1,050 feet msl. An EA is being prepared by NPS, lead federal agency, to grant SNWA's application for an expansion of an existing Right of Way associated with the construction of the proposed Intake No. 3 facilities. The major project components would include a new intake structure and intake tunnel beneath the lake and beneath Saddle Island; Intake Pumping Station No. 3 (IPS-3) on Saddle Island, the caverns or forebays beneath Saddle Island and shafts around IPS-3 for construction and connections; a conveyance pipeline from IPS-3 connecting with Alfred Merritt Smith Water Treatment Facility; and a tunnel interconnecting the Intake No. 3 tunnel with the existing Intake No. 2 tunnel beneath Saddle Island.

The Intake No. 3 project would:

- preserve water delivery system capacity;
- provide reliable water delivery system back-up capability; and

- provide operational flexibility for accessing the best available water quality for the public water supply.

The construction of the Intake No. 3 would allow SNWA to maintain full system capacity at Lake Mead elevations as low as 1,000 feet msl. The Intake No. 3 project does not propose any change or increase in the quantity of Colorado River water authorized for diversion and use by the SNWA. The project is a modification of the location from which SNWA's existing contractual rights to water are withdrawn from the Colorado River at Lake Mead, giving SNWA the flexibility to take water from different elevations and locations in Lake Mead depending on seasonal lake conditions and lake elevations.

5.2.3 Systems Conveyance and Operations Program

Reclamation and NPS prepared an EIS as joint lead federal agencies to analyze the potential impacts associated with the construction, operation, and maintenance of the SCOP. The Clean Water Coalition (CWC) is comprised of the four agencies currently responsible for wastewater treatment in Las Vegas Valley: the City of Las Vegas, the City of Henderson, the Clark County Water Reclamation District, and the City of North Las Vegas. The CWC proposes to implement the SCOP, which would include optimization of the treatment plants, increased treatment (as needed), and a pipeline to discharge the highly treated effluent into Lake Mead, while minimizing impacts to water quality and other natural resources. The SCOP would provide an alternate discharge point for the effluent, which is currently discharged to Lake Mead through the Las Vegas Wash. The purpose of the project is to maintain water-quality standards and NPS's recreational and resource values by operating a system that would allow for flexible management of wastewater flow from Las Vegas Valley to Lake Mead. The quantity of effluent treated and discharged from Las Vegas Valley will increase as the population of Las Vegas Valley increases. Wastewater facilities must accommodate the additional flows while continuing to meet current or future water quality standards for the Las Vegas Wash, Las Vegas Bay, and Lake Mead.

The SCOP EIS analyzed the potential environmental impacts associated with three pipeline alternatives, a Process Improvements Alternative (no pipeline), the No Action Alternative (no pipeline); and the Boulder Islands North (pipeline) alternative, which was identified as the preferred alternative.

5.2.4 Lower Colorado River Multi-Species Conservation Program

This program was developed to address potential effects to listed and other selected special status species (covered species) from identified ongoing and future anticipated federal discretionary actions and non-federal activities on the lower Colorado River (covered actions). The development and implementation of shortage criteria on the lower Colorado River was one of the federal covered actions included in the LCR MSCP and covered under the LCR MSCP BO (FWS 2005). The LCR MSCP BO covered the effects of covered actions for a reduction of Lake Mead reservoir elevations to 950 feet msl and flow reductions of up to 0.845 maf from Hoover Dam to Davis Dam, 0.860 maf from Davis Dam to Parker Dam, and 1.574 maf from Parker Dam to Imperial Dam. The LCR MSCP identified, and it is mitigating for, impacts to the covered species and their habitats from the flow reduction conditions described above. These impacts included the potential loss of up to:

- 2,008 acres of cottonwood-willow habitats;
- 133 acres of marsh habitat; and
- 399 acres of backwater habitat.

To address these impacts, the LCR MSCP will:

- restore 5,940 acres of cottonwood-willow habitat;
- restore 512 acres of marsh habitat;
- restore 360 acres of backwater habitat;
- stock 660,000 razorback sucker over the term of the LCR MSCP; and
- stock 620,000 bonytail over the term of the LCR MSCP.

In addition, these habitats will be actively managed to provide habitat values greater than those of the impacted habitats. While the LCR MSCP is geared toward special status species, it is important to understand that all species that use the habitats impacted by the LCR MSCP covered activities benefit by the conservation actions currently being carried out under the LCR MSCP. The LCR MSCP EIS evaluated the impacts of implementing the Habitat Conservation Plan and the issuance of a Section 10(a)(1)(B) permit by FWS. The LCR MSCP documents (Reclamation 2004a-e) are incorporated by reference into this Final EIS.

5.2.5 All-American Canal Lining Project

Imperial Irrigation District obtains water from the 82-mile long AAC, which diverts water from the Colorado River at Imperial Dam. This water conservation project is proceeding according to Sections 395 and 397 of Public Law 109-432. This project includes construction of a new, parallel canal from one mile west of Pilot Knob to Drop 3, a distance of 23 miles. The centerline of the new canal would be offset from the old centerline of the original canal by a distance of 300 to 600 feet, depending on terrain, ease of construction, and location of existing structures. Operation and maintenance roads would be 20 feet wide to match existing canal roads (Reclamation 1994c,d).

Excavation of 25 million cubic yards of earth is required. Excess material will be placed in waste banks along the new canal. An estimated 530 acres of new right-of-way will be required, all of which is under federal control. Other land disturbances will include a 10-acre concrete batch plant and three, 5-acre staging areas, all of which are on previously disturbed lands. Power lines would be relocated as required. Actual construction will last approximately three years. The canal would be in service year-round, as it is at the present (Reclamation 1994c,d).

Environmental impacts were identified in the following areas: groundwater quantity and quality in Mexico, biological resources (wetlands along the canal and along the impacted reach of the Colorado River, terrestrial plant communities and associated wildlife, and special status species), canal fisheries, cultural resources, hydroelectric power, and recreation (Reclamation 1994c,d). The AAC Lining Project will employ compensation measures to reduce potential air quality impacts. A variety of mitigation measures have been incorporated into the project, including establishing 43 acres of honey mesquite and cottonwood/willow and one acre of marsh, restoring shelter for juvenile fish by constructing artificial reefs in the canal, replacing and protecting habitat for special status species and to help maintain the fishery for recreational fishing, and avoiding cultural resources sites where feasible.

The Final EIS/EIR for the AAC Lining Project was filed with EPA on April 14, 1994 and noticed in the *Federal Register* on April 19, 1994. A ROD was prepared and signed by the Lower Colorado Region's Regional Director on July 29, 1994. On January 12, 2006 Reclamation determined that the EIS and ROD continued to meet the requirements of NEPA. Funding for the AAC Lining Project was authorized by the California legislature in September 2003. Final designs for the AAC Lining Project were completed in January 2006 (Reclamation 2006) and construction began in Summer 2007.

5.2.6 Long-Term Experimental Plan for the Operation of Glen Canyon Dam and Other Associated Management Activities

The Upper Colorado Region of Reclamation has filed a NOI to prepare an EIS regarding experimental actions to benefit resources downstream of Glen Canyon Dam in the GCNRA and Grand Canyon National Park (71 Fed. Reg. 74556). The purpose of this Long-Term Experimental Plan is to increase understanding of the ecosystem downstream of Glen Canyon Dam and to improve and protect important downstream resources. The NEPA process would analyze the implications and impacts of each of the alternatives on all of the purposes and benefits of Glen Canyon Dam as well as on downstream resources. The Long-Term Experimental Plan would implement a structured, long-term program of experimentation (including dam operations, modifications to Glen Canyon Dam intake structures, and other non-flow management actions, such as removal of non-native fish species) and monitoring in Colorado River downstream of Glen Canyon Dam.

The Long-Term Experimental Plan is intended to ensure a continued, structured application of adaptive management in such a manner as to protect, mitigate adverse impacts to, and improve the values for which Grand Canyon National Park and GCNRA were established, including, but not limited to, natural and cultural resources and visitor use, consistent with applicable federal law.

The Long-Term Experimental Plan will build on a decade of scientific experimentation and monitoring that has taken place as part of the Glen Canyon Dam Adaptive Management Program, and will build on the knowledge gained by experiments, operations, and management actions taken under that program. Accordingly, Reclamation intends to tier from earlier NEPA compliance documents prepared as part of the Department's Glen Canyon Adaptive Management Program efforts (40 C.F.R. pt. 1500.4(i), 1502.20, and 1508.20(b)), such as the 2002 EA prepared on adaptive management experimental actions at Glen Canyon Dam (Reclamation 2002).

The anticipated implementation of a Long-Term Experimental Plan for the operation of Glen Canyon Dam is not anticipated to contribute to cumulative adverse effects to the resources described below.

5.2.7 Cumulative Impacts by Resource

5.2.7.1 Hydrologic Resources and Water Delivery

Water from SNWA Clark, Lincoln, and White Pine Counties groundwater development projects will be fully consumptively used in southern Nevada and will increase return flows to Lake Mead. This increase was modeled as part of the hydrologic analysis in this Final EIS. Similarly, water conserved under the AAC lining project, and planned changes in point of delivery (a covered action under the LCR MSCP), were also accounted for in the hydrologic modeling for this Final EIS. The SCOP and SNWA Lake Mead Intake No. 3 project would not result in any cumulative effects because these projects would not alter water system operations. The Long-Term Experimental Plan would implement a structured, long-term program of experimentation (including dam operations, modifications to Glen Canyon Dam intake structures, and other non-flow management actions such as removal of non-native fish species) and monitoring in Colorado River downstream of Glen Canyon Dam. It is not expected to result in cumulative adverse impacts to hydrologic resources or water delivery.

5.2.7.2 Water Quality

For the reasons described immediately above, the potential cumulative impacts on water quality from SNWA groundwater development projects, AAC lining project, and planned changes in point of delivery were included in the modeling assumptions, and are included in the analyses presented in Section 4.5 of this Final EIS. The Long-Term Experimental Plan for Glen Canyon Dam could result in some alteration of water quality parameters, particularly temperature, in the Colorado River reach between Glen Canyon Dam and Lake Mead. Because the outcome of the planning process is not known, it would be speculative to address potential cumulative effects at this time.

The SCOP has the potential to affect water quality in Lake Mead. However, the SCOP is intended to accommodate Lake Mead's lowering elevations since the amount of mixing and dilution available in the inner Las Vegas Bay would decrease as Lake Mead elevations decrease. The SCOP also intends to provide flexibility to avoid possible impacts to source-water quality at SNWA's intake structure. As a result of these project planning criteria, no significant cumulative impacts are anticipated.

5.2.7.3 Air Quality

Changed operations due to the AAC lining project and changed points of diversion envisioned under the LCR MSCP have the potential to change storage elevations and exposed shoreline at Lake Mead. Potential effects from these operations were taken into account in the modeling performed for this EIS, and potential impacts of wind-blown dust from exposed reservoir shoreline is already included in the analyses presented in Section 4.6. The slight increase in return flow credits from the northern Nevada groundwater projects would have no cumulative effect on air quality. The LCR MSCP may result in minor reductions in fugitive dust emissions through the creation of habitat on lands that currently may be less vegetated and therefore potentially produce more fugitive dust.

5.2.7.4 Visual Resources

Potential cumulative impacts related to the exposure of the calcium carbonate ring around Lake Mead was included in the modeling for this EIS, as described above.

Implementation of the LCR MSCP will result in the creation of new habitat areas, which viewers may perceive as attractive. The proposed federal action would not affect the creation of this habitat.

5.2.7.5 Biological Resources

As noted above, the potential cumulative impacts on Lake Mead storage and releases from the increased return flows from SNWA groundwater development projects, AAC lining project, and other planned changes in point of diversion were accounted for in the hydrologic modeling for this Final EIS and are reflected in the biological impact analysis presented in Section 4.8. The LCR MSCP will result in substantial habitat creation along the lower Colorado River. This habitat creation will provide benefits to biological resources. No adverse cumulative effects to biological resources are anticipated from the SCOP or SNWA Lake Mead Intake No. 3 project. The Long-Term Experimental Plan has the potential to affect biological resources in the reach of the Colorado River between Lake Powell and Lake Mead, especially from potential flow and non-flow actions and temperature changes. It would be speculative to address potential cumulative effects associated with the ongoing Long-Term Experimental Plan process at this time because the outcome of the planning process is not known.

5.2.7.6 Cultural Resources

The proposed federal action’s effects on cultural resources result from hydrologic changes in reservoir elevations and river flows. Projects with potential for cumulative impacts were included in the hydrologic modeling; such as, cumulative impacts on cultural resources are already addressed in Section 4.9. The conservation projects to be implemented under the LCR MSCP have the potential to impact cultural resources through construction activities, as do the AAC lining, SCOP, and SNWA Lake Mead Intake No. 3 projects. Each of these projects will comply with Section 106 of the NHPA; significant adverse cumulative impacts are not anticipated.

5.2.7.7 Indian Trust Assets

The proposed federal action would not result in any substantive effects on ITAs. Therefore, it would not contribute to any cumulative effects.

5.2.7.8 Electrical Power

Effects on electrical power production related to the proposed federal action are described in Section 4.11. The hydrologic effects of the related projects discussed above were included in the modeling assumptions, have been included in the analyses. The SNWA Lake Mead Intake No. 3 project and SCOP would not have cumulative impacts related to electrical power production. The Long-Term Experimental Plan has the potential to affect power production at Glen Canyon Dam. It would be speculative to address potential cumulative effects associated with the ongoing Long-Term Experimental Plan process at this time because the outcome of the planning process is not known.

5.2.7.9 Recreation

Effects on recreation activities related to the proposed federal action are described in Section 4.12. To the extent these recreation impacts are dependent on reservoir elevations, the effects of the projects listed above are included in the analyses. The LCR MSCP, SCOP, SNWA Lake Mead Intake No. 3, and AAC lining projects would not contribute to any cumulative effects on recreation. The Long-Term Experimental Plan for Glen Canyon Dam could result in some alteration of flow and water quality parameters, particularly temperature, in the Colorado River reach between Glen Canyon Dam and Lake Mead. This could result in recreational fishing and boating impacts. It would be speculative to address potential cumulative effects associated with the ongoing Long-Term Experimental Plan process at this time because the outcome of the planning process is not known.

5.2.7.10 Transportation

Effects on transportation related to the proposed federal action are described in Section 4.13. To the extent these transportation impacts are dependent on reservoir elevations, the effects of the projects listed above are included in the analyses. The LCR MSCP, SCOP, SNWA Lake Mead Intake No. 3 project, and the Long-Term Experimental Plan would not contribute to any cumulative effects on transportation. The AAC lining project would have temporary and localized impacts on transportation during construction. These impacts would be at a significant distance from the Colorado River corridor, and no cumulative impacts are anticipated.

5.2.7.11 Socioeconomics

Effects on socioeconomics related to the proposed federal action are described in Section 4.14, and occur in the service areas of Colorado River water users, primarily in Arizona. The projects listed above would not contribute to any cumulative effects on socioeconomic conditions. The AAC lining, SCOP, SNWA Lake Mead Intake No. 3, and implementation of the LCR MSCP conservation projects will result in short-term economic benefits from creation of jobs for these construction projects. However, these temporary effects would not contribute to any cumulative effects associated with the proposed federal action.

5.2.7.12 Environmental Justice

The proposed federal action would not result in any substantive effects on environmental justice communities. Therefore, it would not contribute to any cumulative effects.

5.3 Relationship Between Short-term Uses of the Environment and Long-term Productivity

For purposes of this required regulatory assessment, Reclamation considers the interim period of the proposed federal action (through 2026) short-term, especially when compared with the longer modeling period of through 2060 or even longer durations. Within this time-frame, Reclamation would implement water management practices that would result in an increased predictability of water operations, particularly under drought and low reservoir conditions. This predictability is expected to have a stabilizing effect on the use of water in the region by ensuring that all parties have a better understanding of how the system would operate and, therefore, what management actions water users may need to undertake under such conditions, thus ensuring long-term productivity.

The trade-off between short-term uses of the environment and long-term productivity is such that Reclamation, and state and local water managers and users will gain valuable experience operating under shortage conditions, thus ultimately resulting in enhanced long-term productivity throughout the region. Adoption of the proposed federal action would contribute to the long-term predictability of water use through highly defined water operations.

5.4 Irreversible and Irretrievable Commitments of Resources

Irreversible commitments are decisions impacting non-renewable resources such as soils, wetlands, and waterfowl habitat or commitments that cannot be reversed. Such decisions are considered irreversible because their implementation would impact a resource to the point that renewal can occur only over an extremely long period of time or at great expense or because they would cause the resource to be destroyed, become extinct, or removed. The term “irreversible” describes the loss of future options and applies to the impacts of using nonrenewable resources or resources that are renewable only over a long period of time. Irretrievable commitments are those that are lost for a period of time.

Implementation of the proposed federal action would not result in irreversible or irretrievable commitment of resources. Managing water supplies in a more structured way will help conserve resources. In addition, the proposed guidelines are intentionally interim in order to provide opportunities for gaining valuable operation experience under a wide range of reservoir conditions.

Chapter Six

6.1 Introduction

This chapter describes Reclamation's public involvement program and coordination with specific federal, state and local agencies, NGOs, and the general public for the preparation of this EIS. In addition, this chapter describes Reclamation's government-to-government consultation with Indian tribes and with Mexico.

6.2 General Public Involvement Activities

The public involvement program leading to this Final EIS included project scoping, consultation, and coordination with interested stakeholders and the public. Reclamation developed and implemented a robust public involvement plan to satisfy the public participation requirements set forth in NEPA and also to establish a consistent and constant level of engagement with interested parties and stakeholders. The multi-faceted approach consisted of informational materials, formal consultations, general and stakeholder outreach, and media relations.

A variety of informational materials to educate and inform audiences about the study and related issues were employed. Fact sheets were produced and distributed that provided general project updates and also targeted specific issues or processes throughout the period of preparing this EIS. A website was established and maintained for this EIS, and contained project documents, press releases, fact sheets, points of contact, and the project schedule. An electronic mailing list was used to notify interested parties of website postings, project meetings, and documents. A project phone line and email account were maintained live during the entire period of preparing this EIS for interested parties to express opinions, ask questions, and submit comments.

Briefing packets were developed for the media, periodic media briefings with direct access to project staff were offered, and one-on-one interviews with various news outlets and journals were held.

Reclamation discussed the development of the proposed federal action with various agencies and organizations at: (1) agency/organization regular meetings; (2) public conferences and events sponsored by the agencies/organizations; and (3) meetings sponsored by Reclamation. The entities included the Basin States' water resource departments, water agencies within these states, contractors and associations for federal hydroelectric power, and NGOs. Reclamation also consulted with Indian tribes and Mexico. The coordination activities with each agency, entity or group are summarized below in this chapter. Table 6.9-1 in Section 6.9 lists the agencies and organizations that were invited to such meetings by letter, met with Reclamation and/or invited Reclamation to their meetings or events. Entities participating in these meetings and the meeting dates are listed in Appendix I. Public conferences and events that Reclamation attended and presented information on the proposed federal action are also listed in Appendix I.

A synopsis of the NEPA-related outreach efforts for this EIS follows:

In a May 2, 2005 letter to the Governors of the Colorado River Basin States issued to complete the 2005 AOP mid-year review, the Secretary directed Reclamation to develop additional strategies to improve coordinated management of the reservoirs in the Colorado River system. Pursuant to that direction, Reclamation conducted a public consultation workshop on May 26, 2005 in Henderson, Nevada; issued a *Federal Register* notice on June 15, 2005 soliciting public comments (70 Fed. Reg. 34794); and conducted public meetings on July 26 and July 28, 2005, in Henderson, Nevada, and Salt Lake City, Utah, respectively. Reclamation received a broad range of comments and suggestions from the public, and based in part on these comments, Reclamation determined that a process consistent with NEPA would be the appropriate method to use for the development of Lower Basin shortage guidelines and management strategies for coordinated operations of Lake Powell and Lake Mead under low reservoir conditions.

On September 30, 2005 Reclamation published a NOI (70 Fed. Reg. 57322) to prepare an EIS. The NOI also initiated a public scoping process for soliciting input on the scope of specific shortage guidelines and coordinated reservoir management strategies, and the issues and alternatives to be considered and analyzed in the EIS. As part of this process, Reclamation conducted public scoping meetings on November 1, 2, 3, and 8, 2005. The meetings took place in Salt Lake City, Utah; Denver, Colorado; Phoenix, Arizona; and Henderson, Nevada, respectively. Reclamation also consulted with representatives from the Basin States, Tribal representatives, NGOs, and other interested parties. A 62-day public comment period was noticed by the NOI which started on September 30, 2005 and ended on November 30, 2005. A total of 1,153 written comment letters were received during the scoping process. The comment letters were submitted by a wide-range of interested parties that included businesses; federal, state and local agencies; Indian tribes; special interest groups; and individuals.

Reclamation prepared and published a Scoping Summary Report on the development of Lower Basin shortage guidelines and management strategies for coordinated operations of Lake Powell and Lake Mead. A NOA was published on March 31, 2006 (71 Fed. Reg. 16341). This Scoping Summary Report provided a summary of the comments received and the issues raised during the scoping process and provided a summary of the proposed scope of the environmental analysis to be included in the EIS.

On February 28, 2007, Reclamation published a NOA (72 Fed. Reg. 9026) for the Draft EIS which commenced a 61-day public review period that ended on April 30, 2007. As part of this review process, Reclamation conducted three public hearings, on April 3, 4, and 5, 2007. The hearings took place in Henderson, Nevada; Phoenix, Arizona; and Salt Lake City, Utah, respectively, to invite public input on the Draft EIS. Additionally, a Modeling Workshop was held on March 6, 2007 in Henderson, Nevada to provide the public with information on the modeling performed in the Draft EIS to analyze the potential impacts of hydrologic resources and water deliveries. A total of 78 written comment letters were received in response to the Draft EIS public review period and two individuals provided oral comments during the public hearings. The comment letters were submitted by a wide-range of interested parties that included businesses; federal, state and local agencies; Indian tribes; special interest groups; and individuals. Volume IV of this Final EIS contains reproductions of letters received from the public and transcripts of the three public hearings held in connection with the public review of the Draft EIS and Reclamation's responses to the comments received.

6.3 Cooperating Agency Involvement

In compliance with NEPA and its implementing regulations, Reclamation worked with five cooperating agencies in the preparation of this EIS. The primary role of the cooperating agencies was in the development of alternatives considered in this EIS. Specific contributions of the cooperating agencies are summarized here.

6.3.1 Bureau of Indian Affairs

The BIA is a cooperating agency in recognition of its administration of the federal trust responsibility to Indian tribes. The BIA staff provided updated lists of Tribal governmental representatives, assisted in government-to-government consultations, and assisted in the preparation of ITA analyses. The BIA also assisted Reclamation with the Tribal consultations (Section 6.4) and generally served in an advisory capacity to Reclamation and the Indian tribes.

6.3.2 Fish and Wildlife Service

The FWS is a cooperating agency in recognition of its jurisdiction by law and special expertise with respect to the ESA and biological resources within the study area, and its administration of several wildlife refuges in the study area.

Under Section 7(a)(2) of the ESA, each federal agency must, in consultation with either the Secretary of Commerce through the National Marine Fisheries Service or the Secretary of the Interior through the FWS, insure that any proposed discretionary action authorized, funded or carried out by that agency is not likely to jeopardize the continued existence of any listed species or result in the destruction or adverse modification of designated critical habitat. To assist agencies in complying with the requirements of Section 7(a)(2), ESA's implementing regulations set out a detailed consultation process for determining the biological impacts of a proposed discretionary activity. The consultation process is described in regulations promulgated at 50 C.F.R. pt. 402.

Adoption of the proposed federal action by the Secretary is a discretionary federal action and it is, therefore, subject to compliance with ESA. Reclamation prepared a Draft BA (Appendix R) to address the potential effects of the proposed federal action on listed species. Formal consultation was initiated in September 2007 with the intent of completing a BO prior to the ROD in December 2007.

6.3.3 National Park Service

The NPS is a cooperating agency in recognition of its administration of park units along the Colorado River. The NPS staff participated in developing the Reservoir Storage Alternative (along with Western), and in providing data on visual resources and recreation. NPS staff at GCNRA, Grand Canyon National Park, and the LMNRA, assisted in the preparation of this EIS.

6.3.4 Western Area Power Administration

Western is a cooperating agency in recognition of its role in marketing and transmitting electricity from various Reclamation-operated powerplants located within the study area. Western customers include municipalities, cooperatives, public utility and irrigation districts, federal and state agencies, investor-owned utilities (only one of which purchases firm power from Western), marketers, and Indian tribes located throughout the Colorado River Basin. The wholesalers, in turn, provide retail electric service to millions of consumers within the seven Colorado River Basin states. Western participated in developing the Reservoir Storage Alternative (along with the NPS), and in preparing the hydroelectric power analyses contained in this EIS.

6.3.5 United States Section of the International Boundary and Water Commission

The USIBWC is a cooperating agency in recognition of its administration of the 1944 Treaty obligations with Mexico. As such, USIBWC staff participated in numerous meetings with Reclamation's project evaluation team and participated in internal document reviews as sections of the EIS were prepared. These activities facilitated close coordination with the USIBWC in developing information needed for this EIS and in Reclamation's participation in support of USIBWC's consultations with Mexico as discussed further below. USIBWC's input on this EIS was coordinated through the Commissioner of the USIBWC, as well as USIBWC staff located in their offices in El Paso, Texas; Yuma, Arizona; and San Ysidro, California.

6.4 Tribal Consultation

For purposes of this NEPA process, Reclamation, assisted by BIA, conducted government-to-government consultations with Tribal entities having entitlements to or contracts for Colorado River water, and those that may be affected by or have interests in the proposed federal action. The correspondence concerning consultation efforts is provided in Appendix I. Representatives of various Indian tribes also attended the scoping meetings in November 2005 and the public hearings in April 2007, and some provided Reclamation with written and oral comments on the proposed federal action and its potential effects on resources of Tribal concern, including ITAs. Table 6.9-1 lists the federally-recognized Indian tribes that participated in this NEPA process.

6.5 State and Local Water and Power Agency Coordination

Since the June 15, 2005 *Federal Register* notice announcing Reclamation's interest in soliciting comments on the development of management strategies for Lake Powell and Lake Mead, including Lower Basin shortage guidelines, Reclamation has had various discussions with state and local water agencies regarding the proposed federal action. These meetings are listed in Appendix I by entity and date. However, the Basin States have been continuously engaged in drought mitigation discussions since 2004, at the request of the Secretary, to develop recommendations on how to lessen the impacts of droughts. Reclamation provided the Basin States technical support during these discussions by modeling various strategies, including protection of key elevations of Lake Powell and Lake Mead.

As a result of these ongoing discussions, the Basin States provided Reclamation with projections of future depletions of Colorado River water anticipated in each state. The Upper Colorado River Commission compiled Upper Basin depletions, and the Lower Division states compiled their respective depletions. These projections were used as input to Reclamation's operational modeling analysis, as discussed in this EIS.

In 2004, the Basin States began formulation of a proposal for management strategies for Lake Powell and Lake Mead, and Lower Basin shortage guidelines. The Basin States submitted their "Seven Basin States' Preliminary Proposal Regarding Colorado River Interim Operations" in a letter addressed to the Secretary dated February 3, 2006. A copy of this proposal is included in Appendix J. Reclamation subsequently conducted several consultations with representatives from the Basin States and several water agencies and worked with them to formulate an alternative (Basin States Alternative) that reflected the contents of the Seven Basin States' proposal. In response to the Draft EIS public review, the Basin States revised and submitted a final multi-agreement proposal on April 30, 2007 (Appendix J). That proposal has been analyzed herein.

6.6 Non-Governmental Organizations Coordination

Reclamation contacted and coordinated the preparation of this EIS with multiple recreational and environmental groups. A consortium of environmental NGOs that included the Defenders of Wildlife, Environmental Defense, National Wildlife Federation, The Nature Conservancy, Pacific Institute, Sierra Club, Sonoran Institute, and Rivers Foundation of the Americas, developed what became the Conservation Before Shortage Alternative analyzed in this EIS.

This consortium of environmental NGOs developed and submitted its first proposal, "Conservation Before Shortage", on July 18, 2005. After publication of the Summary Scoping Report, this consortium of environmental NGOs modified elements of its proposal. The final proposal of this consortium, "Conservation Before Shortage II," was submitted to Reclamation on July 7, 2006. A copy of this proposal is included in Appendix K. From 2005 through 2006, Reclamation met with representatives of the consortium of environmental NGOs and worked with them to formulate what became the Conservation Before Shortage Alternative, as analyzed herein. These meetings are listed in Appendix I by entity and date.

6.7 Other Consultations

In compliance with the NHPA, Reclamation has initiated the process of consultation with SHPOs in Arizona, California, Nevada, and Utah. Consultations regarding eligibility of cultural resources to the National Registry and effect of the proposed federal action are ongoing. In addition, consultations are underway with THPOs (e.g., Navajo Nation THPO, Hualapai Indian Tribe THPO). Indian tribes with concerns under Exec. Order No. 13007 and the Native American Graves Protection and Repatriation Act are also being consulted.

6.8 Consultation with the Government of Mexico Agencies

The USIBWC has engaged in consultation with agencies of Mexico regarding the proposed federal action. Reclamation has assisted USIBWC in conducting this consultation by providing information on the proposed federal action and by participating in briefings with the Mexican Section of the IBWC, the Mexico National Water Commission, and Mexico Secretariat of Foreign Relations. Consistent with these consultations, Section 397 of Public Law 109-432 directs Reclamation to utilize these treaty-related processes to identify potential impacts beyond the borders of the United States. Accordingly, meetings with representatives of Mexico were conducted, during which representatives of Mexico provided their views, input, and concerns regarding the potential effects of the proposed federal action. These meetings are listed in Appendix I by entity and date.

Exec. Order No. 12114 instructs federal agencies to investigate the effects of proposed federal actions in other countries. This Final EIS documents the hydrologic and water quality effects of the proposed federal action on water deliveries to Mexico.

The modeling assumptions used in this Final EIS are not intended to constitute an interpretation or application of the 1944 Treaty or to represent current United States policy or a determination of future United States policy regarding deliveries to Mexico.

6.9 Summary of Coordination and Consultation Contacts

Table 6.9-1 lists those Indian tribes, agencies, organizations, interest groups, and representatives of Mexico that Reclamation notified, consulted and coordinated with regarding the proposed federal action. Consultations are ongoing with most of these entities. These entities, meeting dates and related correspondence are listed and/or provided in Appendix I.

6.10 Federal Register Notices

Several *Federal Register* notices have been issued to inform the public about the formulation of interim operational guidelines and the preparation and availability of the Draft EIS and this Final EIS. Table 6.10-1 lists the *Federal Register* notices; their full text is provided in Appendix L. In addition to the notices issued, additional notices are planned to announce the publication and availability of the Final EIS and Secretary's ROD based on the Final EIS.

Table 6.10-1
Federal Register Notices Regarding the Proposed Federal Action

Notice	Title
70 Fed. Reg. 34794 (June 15, 2005)	Notice to solicit comments and hold public meetings on the development of management strategies for Lake Powell and Lake Mead, including Lower Basin shortage guidelines, under low reservoir conditions.
70 Fed. Reg. 57322 (September 30, 2005)	Notice of intent to prepare an environmental impact statement (EIS) and notice to solicit comments and hold public scoping meetings on the development of Lower Basin shortage guidelines and coordinated management strategies for the operation of Lake Powell and Lake Mead.
71 Fed. Reg. 16341 (March 31, 2006)	Notice of public availability of a Scoping Summary Report on the development of Lower Basin shortage guidelines and coordinated management strategies for the operation of Lake Powell and Lake Mead, particularly under low reservoir conditions.
72 Fed. Reg. 9026 (February 28, 2007)	Notice of availability and notice of public hearings for the Draft EIS for the Colorado River interim guidelines for Lower Basin shortages and coordinated operations for Lake Powell and Lake Mead.

Glossary

Glossary

A

acre-foot (af)	Volume of water (43,560 cubic feet) that would cover one acre to a depth of one foot.
adaptive management	A method for examining alternative strategies for meeting measurable biological goals and objectives, and then if necessary, adjusting future conservation management actions according to what is learned.
affected environment	Existing biological, physical, social, and economic conditions of an area that are subject to change, both directly and indirectly, as the result of a proposed human action.
algae	Simple plants containing chlorophyll; most live submerged in water.
allocation, allotment	Refers to a distribution of water through which specific persons or legal entities are assigned individual rights to consume pro-rata shares of a specific quantity of water under legal entitlements. For example, a specific quantity of Colorado River water is distributed for use within each Lower Division state through an apportionment. Water available for consumptive use in that state is further distributed among water users in that state through the allocation. An allocation does not establish an entitlement; the entitlement is normally established by a written contract with the United States government. *See also* Lower Division states.
alluvium	Sedimentary material transported and deposited by the action of flowing water.
ambient	Surrounding natural conditions (or environment) in a given place and time.
amphibian	Vertebrate animal that has a life stage in water and a life stage on land (e.g., salamanders, frogs, toads).
annual flow-weighted average concentration	A weighted average of monthly total dissolved solids (TDS) concentrations for a year, where the weight for each month is based on the relative flow for each month.
Annual Operating Plan for Colorado River Reservoirs (AOP)	The AOP describes how Reclamation will manage Colorado River resources over a 12-month period, consistent with the Long-Range Operating Criteria and the *Arizona v. California* 1964 Supreme Court Decree. The AOP is prepared annually by Reclamation in cooperation with the Basin States, appropriate federal agencies, Indian tribes, state and local agencies, and the general public, including governmental interests as required by federal law. As part of the AOP process, the Secretary of the Department of the Interior (Secretary) makes annual determinations regarding the availability of Colorado River water for deliveries to the Lower Division states of the Colorado River Basin. *See also* Lower Division states.
apportionment	Refers to the distribution of water available to each Lower Division state in Normal, Surplus or Shortage condition years, as set forth, respectively, in Articles II(B)(1), II(B)(2), and II(B)(3) of the 1964 Supreme Court Decree in the case of *Arizona v. California*.
appropriative rights	The right to divert a specified quantity of water at a specified point of diversion for reasonable and beneficial uses at a specified place of use for a specified manner of use. Appropriative rights are generally “first-in-time, first-in-right”; that is, one appropriative right has priority over appropriative rights established later.

B

backwater	A relatively small, generally shallow area of a river with little or no current.
banked groundwater	Water that has been stored temporarily in a groundwater aquifer. Banked groundwater can be recovered for use at a later time.
base load	Minimum load in a power system over a given period of time.
Basin States	In accordance with the Colorado River Compact of 1922, the Colorado River Basin is comprised of those parts of Arizona, California, Colorado, Nevada, New Mexico, Utah, and Wyoming, within and from which waters drain naturally into the Colorado River. These seven states are referred to as the Basin States. *See also* Colorado River Compact of 1922.
Biological Assessment (BA)	To facilitate compliance with Section 7(a)(2) of the Endangered Species Act (ESA), federal agencies must prepare a BA pursuant to Section 7(c)(1) of ESA that identifies the likely effects of the proposed federal action on threatened and endangered species. *See also* Endangered Species Act.
Biological Opinion (BO)	Document stating the United States Fish and Wildlife Service (FWS) and/or the National Marine Fisheries Service opinion as to whether a federal action is likely to jeopardize the continued existence of a threatened or endangered species or result in the destruction or adverse modification of critical habitat.
bypass flows	Saline agricultural return flows from the Wellton-Mohawk Irrigation and Drainage District that are routed to the Cienega de Santa Clara in Mexico in order to ensure compliance with the salinity provisions of Minute 242 of the 1944 Treaty.

C

candidate species	Plant or animal species not yet officially listed as threatened or endangered under the ESA, but which is undergoing status review by the United States Fish and Wildlife Service.
catch	At a recreational fishery, refers to the number of fish captured, whether they are kept or released.
channel (watercourse)	An open conduit either naturally or artificially created which periodically or continuously contains moving water, or which forms a connecting link between two bodies of water. River, creek, run, branch, and tributary are some of the terms used to describe natural channels. Natural channels may be single or braided. Canal and floodway are some of the terms used to describe artificial channels.
Cladophora	Filamentous green alga important to the food chain in the Colorado River downstream of Glen Canyon Dam.
Colorado River Basin	All of the drainage area of the Colorado River system and all other territory within the United States to which the waters of the Colorado River system shall be beneficially applied.
Colorado River Basin Project Act of 1968 (CRBPA)	This Act authorized construction of a number of water development projects, including the Central Arizona Project (CAP), and required the Secretary to develop the Criteria for Coordinated Long-Range Operation of Colorado River Reservoirs, or Long-Range Operating Criteria (LROC).
Colorado River Basin Salinity Control Forum	The organization dedicated to controlling Colorado River salinity, consists of representatives of the seven Basin States.

Colorado River Compact of 1922	The agreement concerning the apportionment of the use of the waters of the Colorado River Basin, dated November 24, 1922, executed by Commissioners for the States of Arizona, California, Colorado, Nevada, New Mexico, Utah and Wyoming, approved by Herbert Hoover, representative of the United States, and proclaimed effective by the President of the United States, June 25, 1929.
Colorado River Simulation System (CRSS)	An operational model of the Colorado River Basin based on a monthly time step.
Colorado River system	The portion of the Colorado River and its tributaries within the United States as defined in the Colorado River Compact of 1922.
Compact	The Colorado River Compact of 1922.
Compact Point	Lee Ferry, Arizona, the reference point designated by the Colorado River Compact of 1922 as dividing the Colorado River Basin into two sub-basins, the Upper Basin and the Lower Basin. *See also* Lee Ferry Compact Point.
Consolidated Decree	Entered by the United States Supreme Court on March 27, 2006 in the case of *Arizona v. California*, 547 U.S. 150 (2006). In 1963 the Supreme Court reached a Decision in the case of *Arizona v. California.* The 1964 Supreme Court Decree in the case of *Arizona v. California* implemented the 1963 Decision. This 1964 Supreme Court Decree was supplemented over time after its adoption and the Supreme Court entered a Consolidated Decree in 2006 which incorporates all applicable provisions of the earlier-issued Decisions and Decrees.
consumptive use	For purposes of this Environmental Impact Statement (EIS), diversions of water from mainstream Colorado River, including water withdrawn from the mainstream through underground pumping, minus any measured and unmeasured return flows.
Contractors	Those who hold entitlements to Colorado River water are referred to as Contractors. Contractors consist of the federal government, states, Indian tribes, and various public and private entities that are recognized under the Consolidated Decree, hold a Section 5 Contract with the Secretary, or have a Secretarial Reservation of water. *See also* Consolidated Decree.
conveyance loss	Water that is lost in transit from a pipe, canal, conduit, or ditch by leakage or evaporation. If the water is lost due to leakage, it may be considered return flow if it percolates to an aquifer and is available for reuse. If the water evaporates, it is considered consumptive use.
Cooperating Agency	With respect to the National Environmental Policy Act of 1969, as amended, (NEPA) process, an agency that has jurisdiction by law or special expertise concerning an aspect of a proposed federal action, and that is requested by the lead agency to participate in the preparation of an Environmental Impact Statement.
coordinated operation	As applied to hydroelectric power resources, the operation of a group of hydroelectric powerplants to obtain optimal power benefits with due consideration for all other uses. Generally, the operation of two or more interconnected electrical systems to achieve greater reliability and economy.
covered species	Those species addressed in the Lower Colorado River Multi-Species Conservation Program (LCR MSCP) for which conservation measures would be implemented and for which authorization for "take" is being requested under Section 10 of the ESA. *See also* take.
criteria	Standards used for making a determination.
critical habitat	Specific areas with physical or biological features essential to the conservation of a listed species and which may require special management considerations or protection. These areas have been legally designated via *Federal Register* notices.

cubic foot per second (cfs)	A measure of water flow equal to one cubic foot of water passing a point on the stream in one second of time.
cultural resource	Building, site, district, structure, or object significant in history, architecture, archeology, culture, or science.

D

dead pool	Reservoir elevation corresponding to dead storage.
dead storage	Reservoir space from which stored water cannot be evacuated by gravity.
delta	Sediment deposit formed at the mouth of the Colorado River and other rivers where they enter Lake Powell, Lake Mead or the Gulf of California.
depletion	Loss of water from a stream, river, or basin resulting from consumptive use.
deposition	Settlement of material out of the water column and on to the streambed. Occurs when the energy of flowing water is unable to support the load of suspended sediment.
discharge (flow)	Volume of water that passes a given point within a given period of time; expressed in this EIS in cubic feet per second. *See also* cubic foot per second.
dissolved oxygen (DO)	Amount of free oxygen found in water; perhaps the most commonly employed measurement of water quality. Low DO levels adversely affect fish and other aquatic life. The ideal dissolved oxygen for fish life is between 7 milligrams per liter (mg/L) and 9 mg/L; most fish cannot survive when DO falls below 3 mg/L.
diversion(s)	Colorado River water withdrawn from the mainstream, including water diverted from reservoirs or drawn from the mainstream by underground pumping.
domestic use	Refers to the use of water for household, stock, municipal, mining, milling, industrial, and other like purposes, but excludes the generation of electrical power.
draw down	Lowering of a reservoir's elevation; process of depleting reservoir or groundwater storage.

E

ecosystems	Complex system composed of a community of fauna and flora and that system's chemical and physical environments.
electric power system	Physically connected electric generating, transmission, and distribution facilities operated as a unit under one control.
electrical demand	Energy requirement placed upon a utility's generation at a given instant or averaged over any designated period of time.
endangered species	A species or subspecies whose survival is in danger of extinction throughout all or a significant portion of its range.
Endangered Species Act (ESA)	The Endangered Species Act (ESA) of 1973 (16 U.S.C. §§ 1531-1544), as amended, under Section 9, provides for the prohibition of "take" of any fish or wildlife species listed as threatened or endangered under the ESA unless specifically authorized by regulation. *See also* take.
energy	Electric capacity generated and/or delivered over time.

entitlement	Refers to an authorization to beneficially consume Colorado River water pursuant to a decreed right; a contract with the United States through the Secretary; or a Secretarial Reservation of water.
epilimnion	Thermal layering of water in lakes and streams. *See also* stratification.

F

firm energy or power	Non-interruptible energy or power guaranteed by the supplier to be available at all times except for reasons of uncontrollable forces or "continuity of service" contract provisions.
flood	An overflow or inundation that comes from a river or other body of water, and causes or threatens damage. Any relatively high streamflow overtopping the natural or artificial banks in any reach of a river or stream. A relatively high flow as measured by either gage height or discharge quantity.
flood control pool	Reservoir volume above the active conservation and joint-use pool that is reserved for flood runoff and then evacuated as soon as possible to keep that space in readiness for the next flood.
flood control release	The release of water from Lake Mead and the operation of Hoover Dam for flood control purposes pursuant to the reservoir operating criteria specified in the February 8, 1984 Field Working Agreement between the United States Army Corps of Engineers (USACE) and the Bureau of Reclamation (Reclamation), and the USACE regulations contained in 33 C.F.R. pt 208.11.
flow	Volume of water passing a given point per unit of time expressed in cubic foot per second. *See also* cubic foot per second.
forage fish	Generally, small fish that reproduce prolifically and are consumed by predators.
fore bay	Impoundment immediately above a dam or hydroelectric plant intake structure. The term is applicable to all types of hydroelectric developments (storage, run-of-river, and pumped-storage).
fry	Life stage of fish between the egg and fingerling stages.
full pool	Volume of water in a reservoir at maximum design elevation.

G

gaging station	Specific location on a stream where systematic observations of hydrologic data are obtained through mechanical or electrical means.
gigawatt-hour (GWh)	One billion watt-hours of electrical energy.

H

headwater	The source and upper part of a stream.
hydroelectric power	Electrical capacity produced by falling water.
hypolimnetic zone	The deep portion of a lake or reservoir volume generally classified as below the level of the thermocline.
hypolimnion	Thermal layering of water in lakes and streams. *Also see* stratification.

I

Important Farmland	As defined by the United States Department of Agriculture (USDA) Natural Resources Conservation Service (formerly the Soil Conservation Service), Important Farmlands include Prime Farmland, Unique Farmland, Farmland of Statewide Importance, and Farmland of Local Importance. The categorization of farmland is based upon a soil classification system which accounts for the physical and chemical characteristics of the land and the suitability of the land for producing crops. Important Farmlands are afforded special protection due to their importance to agricultural production.
impoundment	Body of water created by a dam.
incidental take	Incidental take is defined under the ESA as take that is “incidental to, and not the purpose of, the carrying out of an otherwise lawful activity” (50 C.F.R. pt. 17.22 and 17.32). *See also* take.
Indian Trust Assets (ITAs)	Indian Trust Assets are ‘legal interests’ in ‘assets’ held in ‘trust’ by the federal government for federally recognized Indian tribes or individual Indians.
inflow	Water flowing into a lake or reservoir from a river and/or its tributaries; or water entering a river from tributaries.
in situ	In archaeology, and as used in this EIS, *in situ* refers to an artifact that has not been moved from its original place of deposit.
Interim Surplus Criteria (ISC)	*See* "Interim Surplus Guidelines".
irrigated area	The gross farm area upon which water is artificially applied for the production of crops, with no reduction for access roads, canals, or farm buildings.
irrigation	The controlled application of water to arable lands to supply water requirements not satisfied by rainfall.

J-K

juvenile	Young fish older than one year but not having reached reproductive age.
kilowatt-hour (kWh)	One thousand watt-hours of electrical energy.

L

land cover type	A classification system to describe vegetation and other habitat types (e.g., cotton-wood willow, honey mesquite type III, marsh).
Las Vegas Valley	The topographic basin containing the City of Las Vegas, the City of North Las Vegas, the City of Henderson, and certain unincorporated townships of Clark County.
Las Vegas Wash	The natural drainage channel for the entire Las Vegas Valley. It is dominated by wastewater flows from the City of Las Vegas, Clark County Sanitation District, and City of Henderson wastewater treatment plants. It terminates in the Las Vegas Bay of Lake Mead.

Law of the River	As applied to the Colorado River, the Secretary is vested with the responsibility to manage the mainstream waters of the Lower Basin pursuant to applicable federal law. This responsibility is carried out consistent with a body of documents referred to as the Law of the River. This collective set of documents comprising numerous operating criteria, regulations, and administrative decisions included in federal and state statues, interstate compacts, court decisions and decrees, an international treaty, and contracts with the Secretary, apportions the Colorado River waters and regulates the use and management of the Colorado River among the seven Basin States and Mexico.
lead agency	A lead agency is an agency initiating and overseeing the preparation of an EIS. For this EIS, Reclamation is the lead agency for compliance with NEPA.
Lee Ferry Compact Point	The Colorado River Compact of 1922 divided the Colorado River Basin into two sub-basins: the Upper Basin, and the Lower Basin. The Lee Ferry Compact Point, identified as the reference point which marks this division between the Upper Basin and the Lower Basin, is located in the mainstream Colorado River in Arizona, one mile below the confluence of the Colorado River with the Paria River.
Lees Ferry Gaging Station	The site of the United States Geological Survey (USGS) stream gage (Lees Ferry Gaging Station) located in Arizona, on the Colorado River upstream of its confluence with the Paria River, downstream of Glen Canyon Dam. Also, the location of Colorado River ferry crossings (1873 to 1928).
limnology	Scientific study of physical characteristics and biology of lakes, ponds, and streams.
load	Amount of electrical power or energy delivered or required at a given point.
Lower Basin (states)	The Colorado River Compact of 1922 divided the Colorado River system into two sub-basins: the Upper Basin, and the Lower Basin, and defined the Lower Basin as including those parts of the states of Arizona, California, Nevada, New Mexico, and Utah, within and from which waters drain naturally into the Colorado River below the Lee Ferry Compact Point in Arizona. *See also* Lee Ferry Compact Point.
Lower Division (states)	The Colorado River Compact of 1922 divided the seven Colorado River Basin states into two groups: Upper Division states, and Lower Division states. The Lower Division states are Arizona, Nevada, and California. *See also* Basin States.

M

magnitude	A number characteristic of a quantity and forming a basis for comparison with similar quantities such as flows.
mean monthly flow	Average flow for the month, usually expressed in cubic feet per second.
mean sea level (msl)	The average height of the surface of the oceans and seas measured throughout all stages of the tidal cycle, determined from hourly readings of tidal height and computed over a long (usually 19-year) period. It is used as a datum plane, i.e., serves as the reference surface, from which elevations and depths are measured.
median	Middle value in a distribution, above and below which lie an equal number of values.
megawatt (MW)	One million watts of electrical power (capacity).
megawatt-hour (MWh)	One million watt-hours of electrical energy.
metalimnion	Thermal layering of water in lakes and streams. *See also* stratification.
milligram per liter (mg/L)	Equivalent to one part per million.

N

National Environmental Policy Act of 1969, as amended (NEPA)	Law requiring federal agencies to integrate environmental values into their decision making processes by considering the environmental impacts of their proposed actions and reasonable alternatives to those actions. To meet this requirement, federal agencies prepare a detailed statement known as an Environmental Impact Statement, or EIS.
National Register of Historic Places (NRHP)	The nation's official list of cultural resources worthy of preservation. Authorized under the National Historic Preservation Act of 1966, the NRHP is part of a national program to coordinate and support public and private efforts to identify, evaluate, and protect our historic and archeological resources. Properties listed in the NRHP include districts, sites, buildings, structures, and objects that are significant in American history, architecture, archeology, engineering, and culture.
natural flow	The flow of any stream undepleted by human activities.
non-system water	Waters originating from outside the Colorado River system.
Normal Condition	When the Secretary has determined that there is available for annual release 7.5 maf to satisfy consumptive use in the Lower Division states pursuant to Article II(B)(1) of the Consolidated Decree.

O

oligotrophic	A body of water characterized by low dissolved plant nutrient and organic matter, and rich in oxygen at all depths.

P-Q

peak flow	Maximum instantaneous flow in a specified period of time.
peak load	Maximum electrical demand in a stated period of time.
penstock	Conduit pipe used to convey water under pressure to the turbines of a hydroelectric plant.
percentile	A statistical term. A descriptive measure that splits ranked data into 100 parts, or hundredths. For example, the 10^{th} percentile is the value that splits the data in such a way that ten percent of the values are less than or equal to the 10^{th} percentile.
Piscivorous	Habitually feeding on fish.
PM_{10} (PM10)	Particulate matter (PM) (dust particles) standard that includes particles with a diameter of ten micrometers or less.
power	Electrical capacity generated, transferred or used.
Present Perfected Right (PPR)	Many Colorado River water rights originated as 'perfected rights' specified in the 1964 United States Supreme Court Decree in the case of *Arizona v. California*. 'Present perfected rights' (PPRs) are the highest priority Colorado River water rights that the 1964 Decree defines as those perfected rights existing on June 25, 1929 (the effective date of the Boulder Canyon Project Act of 1928).
priority	A ranking with respect to diversion of water relative to other water users.

probability	In this EIS, the relative frequency with which a range of modeled values occurs. For example, the probability of Lake Mead elevation exceeding 1,180 feet msl in June 2005 is equal to the number of modeled elevations greater than 1,180 feet msl in June 2005, divided by the total number of modeled elevations in June 2005.
public involvement	Process of obtaining citizen input into each stage of development of planning documents. Required as a major input into any EIS.

R

ramp rate	The rate of change in instantaneous output from a powerplant. The ramp rate is established to prevent undesirable effects due to rapid changes in loading or, in the case of hydroelectric plants, discharge.
rated head	Water depth for which a hydroelectric generator and turbines were designed.
reach	A specified segment of a river, stream, channel, or other water conveyance facility.
recruitment	Survival of young plants and animals from birth to a life stage less vulnerable to environmental change.
reregulating reservoir	A reservoir for reducing diurnal fluctuations resulting from the operation of an upstream reservoir for power production.
resampling	The digital process of changing the sample rate or dimensions of sampled data (e.g., digital imagery or audio) by temporarily or areally analyzing and sampling the original data.
reserved water	In the case of Indian reservations, rights based on the doctrine of Indian reserved rights, and in the case of federal establishments other than Indian reservations, a federal reservation of water for use on property under federal jurisdiction.
reservoir	A pond, lake, or basin, either natural or artificial, for the storage, regulation, and control of water.
return flow	Portion of water previously diverted from a river or stream and subsequently returned to that river or stream, and is available for consumptive use by others.
return flow credit	In the accounting of consumptive use in the Lower Basin, Colorado River water that is returned to the river and is available for consumptive use by others in the year in which it was diverted is credited against a water user's total diversions.
riffle	A stretch of choppy water caused by an underlying rock shoal or sandbar.
riparian	Of, on, or pertaining to the bank of a river, pond, or lake.
river mile (RM)	River miles are numbered along the Colorado River from south to north starting with RM 0.0 at the Southerly International Border (SIB) with Mexico. Dam locations are noted at their respective river miles.
river stage	Water surface elevation of a river above a datum.
RiverWare™	A commercial river system simulation computer program that was configured to simulate operation of the Colorado River for this EIS.
runoff	That part of the precipitation that appears in surface streams. It is the same as streamflow unaffected by artificial diversions, storage, or other works of man in or on the stream channels.

S

salinity	A term used to refer to the dissolved minerals in water, also referred to as total dissolved solids (TDS). *See also* total dissolved solids.
Secretary	The Secretary of the Department of the Interior, and duly appointed successors, representatives and others with properly delegated authority.
Section 10(a)(1)(B) permit	Section 10(a)(1)(B) of the ESA authorizes the FWS to issue non-federal entities a permit for the incidental take of endangered and threatened wildlife species. This permit allows the non-federal entity to proceed with an activity that is legal in all other respects, but that results in the “incidental to, and not the purpose of, the carrying out of an otherwise lawful activity.” *See also* take.
sediment	Unconsolidated solid material that comes from weathering of rock and is carried by, suspended in, or deposited by water or wind.
sediment load	Mass of sediment passing through a stream.
seepage	Relatively slow movement of water through a medium, such as sand.
Shortage Condition	When the Secretary has determined that there is available for annual release less than 7.5 maf to satisfy consumptive use in the Lower Division states pursuant to Article II(B)(3) of the Consolidated Decree.
spawn	To lay eggs, especially fish.
spills	Water releases from a dam in excess of powerplant capacity.
spillway	Overflow facility at a dam, usually consisting of a sill at the full-reservoir elevation.
spinning reserves	Available capacity of generating facilities synchronized to the interconnected electric system so that it can be called upon for immediate use in response to system problems or sudden load changes.
stage	Reservoir elevation.
Standards	A means established by authority as a rule for the measure of quality, such as cosmetic effects (such as skin or tooth discoloration) or aesthetic effects (such as taste, odor, or color) in drinking water.
storage	Water artificially impounded in surface or underground reservoirs, for future use. Water naturally detained in a drainage basin, such as groundwater, channel storage, and depression storage. The term "drainage basin storage" or simply "basin storage" is sometimes used to refer collectively to the amount of water in natural storage in a drainage basin. *See also* conservation storage and dead storage.
stratification	Thermal layering of water in lakes and streams. Lakes usually have three zones of varying temperature: (1) *epilimnion* – top layer with essentially uniform warmer temperature; (2) *metalimnion* – middle layer of rapid temperature decrease with depth; and (3) *hypolimnion* – bottom layer with essentially uniform colder temperatures.
streamflow	The discharge that occurs in a natural channel. Although the term discharge can be applied to the flow of a canal, the word streamflow uniquely describes the discharge in a surface stream course. The term "streamflow" is more general than runoff, as streamflow may be applied to discharge whether or not it is affected by diversion or regulation.
system storage	The total volume of water available in the Colorado River Basin at a specific point in time.

system water — Waters originating from the Colorado River system.

Surplus Condition — When the Secretary has determined that there is available for annual release more than 7.5 maf to satisfy consumptive use in the Lower Division states pursuant to Article II(B)(2) of the Consolidated Decree.

T

tail water — Water immediately downstream of the outlet from a dam or hydroelectric powerplant.

take — As defined by the ESA, "take" means to harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, or collect, or to attempt to engage in any such conduct (16 U.S.C. §§ 1531[18]).

thermocline — The zone of maximum change in temperature in a water body, separating upper (epilimnetic) from lower (hypolimnetic) zones.

threatened species — A species or subspecies that is likely to become endangered in the foreseeable future.

total dissolved solid (TDS) — A measure of the inorganic or mineral content of water, commonly expressed in milligrams per liter. *See also* salinity.

traditional cultural property — A site or resource that is eligible for inclusion in the National Register of Historic Places because of its association with cultural practices or beliefs of a living community. *See also* National Register of Historic Places.

tributary — River or stream flowing into a larger river or stream.

Turbidity — Cloudiness of water, measured by how deeply light can penetrate into the water column from the surface.

U-V

Upper Basin (states) — The Colorado River Compact of 1922 divided the Colorado River system into two sub-basins: the Upper Basin, and the Lower Basin, and defined the Upper Basin as including those parts of the states of Arizona, Colorado, New Mexico, Utah, and Wyoming, within and from which waters drain naturally into the Colorado River above the Lee Ferry Compact Point in Arizona. *See also* Lee Ferry Compact Point.

Upper Colorado River Commission — Commission established by the Upper Colorado River Basin Compact of appointed members from the Upper Division states whose purpose is to secure the storage of water for beneficial consumptive use in the Upper Basin.

Upper Division (states) — The Colorado River Compact of 1922 divided the seven Colorado River Basin states into two groups: Upper Division states, and Lower Division states. The Upper Division states are Colorado, New Mexico, Utah, and Wyoming. *See also* Basin States.

W-X

water year	That period of twelve months ending September 30 of each year.
Waters of the United States	In accordance with the Clean Water Act, Waters of the United States include: (1) all waters which may be susceptible to use in interstate or foreign commerce; (2) all interstate waters including interstate wetlands; (3) all other waters such as intrastate lakes, rivers, streams (including intermittent streams), mud flats, sand flats, wetlands, sloughs, prairie potholes, wet meadows, playa lakes, or natural ponds, the use, degradation, or destruction of which could affect interstate or foreign commerce including any such waters; (4) all impoundments of waters otherwise defined as waters of the United States; (5) tributaries of waters identified in this EIS; (6) the territorial seas; and (7) wetlands adjacent to waters (other than waters that are themselves wetlands) identified in this EIS.
watershed	The drainage area upstream of a specified point on a stream.

Y-Z

List of Preparers

List of Preparers

This Final Environmental Impact Statement was prepared by the Bureau of Reclamation, Upper and Lower Colorado Regions. This List of Preparers presents the persons who developed significant background material and various sections, or participated to a significant degree in the preparation of this Final Environmental Impact Statement.

Alan G.K. Solbert
1950-2006

Alan Solbert of Jones & Stokes, a dear friend and colleague, contributed substantially to the completion of this document. The project team as well as many others will miss Alan's leadership, enthusiasm, and friendship. This effort is dedicated to his memory.

BUREAU OF RECLAMATION, LOWER COLORADO REGION

Name	Education	Qualifications	Experience	Project Role
Belew, Stephen	B.S., Civil Engineering	GIS	10	GIS
Blasius, Becky	B.S., Physiology M.S., Entomology	Aquatic ecology	9	Water Quality
Callejo, Russell	M.S., Civil Engineering	Hydrologic modeling and data analysis	5	Hydrologic Resources/Modeling Team

A.1 Background

Long-term policy and planning studies on the Colorado River have typically used computer modeling results from Bureau of Reclamation's (Reclamation) Colorado River Simulation System (CRSS). Developed in the 1980's as a Fortran-based modeling system, CRSS originally ran on a Cyber mainframe computer. CRSS modeled twelve major reservoirs and approximately 115 diversion points throughout the Colorado River Upper Basin and Lower Basin on a monthly time step. A major drawback of the Fortran-based CRSS was that the operating policies or rules were hardwired into the modeling code, making modification of those policies difficult.

Based on the need to initiate surplus and shortage studies for the Lower Basin in the early 1990s, Reclamation developed an annual time step model, CRSSez, implemented in Visual Basic (Bureau of Reclamation 1998). CRSSez primarily modeled the operation of Lake Powell and Lake Mead, representing the reservoirs upstream of Lake Powell as one aggregate reservoir, and the effect of reservoirs downstream of Lake Mead as part of the water demand from Lake Mead. CRSSez was used in the Interim Surplus Criteria Environmental Impact Statement (EIS) process to develop a model, and evaluate a range of alternatives.

In 1994, Reclamation began a collaborative research and development program with the University of Colorado and the Tennessee Valley Authority with the goal of developing a general-purpose modeling tool that could be used for both operations and planning on any river basin. This modeling tool, known as RiverWare™, is now being used by Reclamation's Upper and Lower Colorado Regions for both planning and operations (Fulp 1999). A major advantage of RiverWare™ is that the operational policies or rules are no longer hardwired into the modeling code (Zagona et al. 2001). The user expresses and prioritizes the rules through the RiverWare™ graphical user interface, and RiverWare™ then interprets the rules when a simulation is performed. Multiple rule sets can be used to perform different simulations using the same model and this provides the capability for efficient "what-if" analysis with respect to different policies.

Reclamation replaced the original CRSS model with a new model implemented in RiverWare™ in 1996. The new model has the same spatial and temporal resolution, uses the same basic input data (hydrology and consumptive use schedules), and uses the same physical process algorithms as the original CRSS. A rule set was also developed to mimic the policies contained in the original model. Comparison simulations were made between the original CRSS and the new model and rule set, with typical differences of less than 0.5 percent (Reclamation 1996).

Since 1996, enhancements to CRSS have consisted of developing new rule sets to reflect current operational policy as well as investigating and improving, where necessary, the physical process methodologies. A team of Reclamation engineers from the Upper and Lower Colorado Regions has been established for these purposes and continues to assess the need to further enhance CRSS to reflect new operational policies.

In 2005 a policy-screening model, CRSS-Lite was developed to replace CRSSez (Reclamation 2005). CRSS-Lite was developed in RiverWare™ and preserves the complexity and accuracy of CRSS with a significantly shorter model execution time, an advantage over CRSSez. CRSS-Lite was used extensively to evaluate and compare a multitude of operational strategies and alternatives in this EIS.

A.2 Description of the Model

In summary, twelve Upper Basin and Lower Basin reservoirs are modeled: Fontenelle, Flaming Gorge, Starvation, Taylor Park, Blue Mesa, Morrow Point, Crystal, Navajo, Powell, Mead, Mohave, and Havasu in CRSS. Critical to this EIS was the allocation of shortages, which required breaking out several of the approximately 115 modeled diversions (demands and return flows) throughout the basin that had been aggregated in the original CRSS. The hydrologic "natural" inflows (flows corrected for upstream regulation and consumptive uses and losses) at 29 inflow points throughout the basin were also used from the standard CRSS hydrology data set covering the period 1906–2005.

A.3 Initial Reservoir Conditions

The first year considered for the interim period of the proposed federal action is 2008. Since the initial modeling was performed in 2006, some projection of Colorado River system conditions was need. In order to establish the reservoir starting conditions for CRSS modeling, Reclamation's 24-Month Study model is used to project the reservoir storage conditions as of end-of-calendar year 2007. This process inputs the storage conditions at the time the modeling is performed and adds to that several assumptions including estimates of snow pack and run-off for the intervening period (the period between when the model is run and December 31, 2007).

The hydrologic modeling that was performed and used in the analyses for the Draft EIS was undertaken in the fall of 2006 and used the August 2006 24-Month Study. For the Final EIS, more current estimates of inflow to Lake Powell in 2007 were available and these differed somewhat from the original assumptions that were used in the modeling for the Draft EIS. The lower inflow projections reflected the effects of the continued drought in the Colorado River Basin (which began in 2000). In order to provide the most current information available for the Final EIS, the alternatives were remodeled using the latest available inflow projections. Using this latest inflow forecast in the June 2007 24-Month Study provides different starting conditions for Lake Powell and Lake Mead from those used in the Draft EIS and shows that the projected Lake Powell and Lake Mead elevations for January 1, 2008 would be approximately 20 feet and one foot lower, respectively, than the starting elevations that were used in the Draft EIS.

Table A-1 provides the initial conditions for the Upper Basin and Lower Basin reservoirs that were used in the CRSS simulations for the Draft EIS and the Final EIS. Since the simulation begins in January 2008, these values reflect the end-of-calendar year 2007 reservoir elevations, as projected by the August 2006 24-Month Study and June 2007 24-Month Study, respectively.

Table A-1
Initial Reservoir Conditions
(End-of-Calendar Year 2007 Forecast)

Reservoir	Draft EIS Initial Conditions[1]		Final EIS Initial Conditions[2]	
	Elevation (feet msl)	Storage (af)	Elevation (feet msl)	Storage (af)
Fontenelle	6,486.29	203,787	6,481.89	177,000
Flaming Gorge	6,029.67	3,336,300	6,023.89	3,119,000
Starvation	5,734.92	255,000	5,734.92	255,000
Taylor Park	9,308.32	67,260	9,306.45	64,000
Blue Mesa	7,489.99	581,270	7,490.00	581,000
Morrow Point	7,153.73	112,000	7,153.73	112,000
Crystal	6,753.04	16,970	6,753.04	17,000
Navajo	6,080.33	1,629,760	6,070.99	1,494,000
Powell	3,614.80	13,219,550	3,596.77	11,445,000
Mead	1,116.53	13,023,940	1,114.85	12,864,000
Mohave	638.71	1,582,960	638.71	1,583,000
Havasu	445.80	539,520	445.80	539,000
Total Storage Volume	NA	34,568,317	NA	32,250,000

1 Projected initial conditions based on August 2006 24-Month Study.
2 Projected initial conditions based on June 2007 24-Month Study.
msl: mean sea level
af: acre-foot

A.4 Reservoirs Upstream of Lake Powell

The reservoirs upstream of Lake Powell are operated to meet monthly storage targets (or “rule curves”) and downstream demands. The basic procedure is that given the inflow for the current month, the release will be either the release necessary to meet the target storage, or the release necessary to meet demands downstream of the reservoir, whichever is greater. The rule curves are input for each reservoir, but are modified during the simulation for Flaming Gorge, Blue Mesa, and Navajo to simulate operations based on the imperfect inflow forecasts that are encountered in actual reservoir operations. Furthermore, each reservoir is constrained to operate within user-supplied minimum and maximum releases (mean monthly release in cubic feet per second [cfs]) as specified in Table A-2.

Table A-2
Release Constraints for Reservoirs Upstream of Lake Powell

Reservoir	Minimum Release (cfs)	Maximum Release (cfs)
Fontenelle	500	18,700
Flaming Gorge	800	4,900
Starvation	100	5,000
Taylor Park	50	5,000
Blue Mesa	270	5,000
Morrow Point	300	5,000
Crystal	300	4,200
Navajo	300	5,900

For Flaming Gorge, Blue Mesa, and Navajo, the target storage is computed by using an inflow forecast for the period January through July, again to mimic the imperfect forecasts seen in actual operations. The inflow forecast (for the current month through July) is computed as a weighted average of the long-term average natural inflow and the natural inflow assumed for the year being modeled. The weights used are listed in Table A-3.

Table A-3
Weights for Inflow Forecast for Reservoirs Upstream of Lake Powell

Month	Natural Inflow Weight	Average Natural Inflow Weight
January	0.3	0.7
February	0.4	0.6
March	0.5	0.5
April	0.7	0.3
May	0.7	0.3
June	0.7	0.3
July	0.6	0.4

The long-term, average natural inflows into the Flaming Gorge, Blue Mesa and Navajo reservoirs are listed in Table A-4 (in thousand acre-feet [kaf]).

Table A-4
Average Natural Inflows for Reservoirs Upstream of Lake Powell (kaf)

Reservoir	Jan	Feb	Mar	Apr	May	Jun	Jul
Flaming Gorge	23.3	20.9	33.8	87.9	250.4	327.8	157.5
Blue Mesa	34.0	39.5	94.6	176.0	339.8	561.6	346.8
Navajo	18.8	24.6	69.3	176.9	297.3	284.7	120.1

Based on the inflow forecast, the rule computes the volume necessary to release from the current month through July, assuming the reservoir will fill in July:

> Release needed for the current month = (current contents - live capacity + predicted remaining inflow) divided by the number of months remaining until the end of July

The target storage for the current month is then computed, adjusting the storage at the end of the previous month for any gains or losses upstream of the reservoir:

> Target storage = previous storage - release needed + gains – losses

A.5 Lake Powell Operation

The operation of Lake Powell depends on a rule curve consisting of a forecast-driven operation from January through July that attempts to fill the reservoir to July target storage, and an operation from August through December that attempts to draw down the reservoir to December target storage. The July and December targets are 23.822 million acre-feet (maf) (500,000 af of space) and 21.900 maf (2.422 kaf of space), respectively. Another rule simulates the occurrence of Beach/Habitat-Building Flows (BHBFs or spike flows). Two other higher priority rules ensure that the minimum objective release of 8.23 million acre-feet per year (mafy) is met and that equalization of Lake Powell and Lake Mead is accomplished when necessary. Release constraints that reflect the 1996 Record of Decision on the Operation of Glen Canyon Dam are also part of the Lake Powell rule set.

Sections A.5.1 through A.5.6 that follow describe modeling assumptions for Lake Powell operation that are common to all six alternatives. A summary comparison of the Lake Powell operational strategy for each alternative is provided in Attachment A to this Appendix (Table Att. A-1).

A.5.1 Lake Powell Inflow Forecast

The unregulated Lake Powell inflow forecast from the current month through July is computed as

> unregulated Lake Powell inflow = natural flow into Lake Powell - estimated Upper Basin depletions + the forecast error
>
> where: the forecast error is computed using equations derived from an analysis of past Colorado River forecasts and runoff data for the period 1947 to 1983.

An analysis of these data reveals two strongly established patterns: (1) high runoff years are under-forecast, and low runoff years are over-forecast; and (2) the error in the current month's seasonal forecast is strongly correlated with the error in the preceding month's forecast (Reclamation 1985). A regression model was developed to aid in determining the error to be incorporated into the seasonal forecast for each month from January to June. The error is the sum of a deterministic component and a random component. The deterministic component is computed from the regression equation. The random component is computed by multiplying the standard error of the regression equation by a random mean deviation selected from a standard normal distribution.

The forecast error equation has the following form (all runoff units are maf):

$$E_i = a_i X_i + b_i E_{(i-1)} + c_i + Z_r d_i$$

where:

i = month,

E_i = error in the forecast for month "i,"

X_i = natural runoff into Lake Powell from month "i" through July,

a_i = linear regression coefficient for Xi,

$E_{(i-1)}$ = previous month's forecast error,

b_i = linear regression coefficient for E(i-1),

c_i = constant term in regression equation for month "i,"

Z_r = randomly determined deviation, and

d_i = standard error of estimate for regression equation for month "i."

Table A-5 summarizes the regression equation coefficients for each month.

Table A-5
Lake Powell Inflow Forecast Regression Equation Coefficients

Month	a_i	b_i	c_i	d_i
January	0.70	0.00	-8.195	1.270
February	0.00	0.80	-0.278	0.977
March	0.00	0.90	0.237	0.794
April	0.00	0.76	0.027	0.631
May	0.00	0.85	0.132	0.377
June	0.24	0.79	0.150	0.460

The magnitude of the June forecast error is constrained to not exceed 50 percent of the May forecast error and the July forecast error is equal to 25 percent of the June forecast error.

A.5.2 January through July Operation

To accomplish the operation from January through July, the unregulated forecast is first adjusted to account for potential reservoir regulation upstream of Lake Powell. This potential regulation is currently computed as just the sum of the available space (live capacity – previous month’s storage) in Fontenelle, Flaming Gorge, Blue Mesa, and Navajo reservoirs. Using the regulated forecast inflow, the total volume of water necessary to release from the current month through July is computed as

total volume to release = end of previous month’s storage – July target storage + forecast regulated inflow – loss due to evaporation – loss due to bank storage

The release for the current month is then computed by multiplying the total volume to release by a fraction for the current month, where the fraction reflects a user-supplied preferred weighting pattern. The weights and resulting fractions used for this study are listed in Table A-6.

Table A-6
Lake Powell January through July Operation Weights and Resulting Fractions

Month	Weights	Fractions
January	0.170	0.170
February	0.160	0.193
March	0.130	0.194
April	0.100	0.185
May	0.100	0.227
June	0.160	0.471
July	0.180	1.000

The fraction is computed as current month's weight divided by the sum of the current and remaining month's weights for the season.

During the operation from January through July, the computed release is constrained to be at least as great as the total volume divided by the number of months remaining. This constraint ensures that sufficient water is released early during high forecast years. Lake Powell’s operational release during January through July is further constrained in each month to be within a minimum and maximum range (currently set to 6,500 and 25,000 cfs, respectively).

An additional constraint is placed on computed monthly release during spill avoidance. If the calculated average flow for a given month is in excess of 1.0 maf, then it is held to a maximum of 1.0 maf each month.

A.5.3 August through December Operation

Conceptually, the computation for the operation from August through December is identical to the computation made for the operation from January through July. The regulated inflow forecast is simply the natural inflow, adjusted for Upper Basin depletions, and potential reservoir regulation with no forecast error added. The potential reservoir regulation is again computed as the sum of the available space in Fontenelle, Flaming Gorge, Blue Mesa, and Navajo reservoirs, where the space is the target storage in December for each reservoir minus the end of the previous month’s storage. User-supplied weights are also used to compute the current month release from the total volume to release. The weights and resulting fractions are listed in Table A-7.

Table A-7
Lake Powell August through December Operation Weights and Resulting Fractions

Month	Weights	Fractions
August	0.266	0.266
September	0.200	0.272
October	0.156	0.292
November	0.156	0.413
December	0.222	1.000

Two additional constraints are placed on the computed monthly release to ensure a smooth operation. In July, the release is constrained to be at least 1.0 maf if Lake Powell's storage is greater than 23.0 maf. From July through December, the release is constrained to not exceed 1.5 maf, as long as a 1.5 maf release results in storage at Lake Powell less than 23.822 maf. Lake Powell's operational release during August through December is further constrained in each month to be within a minimum and maximum range (currently set to 6,500 and 25,000 cfs, respectively).

A.5.4 602(a) Storage Requirement

The 602(a) storage requirement refers to the quantity of water required to be in storage in the Upper Basin so as to assure future deliveries to the Lower Basin without impairing annual consumptive uses in the Upper Basin (Bureau of Reclamation 1985). The current implementation of that storage requirement duplicates the original CRSS calculation. It computes a storage amount necessary in the Upper Basin to meet the minimum objective release and Upper Basin depletions over the next "n" years, assuming the inflow over that period would follow that seen in the most "critical period on record." The critical period in the Colorado River basin occurred in 1953 through 1964, a length of 12 years. Inflows from these years are used in the calculation of 602(a) storage.

At the beginning of each calendar year, a value for 602(a) storage is computed by the following formula:

602a = {(UBDepletion + UBEvap)* (1 – percentShort/ 100) + minObjRel – criticalPeriodInflow} * 12 + minPowerPoolStorage

where:

602a	=	the 602(a) storage requirement
UBDepletion	=	the average over the next 12 years of the Upper Basin scheduled depletions
UBEvap	=	the average annual evaporation loss in the Upper Basin (currently set to 560 kaf)
percentShort	=	the percent shortage that will be applied to Upper Basin depletions during the critical period (currently set to zero)
minObjRel	=	the minimum objective release to the Lower Basin (currently set to 8.23 maf)
criticalPeriodInflow	=	average annual natural inflow into the Upper Basin during the critical period (1953–1964) (currently set to 12.18 maf)
minPowerPoolStorage	=	the amount of minimum power pool to be preserved in Upper Basin reservoirs (currently set to 5.179 maf)

All parameter values currently used were as found in the original CRSS data files converted from the Cyber mainframe in 1994.

Additionally, since 2004, the Interim 602(a) Storage Guideline (69 Fed. Reg. 28945) has been included in CRSS. This guideline necessitates that for the 602(a) storage requirement to be met, Lake Powell storage must be greater than 14.85 maf (elevation 3,630 feet msl) on September 30. This interim guideline provides guidance to the Secretary in making a determination of the quantity of water considered necessary as of September 30 of each year to assist in implementation of and as required by Article II(1) of the 1970 Criteria for Coordinated Long-Range Operation of Colorado River Reservoirs (Long-Range Operating Criteria or LROC) pursuant to the Colorado River Basin Project Act of September 30, 1968. The interim guideline specifies that:

1. through the year 2016, 602(a) storage requirements determined in accordance with Article II(1) of the LROC shall utilize a value of not less than 14.85 maf (elevation 3,630 feet msl) for Lake Powell. Accordingly, when projected September 30 Lake Powell storage is less than 14.85 maf (elevation 3,630 feet msl), the objective will be to maintain a minimum annual release of water from Lake Powell of 8.23 maf, consistent with Article II(2) of the LROC;

2. under the current area-capacity relationship at Lake Powell, a reservoir elevation of 3,630 feet msl corresponds to 14.85 maf of storage. In the event that a sediment survey is performed at Lake Powell and a revised area-capacity relationship is determined before 2016, the revised water storage volume that correlates with the

reservoir elevation of 3,630 feet msl at Lake Powell shall be used in Section V(1) of this Interim 602(a) Storage Guideline; and

3. the Interim 602(a) Storage Guideline shall be utilized in the operation of the Colorado River from 2005 through 2016. This guideline will first be implemented in the development of the 2005 Colorado River Annual Operating Plan (AOP) and for all subsequent AOPs through 2016.

In the modeling for the Final EIS, the Interim 602(a) Storage Guideline is in effect through 2016. In the CRSS simulation, following the 602(a) storage computation described above, a subsequent rule checks to see if Lake Powell elevation is above 3,630 feet msl on September 30. The 602(a) requirement is not met if projected September 30 elevation of Lake Powell is below 3,630 feet msl, through 2016.

A.5.5 Predicting End-of-Water Year Volumes of Lake Powell and Lake Mead

Lake Powell end-of-water year (EOWY) volume is predicted each month by taking the end of the previous month's storage, adding the estimated inflow, subtracting the estimated release, and subtracting the estimate of evaporation and change in bank storage. All estimated values are for the period from the current month through September. The estimated inflow is just the regulated inflow forecast previously discussed, where the forecast error is included through July. The estimated release is based on the operation from January through July and the operation for August and September. The estimated evaporation and bank storage losses are based on an initial estimate of the EOWY volume.

Similarly, the Lake Mead EOWY volume is predicted each month by taking the end of previous month's volume, adding the estimated Lake Powell release, subtracting the estimated Lake Mead release, adding the average gain between Lake Powell and Lake Mead, subtracting the Southern Nevada depletion, and subtracting the estimate of evaporation and change in bank storage. Again, all values are for the period from the current month through September. Lake Mead's release is estimated as the sum of the depletions downstream of Lake Mead and the reservoir regulation requirements (including evaporation losses) for Lake Mohave and Lake Havasu minus the gains below Lake Mead.

The changes in volume of water storage in Lake Powell and Lake Mead are calculated by the model using relationship curves that are programmed into the model. These relationship curves correlate the water surface elevation to live capacity, total capacity, and surface area for each respective reservoir. Tables which present the corresponding values for the range of operational elevations at Lake Powell and Lake Mead are provided in Attachment B to this appendix (Table Att. B-1 and Table Att. B-2, respectively).

A.5.6 Beach/Habitat-Building Flows

Under the current rule that implements BHBFs, a BHBF is triggered for the current month if the following conditions are met:

- in January, if the unregulated inflow forecast for January through July (the natural flow – Upper Basin depletions plus forecast error) is greater than the “January trigger volume” (currently set to 13.0 maf); and

- in January through July, if the current month’s Lake Powell release is greater than the “release trigger” (currently set to 1.5 maf) or if the release volume for the current month through July equally distributed over those months would result in a release greater than the release trigger.

Once a BHBF has been triggered, if Lake Powell would have had to spill in that month anyway, the total outflow from Lake Powell is not increased; rather the volume for the BHBF (currently set to 200 kaf) is taken from the total outflow already determined by the operational rule. If Lake Powell was not going to spill in that month, then the total outflow from Lake Powell is increased (i.e., the volume for the BHBF is taken from Lake Powell’s storage). Under the case where the BHBF is triggered even though the current month’s release is less than the release trigger, the rule re-sets Lake Powell’s outflow for that month to the trigger release amount (1.5 maf).

Under all circumstances, only one BHBF is made per calendar year in the model.

A.5.7 Minimum Objective Release

A minimum objective release is required from Lake Powell only under the No Action Alternative, as discussed below. The minimum release required under the action alternatives varies by alternative and Lake Powell volume. These releases are described in Section A.5.9.

A.5.7.1 No Action Alternative

Under the No Action Alternative, a higher priority rule ensures that the previously described Lake Powell operation will satisfy a minimum objective release to the Lower Basin, currently equal to 8.23 maf over each water year (October through September). Similar to the weighting and release fraction scheme used for the operational rule, a preferred release pattern for each month to meet the minimum objective release is supplied and a fraction is computed. The release pattern (in kaf) and resulting fractions are listed in Table A-8.

Table A-8
Lake Powell Release Pattern and Resulting Fractions
No Action Alternative

Month	8,230 kaf	
	Release (kaf)	Fraction
October	600	0.073
November	600	0.079
December	800	0.114
January	800	0.128
February	600	0.110
March	600	0.124
April	600	0.142
May	600	0.165
June	650	0.215
July	850	0.357
August	900	0.588
September	630	1.000
Total	8,230	-----

The fraction is computed as current month's release divided by the sum of the current and remaining months' releases through September.

Each month the rule computes the volume of water remaining to meet the minimum objective release for the current water year (accounting for the water released previously in the water year) and multiplies that volume by the release fraction. The release determined by the operational rule must then be at least as great as this resulting minimum objective release for the month.

A.5.8 Equalization of Lake Powell and Lake Mead

A.5.8.1 No Action Alternative

Under the No Action Alternative, the equalization of storage between Lake Powell and Lake Mead is implemented in a rule that accurately models the past and current operations of equalization at Glen Canyon Dam. The rule first determines if equalization needs to occur, and if so, determines how much water to release from Lake Powell to accomplish it. The rule is in effect from January through September of each year. The rule states that equalization needs to occur if two criteria are met: (1) if the storage in the Upper Basin meets the 602(a) storage requirement; and (2) if the projected EOWY storage in Lake Powell is greater than that in Lake Mead.

The storage in the Upper Basin is computed for each month (January through September) and consists of the predicted EOWY storage in Lake Powell, plus the sum of the end of previous month's storage for Flaming Gorge, Blue Mesa, and Navajo reservoirs. That storage is then compared to the computed value of 602(a) storage, described above, to determine if the 602(a) storage requirement is met each month. The method of estimating the EOWY storage is described above.

The release for equalization is computed by taking half of the difference between the predicted EOWY volumes of Lake Powell and Lake Mead and dividing by the number of months remaining through September. Evaporation and bank storage losses at Lake Powell and Lake Mead are included in the calculation, resulting in an iterative procedure to arrive at the computed equalization release. The iteration stops when the forecast EOWY volumes of Lake Powell and Lake Mead are within a user-specified tolerance. That tolerance is currently set to 250,000 af.

The computed equalization release for each month is constrained in three ways: (1) if the additional release due to equalization would cause the total Upper Basin storage to drop below the 602(a) storage requirement, then the amount of the equalization release can be adjusted downward but cannot be reduced below 8.23 maf; (2) the equalization release is reduced if it would cause Lake Mead volumes to exceed its exclusive flood control space; and (3) the equalization release is constrained to be not greater than 25,000 cfs, the maximum normal release as per the Glen Canyon Operating Criteria.

A.5.8.2 Basin States Alternative

Under the Basin States Alternative, the equalization of storage between Lake Powell and Lake Mead is implemented in a rule that first determines if equalization needs to occur, and if so, then determines how much water to release from Lake Powell to accomplish it. The rule is in effect from January through September of each year. The rule states that equalization needs to occur if two criteria are met: (1) if the EOWY elevation of Lake Powell is predicted to be equal to or higher than the Equalization Level (see Table A-9); and (2) if the EOWY storage in Lake Powell is greater than EOWY storage in Lake Mead. The Basin States Alternative substitutes the 602(a) Storage and Interim 602(a) Storage Guideline with the Equalization Level for each year 2008 through 2026.

In years when Lake Powell EOWY elevation is projected to be equal to or above the Equalization Level and the EOWY volume of Lake Powell is projected to be above the EOWY volume of Lake Mead, a volume of water greater than 8.23 maf is scheduled for annual release from Lake Powell to the extent necessary to equalize storage in the two reservoirs. Otherwise, if Lake Powell EOWY volume is not higher than Lake Mead EOWY volume, the annual release volume from Lake Powell is scheduled at 8.23 maf.

The release for equalization is computed by taking half of the difference between the predicted EOWY volumes of Lake Powell and Lake Mead and dividing by the number of months remaining through September. Evaporation and bank storage losses at Lake Powell and Lake Mead are included in the calculation, resulting in an iterative procedure to arrive at the computed equalization release. The iteration stops when the forecast EOWY volumes of Lake Powell and Lake Mead are within a user-specified tolerance. That tolerance is currently set to 250,000 af.

Table A-9
Lake Powell Equalization Elevation
Basin States Alternative

Year	Equalization Elevation (feet msl)
2008	3,636
2009	3,639
2010	3,642
2011	3,643
2012	3,645
2013	3,646
2014	3,648
2015	3,649
2016	3,651
2017	3,652
2018	3,654
2019	3,655
2020	3,657
2021	3,659
2022	3,660
2023	3,662
2024	3,663
2025	3,664
2026	3,666

The computed equalization release for each month is constrained in three ways: (1) if the additional release due to equalization would cause the Lake Powell EOWY elevation to drop below the Equalization Line, then the amount of the equalization release is reduced to prevent this from happening; (2) the equalization release is reduced if it would cause Lake Mead volumes to exceed its exclusive flood control space; and (3) the equalization release is constrained to be not greater than 25,000 cfs, the maximum normal release as per the Glen Canyon Operating Criteria.

A.5.8.3 Conservation Before Shortage Alternative
The equalization method for Lake Powell under the Conservation Before Shortage Alternative is identical to that of the Basin States Alternative.

A.5.8.4 Water Supply Alternative
The equalization criteria for Lake Powell under the Water Supply Alternative are identical to those of the No Action Alternative.

A.5.8.5 Reservoir Storage Alternative
The equalization criteria for Lake Powell under the Reservoir Storage Alternative are identical to those of the No Action Alternative.

A.5.8.6 Preferred Alternative

The equalization method for Lake Powell under the Preferred Alternative is identical to that of the Basin States and Conservation Before Shortage Alternatives.

A.5.9 Water Year Releases When Equalization Does Not Apply

A.5.9.1 No Action Alternative

Under the No Action Alternative, Lake Powell water releases are constrained by the minimum objective release as described in Section A.5.7.

A.5.9.2 Basin States Alternative

Under the Basin States Alternative, when the EOWY level of Lake Powell is below the Equalization Level (see Table A-9), a higher priority rule ensures that the Lake Powell operation will satisfy a water year release to the Lower Basin, between 7.00 maf and 9.50 maf, depending on elevations in Lake Powell and Lake Mead. Similar to the weighting and release fraction scheme used for the operational rule in the No Action Alternative, a preferred release pattern for each month to meet the water year release is supplied and a fraction is computed. The fraction is computed as current month’s release divided by the sum of the current and remaining months’ releases through September. Each month the rule computes the volume of water remaining to meet the release for the current water year (accounting for the water released previously in the water year) and multiplies that volume by the release fraction. The release determined by the operational rule must then be at least as great as this resulting release for the month.

Specific release patterns (in kaf) and resulting fractions for the Basin States Alternative are provided in Table A-10.

Table A-10
Lake Powell Release Patterns and Resulting Fractions
Basin States Alternative

Total Release	7,000 kaf		7,480 kaf		8,230 kaf		9,000 kaf		9,500 kaf	
Month	Release (kaf)	Fraction	Release (kaf)	Fraction	Release (kaf)	Fraction	Release (kaf)	Fraction	Release (kaf)	Fraction
October	480	0.069	480	0.064	600	0.073	600	0.067	600	0.063
November	500	0.077	500	0.071	600	0.079	600	0.071	600	0.067
December	600	0.100	600	0.092	800	0.114	800	0.103	800	0.096
January	600	0.111	800	0.136	800	0.128	800	0.114	850	0.113
February	600	0.124	600	0.118	600	0.110	650	0.105	650	0.098
March	500	0.118	600	0.133	600	0.124	650	0.117	650	0.108
April	500	0.134	500	0.128	600	0.142	600	0.122	650	0.121
May	500	0.155	600	0.176	600	0.165	650	0.151	800	0.170
June	600	0.221	600	0.214	650	0.215	800	0.219	900	0.231
July	800	0.377	800	0.364	850	0.357	1,000	0.351	1,050	0.350
August	800	0.606	800	0.571	900	0.588	1,050	0.568	1,100	0.564
September	520	1.000	600	1.000	630	1.000	800	1.000	850	1.000
Total	7,000	-----	7,480	-----	8,230	-----	9,000	-----	9,500	-----

In years when Lake Powell EOWY elevation is projected to be lower than the Equalization Level and equal to or above 3,575 feet msl, and the projected Lake Mead EOWY elevation is equal to or above 1,075 feet msl, then the annual release volume is scheduled to be 8.23 maf. If the projected Lake Mead EOWY elevation is below 1,075 feet msl, however, then a volume of water is scheduled for annual release from Lake Powell to the extent necessary to balance storage in the two reservoirs, constrained by being no more than 9.00 maf and no less than 7.00 maf.

In years when Lake Powell EOWY elevation is projected to be lower than 3,575 feet msl and at or above 3,525 feet msl, and the projected Lake Mead EOWY elevation is equal to or above 1,025 feet msl, then the annual release volume is scheduled at 7.48 maf. However, if Lake Powell EOWY elevation is projected to be lower than 3,575 feet msl and at or above 3,525 feet msl, but the projected Lake Mead EOWY elevation is below 1,025 feet msl, then the annual release volume is scheduled at 8.23 maf.

In years when Lake Powell EOWY elevation is projected to be below 3,525 feet msl, then a volume of water is scheduled for annual release from Lake Powell to the extent necessary to balance storage in the two reservoirs, constrained by being no more than 9.50 maf and no less than 7.00 maf.

A.5.9.3 Conservation Before Shortage Alternative

Water year releases for Lake Powell under the Conservation Before Shortage Alternative are identical to those of the Basin States Alternative.

A.5.9.4 Water Supply Alternative

Under the Water Supply Alternative, when projected EOWY storage in the Upper Basin is less than the 602(a) storage requirement, a higher priority rule ensures that the Lake Powell operation will satisfy a water year release to the Lower Basin between 7.00 maf and 9.50 maf, depending on projected EOWY elevations in Lake Powell and Lake Mead. Similar to the weighting and release fraction scheme used for the operational rule, a preferred release pattern for each month to meet the water year release is supplied and a fraction is computed. The fraction is computed as current month's release divided by the sum of the current and remaining months' releases through September. Each month the rule computes the volume of water remaining to meet the release for the current water year (accounting for the water released previously in the water year) and multiplies that volume by the release fraction. The release determined by the operational rule must then be at least as great as this resulting release for the month.

Specific release patterns (in kaf) and resulting fractions for the Water Supply Alternative are provided in Table A-11.

In years when the Lake Powell EOWY volume is projected to be below the 602(a) storage requirement and equal to or above 3,575 feet msl, and the projected Lake Mead EOWY elevation is equal to or above 1,075 feet msl, then the annual release volume is scheduled to be 8.23 maf. If the projected Lake Mead EOWY elevation is below 1,075 feet msl, however, then a volume of water is scheduled for annual release from Lake Powell to the extent necessary to balance storage in the two reservoirs, constrained by being no more than 9.50 maf and no less than 7.00 maf.

In years when the Lake Powell EOWY elevation is projected to be less than 3,575 feet msl, then a volume of water is scheduled for annual release from Lake Powell to the extent necessary to balance storage in the two reservoirs, constrained by being no more than 9.50 maf and no less than 7.00 maf.

Table A-11
Lake Powell Release Patterns and Resulting Fractions
Water Supply Alternative

Total Release	7,000 kaf		8,230 kaf		9,500 kaf	
Month	Release (kaf)	Fraction	Release (kaf)	Fraction	Release (kaf)	Fraction
October	480	0.069	600	0.073	600	0.063
November	500	0.077	600	0.079	600	0.067
December	600	0.100	800	0.114	800	0.096
January	600	0.111	800	0.128	850	0.113
February	600	0.124	600	0.110	650	0.098

September	520	1.000	630	1.000	850	1.000
Total	7,000	-----	8,230	-----	9,500	-----

A.5.9.5 Reservoir Storage Alternative

Under the Reservoir Storage Alternative, when projected EOWY storage in the Upper Basin is less than the 602(a) storage requirement, a higher priority rule ensures that the Lake Powell operation will satisfy a water year release to the Lower Basin between 7.80 maf and 9.50 maf, depending on projected EOWY elevations in Lake Powell and Lake Mead. Similar to the weighting and release fraction scheme used for the operational rule, a preferred release pattern for each month to meet the water year release is supplied and a fraction is computed. The fraction is computed as current month’s release divided by the sum of the current and remaining months’ releases through September. Each month the rule computes the volume of water remaining to meet the release for the current water year (accounting for the water released previously in the water year) and multiplies that volume by the release fraction. The release determined by the operational rule must then be at least as great as this resulting release for the month.

Specific release patterns (in kaf) and resulting fractions for the Reservoir Storage Alternative are provided in Table A-12.

Table A-12
Lake Powell Release Patterns and Resulting Fractions
Reservoir Storage Alternative

Total Release	7,800 kaf		8,230 kaf		9,500 kaf	
Month	Release (kaf)	Fraction	Release (kaf)	Fraction	Release (kaf)	Fraction
October	600	0.077	600	0.073	600	0.063
November	600	0.083	600	0.079	600	0.067
December	600	0.091	800	0.114	800	0.096
January	800	0.133	800	0.128	850	0.113
February	600	0.115	600	0.110	650	0.098
March	600	0.130	600	0.124	650	0.108
April	600	0.150	600	0.142	650	0.121
May	600	0.176	600	0.165	800	0.170
June	600	0.214	650	0.215	900	0.231
July	800	0.364	850	0.357	1,050	0.350
August	800	0.571	900	0.588	1,100	0.564
September	600	1.000	630	1.000	850	1.000
Total	7,800	-----	8,230	-----	9,500	-----

In years when Lake Powell EOWY volume is projected to be below the 602(a) storage requirement, and Lake Powell EOWY elevation is equal to or above 3,595 feet msl, then the annual release volume is scheduled at 8.23 maf.

In years when the Lake Powell EOWY elevation is projected to be lower than 3,595 feet msl and equal to or above 3,560 feet msl, then the annual release volume is scheduled at 7.80 maf.

In years when Lake Powell EOWY elevation is projected to be below 3,560 feet msl, the annual release is scheduled at the volume of water required to balance the volumes of Lake Powell and Lake Mead, constrained by being no more than 9.50 maf and no less than 7.80 maf.

A.5.9.6 Preferred Alternative

Water year releases for Lake Powell under the Preferred Alternative are identical to those of the Basin States and Conservation Before Shortage alternatives.

A.6 Lake Mead Operation

Lake Mead is operated primarily to meet downstream demands, including downstream depletions (both United States and Mexico) and reservoir regulation requirements. In any month, the rule computes the downstream depletions based on schedules that have been set as input data (or by other rules) and the amount of water necessary to meet the storage targets for downstream Lake Mohave and Lake Havasu and to overcome evaporation losses at those lakes. The rule sets the total release necessary each month from Lake Mead to meet the total downstream demand, taking into account gains and losses below Lake Mead.

The depletions from Lake Mead and downstream of Hoover Dam are affected by the determination of the water supply conditions (Normal, Surplus, or Shortage). Additional rules determine the water supply condition and set the appropriate depletion schedule for the entities affected, as described in Sections A.6.2 and A.6.3.

Under certain conditions, Lake Mead may release water in addition to downstream demand. This condition is termed “flood control” and is guided by the United States Army Corps of Engineers’ (USACE) flood control regulations as contained in the USACE’s Water Control Manual for Flood Control, Hoover Dam and Lake Mead, Colorado River, Nevada and Arizona (Water Control Manual) dated December 1982. These flood control operations and their simulation in the CRSS model are described in Section A.6.1.

A.6.1 Lake Mead/Hoover Dam Flood Control

There are three flood control procedures currently in effect for different times of the year. These procedures were developed in the original CRSS and are based on the Field Working Agreement between Reclamation and the USACE (United States Army Corps of Engineers 1982). The first procedure is in effect throughout the year. Its objective is to maintain a minimum space of 1.5 maf in Lake Mead, primarily for extreme rain events. This space is referred to as the exclusive flood control space and is represented by the space above elevation 1,219.61 feet msl. The second procedure is used during the period from January through July. The objective during this period is to route the maximum inflow forecast through the reservoir system using specific rates of Hoover Dam discharge, assuming that Lake Mead will fill to elevation 1,219.61 feet msl at the end of July. The third procedure is used during the space building or drawdown period (August through December). The objective during this period is to gradually draw down the reservoir system to meet the total system space requirements in each month in anticipation of the next year’s runoff.

A.6.1.1 Exclusive Flood Control Space Requirement

This requirement states that there must be a minimum space of 1.5 maf in Lake Mead at all times. If the release computed to meet downstream demand results in a Lake Mead storage that would violate this space requirement, the rule computes the additional release necessary to maintain that space.

A.6.1.2 January through July Operation

The flood control policy requires that the maximum forecast be used where that forecast is defined as the estimated inflow volume that, on average, will not be exceeded 19 times out of 20 (a 95 percent non-exceedance). The rule first computes the inflow forecast to Lake Mead by taking the Lake Powell forecast (Section A.5) and adds the long-term, average natural tributary inflows between Lake Powell and Lake Mead. The maximum forecast is then estimated by adding an additional volume (the “forecast error term”) to that inflow forecast. The forecast error term (in maf) is provided in Table A-13, taken from the original CRSS data.

Table A-13
Lake Mead January through July Forecast Error

Forecast Period	Forecast Error Term (maf)
January – July	4.980
February – July	4.260
March – July	3.600
April – July	2.970
May – July	2.525
June – July	2.130
July – July	0.750

The Field Working Agreement defines an iterative algorithm by which the current month's release (in cfs) is determined. Certain release levels are specified, as listed in Table A-14.

Table A-14
Lake Mead Flood Control Release Levels

Release Level	Release (cfs)	Description
1	19,000	Parker Powerplant capacity
2	28,000	Davis Powerplant capacity
3	35,000	Hoover Powerplant capacity (in 1987)
4	40,000	Approximate maximum flow non-damaging to streambed
5	73,000	Hoover Dam controlled discharge capacity

The flood control release needed for the current month is determined by:

> release needed for the current month = maximum forecast inflow – current storage space in Lake Powell (below 3,700 feet msl) – current storage space in Lake Mead (below 1,229 feet msl) + 1.5 maf (exclusive space) – evaporation and bank storage losses from Lake Powell and Lake Mead – Southern Nevada depletion – future volume of water released (assuming a release level from Table A-14 for the remaining months through July)

If the computed release for the current month is greater than that assumed for the future months, the future level is increased and the current month release is re-computed. The computation stops once the computed release for the current month is less than or equal to that assumed for the future months. If the computed release is greater than the previously assumed level, that release is used for the current month; otherwise, the previously assumed level is used.

The rule sets Lake Mead's release to the flood control release if it is greater than the release previously computed to meet downstream demands.

A.6.1.3 Space Building (August to December)

The flood control policy states the flood control storage space (in maf) in Lake Mead (storage below elevation 1,229 feet msl) required at the beginning of each month from August through January, as listed in Table A-15.

Table A-15
Lake Mead Flood Control Required Storage Space

Date	Required Storage Space (maf)
August	1.50
September	2.27
October	3.04
November	3.81
December	4.58
January	5.35

However, these targets may be reduced to the minimum of 1.5 maf in each month if additional space is available upstream in live storage. Certain upstream reservoirs are specified with a maximum creditable space (in maf) that can be applied towards the total required flood control space. The creditable storage space allowed for each of these reservoirs is listed in Table A-16.

Table A-16
Lake Mead Flood Control Maximum Creditable Storage Space

Reservoir	Maximum Creditable Storage Space (maf)
Powell	3.8500
Navajo	1.0359
Blue Mesa	0.7485
Flaming Gorge plus Fontenelle	1.5072

In each month (July through December), if the release computed to meet downstream demands results in an end-of-month Lake Mead storage that would violate the space requirement adjusted for upstream storage, the rule computes the additional release necessary to maintain that space. However, these releases are constrained to be less than or equal to 28,000 cfs.

A.6.2 Lower Basin Surplus Strategies

Under the No Action Alternative, the Interim Surplus Guidelines (ISG) are assumed to be in effect through 2016. Beginning in 2017, surpluses are determined based on the 70R Strategy (Section A.6.2.4.). The action alternatives use some or all of the surplus conditions and vary by the duration that each type is in effect. A summary comparison of the surplus strategy for each alternative is provided in Attachment A to this appendix (Table Att. A-2). Surplus schedules by entity are provided in Appendix D. The ISG are specified in the Record of Decision (ROD), Colorado River ISG, Final Environmental Impact Statement, January 2001, and the model implements those as follows:

A.6.2.1 Normal Conditions

If the model determines that neither surplus or shortage conditions exists, the model assigns the Normal schedules to all diversion points in the Lower Basin. The Normal schedules total 7.5 maf of annual consumptive use in the Lower Basin.

A.6.2.2 Partial Domestic Surplus

If the modeled January 1 Lake Mead elevation is at or above 1,125 feet msl and below 1,145 feet msl, the model assigns the Partial Domestic Surplus schedules to Metropolitan Water District of Southern California (MWD) and the Southern Nevada Water Authority (SNWA). All other diversion points remain at Normal schedules. The Partial Domestic Surplus schedules yield the amount of surplus for MWD and SNWA as specified in the ROD, and are documented in the Final Environmental Impact Statement, Implementation Agreement, Inadvertent Overrun and Payback Policy, and Other Federal Actions (SIA-EIS, Bureau of Reclamation 2002).

A.6.2.3 Full Domestic Surplus

If the modeled January 1 Lake Mead elevation is at or above 1,145 feet msl but below the spill avoidance strategy assuming the runoff value of the 70^{th} percentile of exceedance based on the historic record of runoff above Lake Powell (i.e., the 70R Strategy), the model assigns the Full Domestic Surplus schedules to MWD and SNWA. All other diversion points remain at Normal schedules. The Full Domestic Surplus schedules yield the amount of surplus for MWD and SNWA as specified in the ROD, and are documented in the Implementation Agreement Final EIS (Reclamation 2002).

A.6.2.4 Quantified Surplus (70R Strategy)

Under the 70R Strategy, a surplus condition is based on the system space requirement at the beginning of each year. Based on the 70^{th} percentile historical runoff, a normal 7.5 maf delivery to the Lower Division states, the Upper Basin scheduled use, and Lake Powell and Lake Mead volumes at the beginning of the year, the volume of water in excess of the system space requirement at the end of the year is estimated. If that volume is greater than zero, a Surplus is declared. The quantity of the surplus volume (*SurVol*) is computed as follows:

SurVol = (PowellStorage + MeadStorage – maxStorage)* (1 + aveBankStorCoef) + runoff – UBDemand – LBDemand

Where:

Powell Storage	=	Lake Powell storage at the beginning of the year
Mead Storage	=	Lake Mead storage at the beginning of the year
maxStorage	=	maximum combined storage of Lake Powell and Lake Mead that will meet the system space requirement at the beginning of the year, assuming 30% of that requirement will be met by the reservoirs upstream of Lake Powell (computed as live capacity of Lake Powell and Lake Mead – 70% * Lake Mead space requirement at the beginning of the year equal to 5.35 maf = 47.96 maf)
aveBankStorCoef	=	average of Lake Powell and Lake Mead bank storage coefficients
runoff	=	assumed percentile runoff
UBDemand	=	Upper Basin depletion scheduled for the year + the average evaporation loss in the Upper Basin (same as assumed in the 602(a) calculation, 560 kaf)
LBDemand	=	sum of depletions below Lake Powell + the evaporation losses in the Lower Basin (average loss of 900 kaf at Lake Mead and computed for Lake Mohave and Lake Havasu, based on target storage) – average gains between Lake Powell and Lake Mead – average gains below Lake Mead

Once the quantity of surplus volume is known, the model computes each state's share (50 percent to California, 46 percent to Arizona, and 4 percent to Nevada). The model then assigns the Full Domestic Surplus schedules to MWD and SNWA. Arizona's share of the surplus is assigned to the Central Arizona Project (CAP), up to their Full Surplus schedule. If surplus water is still available for California, up to 300 kaf is made available to the Imperial Irrigation District (IID) and the Coachella Valley Water District (CVWD).

A.6.2.5 Flood Control Surplus

If the modeled January 1 system volumes projects Hoover Dam flood control releases based on the Field Working Agreement between Reclamation and the USACE for the flood control operation of Hoover Dam and Lake Mead (USACE 1982), the model assigns the Full Surplus schedules to MWD, SNWA, CAP, IID, and CVWD. In addition, the model assigns an additional delivery of up to 200 kaf to Mexico. All other diversion points remain at Normal schedules. The Full Domestic Surplus schedules are documented in the Secretarial Implementation Agreement Final EIS (2002).

A.6.3 Lower Basin Shortage Strategies

A summary comparison of the shortage strategy for each alternative is provided in Attachment A to this appendix (Table Att. A-2).

A.6.3.1 No Action Alternative

In the absence of specific shortage guidelines, modeling assumptions were made that followed assumptions for previous environmental compliance documents. Based on these assumptions a two-level shortage protection strategy was employed. This strategy established the elevations in Lake Mead to be protected and the protection strategy (probabilistic or absolute). Within the two protection levels are two methods or stages for allocating the required shortage amount as explained below. See Section 4.2, Volume I, in this Final EIS for a description of the methodology regarding the shortage sharing assumptions under the two stages of shortage.

In Level 1 protection, the shortage determination is based on comparing the January 1 Lake Mead elevation to a user-input trigger elevation, where the trigger elevations are determined from other modeling studies to protect a significant elevation within a given degree of confidence. The Level 1 shortage trigger elevations are presented in Table A-17.

Table A-17
Level 1 Shortage Trigger Elevations

Year	Elevations (feet msl)	Year	Elevations (feet msl)	Year	Elevations (feet msl)
2008	1,079	2026	1,101	2043	1,127
2009	1,082	2027	1,103	2044	1,129
2010	1,083	2028	1,104	2045	1,132
2011	1,084	2029	1,106	2046	1,133
2012	1,085	2030	1,107	2047	1,135
2013	1,086	2031	1,108	2048	1,137
2014	1,086	2031	1,108	2049	1,138
2015	1,087	2032	1,109	2050	1,140
2016	1,088	2033	1,110	2051	1,142
2017	1,090	2034	1,112	2052	1,144
2018	1,091	2035	1,113	2053	1,145
2019	1,093	2036	1,114	2054	1,147
2020	1,094	2037	1,116	2055	1,149
2021	1,095	2038	1,117	2056	1,151
2022	1,096	2039	1,119	2057	1,152
2023	1,097	2040	1,120	2058	1,154
2024	1,098	2041	1,123	2059	1,156
2025	1,100	2042	1,125	2060	1,157

Under Level 1 protection, if Lake Mead's elevation at the beginning of the year is less than the trigger elevation, a Stage 1 shortage is declared and certain Lower Basin depletions are reduced. The shortage remains in effect for that calendar year. A Stage 1 shortage is defined as a shortage of magnitude less than that which would cause Arizona 4th priority uses to be reduced to zero.

Level 1 protection of elevation 1,050 feet msl (minimum water level for operation of Southern Nevada's upper diversion intake and minimum power pool) was used in this study. Trigger elevations were input to protect each elevation with an approximately 80 percent probability; however, actual model simulations showed that the protection was less, approximately 70 percent over the entire simulation period. Under Level 1 protection a Stage 1 shortage is declared and the CAP depletion is set to 1.0 maf, and other Arizona 4th priority uses are reduced proportionately, as described in the equations below.

$$CAP_{short} = CAP_{norm} - 1.0maf$$

$$OtherAZP4_{short} = (CAP_{short} * \frac{CAP_{norm} + OtherAZP4_{norm}}{CAP_{norm}}) - CAP_{short}$$

Where: the subscript norm denotes the normal depletion amount and the subscript short denotes the shortage amount. The shortage amount is subtracted from the normal depletion amount to solve for the shorted depletion amount.

The percent shortage applied to each Arizona 4th priority in OtherAZP4 is computed as a fraction of their normal use divided by the total other Arizona 4th priority use.

Other Lower Basin depletions are reduced according to the percents presented in Table A-18.

Table A-18
Modeling Assumptions for Distribution of Stage 1 Shortages[a]

Entity	Percentage of Total Lower Basin Shortage	Calculation
Arizona[b]	80	♦ Computed assuming that Arizona takes the remaining amount of shortage after Nevada and Mexico take their respective shares ♦ Calculated as: 1.0 – 0.1667 – 0.0333 = 0.80 or 80.0 percent
California	0	♦ Does not receive shortage under Stage 1
Nevada	3.33	♦ Computed as a ratio of Nevada's apportionment to the total apportionments of the Lower Division states and Mexico ♦ Calculated as: 0.3 maf / 9.0 maf – 0.0333 or 3.33 percent
Mexico [1]	16.67	♦ Computed as a ratio of Mexico's allotment to the total allotments of the Lower Division states and Mexico ♦ Calculated as: 1.5 maf / 9.0 maf = 0.1667 or 16.67 percent

a. *These modeling assumptions do not reflect policy decisions and are not intended to constitute an interpretation or application of the 1944 Treaty.*
b. *Within the CAP, Ak-Chin and Salt River Pima-Maricopa Indian Community tribes have pre-1968 contracts for the delivery of 72 kaf that is not reduced until a Stage 2 Shortage is applied.*

Mexico and SNWA are reduced by 16.67 and 3.33 percent of the total Stage 1 shortage, respectively. The MWD does not take a Stage 1 shortage. The total Stage 1 shortage is computed as:

$$TotalStage1Short = \frac{CAP_{short} + OtherAZP4_{short}}{100\% - (3.33\% + 16.67\%)}$$

Under Level 2 protection, the shortage required to keep Lake Mead above elevation 1,000 feet msl (minimum elevation for operation of Southern Nevada's lower diversion intake) is computed and distributed among Lower Basin users as described in Table A-19. In each month, January through September, a rule estimates the end-of-April through end-of-September Lake Mead elevation (using Stage 1 shortage schedules and normal schedules for other users). April through September is generally the high demand period from Lake Mead. If in any month during the high demand period the estimated Lake Mead elevation is below 1,000 feet msl, Arizona 4th priority users are reduced to zero and SNWA and Mexico take their respective percents of the total shortage for the current month. This type of pre-emptive shortage approach is required to avoid the

[1] The proposed federal action is for the purpose of adopting additional operational guidelines to improve the Department's annual management and operation of key Colorado River reservoirs for an interim period through 2026. However, in order to assess the potential effects of the proposed federal action in this Final EIS, certain modeling assumptions (discussed in Chapter 2, Volume I) are used that display projected water deliveries to Mexico. Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 Treaty or to represent current United States policy or a determination of future United States policy regarding deliveries to Mexico.

The United States will conduct all necessary and appropriate discussions regarding the proposed federal action and implementation of the 1944 Treaty with Mexico through the IBWC in consultation with the Department of State.

situation when, in a given month, the shortage required to keep Lake Mead above elevation of 1,000 feet msl is greater than the available demand. If, in the current month the shortage required to protect elevation 1,000 feet msl does not require Arizona 4th priority users to be reduced to zero, the lesser shortage amount is allocated.

If, in any month additional shortage beyond Stage 1 is required to protect Lake Mead elevation of 1,000 feet msl, a Stage 2 shortage is declared. The Stage 2 shortage amount is the amount in excess of the Stage 1 shortage amount required to protect elevation 1,000 feet msl absolutely. In a Stage 2 shortage Mexico and SNWA are further reduced and Arizona 2nd and 3rd priority uses and MWD are reduced. These entities are reduced according to the percentage values provided in Table A-19.

Table A-19
Modeling Assumptions for Distribution of Stage 2 Shortages[1]
No Action Alternative

Entity	Percentage of Total Lower Basin Shortage	Calculation
Arizona	15 to 20	▪ The percentage changes as Arizona's 4th priority use schedule changes and ranges between 15 and 20 percent ▪ Computed as a ratio of Arizona's apportionment less the amount of shortage applied to Arizona under Stage 1, to the total apportionments of the Lower Division states and Mexico less the total amount shorted to users under Stage 1 ▪ Calculated as: (2.8 – Arizona Stage 1 shortage) / (9.0 – total Stage 1 shortage)
California	60 to 65	▪ California shortage sharing percentage changes as Arizona's 4th priority use schedule changes and ranges between 60 and 65 percent ▪ Computed assuming that California takes the remaining amount of the additional shortage ▪ Calculated as: 1.0 – 0.1667 – 0.0333 – Arizona's Stage 2 percentage expressed as a fraction
Nevada	3.33	▪ Computed as a ratio of Nevada's apportionment less the amount of shortage applied to Nevada under Stage 1, to the total apportionments of the Lower Division states and Mexico less the amount shorted to users under Stage 1 ▪ Calculated as: (0.3 – Nevada Stage 1 shortage) / (9.0 – total Stage 1 shortage) = 0.0333 or 3.33 percent
Mexico	16.67	▪ Computed as a ratio of Mexico's apportionment less the amount of shortage applied to Mexico under Stage 1, to the total apportionments of the Lower Division states and Mexico less the total amount shorted to users under Stage 1 ▪ Calculated as: (1.5 – Mexico Stage 1 shortage) / (9.0 – total Stage 1 shortage) = 0.1667 or 16.67percent

1. *These modeling assumptions do not reflect policy decisions and are not intended to constitute an interpretation or application of the 1944 Treaty. They have been developed for comparison of the alternatives.*

The maximum amount of Stage 2 shortage that can be applied is dictated by MWD demand. If the amount of Stage 2 shortage required is greater then MWD demand, then the Stage 2 shortage amount becomes

$$TotalStage2Short_{Constrained} = \frac{MWD_{norm}}{100\% - (3.33\% + 16.67\% + AZP2and3Short\%)}$$

In the event that a Stage 2 shortage is constrained and not fully allocated, Lake Mead elevation decline to below 1,000 feet msl. If Lake Mead elevation drops below 1,000 feet msl, SNWA is reduced to zero (due to physical limitations) for the current month and the other users maintain their shortage amounts as if SNWA had not been completely reduced.

A.6.3.2 Basin States Alternative

The Basin States Alternative provides discrete stepped levels of shortage associated with specific Lake Mead elevations. These shortage amounts and the corresponding elevations are provided in Attachment A to this appendix (Table Att. A-2). The maximum shortage is 600 kaf below elevation 1,025 feet msl. The shortage determination is based on comparing the January 1 Lake Mead elevation to the specific Lake Mead trigger elevations. If Lake Mead's elevation at the beginning of the year is less than the trigger elevation, a shortage of the corresponding amount is declared and certain Lower Basin depletions are reduced. The shortage remains in effect for that calendar year. The shortage is allocated according to the percentages used under a Stage 1 shortage in the No Action Alternative provided in Table A-19. As under the No Action Alternative, SNWA is reduced to zero for the current month if, in the previous month Lake Mead elevation is below 1,000 feet msl.

A.6.3.3 Conservation Before Shortage Alternative

The shortage strategy under the Conservation Before Shortage Alternative is identical to the Level 2 shortage protection in the No Action Alternative. The Level 1 shortage protection in the No Action Alternative is replaced with various levels of voluntary conservation in the Conservation Before Shortage Alternative. Modeling assumptions regarding the voluntary conservation portion of this alternative are located in Appendix M. The amounts of voluntary conservation and the corresponding reservoir elevations are identical to the shortage amounts and corresponding reservoir elevations under the Basin States Alternative.

A.6.3.4 Water Supply Alternative

There is no shortage strategy in place in the Water Supply Alternative. The only reduction in use occurs when, in the previous month Lake Mead elevation is below 1,000 feet msl. In this event SNWA is reduced to zero for the current month.

A.6.3.5 Reservoir Storage Alternative

Like the Basin States Alternative, the Reservoir Storage Alternative provides discrete stepped levels of shortage associated with specific Lake Mead elevations. These shortage amounts and the corresponding elevations are provided in Attachment A to this appendix (Table Att. A-2). The maximum shortage is 1,200 kaf below elevation 1,025 feet msl. Shortage determination and allocation occurs in the same way as under the Basin States Alternative.

A.6.3.6 Preferred Alternative

The Preferred Alternative utilizes identical shortage assumptions as the Basin States Alternative.

A.6.4 Lake Mead Storage and Delivery of Conserved System and/or Non-system Water

Detailed modeling assumptions regarding the Lake Mead storage and delivery mechanism for conserved system and/or non-system water as part of the Basin States, Conservation Before Shortage, and Reservoir Storage alternatives, and the Preferred Alternative, is provided in Appendix M.

A.7 Summary Comparison of Lake Powell and Lake Mead Operations

A summary comparison of Lake Powell and Lake Mead operations under the No Action Alternative and the action alternatives is provided in Attachment A to this appendix (Tables Att. A-1 and Att. A-2, respectively).

A.8 Lake Mohave and Lake Havasu Operations

Lake Mohave and Lake Havasu are operated to meet user-specified target storages at the end of each month. This operation remained consistent for all alternatives. The storage targets and the corresponding elevations for Lake Mohave and Lake Havasu are presented in Tables B-4 and B-5, respectively, in Appendix B.

A.9 Energy Generation

RiverWare™ includes a variety of methods that can be chosen to compute power generation. All methods compute power and energy on a monthly basis. The following sections describe the methods used to compute power at Glen Canyon Dam, Hoover Dam, Davis Dam and Parker Dam.

A.9.1 Glen Canyon Dam

The computation of power and energy generated at Glen Canyon Dam is based on the turbine release for the current month and a power coefficient which is a function of the turbine release and operating head. Turbine release is the lesser value of the maximum power release or the result of outflow minus spill. The power coefficient is computed through table interpolation given the operating head. The table used for interpolation is chosen based on the turbine release and can represent either flow through the turbine for most efficient power generation or the maximum flow through the turbine. The power coefficient may also be an intermediate value, computed through interpolation of both tables, if the turbine release is between the most efficient for power generation and the maximum flow through the turbine.

Once the power coefficient is computed, power generated for the current month is computed as

$$Power = PowerCoefficient * Turbine\ Release$$

Energy is calculated as the power multiplied by the length of the month in hours.

If the previous month's elevation is less than 3,490 feet msl, there is no power or energy generated for the current month. This elevation reflects the minimum power pool elevation at Lake Powell.

A.9.2 Hoover Dam

The method that computes power and energy generated at the Hoover Dam assumes two levels of power generation. The lower level of generation occurs at base flow while the upper level occurs at peak flow. The method computes the fraction of the month that the powerplant is operated at peak flow and base flow. The peaking flow is the most efficient flow through the turbines for the current operating head while the baseflow represents the minimum flow through the turbines to produce energy.

The base flow and corresponding power generation is based on the outflow for the current month. The peak flow must be computed through an iterative procedure using operating head, tailwater elevation and turbine release. The initial turbine release is assumed to be that corresponding to maximum power production. Tailwater elevation at Hoover Dam is computed as function of Lake Mohave elevation, and Hoover Dam release.

The monthly Hoover Dam release volume at base flow is computed by applying the base flow over the month. The monthly release volume at peak flow is computed as

$$PeakFlowVolume = TurbineReleaseVolume - BaseFlowVolume$$

Next, the number of hours required for operation at base and peak flows are then computed as

$$PeakHours = \frac{PeakFlowVolume}{(PeakFlow - BaseFlow) * 3600}$$

$$BaseHours = \frac{SecondsInMonth}{3600} - PeakHours$$

where 3600 is the amount of seconds per hour.

If the peak hours are greater than the length of the month, the peak hours value is set equal to the length of the month and base hours value is set to zero. The peak and base hours are then multiplied by the powerplant capacity at each level and added together to obtain the total energy produced for the month. Power is computed as the energy divided by the length of the month in hours.

The algorithm described above allows generation at elevations below 1,050 feet msl, the minimum power pool at Lake Mead. According to the algorithm, power is generated as long as the minimum operating head of 360 feet is available, corresponding to an elevation of about 1,011 feet msl. Because there is no operating experience at these elevations, it is impossible to verify if CRSS mimics the actual turbine performance at such low heads. It is therefore critical to view energy results from CRSS in a relative manner and not in a strict numeric sense.

A.9.3 Davis Dam

The method that computes power and energy generation at Davis Dam is the same method used for Hoover Dam.

A.9.4 Parker Dam

The method that computes power and energy generation at Parker Dam is the same method used for Hoover Dam.

A.10 Reservoir Evaporation

Evaporation at Lake Powell and Lake Mead is calculated in CRSS by multiplying the reservoir surface area by user-supplied evaporation coefficients. Specifically, the average reservoir surface area over the previous and current month (in acres) is multiplied by the monthly evaporation coefficient (in feet per month) to produce the rate of evaporation in acre-feet per month as specified by the following equation:

$$Evaporation(t) = EvaporationCoefficient(t) * \frac{(SurfaceArea(t) + SurfaceArea(t-1))}{2} * TimestepLength$$

Where: t = current time-step

$t\text{-}1$ = previous time-step

The monthly evaporation coefficients for Lake Powell and Lake Mead are presented in Table A-20.

Table A-20
Monthly Evaporation Coefficients for Lake Powell and Lake Mead

Month	Evaporation Coefficient (feet/month)	
	Lake Powell	Lake Mead
January	0.198	0.36
February	0.186	0.33
March	0.233	0.37
April	0.265	0.46
May	0.359	0.53
June	0.411	0.64
July	0.466	0.80
August	0.478	0.85
September	0.415	0.70
October	0.375	0.51
November	0.312	0.51
December	0.261	0.44

A.11 Model Input and Simulation

CRSS is used to simulate the future conditions of the system on a monthly time step. Output data include reservoir storage, releases from dams, hydroelectric generation, etc. Input data for the model includes monthly natural flow at 29 nodes throughout the Colorado River system. Input data also includes physical parameters (e.g., individual reservoir storage capacity, evaporation rates, and reservoir release capabilities), initial reservoir conditions, and the diversion and depletion schedules for entities in the Colorado River Basin States and Mexico. Operating rules for current or proposed operating policies are considered input.

Although several methods are available for ascertaining the range of possible future inflows, Reclamation utilized the existing historical record of natural flows to create several distinct and synthetic hydrologic sequences that are then used in a series of simulations. For this process, Reclamation used a particular technique for sampling from the historical record known as the Indexed Sequential Method, or ISM (Reclamation 1985; Ouarda et al. 1997). Each future hydrologic sequence is generated from the historical natural flow record by "cycling" through the record. This method produces the "n" possible flow sequences, where n corresponds to the number of years in the flow data set. Using the historical natural flow data from 1906 through 2005 with ISM results in a set of 100 separate simulations referred to as "traces." This enables an evaluation of proposed criteria over a broad range of possible future hydrologic conditions. Evaluations typically include all 100 traces using statistical techniques.

A.12 Model Uncertainty

Using ISM, CRSS generates a wide range of hydrologic possibilities which include periods of extreme drought and periods of much above average flow, allowing evaluation of the proposed federal action under a wide range of future flows. However, it is possible that future flows may include periods of wet or dry conditions that are outside of all the possible sequences seen in the historical record. Appendix N provides alternate hydrologic inflow scenarios for comparison with the 1906 through 2005 natural flow record using ISM.

Model output is also sensitive to input diversion and depletion schedules. The best available data for future diversions and depletions are input to CRSS (Appendix C and Appendix D). Actual future depletion schedules, especially when simulating system conditions far into the future (beyond about 20 years from the present) may differ.

Appendix B

Colorado River System Facilities and Current River System Operations From Lake Powell to SIB

This appendix describes the dams, reservoirs and river reaches on the mainstream of the Colorado River from Lake Powell to the Southerly International Border with Mexico. This appendix also describes the historical and current operation of those facilities.

List of Figures

List of Tables

B.1 Natural Runoff and Storage of Water

The Colorado River serves as a source of water for irrigation, domestic, and other uses in the States of Arizona, California, Colorado, Nevada, New Mexico, Utah and Wyoming, and in Mexico. The Colorado River also serves as a source of water for a variety of recreational and environmental uses. The Colorado River Basin is located in the southwestern United States and occupies an area of approximately 250,000 square miles. The Colorado River is approximately 1,400 miles in length and originates along the Continental Divide in Rocky Mountain National Park in Colorado. Elevations in the Colorado River Basin range from sea level to over 14,000 feet above mean sea level (msl) in the mountainous headwaters.

Climate varies significantly throughout the Colorado River Basin. Most of the Colorado River Basin is comprised of arid or semi-arid rangelands, which generally receive less than 10 inches of precipitation per year. In contrast, many of the mountainous areas that rim the northern portion of the Colorado River Basin receive, on average, over 40 inches of precipitation per year. Most of the total annual flow in the Colorado River Basin results from natural runoff from mountain snowmelt. Because of this, natural flow is very high in the late spring and early summer, diminishing rapidly by mid-summer. While flows in late summer through autumn sometimes increase following rain events, natural flow in the late summer through winter is generally low.

Due to variability in climatic conditions, the natural flow in the Colorado River system is highly variable from year to year. In any case, the natural flow of the river represents an estimate of runoff flows that would exist in a natural setting, without storage, alteration or depletion by man. About 86 percent of the Colorado River System annual runoff originates in only 15 percent of the watershed—in the mountains of Colorado, Utah, Wyoming and New Mexico. While the average annual natural flow at the Lees Ferry Compact Point (Lees Ferry) is calculated at approximately 15.1 million acre-feet (maf), annual flows in excess of 23 maf and as little as 5 maf have occurred.

The flow in the Colorado River above Lake Powell reaches its annual maximum during the April through July period. During the summer and fall, thunderstorms occasionally produce additional peaks in the river. However, these flows are usually smaller in volume than the snowmelt peaks and of much shorter duration.

Flows immediately below Glen Canyon Dam consist almost entirely of water released from Lake Powell. Downstream of Glen Canyon Dam, annual river gains from tributaries, groundwater discharge, and occasional flash floods from side canyons average 900,000 acre-feet (af).

Immediately downstream of Hoover Dam, the river flows consist almost entirely of water released from Lake Mead. Downstream of Hoover Dam, the Colorado River gains additional waters from tributaries such as the Bill Williams River and the Gila River, groundwater discharge, and return flows.

Total storage capacity in the Colorado River system is nearly four times the river's average natural flow or about 60 maf. However, the two largest reservoirs in the system, Lake Powell and Lake Mead account for approximately 50 maf of this storage capacity. The various reservoirs that provide storage, their respective capacities and modes of operation, along with the respective river reaches are described in more detail in Section B.2.

Annually, approximately 9 maf are released from Lake Mead to meet the delivery orders of water entitlement holders in the United States and for 1944 Treaty water deliveries to Mexico. Of this amount, some 7.5 maf are entitlements for the Lower Division states (Arizona, California, and Nevada), while the remaining 1.5 maf is delivered to Mexico.

Figure B-1 presents an overview of the historical natural flow calculated at Lees Ferry for 1906 through 2005 (calendar years). The natural flow represents an estimate of the flows that would originate or exist above the Lees Ferry without storage, alteration or depletion by man. This is different than the recorded or historical stream flows that represent actual measured flows. Figure B-2 presents an overview of the historical flows recorded at Lees Ferry for 1922 through 2005.

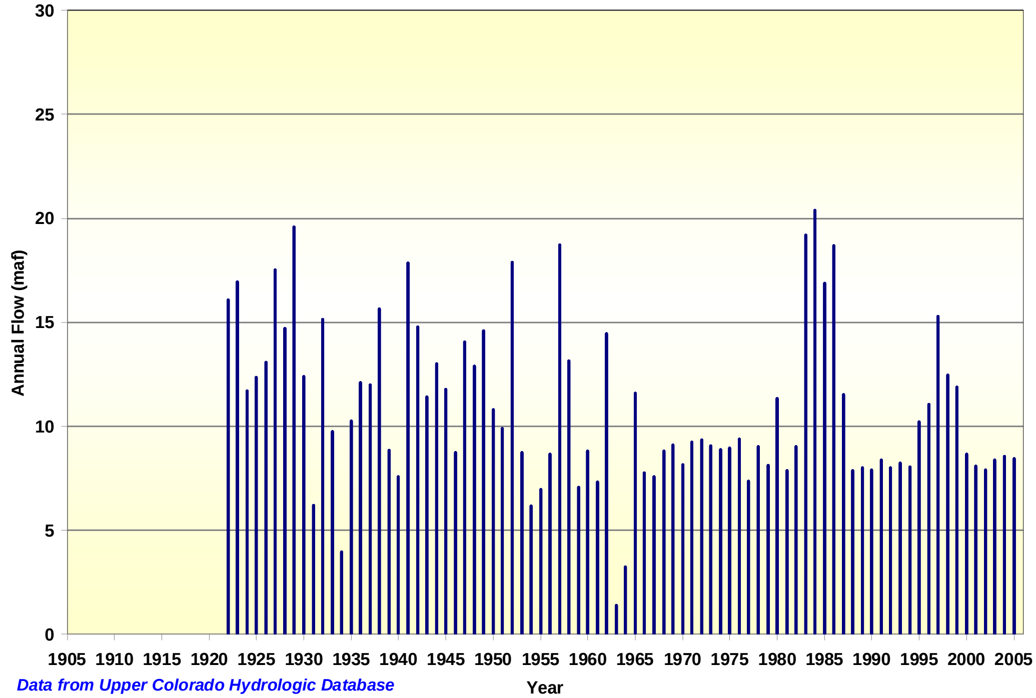
1922 through 2005



B.2 Operation of the Colorado River System

The Secretary of the Department of the Interior (Secretary), acting through the Bureau of Reclamation (Reclamation), is vested with the responsibility of managing the mainstream waters of the lower Colorado River pursuant to applicable federal law. This responsibility is carried out consistent with a body of documents referred to as the Law of the River. The Law of the River comprises numerous operating criteria, regulations, and administrative decisions included in federal and state statutes, interstate compacts, court decisions and decrees, an international treaty, and contracts with the Secretary applicable to the allocation, appropriation, development, exportation and management of the waters of the Colorado River Basin. There is no single, universally agreed upon definition of the Law of the River, but it is useful as a shorthand reference to describe this longstanding and complex body of legal agreements governing the management of the Colorado River.

Operation of the Colorado River system and delivery of Colorado River water to the seven Basin States (Arizona, California, Colorado, Nevada, Utah, New Mexico, and Wyoming) and Mexico are conducted in accordance with the Law of the River. Water cannot be released from storage unless there is a reasonable beneficial use for the water. The exceptions to this are releases required for flood control, river regulation, or dam safety. In the Lower Basin, water is released from the system to satisfy water delivery orders and to satisfy other purposes set forth in the Consolidated Decree entered by the United States Supreme Court in the case of *Arizona v. California*, 547 U.S. 150 (2006) (Consolidated Decree). The principal facilities that were constructed to manage the water in the Colorado River system include Glen Canyon Dam and Hoover Dam.

The Colorado River system is operated by Reclamation pursuant to the Criteria for Coordinated Long-Range Operation of Colorado River Reservoirs Pursuant to the Colorado River Basin Project Act of September 30, 1968 (Long-Range Operating Criteria or LROC) through the issuance of the Annual Operating Plan for Colorado River Reservoirs (AOP). The AOP is required by the Colorado River Basin Project Act of 1968 (CRBPA). The AOP is formulated for the upcoming year under a variety of potential scenarios or conditions. The plan is developed based on projected demands, existing storage conditions, and probable inflows. The AOP is prepared by Reclamation, acting on behalf of the Secretary, in consultation with the Basin States, the Upper Colorado River Commission, Indian tribes, appropriate federal agencies, representatives of the academic and scientific communities, environmental organizations, the recreation industry, water delivery contractors, contractors for the purpose of federal power, others interested in Colorado River operations, and the general public.

Prior to the beginning of the calendar year, Lower Basin diversion schedules are requested from water users entitled to Colorado River water. These schedules are estimated monthly diversions and return flows that allow Reclamation to determine a tentative schedule of monthly releases through the Hoover Powerplant. Actual monthly releases are determined by the demand for water downstream of Hoover Dam, Davis Dam, and Parker Dam. Daily changes in water orders are made to accommodate emergencies, temperature and weather for water orders downstream of Parker Dam.

A minimum of 1.5 maf is delivered annually to Mexico in accordance with the 1944 Treaty. The 1944 Treaty contains provisions for delivery of up to 200,000 af above the 1.5 maf when Lake Mead is in flood control operations and there exists water in excess of that necessary to satisfy the uses in the United States and the guaranteed quantity of 1.5 maf to Mexico. Additionally, excess flows above the 200,000 af may become available to Mexico coincident with Lake Mead flood control releases and Gila River flood flows provided that the reasonable beneficial uses of the Lower Division states have been satisfied.

The Colorado River from Hoover Dam to the Southerly International Boundary with Mexico (SIB) is contained within the shallow Colorado River Valley in which Lake Mohave, Lake Havasu and other smaller diversion reservoirs are located. Within this segment, especially along river reaches below Parker Dam, the Colorado River is fringed with riparian vegetation and marshy backwaters, and contains a number of diversion dams and a system of levees. The northern reach of this segment, including Lake Mohave, lies within the Lake Mead National Recreation Area (LMNRA). The lower reach is bordered by a combination of federal, Tribal and private land. The last 23.7 miles is along the international border with Mexico. Reclamation retains authority and discretion for river operations in the reaches of this segment.

Under the Boulder Canyon Project Act of 1928 (BCPA) and the Decree, releases from Hoover Dam are governed by orders for downstream water deliveries to Arizona, California, Nevada, and Mexico. However, releases may exceed orders when flood releases are required under the United States Army Corps of Engineers' (USACE) flood control criteria, or for other purposes consistent with the BCPA and the Consolidated Decree.

B.2.1 Lake Powell and Glen Canyon Dam

Lake Powell is a large reservoir on the Colorado River formed by Glen Canyon Dam. The reservoir is narrow and over 100 miles long. Lake Powell provides water storage for use in meeting delivery requirements of the Upper Basin to the Lower Basin.

The normal operating range of Lake Powell is between elevations 3,490 feet msl and 3,700 feet msl. Elevation 3,490 feet msl corresponds to the minimum power pool. Releases from Glen Canyon Dam can be made below 3,490 feet msl down to elevation 3,370 feet msl via the river bypass tubes. Elevation 3,700 feet msl corresponds to the top of the spillway radial gates. During floods, the elevation of Lake Powell can go above 3,700 feet msl by raising the radial spillway gates, resulting in spillway releases. In 1983, Lake Powell reached a high elevation of 3,708.34 feet msl. Lake Powell is located within the Glen Canyon National Recreation Area (GCNRA), which is administered by the National Park Service (NPS). Reclamation retains authority and discretion for the operation of Glen Canyon Dam and Lake Powell.

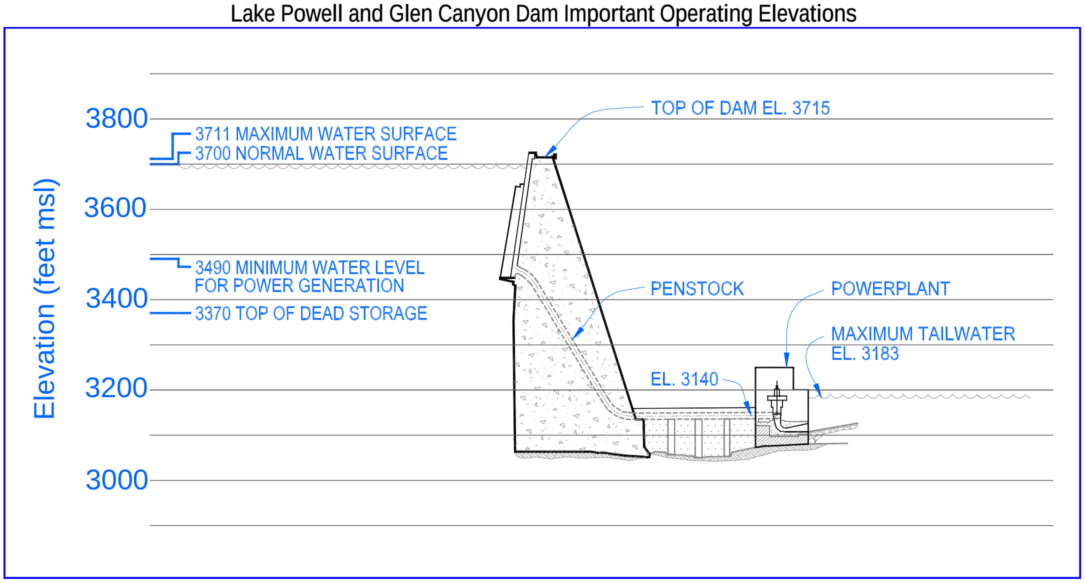
B.2.1.1 Dam and Reservoir Configuration

Glen Canyon Dam is a concrete arch dam rising approximately 700 feet above the level of the Colorado River streambed. A profile of the dam is depicted on Figure B-3. Except during flood conditions, the "full reservoir" water level is 3,700 feet msl, corresponding to the top of the spillway gates. Under normal operating conditions, releases from Glen Canyon Dam are made through Glen Canyon Powerplant by means of gates on the upstream face of the dam. The minimum reservoir elevation at which hydroelectric power can be generated is 3,490 feet msl. Releases in excess of the powerplant capacity may be made when flood conditions are caused by high runoff in the upstream portion of the Colorado River Basin, or when needed to provide Beach/Habitat-Building Flows (BHBF) downstream of the dam.

There are four river outlets at Glen Canyon Dam, comprising 96-inch diameter steel pipes with hollow-jet valves for regulation, each with a capacity of 3,750 cubic feet per second (cfs). The release rate is controlled by the hollow-jet valves from elevation 3,500 feet msl to 3,700 feet msl. At elevation 3,700 feet msl, a hollow-jet valve opening of 79 percent produces the 3,750 cfs. At elevation 3,500 feet msl, the hollow-jet valve must be fully opened to achieve 3,750 cfs.

At elevations below 3,500 feet msl, with the hollow-jet valve fully opened, the flow is reduced below 3,750 cfs as the head is lowered. At elevation 3,490 feet msl, for instance, one river outlet with the hollow-jet valve fully opened will release about 3,660 cfs. At elevation 3,460 feet msl, one river outlet will release about 3,380 cfs. An annual release of 8.23 maf equates to a continuous release of 11,368 cfs. With all four river outlets in service, this release can be achieved down to about elevation 3,440 feet msl. At this elevation, the release capacity from the four river outlets is approximately 11,440 cfs (2,860 cfs per unit).

Figure B-3
Lake Powell and Glen Canyon Dam Important Operating Elevations



B.2.1.2 Operation of Glen Canyon Dam

Flows below Glen Canyon Dam are influenced by storage and release decisions that are scheduled and implemented on an annual, monthly and hourly basis from Glen Canyon Dam.

The annual volume of water released from Glen Canyon Dam is made according to the provisions of the LROC that includes a minimum objective release of 8.23 maf, storage equalization between Lake Powell and Lake Mead under prescribed conditions, and the avoidance of spills. Annual releases from Lake Powell greater than the minimum occur if Upper Basin storage is greater than the storage required by Section 602(a) of the CRBPA, and if the storage in Lake Powell is greater than the storage in Lake Mead. Annual release volumes greater than the minimum objective of 8.23 maf are also made to avoid anticipated spills.

Monthly operational decisions are generally intermediate targets needed to systematically achieve the annual operating requirements. The actual volume of water released from Lake Powell each month depends on the forecast inflow, storage targets and annual release requirements described above. Demand for energy is also considered and accommodated as long as the annual release and storage requirements are not affected.

The National Weather Service's Colorado Basin River Forecast Center (CBRFC) provides the monthly forecasts of expected inflow into Lake Powell and other Upper Basin reservoirs. The CBRFC uses a satellite-telemetered network of hundreds of data collection points within the Upper Basin that gather data on snow water content, precipitation, temperature and streamflow. Telemetry data is input into regression and real-time conceptual computer models to derive an inflow forecast. Reclamation's future release volumes are based on these derived forecasts. Particular attention is paid to April through July forecast which historically has the most impact on the hydrology of the region. Due to the variability in climatic conditions, modeling and data errors, these forecasts are based, in part, on large uncertainties. The greatest period of uncertainty occurs in early winter and decreases as the snow accumulation period progresses into the snowmelt season, often forcing modifications to the monthly schedule of releases.

An objective in the operation of Glen Canyon Dam is to attempt to safely fill Lake Powell each summer. When carryover storage from the previous year in combination with forecast inflow allows, Lake Powell is targeted to reach a storage of about 23.8 maf in July (0.5 maf from full pool). In years when Lake Powell fills or nearly fills in the summer, releases in the late summer and early winter are generally made to lower the reservoir elevation, so that there is at least 2.4 maf of vacant space in Lake Powell on January 1. Storage targets are always reached in a manner consistent with the LROC.

Glen Canyon Dam is operated consistent with the 1996 Glen Canyon Dam Record of Decision (ROD) (62 C.F.R. pt. 9447-9448) developed as directed under the Grand Canyon Protection Act of 1992. The 1996 Glen Canyon Dam ROD describes criteria for dam operations and includes other measures to ensure Glen Canyon Dam is operated in a manner consistent with the Grand Canyon Protection Act of 1992. Among these are an Adaptive Management Program (AMP), BHBFs, and further study of temperature control. Scheduling of BHBF releases from Glen Canyon Dam are discussed in Section B.2.2. The daily and hourly release constraints of Glen Canyon Dam are as provided in Table B-1.

Table B-1
Glen Canyon Dam Release Constraints

Parameter	Flow Rate (cfs)	Conditions
Maximum Flow[1]	25,000	
Minimum Flow	5,000	Nighttime
	8,000	7:00 a.m. to 7:00 p.m.
Ramp Rates		
Ascending	4,000	Per hour
Descending	1,500	Per hour
Daily Fluctuations[2]	5,000 to 8,000	

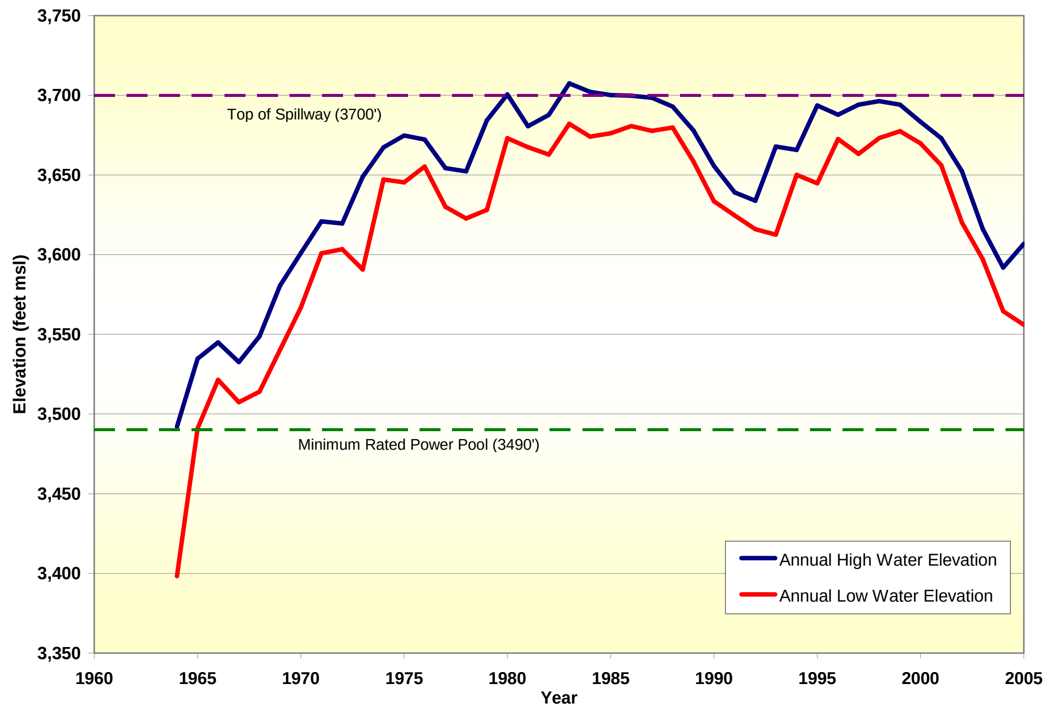
[1] *To be evaluated and potentially increased as necessary and in years when delivery to Lower Basin exceeds 8.23 maf.*

[2] *Daily fluctuation limit is 5,000 cfs for months with release volumes less than 0.6 maf; 6,000 cfs for monthly release volumes of 0.6 maf to 0.8 maf; and 8,000 cfs for monthly volumes over 0.8 maf.*

B.2.1.3 Historic Lake Powell Elevations

Glen Canyon Dam and Lake Powell were designed to operate from a normal maximum elevation of 3,700 feet msl to a minimum elevation of 3,490 feet msl, the minimum for hydroelectric power production. During flood conditions, the elevation of Lake Powell can exceed 3,700 feet msl by raising and adding additional supported panels to the spillway radial gates. Since first reaching equalization storage with Lake Mead in 1974, Lake Powell's elevation has fluctuated from a high of 3,708 feet msl to a low of approximately 3,555 feet msl, as illustrated on Figure B-4.

Figure B-4
Historic Lake Powell Elevations
(Annual Highs and Lows)



B.2.2 Glen Canyon Dam to Lake Mead

The segment of the Colorado River between Glen Canyon Dam and Lake Mead is comprised of a narrow river corridor through the Grand Canyon that is administered primarily by the Grand Canyon National Park.[1] Flows within this reach of the river consist primarily of releases from Glen Canyon Dam as discussed in Section B.2.1.

Issues that may need to be reconsidered within this segment of the river are those associated with a revised program of low steady summer flows and BHBF releases, as well as the ongoing temperature control studies.

B.2.2.1 River Flows between Glen Canyon Dam and Lake Mead

Colorado River flows between Glen Canyon Dam and Lake Mead are a result of controlled releases from Glen Canyon Dam (Lake Powell) and include gains from tributaries in this reach of the river. Releases from Glen Canyon Dam are managed as discussed in Section B.2.1. The most significant gains from tributaries include inflows from the Little Colorado River (approximately 315 miles long) that provides the principal

[1] The 15.9 mile reach between Glen Canyon Dam and Lees Ferry is managed by the Glen Canyon National Recreation Area.

drainageway for the Painted Desert, and the Paria River (approximately 75 miles long) which drains the rugged and arid region northwest of the Colorado River. However, inflows from these perennial streams is concentrated over very short periods of time, and on average, make up approximately two percent of the total annual flow in this reach of the river.

B.2.2.2 Glen Canyon Dam Releases and the Adaptive Management Program

A function of Glen Canyon Dam operations is to maximize power generation. However, power generation was found to be having a negative impact on downstream resources. Realizing the occurrences of such impacts, the Secretary determined in July 1989 that an Environmental Impact Statement (EIS) should be prepared. The *Operation of Glen Canyon Dam EIS* developed and analyzed alternative operation scenarios that met statutory responsibilities for protecting downstream resources and achieving other authorized purposes, while protecting Native American interests. A final EIS was completed in March 1995, and the Secretary signed a ROD on October 8, 1996. Reclamation also consulted with the United States Fish and Wildlife Service (FWS) under the Endangered Species Act of 1973, as amended (ESA) and incorporated FWS's recommendations into the 1996 Glen Canyon Dam ROD. Glen Canyon Dam operates under the 1996 Glen Canyon Dam ROD (Section B.2.1).

The AMP provides a process for assessing the effects of current operations of Glen Canyon Dam on downstream resources, and using the results of these assessments for developing recommendations that in turn can be used to modify operating criteria and other resource management actions. This is accomplished through the Adaptive Management Work Group (AMWG), a federal advisory committee. The AMWG consists of stakeholders that are federal and state resource management agencies, representatives of the seven Basin States, Indian Tribes, hydroelectric power marketers, environmental and conservation organizations and recreational and other interest groups. The duties of the AMWG are in an advisory capacity only. Coupled with this advisory role are long-term monitoring and research activities that provide a continual record of resource conditions and new information to evaluate the effectiveness of the operational modifications.

BHBF and Beach Habitat Maintenance Flow (BHMF) releases are scheduled high releases of short duration that are in excess of power plant capacity required for dam safety purposes and are made according to certain specific criteria. These BHBFs are designed to rebuild high elevation sandbars, deposit nutrients, restore backwater channels, and provide some of the dynamics of a natural system. The first test of a BHBF was conducted in the spring of 1996.

BHFMs releases are releases at or near power plant capacity, which are intended to maintain favorable beach and habitat conditions for recreation and fish and wildlife, and to protect Tribal interests. BHMF releases can be made in years when no BHBF releases are made.

Both BHBFs and BHMFs, along with the testing and evaluation of other types of releases under the AMP, were recommended by FWS to verify a program of flows that would improve habitat conditions for endangered fish. The proposed shortage guidelines and action alternatives could affect the range of storage conditions in Lake Powell and alter the flexibility to schedule and conduct such releases or to test other flow patterns.

In 1994, FWS issued a *Biological Opinion on the Operation of Glen Canyon Dam* (Biological Opinion). One of the elements of the reasonable and prudent alternative in the Biological Opinion, also a common element in the Glen Canyon Dam EIS, was the evaluation of methods to control release temperatures and, if viable, implement controls. Reclamation agreed with this recommendation and included it in the *Operation of Glen Canyon Dam Final Environmental Impact Statement* and subsequent ROD.

Reclamation has also recently initiated planning activities that will consider possible modifications to Glen Canyon Dam for controlling downstream temperatures. The investigations associated with these planning activities are very preliminary and significant information is currently not available to report on this planning process.

In addition, on September 1, 2006, Reclamation and the Center for Biological Diversity, Arizona Wildlife Federation, Living Rivers, Sierra Club – Grand Canyon Chapter, and Glen Canyon Institute entered into a settlement agreement whereby Reclamation agreed to assess the impacts of current and modified operations of Glen Canyon Dam on the Humpback Chub, Bonytail Chub, Razorback Sucker and Colorado Pikeminnow. Reclamation plans to conduct further related environmental studies and anticipates that it will prepare an EIS by October 15, 2008.

B.2.3 Lake Mead and Hoover Dam

Lake Mead is a large reservoir on the Colorado River formed by Hoover Dam. The reservoir provides water storage for use in regulating the water supply and meeting delivery requirements in the Lower Basin. The normal operating range of the reservoir is between elevations 1,219.61 feet msl and 1,050 feet msl. Elevation 1,050 feet msl corresponds to the minimum power-pool of Hoover Dam Powerplant. Releases can be made from Hoover Dam below elevation 1,050 feet msl down to 895 feel msl via the intake towers. During floods, the elevation of Lake Mead can go above 1,219.61 feet msl. The top of the raised spillway gates is at elevation 1,221.0 feet msl. Since its initial filling in the late 1930s, the reservoir elevation has fluctuated from a high of 1,225.85 feet msl (as occurred in July 1983) to a low of 1,083.21 feet msl (as occurred in April 1956).

The reservoir is located within the LMNRA, which is administered by the NPS. However, Reclamation retains authority and discretion for the operation of Hoover Dam and Lake Mead.

The Las Vegas Wash is the primary channel through which the Las Vegas Valley's excess water returns to Lake Mead. The water flowing through the wash comprises less than two percent of the water in Lake Mead and consists of urban runoff, shallow groundwater, stormwater, and releases from the valley's three water reclamation facilities.

The lower wash stretches 12 miles from the southeast part of the Las Vegas Valley to Lake Mead, entering the lake at Las Vegas Bay. Its once-plentiful wetlands helped polish urban flows on their way to Lake Mead. However, erosion in the wash has reduced wetlands acreage from a peak of approximately 2,000 acres to about 200 acres.

B.2.3.1 Dam and Reservoir Configuration

Hoover Dam and Lake Mead are operated with the following three main priorities:

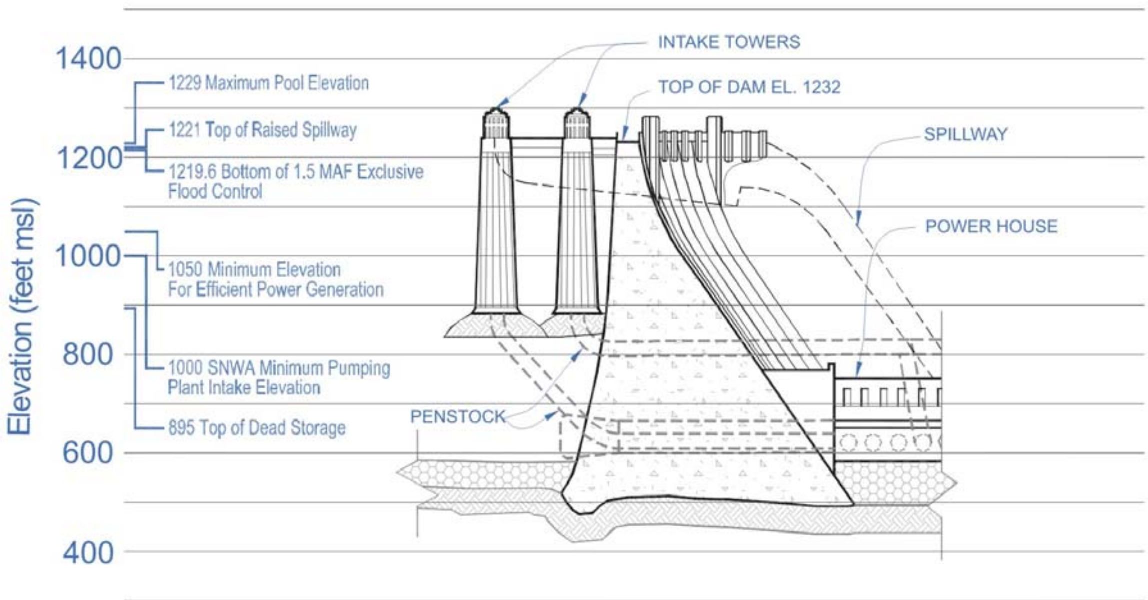
1) river regulation, improvement of navigation, and flood control;
2) irrigation and domestic uses, including the satisfaction of present perfected water rights; and
3) power.

The BCPA specified flood control as the project purpose having first priority for operation of Hoover Dam and Lake Mead.

Hoover Dam is the northernmost Reclamation facility on the lower Colorado River and along with Lake Mead it is located at River Mile 342.2. Hoover Dam provides flood control protection and Lake Mead provides the majority of the storage capacity for the Lower Basin as well as significant recreation opportunities. Lake Mead storage capacity is currently estimated to 27.38 maf at a maximum elevation of 1,229.0 feet msl. At this elevation, Lake Mead’s water surface area would equal 163,000 acres. The dam’s four intake towers draw water from the reservoir at elevations above 895 feet msl to drive 17 generators within the dam’s powerplant. The minimum elevation for effective power generation is 1,050 feet msl.

Flood control regulations for Lake Mead were established to manage potential flood events arising from rain and snowmelt. Lake Mead’s uppermost 1.5 maf of storage capacity, between elevations 1,219.61 feet msl and 1,229.0 feet msl, is defined as exclusive flood control. Within this capacity allocation, 1.218 maf of flood storage is above elevation 1,221.40 feet msl, the top of the raised spillway gates. Figure B-5 illustrates some of the important Hoover Dam and Lake Mead elevations that are referenced in subsequent sections.

Figure B-5
Lake Mead and Hoover Dam Important Operating Elevations



Lake Mead usually is at its maximum water level in November and December. If required, system storage space-building is achieved between the period of August 1 to January 1. Hoover Dam storage space-building releases are limited to 28,000 cfs, while the mean daily releases to meet the water delivery orders of Colorado River water entitlement holders and power users normally range between 8,000 cfs to 18,000 cfs.

In addition to controlled releases from Lake Mead to meet water supply and power requirements, water is also diverted from Lake Mead at SNWA's Saddle Island intake facilities, Boulder City's Hoover Dam intake, and the Basic Management, Inc.'s (BMI) intake facility for use in the Las Vegas area for domestic purposes by SNWA, BMI and other users.

The diversions by SNWA at its Saddle Island intake facilities entail pumping the water from the intake to SNWA's water transmission facilities for treatment and further conveyance to the greater Las Vegas area and Boulder City. SNWA has low intake facilities. The elevation of the original SNWA intake is approximately 1,000 feet msl. However, the minimum required Lake Mead elevation necessary to operate the pumping units at SNWA's original intake facility is 1,050 feet msl. A second SNWA intake was constructed more recently and it has a second pumping plant with an intake elevation of 950 feet msl. The minimum required Lake Mead elevation necessary to operate the pumping units at SNWA's second intake facility is 1,000 feet msl. The second SNWA intake provides only a portion of the capacity required by SNWA to meet its Lake Mead water supply needs. Therefore, the intake elevation of SNWA's original pumping plant is critical to its ability to divert its full Colorado River water entitlement.

B.2.3.2 Operation of Hoover Dam

Hoover Dam is managed to provide at least 7.5 maf annually for consumptive use by the Lower Division states plus the United States' Colorado River water supply obligation to Mexico pursuant to the 1944 Treaty. Hoover Dam releases are managed on an hourly basis to maximize the value of generated power by providing peaking during high-demand periods. This results in fluctuating flows below Hoover Dam that can range from 1,000 cfs to 49,000 cfs. The upper value is the maximum flow-through capacity through Hoover Dam Powerplant (49,000 cfs). However, because these flows enter Lake Mohave downstream, the affected zone of fluctuation is only a few miles because these flows are regulated in Lake Mohave.

Releases of water from Hoover Dam may also be affected by the Secretary's determinations relating to Normal, Surplus or Shortage Conditions (Section 4.4 of this Final EIS). Another type of release includes flood control releases. For Hoover Dam, flood control releases are defined in this Final EIS as releases in excess of downstream demands.

Flood control was specified as a primary project purpose by the BCPA, the act authorizing Hoover Dam. The USACE is responsible for developing the Flood Control Operation Plan for Hoover Dam and Lake Mead as indicated in 33 C.F.R. pt. 208.11. The Flood Control Operation Plan is the result of a coordinated effort by the USACE and Reclamation. However, the USACE is responsible for providing the flood control regulations and has authority for final approval of the flood control operation plan. Any deviations from the flood control operating instructions provided by the flood control operation plan must be authorized by the USACE. The Secretary is responsible for operating Hoover Dam in accordance with these regulations.

Lake Mead's uppermost 1.5 maf of storage capacity, between elevations 1,219.61 feet msl and 1,229.0 feet msl, is defined as exclusive flood control space. Within this capacity allocation, 1.218 maf of flood storage is above elevation 1,221.0 feet msl, which is the top of the raised spillway gates.

Flood control regulations specify that once Lake Mead flood releases exceed 40,000 cfs, the releases shall be maintained at the highest rate until the reservoir drops to elevation 1,221.0 feet msl. Releases may then be gradually reduced to 40,000 cfs until the prescribed seasonal storage space is available.

The regulations set forth two primary criteria for flood control operations related to snowmelt: 1) preparatory reservoir space requirements; and 2) application of runoff forecasts to determine releases.

In preparation for each annual season of snow accumulation and associated runoff, progressive expansion of total Colorado River system reservoir space is required during the latter half of each year. Minimum available flood control space increases from 1.5 maf on August 1 to 5.35 maf on January 1. Required flood storage space can be accumulated within Lake Mead and upstream in Lake Powell, Navajo, Blue Mesa, Flaming Gorge and Fontenelle reservoirs. The minimum space required to be reserved exclusively for flood control storage in Lake Mead is 1.5 maf. Table B-2 presents the amount of required flood storage space within the Colorado River system by date:

Table B-2
Minimum Required Colorado River System Storage Space

Date	Storage Volume (maf)
August 1	1.50
September 1	2.27
October 1	3.04
November 1	3.81
December 1	4.58
January 1	5.35

Normal space-building releases from Lake Mead to meet the required August 1 to January 1 flood control space are limited to a maximum of 28,000 cfs. Releases in any month based on water entitlement holders' demand are much less than 28,000 cfs (on the order of 20,000 cfs or less).

Between January 1 and July 31, flood control releases, based on forecast inflow, may be required to prevent filling of Lake Mead beyond its 1.5 maf minimum space requirement. Beginning on January 1 and continuing through July, the CBRFC issues monthly runoff forecasts. These forecasts are used by Reclamation in estimating releases from Hoover Dam. The release schedule contained in the USACE regulations is based on increasing releases in six steps listed in Table B-3.

Table B-3
Minimum Flood Control Releases at Hoover Dam

Step	Flow Rate (cfs)
Step 1	0
Step 2	19,000
Step 3	28,000
Step 4	35,000
Step 5	40,000
Step 6	73,000

The lowest step, zero cfs, corresponds to times when the regulations do not require flood control releases. Hoover Dam releases are then made to meet water and power objectives. The second step, 19,000 cfs, is based on the Parker Powerplant capacity. The third step, 28,000 cfs, corresponds to Davis Powerplant's capacity. In recent years both Parker and Davis Powerplants have undergone an upgrading program to improve the efficiency of the individual powerplants. The current maximum releases are slightly higher for both the Parker Powerplant and Davis Powerplant outputs, as follows: 22,000 cfs and 31,000 cfs, respectively. The fourth step in the USACE release schedule is 35,000 cfs. This flow corresponds to the powerplant flow-through capacity of Hoover Dam in 1987. However, the present powerplant flow-through capacity at Hoover Dam is 49,000 cfs. At the time Hoover Dam was completed, 40,000 cfs was the approximate maximum flow from the dam considered to be non-damaging to the downstream streambed. The 40,000 cfs flow now forms the fifth step. Releases of 40,000 cfs and greater would result from low-probability hydrologic events. The sixth and final step in the series (73,000 cfs) is the maximum controlled release from Hoover Dam that can occur without spillway flow.

Flood control releases are required when forecast inflow exceeds downstream demands, available storage space at Lake Mead and Lake Powell and allowable space in other Upper Basin reservoirs. This includes accounting for projected bank storage and evaporation losses at both lakes, plus net withdrawal from Lake Mead by the SNWA. The USACE regulations set the procedures for releasing the volume that cannot be impounded, as discussed above.

Average monthly Hoover Dam releases are determined early in each month and apply only to the current month. The releases are progressively revised in response to updated runoff forecasts and changing reservoir storage levels during each subsequent month throughout the January 1 through July 31 runoff period. If the reservoirs are full, drawdown is accomplished to vacate flood control space as required. Unless flood control is necessary, Hoover Dam is operated to meet downstream demands.

During non-flood operations, Lake Mead elevations fluctuate as releases increase and decrease due to downstream water uses, Glen Canyon Dam releases, and 1944 Treaty deliveries to Mexico. Lake Mead's elevations will fluctuate throughout the year for meeting the end-of-month target elevations for Lake Mohave and Lake Havasu, and for releasing to meet downstream requirements. Normally, Lake Mead elevations decline with increasing irrigation deliveries through June or later and then begin to rise again. Lake Mead's storage capacity provides for the majority of Colorado River regulation from Glen Canyon Dam to the border with Mexico.

Each month, Reclamation's water operations personnel send to Western Area Power Administration (Western) a monthly Hoover Powerplant energy target that is based upon Reclamation's most current daily operational data. In order to meet water orders downstream of Hoover Dam, a monthly energy target is set based on water demands below Parker Dam and Davis Dam. The energy target for Hoover Powerplant is broken down into weekly schedules but often it is the monthly target that drives the release at Hoover Dam. Because Hoover Dam is a peaking powerplant, releases will often vary significantly to meet the energy demand. Monitoring of Hoover Dam releases is checked each day for both hourly and daily values.

Hoover Powerplant turbines are fed by four penstocks which in turn are fed by four intake towers. The reservoir elevations that allow water to be fed into the penstocks are 1,045 feet msl and 895 feet msl for the two intake towers, respectively. Eight cylinder gate valves are located at the eight respective intake locations (two for each penstock).

The cylinder gate valves are 75 years old, being part of the original construction of Hoover Dam. Because of their age, each gate valve is operated as either completely open, or completely shut. This is necessary to avoid perturbations associated with partially opening of the valves. Wicket gates located upstream of each turbine control real-time flow and peak power generation.

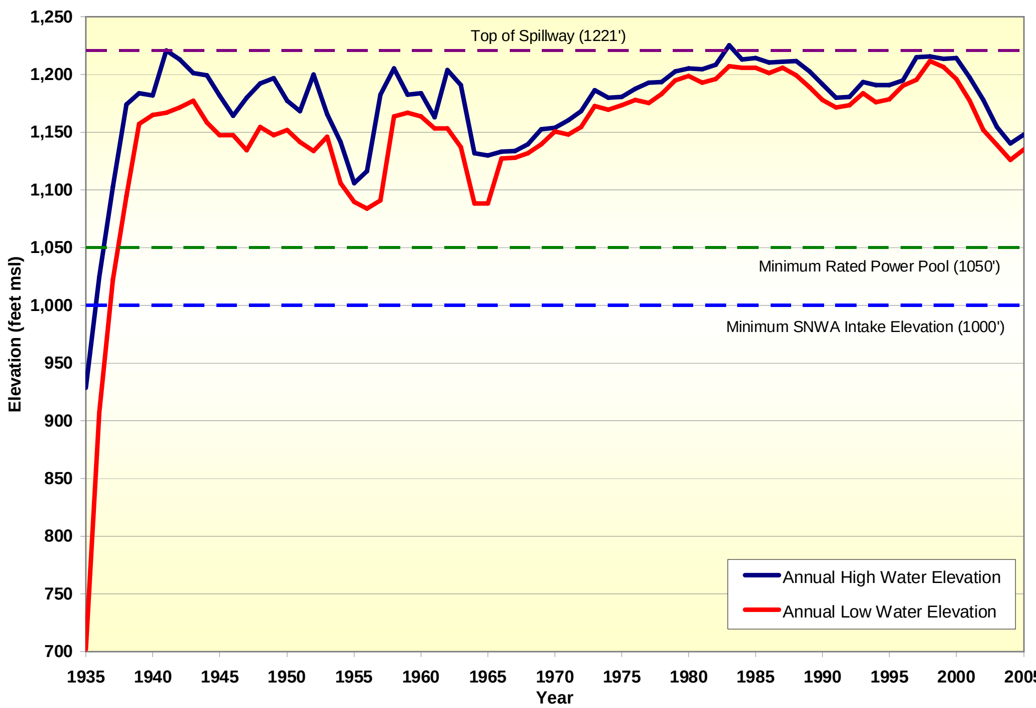
B.2.3.3 Historic Lake Mead Elevations

Figure B-6 illustrates the historic annual elevations (maximum and minimum) of Lake Mead. The annual change in elevations of Lake Mead has ranged from less than ten feet to as much as 75 feet (Figure B-6). The decrease in the elevations within a year observed after the mid-1960s can be attributed to the regulation provided by Lake Powell.

Historic Lake Mead elevations have dropped down to about 1,083 feet msl during two periods (1954 to 1957 and 1965 to 1966). The maximum Lake Mead elevation of approximately 1,225.6 feet msl occurred once, in 1983.

Three Lake Mead elevations of interest are shown in Figure B-6. The first elevation is 1,221 feet msl, the top of the spillway gates. The second elevation is 1,050 feet msl, the minimum elevation for the effective generation of power. The third elevation is 1,000 feet msl, the minimum elevation required for the operation of SNWA's lower intake.

Figure B-6
Historic Lake Mead Elevations
(Annual Highs and Lows)



B.2.4 Hoover Dam to Davis Dam

This reach extends from Hoover Dam to Davis Dam and includes Lake Mohave up to its full pool elevation. Lake Mohave generally comprises the approximately 67-mile length of this reach of the Colorado River. Lake Mohave is formed by Davis Dam and is bound for most of its 67-mile length by the steep walls of Pyramid, El Dorado, and Black Canyons. The lake is relatively narrow, not more than four miles across at its widest point, but provides significant recreation opportunities, and habitat for fish and wildlife. Lake Mohave also captures and delays flash flood discharge from side washes downstream of Hoover Dam. Typical flow time from Hoover Dam to Lake Mohave is four to six hours. Lake Mohave has a storage capacity of approximately 1.818 maf. Davis Dam and Davis Powerplant are located 67 miles downstream from Hoover Dam, and approximately two miles upstream from Laughlin, Nevada, and Bullhead City, Arizona.

B.2.4.1 River Flows between Hoover Dam and Davis Dam

Flows in the Colorado River reach between Hoover Dam and Davis Dam are comprised almost entirely of releases from Hoover Dam. Lake Mohave's primary purpose is to re-regulate Hoover Dam releases and aid in the delivery of water supplies to downstream United States entitlement holders, and to Mexico. Located on the Arizona side of the Colorado River, Davis Dam Powerplant has five generating units, with a generating capacity of 255,000 kW, and with a combined hydraulic capacity of 31,000 cfs. The power is marketed by Western.

Reclamation, as provided in the Interim Surplus Guidelines (ISG) ROD, will continue existing operations in Lake Mohave that benefit native fish through the effective period of the ISG and will explore additional ways to provide benefits to native fish. The normal filling pattern of these two reservoirs coincides well with the fishery spawning period. Since Lake Mohave elevations will be typical of previous years, normal conditions are expected for boating and other recreational uses in future years.

Reclamation is the lead agency in the Native Fish Work Group, a multi-agency group of scientists attempting to augment the ageing stock of the endangered razorback sucker in Lake Mohave. Larval razorback suckers are captured by hand in and around spawning areas in late winter and early spring for rearing at Willow Beach Fish Hatchery which is located below Hoover Dam. The following year, 1-year old razorback suckers are placed into predator-free, lake-side backwaters for rearing through the spring and summer. When Lake Mohave is normally drawn down during August through October, these fish are harvested from these rearing areas and then released to the lake. The razorback suckers grow very quickly, usually exceeding 10 inches in length by September. In 2004, 17,266 razorback suckers were repatriated into Lake Mohave from all sources. In 2005, 12,200 wild larvae were captured from natural spawning congregations on Lake Mohave and delivered to Willow Beach Hatchery.

Under normal conditions, flows in this river reach comprise water deliveries to Colorado River water users that divert water from this reach, and to others located downstream of Parker Dam.

Historic daily river flows since 1963 in this river reach have ranged between 590 cfs to 50,800 cfs. The higher flow rates have been associated with flood flows. Releases since 1963 from Davis Dam have ranged between 1,200 cfs to 44,106 cfs.

B.2.4.2 Historic Lake Mohave Elevations

Hoover Dam flood control releases are passed through Davis Dam. Flood control requirements for Davis Dam were developed through the monthly target elevations developed for Lake Mohave. Flood control releases (from Hoover Dam), as well as side wash inflows, were considered in the development of the target elevations.

Reclamation has discretion to develop and manage Lake Mohave's target elevations and allocated flood control reserved capacity that changes throughout the year by making releases through Davis Dam. This flood control reserved capacity is considered and taken into account in the Davis Dam release calculation. Specifically, the operators use a rule curve with target elevations that coincide with respective vacant storage capacity. The target elevations that are used to assure that sufficient flood control storage capacity is allocated for Lake Mohave are listed in Table B-4 and illustrated on Figure B-7.

Figure B-7
Lake Mohave Monthly Target Elevations

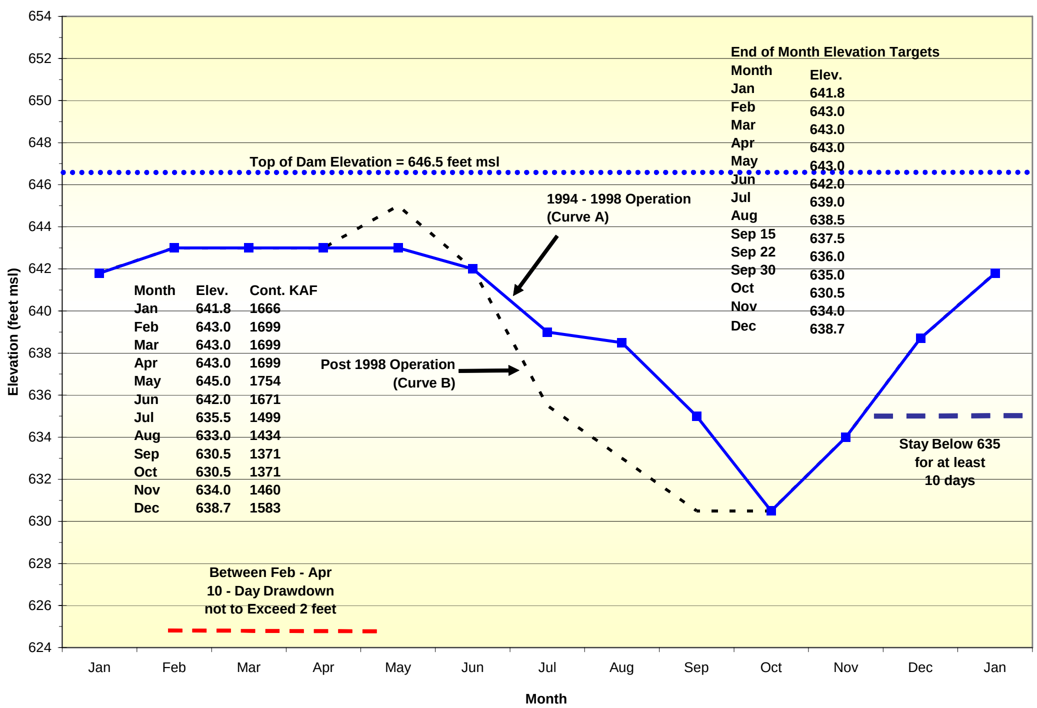


Table B-4
Lake Mohave Monthly Target Elevations

Month	Lake Mohave Target Elevation (feet msl)	Lake Mohave Target Storage (kaf)
January	641.8	1,666
February	643.0	1,699
March	643.0	1,699
April	643.0	1,699
May	645.0	1,754
June	642.0	1,671
July	635.5	1,499
August	633.0	1,434
September	630.5	1,371
October	630.5	1,371
November	634.0	1,460
December	638.7	1,583

The razorback sucker backcove rearing program that began in 1994 can also limit the drawdown to no more than two feet in a ten-day period during the razorback sucker spawning season. Further, the program also requires that the Lake Mohave elevation be maintained above 640 feet msl between March 15 and June 15 to provide sufficient depth for the backcove rearing areas. These limitations require closer coordination of Lake Mohave with that of downstream Lake Havasu as well as adjustment to the Hoover Dam hourly water release and energy production schedules. The operators take all these factors into account in the management of the Lake Mohave daily elevations.

As shown on Figure B-7, Lake Mohave generally reaches its maximum elevation in the spring and its minimum elevation in the fall. Reclamation generally lowers the lake elevation in the fall to provide flood control storage space for runoff that results from large hurricane-type storms coming up-river from Mexico. However, it needs to be noted that these are target elevations only. The actual elevations will sometimes differ from the target elevations with the regulation of Hoover Dam releases and the balancing of arriving flows with downstream water demands.

As with releases from Hoover Dam, factors that must be considered when making the Davis Dam releases include the need to meet downstream water requirements throughout the month and the objective to maintain non-damaging flow levels downstream.

B.2.4.3 Operation of Davis Dam

The primary purpose of Davis Dam is to re-regulate Hoover Dam releases and aid in the delivery of water supplies to downstream United States entitlement holders and the annual delivery of 1.5 maf to Mexico pursuant to the 1944 Treaty. Other benefits provided by Davis Dam and Lake Mohave include flood control protection, navigation, recreation, and power production.

Reclamation's water schedulers collect and compile water delivery orders from the Central Arizona Project (CAP), the Metropolitan Water District of Southern California (MWD), and other Colorado River entitlement holders that divert water between Davis Dam and Parker Dam. The hourly release schedule for Davis Dam is then integrated with the scheduled water releases of Parker Dam and other objectives to coordinate the maximum release through the power facilities at the time of the peak usage of electricity; to the extent such release is compatible with the timing of the water deliveries and other constraints.

Since 1980, annual release from Davis Dam has varied from a low of 7.3 maf to a high of 21.7 maf. The maximum instantaneous release for Davis Dam is approximately 44,000 cfs and the minimum instantaneous release that can be expected under other than normal operating conditions is about 1,000 cfs. The minimum amount represents approximately one half of the release needed to turn one of the Davis Powerplant's turbines. Such low flows are usually associated with downstream flooding, construction, search and rescue, or other emergency conditions.

Davis Powerplant's generating units are capable of providing moment-to-moment dynamic control. However, there is minimal use of this dynamic capability. If there are changes to hourly flows, the schedule change usually begins ten minutes to the hour and the change is fully implemented ten minutes after the hour. These flow changes are computer controlled and the changes to the unit releases are programmed well in advance.

The minimum elevation of Lake Mohave without resetting the intake stops is at about 630 feet msl. The maximum elevation is 646.5 feet msl, where wave action begins to leak into Davis Dam's inspection gallery. The daily releases are coordinated such that the end of month target elevations are achieved.

B.2.5 Davis Dam to Parker Dam

This reach extends from Davis Dam to Parker Dam and includes Lake Havasu up to its full pool elevation. Parker Dam is located approximately 155 miles downstream of Hoover Dam and approximately 88 miles downstream of Davis Dam. The lower portion of this reach comprises Lake Havasu. Formed by Parker Dam, Lake Havasu is about 45 miles long and can store nearly 648,000 af of water. At its maximum elevation of 450.5 feet msl, Lake Havasu has a surface area of approximately 20,390 acres.

Lake Havasu provides a forebay and desilting basin from which water is pumped into the Colorado River Aqueduct (California) and into the CAP aqueduct system. The pumping plant that pumps water into the Colorado River Aqueduct is located on the west side of the Colorado River and it is operated by the MWD. The pumping plant that pumps water into the

CAP aqueduct system is located on the east side of the Colorado River and it is operated by the Central Arizona Water Conservation District (CAWCD).

B.2.5.1 River Flows between Davis Dam and Parker Dam

The majority of the flows in this river reach are releases from Hoover Dam and flows that pass through Lake Mohave and Davis Dam. There are also some minor gains in this river reach from tributaries such as the Bill Williams River, groundwater discharge, and return flows from agriculture.

Under normal conditions, flows in this river reach comprise water deliveries to Colorado River water users that divert water from this reach, and to others located downstream of Parker Dam.

Historical river flows since 1963 in this river reach have ranged between 1,200 cfs to 44,106 cfs. The higher flow rates have been associated with flood flows.

B.2.5.2 Operation of Parker Dam

Parker Dam's primary purpose is to regulate the storage at and releases from Lake Havasu. Parker Dam also has a powerplant function and may provide a minimal amount of flood control, capturing and delaying flash floods into the Colorado River from tributaries below Davis Dam.

Releases at Parker Dam are scheduled on a daily basis to meet the short-term demands of Colorado River water users located downstream. The hourly release profile may be adjusted to meet electric service customer requirements.

Parker Dam Powerplant is located on the California side of the Colorado River immediately below the dam. It houses four hydroelectric generating units. The installed generating capacity is 120,000 kW, but due to high tailrace elevation, the generation production is approximately 108,000 kW. Four 22-foot diameter penstocks carry up to 5,500 cfs each to feed the generating units. About 50 percent of the plant's power output is reserved in perpetuity by MWD for pumping water along the Colorado River Aqueduct to the southern California coastal area. The remaining power is marketed by Western.

B.2.5.3 Historic Lake Havasu Elevations

Hoover Dam flood control releases also are passed through Parker Dam after deliveries are made to the CAP and MWD diversion facilities at Lake Havasu, and to other users upstream of Parker Dam. Flood control requirements for Parker Dam were developed through the monthly target elevations developed for Lake Havasu. Flood control releases from Hoover Dam, as well as side wash inflows and flood flows on Bill Williams River, were considered in those target elevations. Reclamation has discretion to develop and manage the target elevations of Lake Havasu by making releases through Parker Dam. Lakes Havasu is operated to meet a user-specified target storage at the end of each month. These storage target elevations are provided in Table B-5.

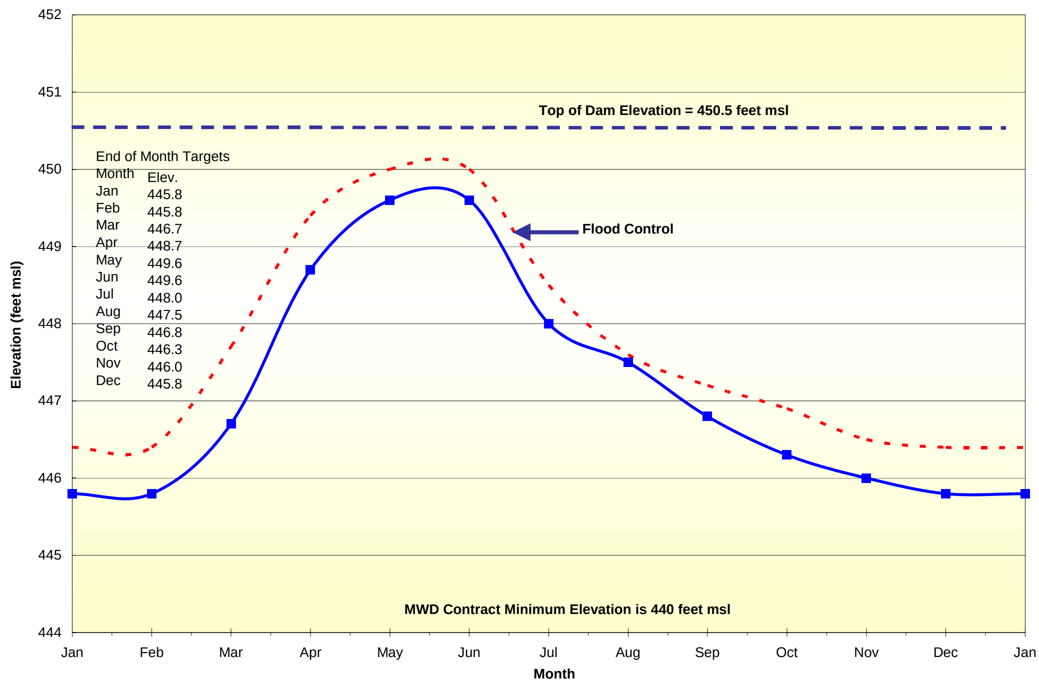
Lake Havasu generally reaches its maximum elevation in the spring and its minimum elevation in the winter. Reclamation generally lowers the lake elevation during the winter months to provide flood control storage space for runoff that results from large storms coming up river from Baja California, Mexico. The actual elevations will sometimes differ from the target elevations (Figure B-8) with the regulation of Hoover Dam and Parker Dam releases and the balancing of arriving flows with downstream water demands.

Figure B-8 illustrates the average, maximum, and minimum monthly elevations of Lake Havasu (elevations measured at midnight on last day of month) for the non-flood control years. The maximum average elevation of approximately 448.7 feet msl occurs in May and the minimum average elevation of about 446.0 feet msl occurs in February. The minimum target elevation for marina operators is 445.8 feet msl. Reclamation attempts to accommodate this minimum target elevation when other higher priority uses are not compromised. The maximum Lake Havasu elevation is 450.5 feet msl.

Table B-5
Lake Havasu Monthly Target Elevations

Month	Lake Havasu Target Elevations (feet msl)	Lake Havasu Target Storage (kaf)
January	445.8	539.1
February	445.8	539.1
March	446.7	557.4
April	448.7	593.6
May	449.6	611.4
June	449.6	611.4
July	448.0	580.0
August	447.5	561.1
September	446.8	557.4
October	446.3	548.2
November	446.0	542.7
December	445.8	539.1

Figure B-8
Lake Havasu Monthly Target Elevations



B.2.6 Parker Dam to Imperial Dam

Parker Dam is the last major dam on the lower Colorado River and provides the last opportunity for Reclamation to provide any significant regulation of river flows. Once released from Parker Dam, water flows relatively unregulated until it reaches Imperial Dam. The transit time between Parker Dam and Imperial Dam is approximately 3 days.

B.2.6.1 River Flows between Parker Dam and Imperial Dam

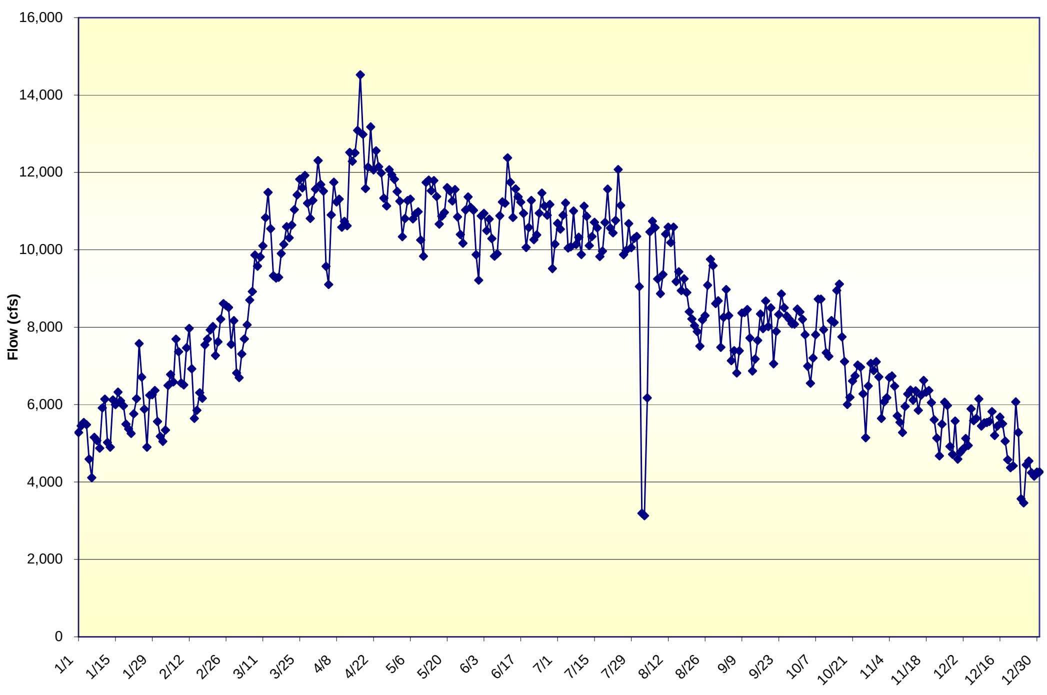
The flow of the Colorado River between Parker Dam and Imperial Dam is normally set at the amount needed to meet the United States consumptive use requirements downstream of Parker Dam plus deliveries to Mexico at the Morelos Diversion Dam. The scheduling and subsequent release of water through Parker Dam creates short-term fluctuations in river flows, depths, and elevations downstream of Parker Dam. These fluctuations of elevations in the Colorado River are most noticeable in the section of the river located immediately downstream of Parker Dam and lessen as the downstream distance increases.

Several features located downstream of Parker Dam are also used to manage the flows in the river and make deliveries to the Colorado River water users that divert water downstream of Parker Dam. These features include the Headgate Rock Dam, Palo Verde Diversion Dam, Senator Wash Dam, Imperial Dam, and Laguna Dam, as discussed in detail below.

Historical river flows since 1963 in this river reach have ranged between 30 cfs to 40,000 cfs. The higher flow rates have been associated with flood flows. An example of the daily fluctuation in flows in this river reach is illustrated on Figure B-9. Historical annual diversions since 1963 from this river reach have ranged between zero af and 152,496 af.

Future flows in this reach of the Colorado River are expected to be affected by the water transfers and exchanges between the California agricultural water agencies and MWD, which will change the point of diversion of some water deliveries. For example, under water transfer between Imperial Irrigation District (IID) and MWD (or San Diego County Water Authority [SDCWA]), the flow that would normally be diverted at Imperial Dam instead would be diverted upstream of Parker Dam. The existing and future California intrastate transfers are included in the simulations of the No Action Alternative and the action alternatives. The California intrastate transfers and any potential environmental effects that would occur as a result of those transfers were previously addressed in the *Implementation Agreement, Inadvertent Overrun and Payback Policy, and Related Federal Actions EIS* (Reclamation 2002).

Figure B-9
Variation of Daily Flows Arriving at Imperial Dam
(reported 1996 daily river flow measurements at Cibola Stream Gage, RM 87.3)



B.2.6.2 Operation of Headgate Rock Dam

Headgate Rock Dam was completed in 1941and forms Lake Moovalya which serves as a diversion dam for the Colorado River Indian Irrigation Project (CRIIP). The dam controls the elevation of a 16-mile stretch of the Colorado River that reaches almost to the tail water of Parker Dam less the diversion by the CRIIP. There is very little daily fluctuation in the elevations upstream of Headgate Rock Dam. Downstream elevations of Headgate Rock Dam reflect the releases from Parker Dam. Irrigation water is diverted from upstream of Parker Dam almost 12 months out of the year. When water is being diverted, the upstream elevation is kept at or around 364.4 feet msl. When water is not being diverted, the elevation of the upstream Lake Moovalya can be lowered by opening the spillway gates, and the elevation is kept at or around 363.4 feet msl and possibly lower, if needed.

When Headgate Rock Powerplant is operational, power is generated through up to three 6.5-megawatt turbine units depending on water release through Parker Dam. The power is used for irrigation projects, Bureau of Indian Affairs' (BIA) needs, power sales, and off-reservation exchanges.

CRIIP's main canal is 18 miles long and includes six major control or diversion structures, as well as minor delivery, drainage, and highway structures. CRIIP operates the diversion on a demand basis. Water users must place their order at least 48 hours in advance, and the irrigation office usually provides that water within 48 hours from the posted end-of-order time each day. Accumulated daily water orders are relayed to Headgate Rock Dam, so that gates on the dam and main canal intake structure are raised or lowered to divert the correct quantity into the irrigation system.

The CRIIP Irrigation Office prepares and submits an annual report that provides the annual projected water use to the River Operations Branch of Reclamation. This report estimates the monthly flow to be diverted for CRIIP use in the next crop year.

B.2.6.3 Operation of Palo Verde Diversion Dam

The Palo Verde Diversion Dam is the intake for the Palo Verde Irrigation District (PVID). Flows between the Palo Verde Diversion Dam and Imperial Dam are set by downstream demands and required deliveries to Mexico.

Palo Verde Diversion Dam is operated by PVID. The diversion dam maintains a constant elevation at the PVID canal intake during periods of normal riverflow. Except during periods of high river discharge, this forebay elevation is maintained at 283.5 feet msl.

B.2.6.4 Operation of Senator Wash Dam

Senator Wash Dam and Regulating Reservoir is located 20 miles northeast of the city of Yuma, Arizona, on the California side of the Colorado River and approximately two miles upstream of Imperial Dam. This strategic off-stream water storage reservoir was constructed by Reclamation to facilitate water scheduling and to help in balancing the river flows and supply with demands. This is achieved by storing part of the Colorado River flow when excess flows are available above Imperial Dam and releasing the water in storage back to the river for downstream use when needed.

Senator Wash Reservoir was designed to have a water surface area of about 470 acres at a maximum operating elevation of 251 feet msl. At this elevation, the design storage capacity is approximately 13,840 af. The reservoir has inactive (dead) storage below elevation 210 feet msl which has an estimated capacity of about 1,577 af. The design active storage is located between elevations 210 feet msl and 251 feet msl and is estimated to be about 12,259 af.

Current operational restrictions limit the use of the full storage capacity available at Senator Wash Reservoir. The operational restriction of Senator Wash Reservoir is associated with Safety of Dams concerns. Previous structural evaluation, studies of the dam, and related facilities have shown evidence of potential piping through and around the foundation of the dam (transportation of dam embankment foundation material caused by seepage that could lead to failure of the dam or dikes). There is a potential for failure of the foundation or embankment which could result from liquefaction during an earthquake. The maximum operating elevation of Senator Wash Reservoir was previously restricted to 235 feet msl with temporary incursions up to 240 feet msl. However, with the recent installation of a geomembrane liner along the bottom of a portion of the reservoir, the maximum unrestricted operating elevation has been raised to 240 feet msl.

B.2.7 Imperial Dam to NIB

This reach extends from Imperial Dam to the NIB between the United States and Mexico. The entire extent of the channel is bound by a system of levees. Several features located between Imperial Dam and the NIB are used to manage river flows and make deliveries to the Colorado River water users that divert water at and downstream of Imperial Dam. This includes Imperial Dam, Laguna Dam, Laguna Desilting Basin, Morelos Diversion Dam, California Wasteway, and Pilot Knob Wasteway. Other features include water conveyance system components (levees, bypass channels, wasteways, etc.), access roads, farmlands, and vegetation. Mittry Lake is also located on the Arizona side of the Colorado River.

The All-American Canal (AAC) system diverts water from the California side of Imperial Dam and serves IID, Coachella Valley Water District (CVWD), the Yuma Project in Arizona and California, and the City of Yuma.

The Gila Gravity Main Canal system diverts water from the Arizona side of Imperial Dam and serves the north and south Gila Valley, Yuma Mesa, and Wellton-Mohawk area. Imperial Dam is also used to regulate deliveries to Mexico.

The AAC Desilting Works, which is located adjacent to the AAC diversion structure, is used to remove most of the sediment carried by the Colorado River prior to the water entering the AAC. The Imperial National Wildlife Refuge (NWR) is located mostly on the Arizona side of the Colorado River. Martinez Lake is a small water cove formed by the impoundment and backwater area located above Imperial Dam.

B.2.7.1 Operation of Imperial Dam

Imperial Dam and the impoundment that it forms upstream of the dam is used to raise the elevation of the upstream river flows by approximately 25 feet to provide controlled gravity flow of water into the AAC and into the Gila Gravity Main Canal. Imperial Dam is situated on the Colorado River some 18 miles northeast of Yuma, Arizona.

The flows arriving at Imperial Dam normally range from a high of about 14,400 cfs (usually occurring in late spring to summer) to a low of about 2,500 cfs. The low flow period usually follows heavy rainfall in the area below Imperial Dam (usually November, December, and January). During these wet weather periods, the rain saturates the farm fields, and the farmers and respective water agencies adjust or cancel their water delivery orders. Mexico's water order is required to be delivered regardless of wet weather or excess rainfall conditions.

The reservoir created by Imperial Dam initially had a capacity of 83,000 af. This storage capacity was not considered a project feature and, as anticipated, the reservoir quickly filled with sediment. The reservoir capacity is now considered to be approximately 1,000 af and intermittent dredging is required to maintain the required diversion capacity at the AAC and the Gila Gravity Main Canal headworks.

The normal operating range of reservoir elevations for Imperial Dam is between 180 feet msl and 180.85 feet msl. However, if the amount of water arriving at Imperial Dam is less than the demands, and pulling water out of the Senator Wash Reservoir cannot keep the reservoir elevation of Imperial Dam from continuing to fall, diversions at elevations below 180.0 feet msl can be made to the AAC or the Gila Gravity Main Canal. Under certain conditions, it is possible to draw down reservoir elevations of Imperial Dam to as low as 178.5 feet msl.

Imperial Dam is operated primarily as a diversion dam, providing water to the AAC and the Gila Gravity Main Canal to meet the beneficial use requirements of entitlement holders in California and Arizona. Releases may also be made to meet a portion of the 1944 Treaty deliveries to Mexico. Occasionally (two to three times per month), water is released through the sluice gates at Imperial Dam to move accumulated sediment to the Laguna Desilting Basin which is located about two miles downstream from Imperial Dam. The Laguna Desilting Basin, located within the Colorado River channel, is used to decant the water that is released from or that passes Imperial Dam.

B.2.7.2 River Flows between Imperial Dam and NIB

The flows in the Colorado River below Imperial Dam are primarily comprised of water delivered to Mexico in accordance with the 1944 Treaty. Mexico's principal diversion is at Morelos Diversion Dam, which is located approximately nine miles southwest of Yuma, Arizona. Mexico owns, operates, and maintains Morelos Diversion Dam.

Much of the water that is delivered to Mexico at the NIB is diverted at Imperial Dam into the AAC where it is conveyed and then returned to the Colorado River through Siphon Drop and Pilot Knob Powerplants. A portion of the NIB deliveries remains in the river, passing through Imperial Dam and Laguna Dam to the Morelos Diversion Dam.

Under normal conditions and when there is no runoff from the Gila River, the delivery of scheduled water to Mexico at the NIB comes from two principal sources: 1) drainage return flows that occur downstream of Imperial Dam; and 2) the diversion of flows to Mexico from Imperial Dam. The drainage return flows are nearly constant throughout the year and from year to year and comprise both gravity and pumped drainage flows.

Water may be delivered to Mexico at the NIB via one or a combination of three routes. Figure B-10 presents a schematic that shows these routes. The following provides an explanation of these three flow routing methods:

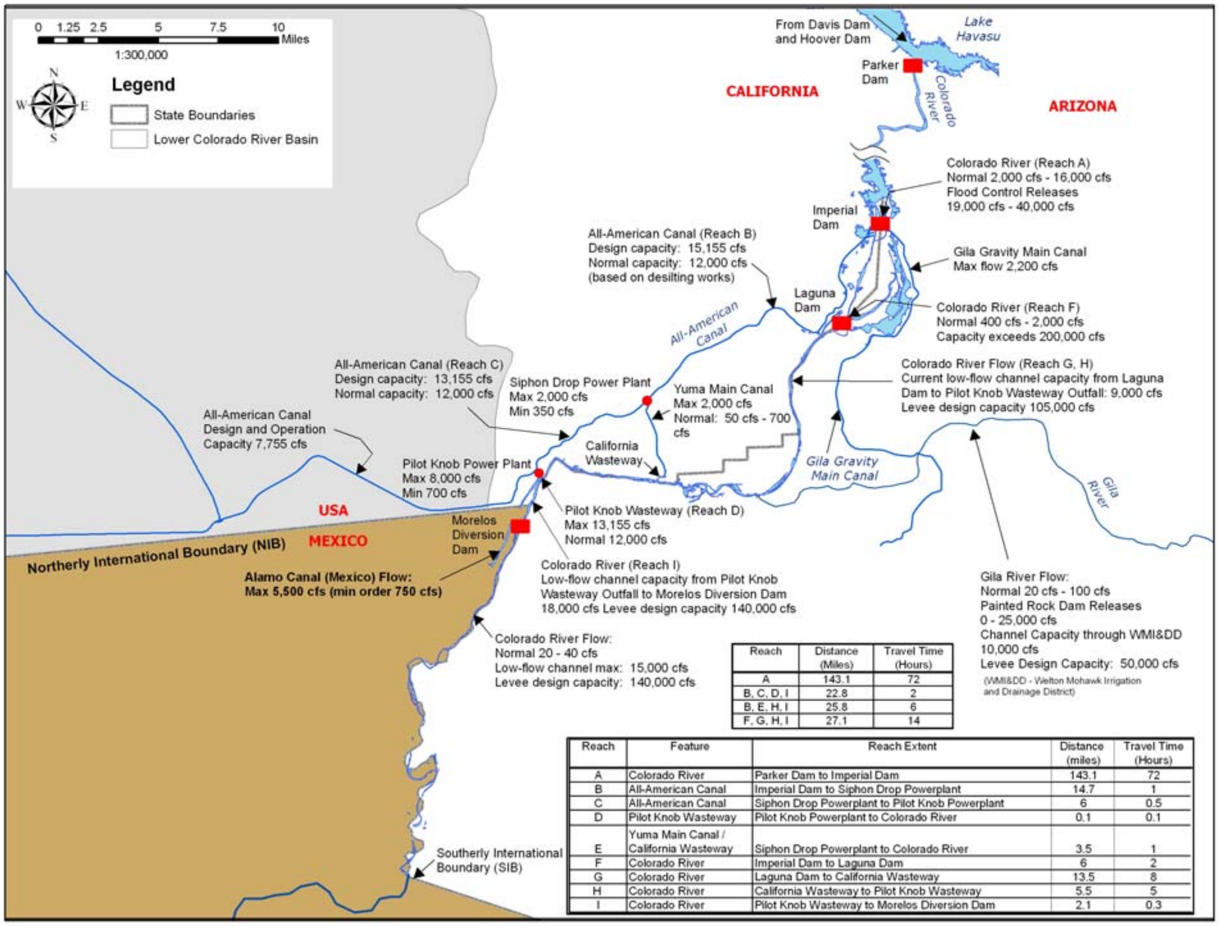
1) water scheduled to be delivered to Mexico is diverted at Imperial Dam, conveyed through the AAC to the Pilot Knob Check, and at a point above the Pilot Knob Check, the flows are diverted from the AAC through the Pilot Knob Power Plant and Wasteway back into the Colorado River. The Pilot Knob Wasteway channel discharges to the Colorado River at a point located approximately 2.1 miles upstream of the NIB;

2) water scheduled to be delivered to Mexico is diverted at Imperial Dam, conveyed through the AAC to the Siphon Drop, and at a point above the Siphon Drop, the flows are diverted from the AAC through the Siphon Drop Wasteway and into the Yuma Main Canal. The water is then conveyed some 3.5 miles within the Yuma Main Canal and then is diverted and discharged back into the Colorado River via the Yuma Main Canal Wasteway. The Yuma Main Canal Wasteway discharges to the Colorado River at a point located approximately 7.6 miles upstream of the NIB; or

3) water scheduled to be delivered to Mexico is delivered directly to the NIB via the Colorado River. Under this method, water is passed through Imperial Dam and Laguna Dam and is allowed to flow via the river channel to the NIB. These flows are in addition to the base flows in the riverbed downstream of Laguna Dam. The base flows are generally consistent throughout the year and result from gate leakage at Imperial Dam, returns to the river below Imperial Dam from the AAC Desilting Basin, and drainage flows from downstream sources. These base flows normally range from 600 cfs to 800 cfs.

Another intermittent water source that is available for delivery to Mexico at the NIB is Gila River. When releases from Painted Rock Dam occur, these flows are used to satisfy a portion of Mexico's delivery, depending on the amount of flow from the Gila River that enters the Colorado River upstream of the NIB.

Figure B-10
Water Routing from Imperial Dam to the NIB
Deliveries to Mexico Pursuant to 1944 Treaty



Reach	Distance (Miles)	Travel Time (Hours)
A	143.1	72
B, C, D, I	22.8	2
B, E, H, I	25.8	6
F, G, H, I	27.1	14

Reach	Feature	Reach Extent	Distance (miles)	Travel Time (Hours)
A	Colorado River	Parker Dam to Imperial Dam	143.1	72
B	All-American Canal	Imperial Dam to Siphon Drop Powerplant	14.7	1
C	All-American Canal	Siphon Drop Powerplant to Pilot Knob Powerplant	6	0.5
D	Pilot Knob Wasteway	Pilot Knob Powerplant to Colorado River	0.1	0.1
E	Yuma Main Canal / California Wasteway	Siphon Drop Powerplant to Colorado River	3.5	1
F	Colorado River	Imperial Dam to Laguna Dam	6	2
G	Colorado River	Laguna Dam to California Wasteway	13.5	8
H	Colorado River	California Wasteway to Pilot Knob Wasteway	5.5	5
I	Colorado River	Pilot Knob Wasteway to Morelos Diversion Dam	2.1	0.3

B.2.7.3 Operation of Laguna Dam

Laguna Dam is located on the Colorado River some 13 miles northeast of Yuma, Arizona, and about five miles downstream from Imperial Dam. The original purpose of this dam was to divert Colorado River water to the Yuma Project area. Laguna Dam now serves as a regulating structure for Colorado River water, for regulating sluicing flows from Imperial Dam, and for downstream toe protection for Imperial Dam. The reservoir created by Laguna Dam is commonly referred to as Laguna Reservoir.

Water can be stored in Laguna Reservoir between elevations 142 feet msl to 151.3 feet msl. The top of the overflow weir at Laguna Dam is at elevation

151.3 feet msl. A small amount of additional storage can be obtained by forcing water into surcharge above the weir. The current estimate of the available storage capacity at Laguna Reservoir, between elevation 142 feet msl and 151.3 feet msl, is about 400 af.

The flows that occur below Imperial Dam and that flow into the Colorado River channel and Laguna Reservoir typically range from about 250 cfs to 350 cfs and comprise principally the return flows from the AAC desilting basins and gate leakage from the California sluiceway gates at Imperial Dam. Occasionally, sluicing flows are released to remove sediment accumulated from the desilting basins in the sluiceway channel. These flows occur two to three times per month, may range from 8,000 cfs to 12,000 cfs, and the duration may be up to 20 minutes. These flows carry the sediment to the Laguna Desilting Basin located about two miles downstream of Imperial Dam.

Flow releases from Laguna Dam typically range between 300 and 500 cfs. Occasionally, flows up to 4,000 cfs or higher may occur coincident with or following heavy rainfall.

Laguna Dam is operated to regulate river flows and to temporarily store water used in sluicing operations at Imperial Dam. Any water that is captured and temporarily stored at Laguna Reservoir is released to meet a portion of the 1944 Treaty deliveries to Mexico.

B.2.7.4 Mittry Lake

Mittry Lake is located on the east side of the Colorado River between Laguna Dam and Imperial Dam. The Mittry Lake Wildlife Area generally surrounds and includes Mittry Lake and includes approximately 600 acres of water surface and 2,400 acres of marsh or upland habitat. Numerous serpentine waterways connect to the main lake body. The Mittry Lake Wildlife Area is jointly managed by the United States Bureau of Land Management, Reclamation, and the Arizona Game and Fish Department.

B.2.8 NIB to SIB

This reach extends from the NIB to the SIB between the United States and Mexico and is approximately 23.7 miles long. This section of the Colorado River serves as the international boundary between the United States and Mexico. This segment of the Colorado River has been highly altered and has levees on both sides.

Located approximately 1.1 miles downstream of the NIB is Morelos Diversion Dam. This dam functions as a diversion control structure for the Alamo Canal, which conveys water to Mexico. Morelos Diversion Dam and the limitrophe section of the Colorado River channel, including the floodplain, are designed to convey a maximum flow of 140,000 cfs. Other major features located within this reach include water conveyance system components (levee, bypass channel, wasteways, etc.), access roads, farmlands, and vegetation.

B.2.8.1 Operation of Morelos Diversion Dam

In accordance with the 1944 Treaty and Minute 242, up to 140,000 afy of Mexico’s treaty allocation of 1.5 mafy may be delivered at the SIB. Consequently, Mexico diverts the majority (approximately 1.36 mafy) of its 1944 Treaty allocation at Morelos Diversion Dam.

B.2.8.2 River Flows between Morelos Diversion Dam and the SIB

Flows in this reach of the Colorado River vary. At times the lower part of this reach is dry. Cohen and Henges-Jeck (2001) reported average total flows in this reach of 22,000 af in non-flood years and 2.12 maf in flood years.

The flows that are observed in this river reach typically are the result of seepage from Morelos Diversion Dam, flow releases from Morelos Diversion Dam (flood flows and excess water not diverted by Mexico), irrigation return flows from Mexico and canal wasteways in the United States, and groundwater accumulation from both the United States and Mexico.

The reach of the Colorado River between the NIB and the SIB is commonly referred to by Reclamation as the Limitrophe Reach. Reclamation's authority in this division is limited to maintaining the bankline road, the levee, various drains to the river, and the United States Bypass drain that carries agricultural drainage water to the Cienega de Santa Clara in Mexico. The United States Section of the International Boundary and Water Commission (USIBWC) is obligated to maintain the river channel within this division although Reclamation provides assistance to the USIBWC, when requested, for maintenance needs in this reach of the river.

Under current practice, Mexico is allowed to schedule up to an additional 200 kaf pursuant to the 1944 Treaty during flood control years when water supplies exceed those required for use in the United States. Often, the flood control releases are greater than the surplus uses in both the United States and Mexico and water in excess of Mexico's water schedule (termed excess flows) arrive at the NIB. Excess flows may also arrive at the NIB due to flooding on the Gila River and from operational activities upstream (i.e., cancelled water orders in the United States, maintenance activities, etc.). Mexico has the ability to divert the excess flows that arrive at Morelos Diversion Dam. Excess flows that are of magnitudes greater than what can be used by Mexico are passed through the Morelos Diversion Dam and flow through the Limitrophe Reach to the Colorado River Delta.

Appendix C

Upper Basin
States Depletion Schedules

This appendix consists of a table displaying the schedule of projected Colorado River system depletions for the Upper Basin states. These depletions were used to model the operation of the Colorado River system under the No Action Alternative and the action alternatives. Presented in the table are projected depletions of the Upper Division states (Colorado, Utah, Wyoming, and New Mexico), and Arizona's apportionment of water from the Upper Basin. The depletion schedules were developed by the Upper Basin states and compiled and submitted to Reclamation by the Upper Colorado River Commission in December 1999.

Appendix D

Lower Division States Depletion Schedules

This appendix contains schedules of projected Colorado River system depletions by the Lower Division states (Nevada, California, and Arizona). These schedules were used to model the operation of the Colorado River system under the No Action Alternative and the action alternatives. The schedules used to model depletions under Normal and Surplus conditions are included.

D.1 Normal Condition Depletion Schedules

The following schedules of projected Colorado River system depletions under Normal Conditions for the Lower Division states (Nevada, California, and Arizona) were used to model the operation of the Colorado River system under the No Action Alternative and the action alternatives. The depletion schedules were developed by the Lower Division states and submitted to Reclamation in 2006. Additionally, the Arizona Department of Water Resources provided updated depletion schedules for the Central Arizona Project (CAP) which included adjusted schedules for the CAP fourth priority entitlement holders in the summer of 2007. The Normal depletion schedules include:

Table Number	Depletion Schedule
D-1	Nevada
D-2a through D-2b	California
D-3a through D-3l	Arizona
D-4a through D-4d	Arizona CAP 2 M&I
D-5a through D-5b	Arizona CAP 2 Indian
D-6a through D-6b	Arizona CAP 3 NIA
D-7	Arizona CAP Summary

Tables D-1 through D-3 were used as input to the Colorado River Simulation System (CRSS), and Tables D-3 through D-7 were used as input to the Shortage Allocation Model. In some cases, slightly different schedules for Arizona on-river water users were used in CRSS and the Shortage Allocation Model. Further explanation is presented in Appendix G. Table D-3 consequently displays two columns for certain Arizona entitlement holders and the column heading indicates which schedule was used by which model. The sums of the depletions for each state do not include the columns denoted as used in the Shortage Allocation Model.

Table D-1
State of Nevada Users (af)

Calendar Year	Laughlin M&I	Mohave Steam Plant	Ft Mohave Ind. Res.	Moapa Valley WQIP	Lower Virgin WQIP	Uses Above Hoover Dam	Total State of Nevada
2008	4,000	16,000	9,000	0	0	271,000	300,000
2009	4,000	16,000	9,000	0	0	271,000	300,000

D.2 Surplus Condition Depletion Schedules

The depletion schedules for the various Surplus conditions under each alternative are presented in Tables D-9 through D-13. The modeling for all alternatives assumed that surplus would be delivered to MWD, IID, and CVWD in California, CAP in Arizona, and SNWA in Nevada.[1]

Table D-8 presents the effective dates that each type of surplus is in effect for each alternative. The details for each alternative are discussed below.

Table D-8
Type of Surplus In Effect For Each Alternative

Action Alternative	Tables	Applicable Surplus Condition and Modeling Period				
		Flood Control	70R[1]	Quantified (70R)	Full Domestic	Partial Domestic
No Action	D-9 and D-13	2008-2060	2017-2060	2008-2016	2008-2016	2008-2016
Basin States	D-10 and D-13	2008-2060	2027-2060	2008-2026	2008-2026	-
Conservation Before Shortage	D-10 and D-13	2008-2060	2027-2060	2008-2026	2008-2026	-
Water Supply	D-11 and D-13	2008-2060	2027-2060	2008-2026	2008-2026	2008-2026
Reservoir Storage	D-12 and D-13	2008-2060	2008-2060	-	-	-
Preferred Alternative	D-10 and D-13	2008-2060	2027-2060	2008-2026	2008-2026	-

1. Deliveries under a 70R Surplus Condition are assumed to follow the Flood Control Surplus Schedules.

D.2.1 No Action Alternative

Under the No Action Alternative, the existing ISG are assumed to be in place through 2016. Depletion schedules under Flood Control, Quantified (70R), Full Domestic, and Partial Domestic Surplus conditions are shown in Table D-9. After 2016, the modeled operation is assumed to revert back to the assumptions used for Flood Control Surplus and 70R Surplus conditions, as shown in Table D-9 and D-13.

D.2.2 Basin States Alternative

The Basin States Alternative includes both a modification and an extension of the ISG. The existing ISG would be extended through 2026 and be modified by eliminating the Partial Domestic Surplus condition, beginning in 2008, and limiting the amount of water available under the Full Domestic Surplus conditions during the period 2017 through 2026 (Section 2.4). Depletion schedules under Flood Control, Quantified (70R) and Domestic Surplus conditions are shown in Table D-10. After 2026, the modeled operation is assumed to revert back to the assumptions used for the No Action Alternative (Flood Control Surplus and 70R Surplus) as shown in Table D-13.

[1] Other entities currently, or may in the future, have contracts for surplus deliveries. However, for modeling purposes, the entities listed were assumed to receive the surplus deliveries in their respective states.

D.2.3 Conservation Before Shortage Alternative

The Conservation Before Shortage Alternative assumes the same modifications to and extension of the term of the ISG as described under the Basin States Alternative. These schedules are also shown in Table D-10. After 2026, the modeled operation is assumed to revert back to the assumptions used for the No Action Alternative (Flood Control Surplus and 70R Surplus) as shown in Table D-13.

D.2.4 Water Supply Alternative

The Water Supply Alternative assumes the ISG would be extended through 2026. Depletion schedules under Flood Control, Quantified (70R), Full Domestic and Partial Domestic Surplus conditions are shown in Table D-11. After 2026, the modeled operation is assumed to revert back to the assumptions used for the No Action Alternative (Flood Control Surplus and 70R Surplus) as shown in Table D-13.

D.2.5 Reservoir Storage Alternative

Under the Reservoir Storage Alternative, the permissive provisions of the ISG are terminated beginning in 2008 and the modeled operations revert to the assumptions used for the No Action Alternative (Flood Control and 70R Surplus) from 2008 through 2026. Depletion schedules under Flood Control and 70R Surplus conditions are shown in Table D-12. After 2026, the modeled operation continues using the assumptions for the No Action Alternative (Flood Control Surplus and 70R Surplus) as shown in Table D-13.

D.2.6 Preferred Alternative

The Preferred Alternative assumes the same modifications to and extension of the term of the ISG as described under the Basin States and Conservation Before Shortage alternatives. These schedules are also shown in Table D-10. After 2026, the modeled operation is assumed to revert back to the assumptions used for the No Action Alternative (Flood Control Surplus and 70R Surplus) as shown in Table D-13.

Table D-9
Lower Division States
Surplus Condition Depletion Schedules for the No Action Alternative
2008 through 2026

	Flood Control					Quantified (70R)[1]					Full Domestic		Partial Domestic	
Year	MWD	IID	CVWD	SNWA	CAP	MWD	IID	CVWD	SNWA	CAP	MWD	SNWA	MWD	SNWA

1. During 2017 through 2026, the distribution of Domestic Surplus water is assumed to be limited as follows: 1) for use by MWD, 250 kafy in addition to the amount of California's basic apportionment available to MWD; 2) for use by SNWA, 100 kafy in addition to the amount of Nevada's basic apportionment available to SNWA; and 3) for use in Arizona, 100 kafy in addition to the amount of Arizona's basic apportionment available to Arizona contractors. Based on input received from the Arizona Department of Water Resources, a Domestic Surplus to Arizona was not modeled.

Appendix E

Colorado River Water Entitlements and Priority Systems within Arizona, California, and Nevada

This appendix contains tables that list the Colorado River water entitlement holders within Arizona, California, and Nevada. One table is provided for each state. The entitlement priority system for each of the three Lower Division states is also shown in each respective table. The priorities presented in this appendix are based on contractual arrangements between each entity and Reclamation, as well as key provisions of the Law of the River, including the Consolidated Decree.

Table E-1
State of Arizona Colorado River Water Entitlement Holders and Priorities

Priority	Entitlement Holder	Contract No.	Date	Use	Entitlement (afy) Diversion	Entitlement (afy) Consumptive Use
1st (PPRs)[1]	Molina	PPR No. 15	1928	Agriculture	318	
	Gila Monster Farms (formerly Sturges)	PPR No. 16	1925	Agriculture	780	
	Cocopah Indian Reservation	PPR No. 1	9/27/1917	Indian	7,681	
	Cocopah Indian Reservation	PPR No. 8	1915	Indian	1,140	
	Powers (Power, R.E. & P.)	PPR No. 7	1915	Agriculture	960	
	Zozaya (in MVIDD)	PPR No. 17	1912	Agriculture	720	
	Fort Mohave Indian Reservation	PPR No. 3	2/2/1911	Indian	75,566	
	Brooke Water Company (formerly Graham)	PPR No. 9	1910	M&I[2]	360	
	North Gila Valley Irrigation District	PPR No. 6	7/8/1905	Agriculture	24,500	
	Yuma Auxiliary Project (Unit B)	PPR No. 5 & Certificates	7/8/1905	Agriculture	6,800	
	City of Parker	PPR No. 20	1905	M&I	630	or if less, 400
	Hulet (in MVIDD)	PPR No. 10	1902	Agriculture	1,080	
	Hoover (in MVIDD/formerly Hopal)	4-07-30-W0052/PPR 11	1902	Agriculture	1,050	
	Miller (in MVIDD)	PPR No. 12	1902	M&I	240	
	McKellips and Granite Reef Farms (in MVIDD)	PPR No. 13	1902	Agriculture	810	
	Sherill & Lafollette (in MVIDD)	PPR No. 14	1902	Agriculture	1,080	
	Swan (in MVIDD)	PPR No 18	1902	M&I	960	
	Yuma County Water Users' Association	PPR No. 4 & Certificates	1901	Agriculture	254,200	
	Phillips, Milton and Jean	PPR No. 19	1900	Agriculture	42	
	City of Yuma	PPR No. 21	1893	M&I	2,333	or if less,1,478
	Fort Mohave Indian Reservation	PPR No. 3	9/18/1890	Indian	27,969	
	Fort Yuma Indian Reservation (new entitlement)	PPR No. 3a	1/9/1884	Indian	6,350	
	Colorado River Indian Reservation	PPR No. 2	11/16/1874	Indian	51,986	
	Colorado River Indian Reservation	PPR No. 2	11/22/1873	Indian	252,016	
	Colorado River Indian Reservation	PPR No. 2	3/3/1865	Indian	358,400	
2nd & 3rd (co-equal)	Cibola National Wildlife Refuge (2nd Priority)	Secretarial Reservation	8/21/1964	M&I	34,500	or if less, 16,793
	Yuma Irrigation District (5,000 af M&I) (2nd Priority)	14-06-300-1270	1962	M&I/Agriculture		67,278
	National Park Service (2nd Priority)	1964 Decree	1961	M&I	unquantified

	Mohave County Water Authority	04-XX-30-W0431	1983		750	
	Mohave County Water Authority	5-07-30-W0320	1995		Upon Request	
	City of Parker	2-07-30-W0025	1998		2,000	
6th - Surplus	Cibola Valley Irrigation & Drainage District	2-07-30-W0028	1983		2,000	
	Gila Monster Farms	6-07-30-W0337	1997		Upon Request	
	Hopi Tribe	04-XX-30-W0432	2004		1,000	
	Mohave County Water Authority	04-XX-30-W0431	2004		1,000	

Note: All units are in afy (acre-feet per year).

Subcontracts are displayed below the Entitlement Holder and indented five spaces.

[1]In a shortage, PPRs are delivered water in order of priority date regardless of state lines.

[2]Municipal and Industrial.

[3]BLM diversion entitlement is estimated from consumptive use entitlement based on 2004 Decree Accounting ratios.

[4]These CAP users are subject to CAP conveyance losses which are assumed to be 5 percent.

[5]Recommended Contracts.

Priority	Entitlement Holder	Contract No.	Date	Use	Entitlement (afy)	
					Diversion	Consumptive Use
& Surplus	Metropolitan Water District of Southern California (5a) (Annexed 5b's Entitlement)	I1r-645	1930, 1931	M&I		662,000
6th - Unused & Surplus	Palo Verde Irrigation District (6b) – Mesa Lands	PVID20733C	1933	Agriculture		300,000
	Coachella Valley Water District (6a)	I1r-781	1934	Agriculture		
	Imperial Irrigation District (6a)	I1r-747	1932	Agriculture		
7th	All remaining water within California available for agricultural use					Unquantified
Surplus	Bureau of Land Management	8-07-30-W0374	1973	M&I		1,000
	City of Needles	5-07-30-W0091	1985	M&I	10,000	
	Coachella Valley Water District	7-07-30-W0150	1987	M&I/ Agriculture	100,000	
	Department of the Navy	6-07-30-W0351	1999	M&I	25	23
	Metropolitan Water District of Southern California	7-07-30-W0171	1987	M&I	180,000	

Note: All units are in afy (acre-feet per year).

M&I: Municipal and Industrial.

These priorities are based on the California Seven Party Agreement, modified to include the PPRs identified by the Consolidated Decree.

Forbearances and transfers are displayed in Appendix G, Attachment 6, Table G-42.

[1]In a shortage, PPRs are delivered water in order of priority date regardless of state lines. It is assumed that each PPR holder would divert and consumptively use all of its entitlement by 2017.

[2]PVID's PPR protects 219,780 af of its Seven Party 1st priority diversion entitlement, which is consumptively estimated to be 93,601 af. Dependent upon call, PVID will fallow a minimum of 25,000 af for the Metropolitan Water District of Southern California.

[3]A portion of this Seven Party Agreement entitlement is protected by two separate PPR entitlements, the Fort Yuma Indian Reservation (PPR 23) and the Yuma Project, Reservation Division (PPR 28).

[4]Incorporation of Yuma Island pumpers' use within this priority does not represent either a final approval of this use by Reclamation or a final determination of the appropriate Decree accounting for this use; and is not an admission by any Colorado River contractor as to the legality of this use or diversion of Colorado River water. No Water Certificates have been issued for use of water on Yuma Island in California.

[5]Coachella Valley Water District's quantified entitlement of 330,000 af is reduced by 3,000 af to permit the Secretary of the Interior to satisfy PPR use not covered by the Seven Party Agreement.

[6]IID's PPR protects 2,600,000 af of its Seven Party 3rd priority diversion entitlement. IID's 3rd priority quantified entitlement of 3,100,000 af is reduced by the estimated PPR consumptive use of 2,527,341 af and 11,500 af to permit the Secretary of the Interior to satisfy PPR use not covered by the Seven Party Agreement.

Table E-3
State of Nevada Colorado River Water Entitlement Holders and Priorities

Priority	Entitlement Holder	Contract No.	Date	Use	Entitlement (afy) Diversion	Entitlement (afy) Consumptive Use
1st[1]	Lake Mead National Recreation Area	PPR 82/1979 Decree	1926	M&I	500	or if less, 300

Appendix F

Water Quality Modeling Documentation

This appendix contains the documentation for the modeling and analyses performed to analyze the potential effects on water quality constituents of concern. Three different models were used to analyze different water quality parameters and each is described in this appendix. The salinity module of the CRSS RiverWare™ model was used to analyze changes in salinity concentrations for all alternatives. The CRSS RiverWare™ model is described in Appendix A. The CE-QUAL-W2 model and the GEMSS model were used to analyze potential changes in temperature and water quality corresponding with reservoir drawdown and respective reservoir releases. The results of the modeling and analysis of these water quality parameters are described in Section 4.5 of this Final EIS.

F.1 Salinity Modeling Using the Salinity Module of the CRSS RiverWare™ Model - Model and Approach Description

F.1.1 Model Description (Salinity Module of the CRSS RiverWare™ Model)

Salinity is the only water quality parameter modeled in CRSS. It is modeled as a conservative substance; therefore, dissolution and precipitation are not modeled. As with the hydrology component, salinity is modeled at a monthly time-step and both reservoir and river reach objects are assumed fully mixed over the month; thereby, requiring no lagging algorithms to route salinity.

Seven of the twelve reservoirs (Flaming Gorge, Starvation, Navajo, Lake Powell, Lake Mead, Lake Mohave, and Lake Havasu) are represented in the CRSS salinity module. The reservoirs Flaming Gorge, Navajo, Lake Powell, Lake Mead, and Lake Mohave use a Huen or Predictor-Corrector numerical method to route salinity through the reservoirs. The reservoirs Starvation and Lake Havasu use a weighting method developed by Reclamation that facilitates routing salinity in a reservoir that has a small storage to inflow ratio. Under this scenario, standard numeric methods, such as the Huen method, can become numerically unstable. Both methods assume the reservoirs are fully mixed at a monthly time-step. Flaming Gorge, Lake Powell, and Lake Mead reservoirs include salinity in their bank storage computation. Water flows into the bank at the current time-step concentration and fully mixes with the bank water. Water flows out of the bank at the current time-step bank concentration.

Salt can enter the river system from either a natural source, salt loading resulting from irrigated agriculture return flows, or from flows imported into the system. Salt can leave the system with flows exported out of the system. Additionally, water quality improvement projects represent salt prevented from entering the system as the result of salinity control measures.

F.1.2 Input data

The CRSS salinity component requires several salinity specific data inputs. These include natural salinity at 24 nodes throughout the Colorado River system, future levels of salt loading resulting from agriculture, the concentration of exported and imported flows, future levels of salinity control, and initial reservoir salinity concentrations.

Salinity associated with the available natural flow data (described in Section 3.3 of this Final EIS) is computed with a single site salinity model presented in Prairie et al. (2005). This model uses a nonparametric regression method based on local polynomial estimation, which describes the variability of salt mass as a function of flow. The model is defined as: natural salt mass = f (natural streamflow). The main feature is that the function f is estimated locally (Loader 1999). The implementation steps are as follows.

a) At any value of the streamflow, say x*, K-nearest neighbors (K-NN) are identified from the observations.

b) To the K-NN a polynomial of order p is fit.

c) The fitted polynomial is then used to estimate the salt mass corresponding to the streamflow x*.

The number of nearest neighbors (K) and the order of polynomial p are estimated for the observed data using objective criteria, Generalized Cross Validation (GCV). The local estimation of the function f provides the capability to capture any arbitrary features (linear or nonlinear) that might be present in the data; besides, this obviates making any assumptions as to the underlying form of the function f (linear in the case of traditional linear regression approach). Prairie et al. (2005) provides details on the methodology and its development for salinity modeling.

Natural salt mass, required to compute the flow-salt regressions, is computed by removing anthropogenic influences (upstream reservoir regulation, salt loading from agriculture return flows, and salt removed with exports) affecting salt from observed historic data. Natural salt mass data from 1971 to 1995 were used for the 15 Upper Basin gages, matching the time period used in the 2005 Triennial Review. The nine Lower Basin gages were modeled based on 1971 to 2005 natural salt mass data. Once the monthly regression relationships were determined for each gage the associated natural salt for the natural flows from 1906 to 2004 are computed.

Salt loading resulting from agriculture is available at an annual time-step and disaggregated to monthly values for modeling purposes. The concentrations of exported and imported flows are developed from available historic data at each export location and held constant through time. Future levels of salinity control are estimated from hydro-salinity studies performed for each salinity control project. Initial reservoir salinity concentrations were set based on the latest historic values available. These are the December 2005 values reported by the United States Geographical Survey (USGS) with the exception of Davis Dam and Parker Dam, which were assumed to be equivalent to Lake Mead concentration since a December 2005 value is not available.

F.1.3 Calibration

To ensure the regressions properly capture the flow-salt relationship, the regressions used to determine natural salt based on the 1971 to 1995 natural flows is input in a CRSS-based model. The model is run with historic data representing salt loading from agriculture, concentration of exported flows, levels of salinity control, and initial reservoir salinity concentrations for the time period 1971 to 1995. If the simulated historic salinity concentrations downstream of Lake Powell and upstream of Imperial Dam compare well with the actual historic salinity at these locations the model is properly calibrated. An example of this is shown in Prairie and Callejo (2005).

F.1.4 Limitations

Since the regression relationship between flow and salt is based on post-1971 values future projections are limited to simulating the post-1971 flow and salt relationship. A changing relationship cannot be modeled.

Limited data is available describing the monthly salt loading resulting from agriculture. Annual estimates are disaggregated for modeling purposes and monthly salinity results are typically aggregated to an annual time-step before analysis of results. The variability of annual salt loading resulting from agriculture is not well understood; therefore, the annual estimate is held constant over all years. This assumption forces the variability in agricultural salt loading to be back-computed into the natural salt mass. Therefore, it is important to recognize that the natural salt mass, as well as the natural flow, is not only what would naturally have occurred throughout the basin without anthropogenic effects. It also incorporates the error in any assumptions or in the accuracy of the estimates of the anthropogenic effects that were removed from the historic gage records.

Lastly, the CRSS salinity component is generally intended for long-term modeling (15 to 20 years) and reservoir salinity is highly sensitive to initial reservoir conditions for the first ten to 12 years. More accurately determining initial reservoir conditions will greatly improve the accuracy of the first ten to 12 years of results. After these first ten to 12 years the initial conditions have minimal impact on model results.

F.2 Reservoir Modeling Using CE-QUAL-W2 Water Quality Model - Model and Approach Description

F.2.1 Model Description (CE-QUAL-W2 Model)

CE-QUAL-W2 is a two dimensional, longitudinal/vertical, hydrodynamic, and water quality model. Because the model assumes lateral homogeneity, it is best suited for relatively long and narrow waterbodies exhibiting longitudinal and vertical water quality gradients (Cole 2003). Development and evolution of CE-QUAL-W2 has spanned three decades. The United States Army Corps of Engineers (USACE), J.E. Edinger and Associates (Edinger), and Dr. Scott Wells at Portland State University working with Mr. Tom Cole (USACE) have been the major developers in recent years. Edinger was contracted by Reclamation’s Upper and Lower Regions to test the earliest version of this model (LARM) in 1980 on Lake Powell and Lake Mead. All of the above have been helpful and provided some insight on the development of this application.

F.2.2 Model Capabilities & Limitations

The CE-QUAL-W2 model is capable of predicting water surface elevations, velocities, temperatures, and a number of water quality constituents. Water is routed through cells in a computational grid where each cell acts as a completely mixed reactor for each time-step. Geometrically complex waterbodies can be represented through multiple branches and cells. Multiple inflows and outflows to the waterbody are represented through point/nonpoint sources, branches, precipitation, and other methods. Tools for modeling hydraulic structures such as spillways and pipes are available. Output from the model provides options for detailed and convenient analyses.

The model uses several assumptions and approximations to simulate hydrodynamics, transport, and water quality processes. The model solves for gradients in the longitudinal and vertical directions and assumes lateral gradients are negligible. This assumption may be inappropriate for waterbodies with significant lateral variations. Turbulence is modeled through eddy coefficients of which the user must decide which scheme is most appropriate for an application. An algorithm for vertical momentum is not included and results may be inaccurate in waterbodies with significant vertical acceleration. Water quality processes are extremely complex and the model uses simplified approaches to reach solutions. Several water quality processes are not simulated including zooplankton, macrophytes, and a dynamic sediment oxygen demand.

F.2.3 Input Data
The model is limited by the quality and availability of input data. This includes meteorological, inflow and outflow, water temperature, water quality, and calibration data. These data most often determine the accuracy and usefulness of the application.

F.2.4 Bathymetry
The bathymetry file of a CE-QUAL-W2 model is the two-dimensional numeric representation of a waterbody and is also referred to as the computational grid. The two dimensions represented are the longitudinal and vertical dimensions, or the length and depth of a waterbody which are divided into longitudinal segments and vertical layers. The lateral dimension, or width, is not represented in the grid but an average width is computed and used to determine volume. Since the model grid is two-dimensional all modeled parameters such as temperature, velocity, and water quality constituents can only vary in the longitudinal and vertical directions. This assumes that modeled parameters do not vary significantly in the lateral direction. This assumption has been found appropriate in relatively long and narrow waterbodies.

The components of the grid are, from smallest to largest, cells, segments, branches, and waterbodies. The cell is a single vertical layer within a single segment. Segments consist of one or more cells, branches are one or more longitudinal segments, and a waterbody is one or more branches. Bathymetry files are dimensions from a single waterbody.

The volume of the grid is computed by multiplying a cell's length, thickness, and width. The sum of all cells within the grid is then the total storage for the waterbody. The computational grid storage is compared to actual storage-capacity charts to verify the model bathymetry accuracy.

F.2.5 Model Calibration
Model calibration involves comparing observed data to modeled, or predicted, results. The observed values are typically vertical profile and reservoir discharge observations for temperature and other water quality parameters. Calibration statistics are generated by computing the absolute mean error (AME). This computation is the sum of the absolute value of the predicted value minus the observed value, which is then divided by the total number of observations. This describes, on average, the difference between predicted and observed values.

F.2.6 Code Modifications

The unique chemical fingerprinting in Lake Powell with the build up of saline water, reservoir turn over and routing of the salt presents a unique data base to test the mixing algorithms of various models. The original WRE one-dimensional model, LARM, and earlier versions of CE-QUAL-W2 all completely mixed the reservoir each year, and thus multi-year runs were not possible. These models all fairly represented temperatures of the releases from the dam to test selective withdrawal alternatives. The version of CE-QUAL-W2 being utilized for this analysis is version 3.2; however, Reclamation has contracted Environmental Resources Management (ERM) to assist in peer review and in code modification specific to this system. Since hydrodynamic mixing is critical to maintaining long term salinity profiles in this reservoir, a modification in the code was made for this modeling to improve seasonal mixing. Evaporation is one of the primary variables affecting vertical mixing in the reservoir. The code has been modified to allow the evaporation coefficients to be changed to a fixed value at any frequency. For the Lake Powell application monthly coefficients are used. By setting monthly evaporation coefficients the model calibration has been significantly improved for the test period in both heat and salinity budgets. Evaporation totals were compared with Reclamation computed monthly evaporation values as a calibration check.

F.2.7 Lake Powell Model

F.2.7.1 General Description

The Lake Powell model simulates hydrodynamics, temperature, salinity, dissolved oxygen, phytoplankton and organic matter decay. The model uses a geometric, computational grid and various input data to simulate these processes. The grid is discussed below. Input data describe meteorological conditions, inflows, outflows, and water quality parameters. Meteorological data are collected from Page, Arizona and Hanksville, Utah. Inflow records are used for the Colorado River (combination of the Colorado, Green, and San Rafael Rivers), San Juan River, and the Dirty Devil River. For inflows where little or no data is available estimates are made. These include:

- North Wash
- Trachyte Creek
- Hansen Creek
- Bullfrog Creek
- Halls Creek
- Escalante River
- Cha Creek
- Rock Creek
- Last Chance Creek

- Warm Creek
- Navajo Canyon
- Wahweap Creek

Outflow is for all releases made through Glen Canyon dam. Data for water quality parameters are from major tributaries where available. These data sets have been collected from Reclamation, United States Geological Survey, National Climatic Data Center, and Utah and Arizona state and local agency records.

F.2.7.2 Lake Powell Bathymetry

The Lake Powell CE-QUAL-W2 bathymetry consists of 9 branches, 90 segments, and 97 layers. All layers are 1.75 meters thick. The branches represent the following channels and/or bays:

- Main (Colorado River) channel – Branch 1 (Br 1)
- Bullfrog Bay – Branch 2 (Br 2)
- Escalante River channel – Branch 3 (Br 3)
- San Juan River channel – Branch 4 (Br 4)
- Rock Creek Bay – Branch 5 (Br 5)
- Last Chance Bay – Branch 6 (Br 6)
- Warm Creek Bay – Branch 7 (Br 7)
- Navajo Canyon – Branch 8 (Br 8)
- Wahweap Bay – Branch 9 (Br 9)

Figure F-1 is a diagram of the Lake Powell model bathymetry with top, front, and side views of the grid.

Figure F-1
Lake Powell Bathymetry[1]

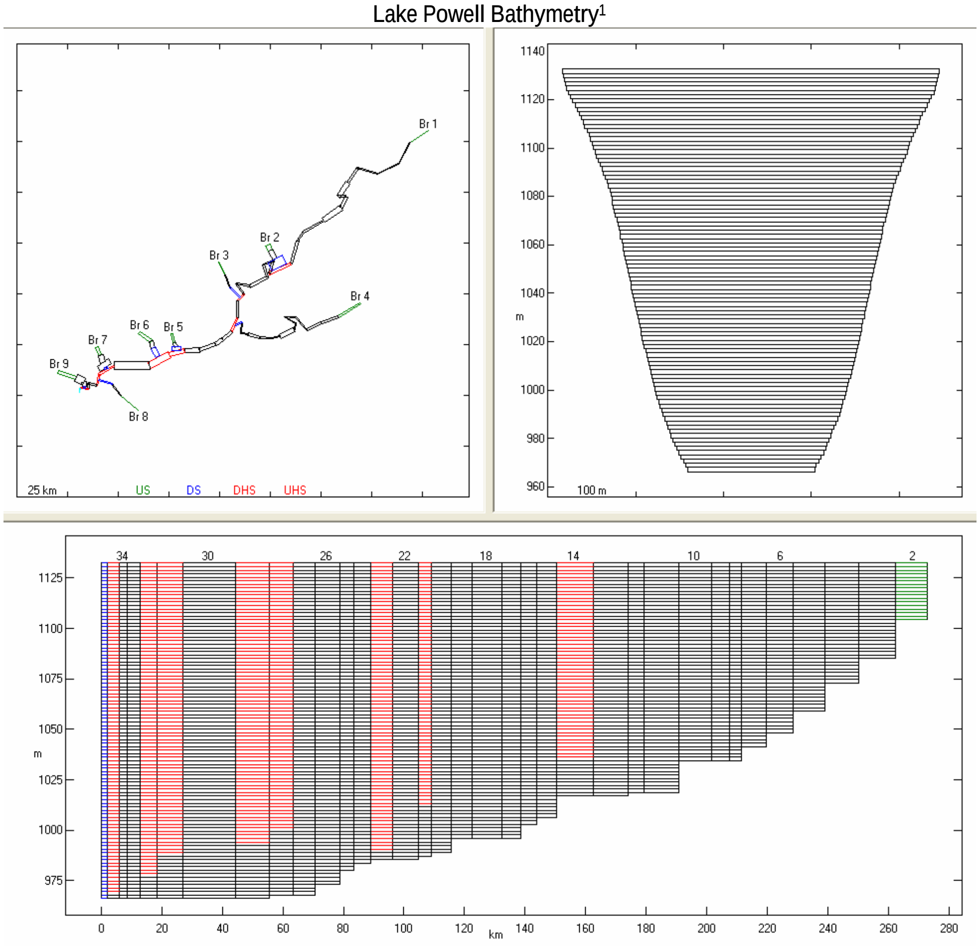

Figure Notes:
[1] Br # indicates the different branches in the Lake Powell Bathymetry two-dimensional model grid. The list of branches can be found in Section F.2.7.2
Blue: indicates a downstream boundary condition
Red: indicates the connection of tributary branches
Green: indicates an upstream boundary condition

F.2.7.3 Lake Powell Model Assumptions

The input data used in the model are the best available and are assumed to be accurate representations of meteorology, flow, and water quality parameters. Additional assumptions, described below, may also affect model accuracy and reliability.

F.2.7.4 Meteorological Conditions

Meteorological conditions are represented in the model by one dataset. Data from the Page, Arizona airport is used to represent meteorological conditions on Lake Powell, mainly because it is the most complete dataset in the region. Page is located at the southernmost end of the reservoir and conditions there are not always representative of conditions on the rest of the lake, especially near the major inflows and northern end. The errors that result, however, are considered acceptable.

F.2.7.5 Water Balance

The model is calibrated to reproduce observed water surface elevations. An additional input referred to as the distributed tributary is created. This input includes flows that are required to balance the water budget, positive or negative. This represents precipitation, ungaged flow, bank storage, and other source/sinks. CE-QUAL-W2 distributes this flow evenly over the water surface in a simulation. Large flows can have water quality impacts. Reasonable assumptions are made for assigning water quality constituent concentrations to these flows.

F.2.7.6 Sediment Delta Interactions

Sediment deltas have built up near the mouth of major and minor inflows. Deposition and scour of these deltas creates interactions that impact several water quality parameters. The CE-QUAL-W2 model does not simulate sediment delta scouring, sediment digenesis of dissolved phosphorus, or chemical and biological oxygen demand release. This is on the edge of modeling and data gathering technology at this time. These processes are either not represented or an alternate approach is used to model them. The impact of these processes is not insignificant and until the approaches used are studied further the dissolved oxygen and nutrient analyses are largely qualitative.

F.2.7.7 Lake Powell Model Calibration

The Lake Powell CE-QUAL-W2 model is considered calibrated for temperature and total dissolved solids for the period 1990-2005. Predicted results are compared to observed data from 13 locations including the tailwater. Calibration efforts for other water quality parameters such as dissolved oxygen, nutrients, and algae are ongoing and considered qualitative at this stage.

F.2.7.8 Temperature Calibration

Calibration statistics for temperature are shown for each station in Table F-1. The number of profiles at each station is also given in the table. The AME of the temperature profiles is 0.8°C. The AME of the dam release temperatures is 0.45°C.

There are hundreds of individual profiles over the 15 year run period within the model. Three select vertical profiles with AME statistics are shown below for Wahweap (Figure F-2), Bullfrog (Figure F-3), and Cha (Figure F-4). A graph of the observed and predicted reservoir discharge temperatures is also shown (Figure F-5).

Table F-1
Lake Powell Temperature Calibration Statistics

Station	Years	AME	# of Profiles
Hite	1991 to 2005	1.39	52
Good Hope	1991 to 2005	1.11	52
Bullfrog	1991 to 2005	0.84	53
Escalante Confluence	1991 to 2005	0.69	54
San Juan Confluence	1991 to 2005	0.59	38
Oak Canyon	1991 to 2005	0.62	58
Crossing of the Fathers	1991 to 2005	0.58	60
Lower Zahn	1991 to 2005	1.21	38
Upper Piute	1991 to 2005	0.97	49
Lower Piute	1991 to 2005	0.80	44
Cha Canyon	1991 to 2005	0.69	51
Wahweap	1991 to 2005	0.65	179
Release Temperature	1991 to 2005	0.45	
Average		0.80	

Figure F-2

Temperature Profile at Bullfrog Station, 169.2 kilometers from Glen Canyon Dam

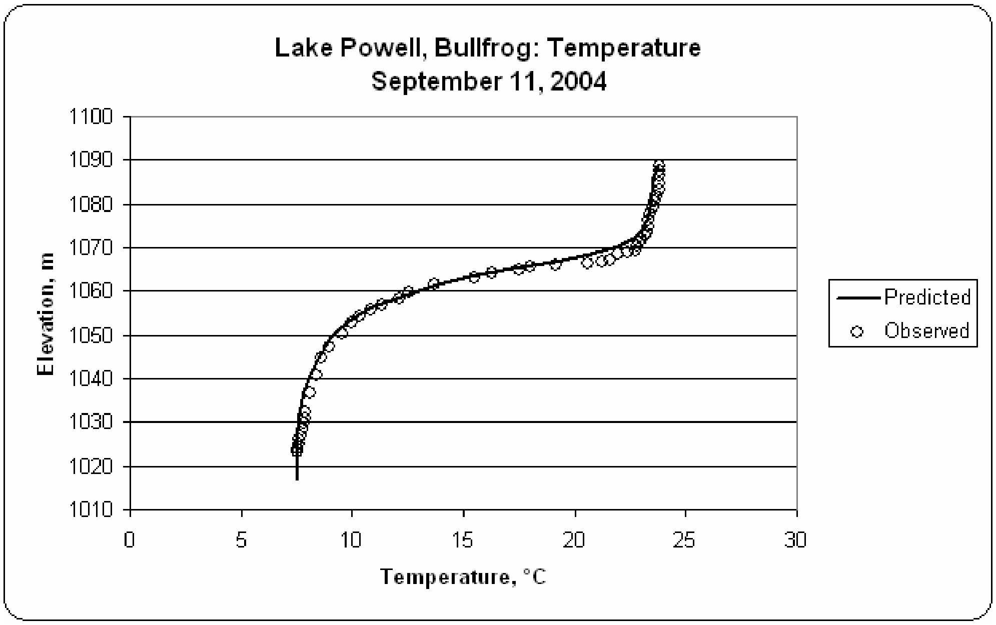

Figure F-4
Temperature Profile at Cha Station, 19.3 kilometers from the Confluence of the
San Juan River and Colorado River Channels (AME = 0.32°C)

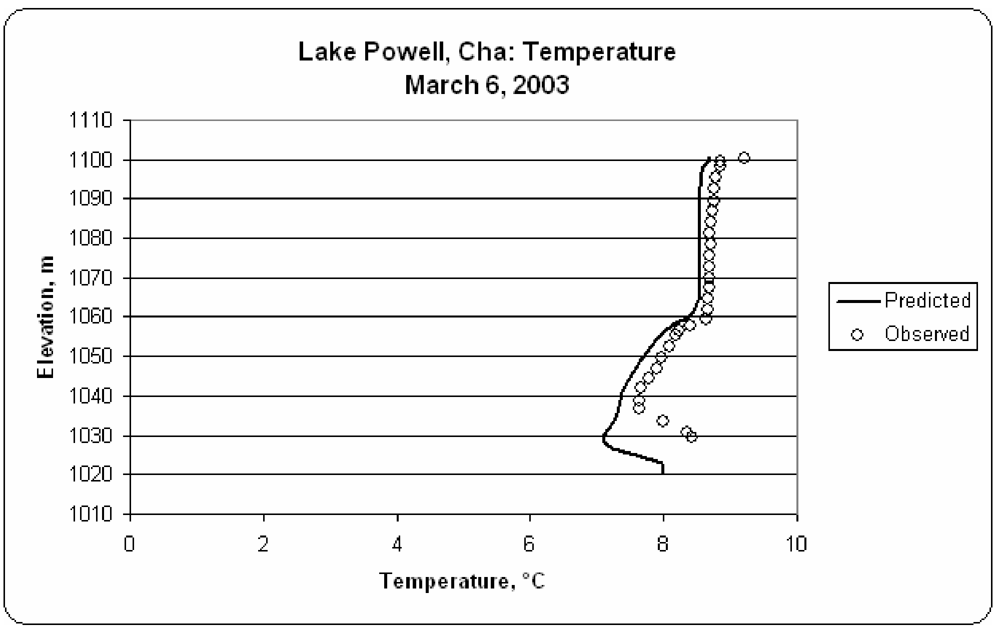

Figure F-5
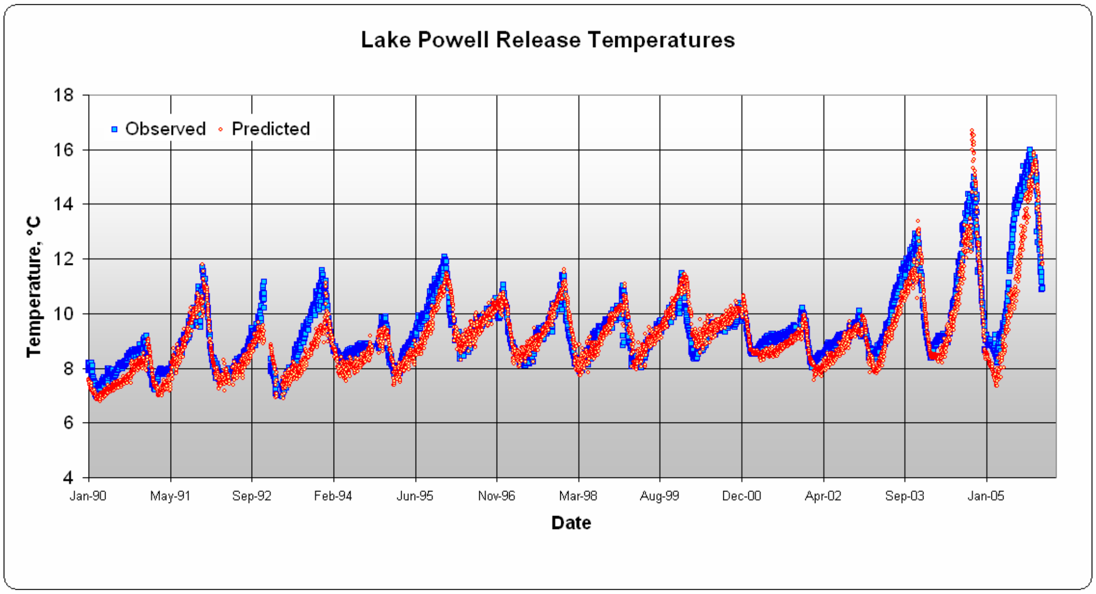
Glen Canyon Dam Discharge Temperature Calibration



F.2.7.9 Total Dissolved Solids Calibration

Total dissolved solids (TDS) are assumed to be a conservative parameter and, therefore, act as a tracer and help verify the hydrodynamic calibration. Calibration statistics and the number of profiles for TDS at each station are shown in Table F-2. The AME of the TDS profiles is 32.6 mg/L. The AME of the tailwater TDS is 14.1 mg/L.

Table F-2
Lake Powell TDS Calibration Statistics

Station	Years	AME	# of Profiles
Hite	1991 to 2005	54.98	52
Good Hope	1991 to 2005	41.61	42
Bullfrog	1991 to 2005	31.04	53
Escalante Confluence	1991 to 2005	27.88	54
San Juan Confluence	1991 to 2005	26.65	38
Oak Canyon	1991 to 2005	25.99	58
Crossing of the Fathers	1991 to 2005	25.42	60
Lower Zahn	1991 to 2005	40.43	38
Upper Piute	1991 to 2005	29.22	49
Lower Piute	1991 to 2005	24.25	44
Cha Canyon	1991 to 2005	27.01	51
Wahweap	1991 to 2005	34.71	179
Release TDS	1991 to 2005	14.1	
Average		32.63	

Three TDS vertical profiles with AME statistics, for the same stations and dates as the temperature profiles, are shown in Figure F-6 through Figure F-9.

TDS Profile at Cha Station, 19.3 kilometers from the Confluence of the San Juan River and Colorado River Channels (AME = 30.8 mg/L)

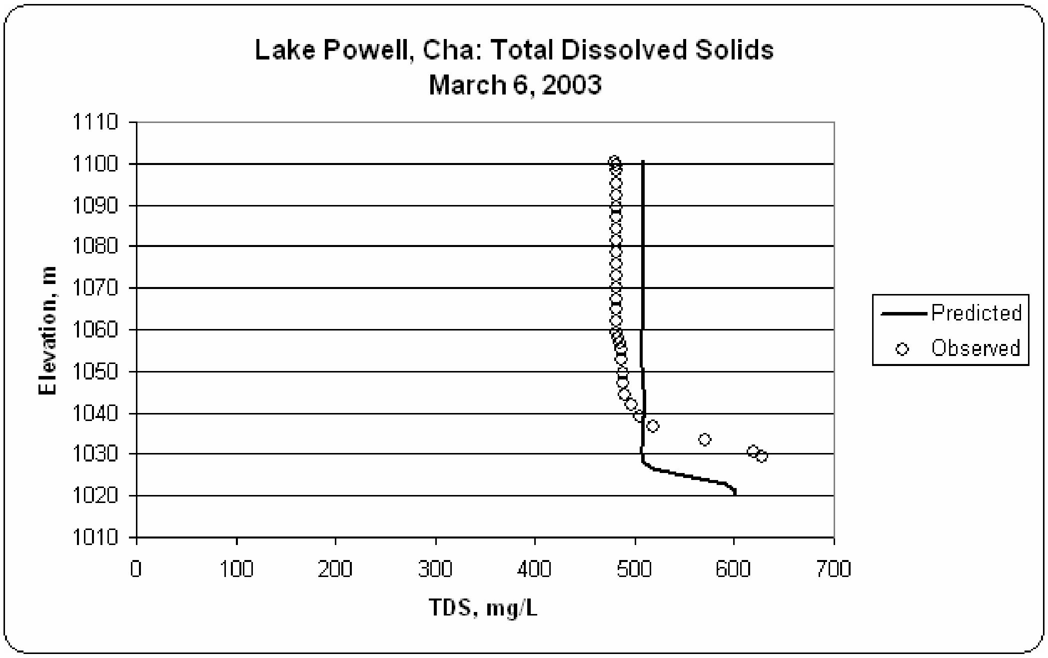

Figure F-9
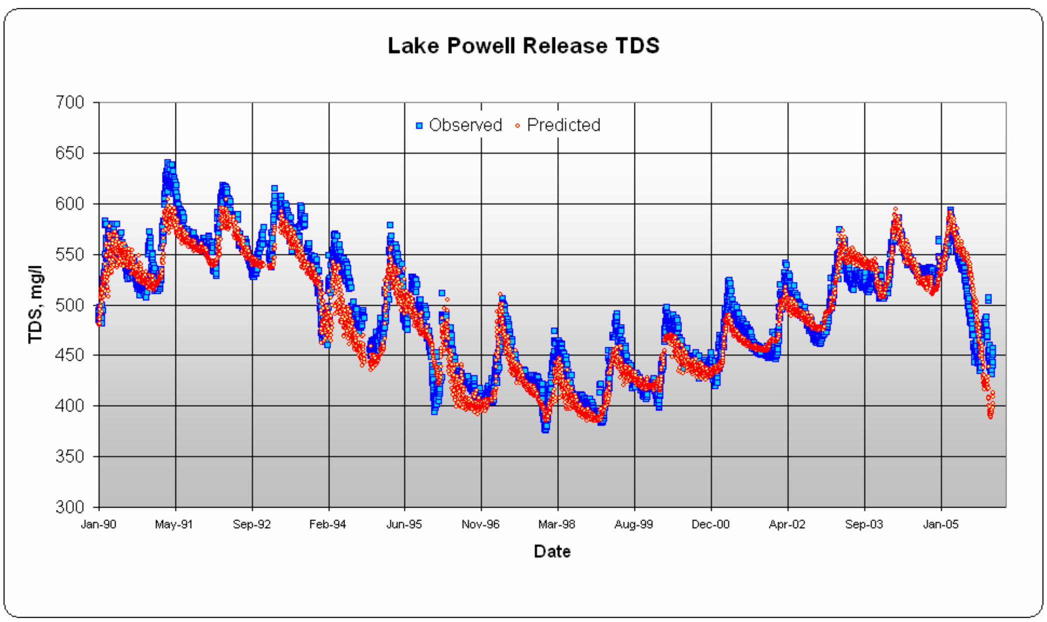
Glen Canyon Dam Discharge TDS Calibration



F.2.7.10 Dissolved Oxygen Calibration

The dissolved oxygen calibration is still in its initial stages of development and is of limited value for use in the Final EIS. It is affected by temperature, wind and wave mixing, plankton production and respiration, organic matter decay, and other chemical and biological oxygen demands. Many of these are complex and not extensively monitored. A qualitative/semi-quantitative analysis using an empirical method is being developed, a summary of which is given below.

Dissolved oxygen trends and cycles appear to be related to hydrology and reservoir drawdown. Based on these two parameters two CBOD compartments in the CE-QUAL-W2 model are being utilized to represent the sum total oxygen demand. They are loaded as part of the parameters in the inflow constituent file. The loading values in these two inflow CBOD boxes are being calculated by a set of rules and relationships based on changes in reservoir elevation, inflow volume, and water temperature. One box is used to represent chemical oxygen demand processes predominating cold water inflow conditions, while the other is used more to represent summer time carbonate biological oxygen demand processes associated with bacteriological decay of organic matter. Calibration is accomplished by iterative runs (trial and error) and comparison with downstream segment oxygen, phosphorus, carbon, and phytoplankton profile numbers. The overall DO calibration has an AME of 1.2 mg/L for vertical profiles and 0.9 mg/L for reservoir discharge DO (see Table F-3). Vertical profiles of the dissolved oxygen calibration at Wahweap (Figure F-10 and Figure F-11), Bullfrog (Figure F-12), and Cha Canyon (Figure F-13) are shown below as well as the discharge concentrations (Figure F-14). Calibration is expected to be further improved with additional iterative runs and refinement to the method.

Table F-3
Lake Powell DO Calibration Statistics

Station	Years	AME	# of Profiles
Hite	1991 to 2005	1.11	52
Good Hope	1991 to 2005	0.96	51
Bullfrog	1991 to 2005	1.00	54
Escalante Confluence	1991 to 2005	1.04	54
San Juan Confluence	1991 to 2005	1.13	38
Oak Canyon	1991 to 2005	1.00	58

F.3 Temperature Modeling of Colorado River Flows Between Glen Canyon Dam and Lake Mead Using the GEMSS Water Quality Model - Model and Approach Description

F.3.1 Model Description (GEMSS Model)

The 1-D hydrodynamic and water quality model GEMSS was developed by Edinger. The transport equations for this model were similar to W2 which was based on the Generalized Longitudinal Hydrodynamic and Transport (GLHT) computation derived from the three-dimensional equations of fluid motion and continuity (Edinger and Buchak 1980). This model was selected because of its successful applications of the 1-D water quality/hydrodynamic module in TMDL studies. Like the CE-QUAL-W2 model it can model numerous water quality parameters; however, only water temperature was modeled for this study.

F.3.2 Model Geometry

The model's geometry data downstream of Glen Canyon Dam to Lake Mead was based upon GIS spatial information and river cross sections available from USGS Grand Canyon Monitoring and Research Center (GCMRC). This information was used to generate a simplified geometry grid covering 280 miles of the Colorado River using 102 segments with averaged length of 7,000 m (23,000 ft) each and 234 slope points.

F.3.3 Model Time-varying Data

The model's time-varying data sets included flow rates, water temperatures, downstream water surface elevation, and meteorological data which were used to compute surface heat exchange. The boundary hydrology included daily average release data from Lake Powell and daily inflows of an average year (1947 to 2004) from the Little Colorado River. These data came from USGS gaging stations and Reclamation database. The water temperature boundary conditions included daily measured temperatures at Lees Ferry and daily temperature of an average year from the Little Colorado River. Meteorological data from Page, Arizona was required to compute surface wind shear and heat exchange and consisted of hourly air and dew point temperature, wind speed, wind direction, cloud cover, solar radiation, and atmospheric pressure.

F.3.4 Temperature Calibrations

The GEMSS model was calibrated to observed Diamond Creek hydrology and observed water temperature at three locations (Lees Ferry, Little Colorado River confluence, and Diamond Creek) that were provided by GCMRC. The calibration period was based on the same period used in CE-QUAL-W2 (1990 to 2005); however observed data for these three locations were sporadic for this time period.

To verify the mass balance calculation of the model, the modeled flows were compared with actual flows at Diamond Creek. The modeled flows at Diamond Creek were consistently lower than observed flows by about six percent due to tributary inflows and assumed average daily flows from the Little Colorado River. The average errors for comparison between modeled and observed water temperatures were -0.08 °C at Lees Ferry, 0.09 °C below the Little Colorado River, and -1.1 °C at Diamond Creek (Figures F-15, F-16, and F-17 respectively). The modeled water temperatures at the Diamond Creek station were consistently lower than the observed data. This was likely caused by the difference in meteorological data between Diamond Creek and Page.

Figure F-15
GEMSS Modeled and Observed Temperatures at Lees Ferry (a sample period of 1995 to 2002)

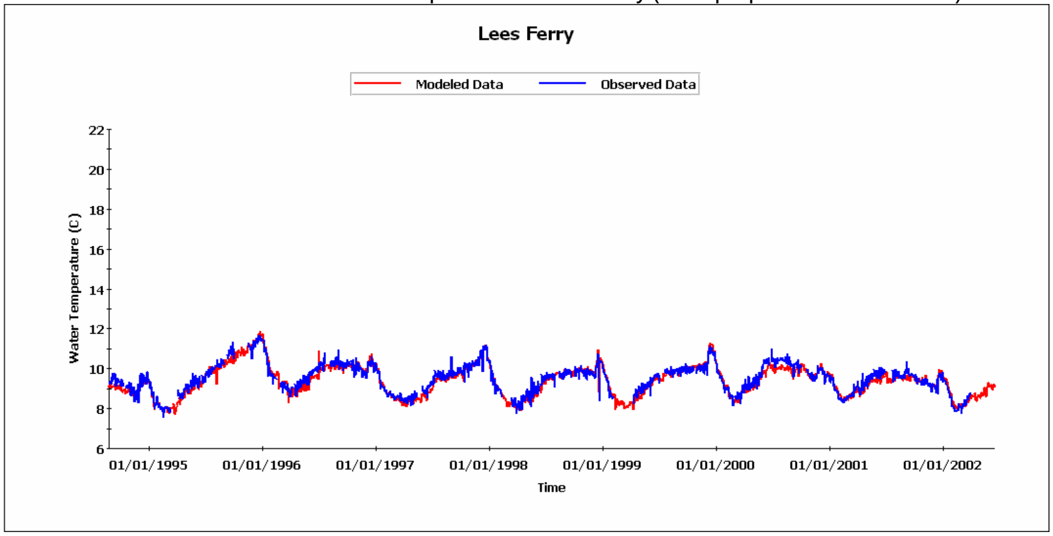

Figure F-16
GEMSS Modeled and Observed Temperatures at Diamond Creek (a sample period of 1999 to 2002)

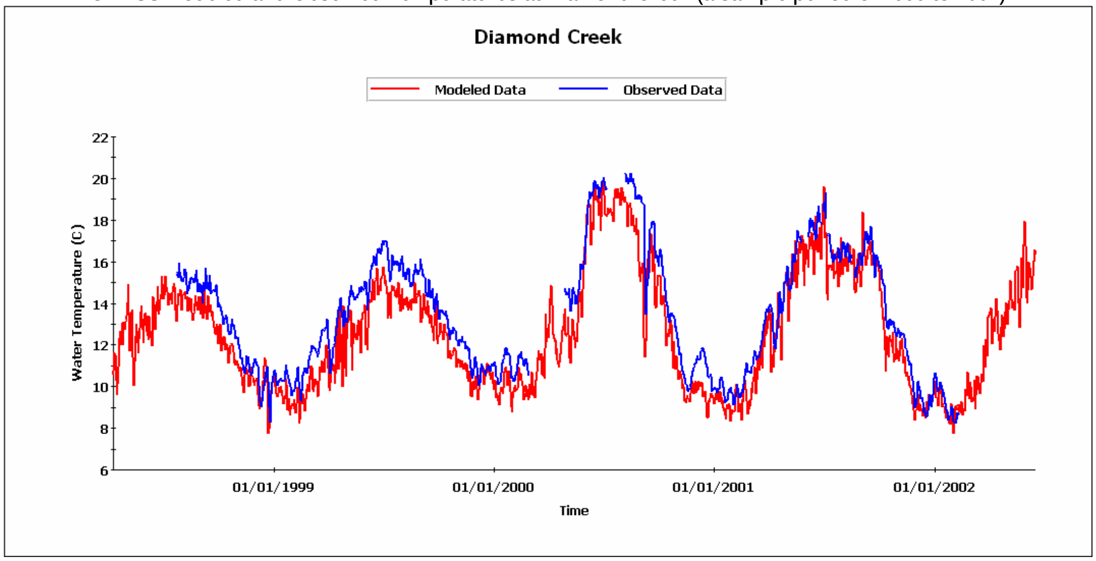

Figure F-17
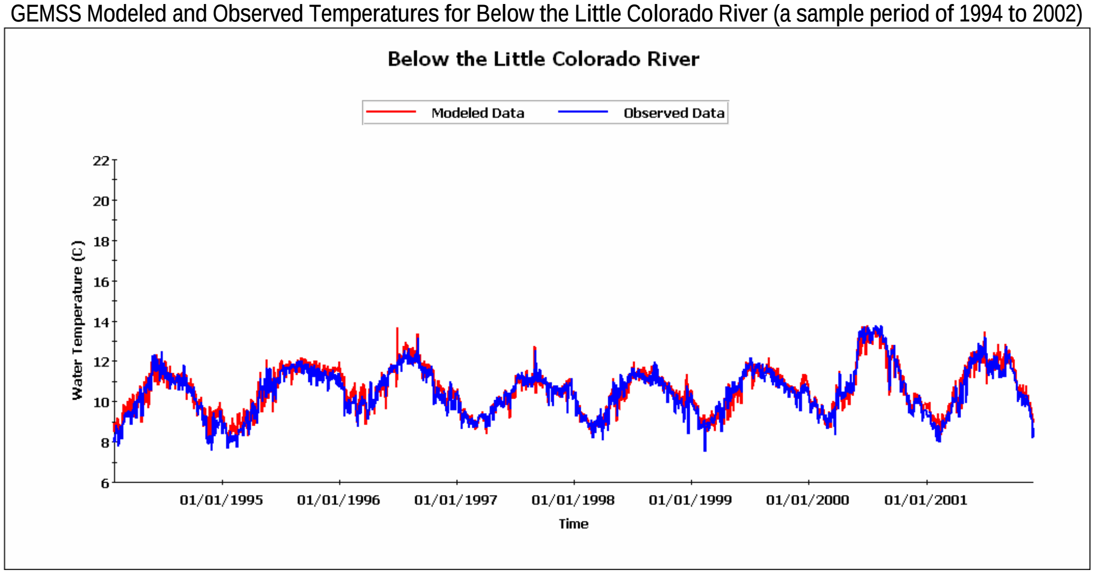
GEMSS Modeled and Observed Temperatures for Below the Little Colorado River (a sample period of 1994 to 2002)



F.3.5 Analysis of Alternatives

The calibrated GEMSS model was used to analyze downstream temperature regimes for the Shortage alternatives. Release water temperatures from the CE-QUAL-W2 model and the flows from the CRSS model were used as inputs to the GEMSS model. The following assumptions were made in analyzing water temperatures downstream of Glen Canyon Dam:

- monthly average reservoir release volumes were used for each of the CRSS 90th, 50th, and 10th percentile Lake Powell elevations;
- minimum and maximum release volumes based on each of the alternatives (including the No Action Alternative) were used for each of the CRSS percentiles as mentioned above;
- minimum and maximum release temperatures from CE-QUAL-W2 for all shortage alternatives were used for each of the CRSS percentiles;
- a warm and a cool meteorological year (i.e. warmer or cooler air and dew point temperatures) were applied across alternatives and CRSS percentiles; and
- the Basin States Alternative and Conservation Before Shortage Alternative were analyzed as one alternative.

The outcome from combination of variable release volume, temperature, and meteorological conditions resulted in an average and a range of temperatures at any given location and time of year.

Appendix G

Shortage Allocation Model Documentation

This appendix describes the Shortage Allocation Model and assumptions that were used to allocate shortages to water users in the states of Arizona, California, and Nevada (Lower Division states) as part of the analysis of water deliveries in this Final EIS.

Table of Contents

List of Tables

List of Attachments

G.1 Introduction

In order to assess the potential shortages and socioeconomic effects to users under each of the alternatives, specific modeling assumptions were made and these are documented in this appendix. The proposed federal action is for the purpose of adopting additional operational guidelines to improve the Department of the Interior's (Department) annual management and operation of key Colorado River reservoirs for an interim period through 2026. However, in order to assess the potential effects of the proposed federal action in this Final EIS, certain modeling assumptions are used that display projected water deliveries to Mexico. Reclamation's modeling assumptions are not intended to constitute an interpretation or application of the 1944 Treaty or to represent current United States policy or a determination of future United States policy regarding deliveries to Mexico.

The United States will conduct all necessary and appropriate discussions regarding the proposed federal action and implementation of the 1944 Treaty with Mexico through the International Boundary and Water Commission in consultation with the Department of State.

G.2 Background and Purpose

The Shortage Allocation Model was created to calculate the quantity of Colorado River water that would be available to water entitlement holders under shortage conditions on the mainstream of the lower Colorado River. A shortage condition would exist during a year when the Secretary of the Department of the Interior (Secretary), as part of the Annual Operating Plan (AOP), determines that there is less than 7.5 million acre-feet (maf) of water available to the Lower Division states.

The Shortage Allocation Model simulates shortage allocations and adjusts deliveries of Colorado River water in accordance with the apportionment to the Lower Division states prescribed in the Boulder Canyon Project Act of 1928, as confirmed by the Consolidated Decree. Certain modeling assumptions were made with regard to how shortages may be allocated. Reclamation acknowledges that there may be other interpretations of how shortages should be distributed. Reclamation's modeling assumptions are not intended to represent current or future policy with respect to shortage sharing or to limit Secretarial discretion to distribute shortages.

The Shortage Allocation Model simulates shortage allocations to individual Colorado River entitlement holders within each state. Entitlement holders are all persons or entities authorized to beneficially use Colorado River water pursuant to: 1) a right decreed by the United States Supreme Court, 2) a contract for the delivery of Colorado River water through the Secretary, or 3) a Secretarial reservation. For a list of each State's Colorado River water entitlement holders, please see Attachment A, Table Att. A-2 through Att. A-4.

Under the Colorado River Basin Project Act of 1968 (CRBPA) (Section 301(b)), the Central Arizona Project (CAP) incurs most of any initial shortage to the Lower Division states. Consequently, there is great interest in how shortages are allocated among the individual CAP users. The distribution of CAP water during a time of shortage is complex, and the Shortage Allocation Model has been developed to accommodate the unique shortage provisions of the Arizona Water Settlements Act (Public Law 108-451 dated December 10, 2004) and the CAP shortage framework as defined in various CAP water delivery contracts.

G.3 Description of the Shortage Allocation Model

The Shortage Allocation Model was developed as worksheets in Microsoft Office 2003 Excel software using the Excel Visual Basic Editor. The Shortage Allocation Model contains 18 worksheets, which are summarized in Table G-1.

Table G-1
Relationship Between Worksheets in the Shortage Allocation Model

	Worksheet	Function	Retrieves Data from:	Sends Data to:
1	Region Worksheet	Calculates Stage I and Stage II Shortages to Nevada, California, Arizona, and Mexico	Arizona worksheets & Projected Use Schedules	Arizona, California, & Nevada worksheets
2	Nevada Worksheet	Calculates shortages to Nevada Entitlement Holders	Region Worksheet	
3	California Worksheet	Calculates shortages to California Entitlement Holders	Region Worksheet & Quantification Settlement Agreement (QSA) Worksheet	
4	Arizona Worksheet	Calculates shortages to Arizona Entitlement Holders	Region Worksheet & Arizona Projected Consumptive Use (CU) Schedules	CAP Worksheet
5	CAP Worksheet	Calculates shortages to CAP Entitlement Holders	Arizona Worksheet & CAP Projected CU Schedules	CAP Summary Worksheet
6	CAP Summary Worksheet	Displays all CAP Entitlements, Scheduled CU, Adjusted Delivery, and Reductions	CAP Worksheet & CAP Projected CU Schedules	
7	Present Perfected Rights (PPRs) Worksheet	Displays PPRs in date order regardless of state lines		
8	QSA Worksheet	Displays Exhibit B of the QSA		California Worksheet
9	Arizona CU Schedules for Priorities 1-3	Projected Consumptive Use Schedules Provided to model Stage I and II Shortages and shortages to Arizona Entitlement Holders		Arizona and Region Worksheet
10	Arizona CU Schedules for Fourth Priority	Projected Consumptive Use Schedules Provided to model Stage I and II Shortages and shortages to Arizona Entitlement Holders		Arizona and Region Worksheet
11	Summary of Arizona State and CAP Schedules	Shows that all Arizona Projected CU does not exceed 2.8 maf		CAP Non-Indian Agricultural (NIA) and Excess Agricultural Schedules

Table G-1
Relationship Between Worksheets in the Shortage Allocation Model

	Worksheet	Function	Retrieves Data from:	Sends Data to:
12 13 14 15	CAP Municipal & Industrial (M&I), Tribal, NIA, and Excess Agricultural Schedules	Used to show CAP water availability and capture simulated shortage impacts in future years		CAP Worksheet
16 17 18	Decree Worksheets	Shows how Diversion and CU ratios are calculated to estimate full CU Entitlements in Nevada and California, and ratios between Diversion and CU for all users		

The purpose and function of each worksheet is described as follows.

The Region worksheet (see Attachment A, Table Att. A-1) is the key worksheet for operating the Shortage Allocation Model. Once the Shortage Allocation Model is open, the user may enter any shortage volume in the “total reduction” yellow box of the Region tab. Next, to the left of the yellow box a shortage year must be selected by clicking on the “process” button, which provides various years that may be chosen. Each year is associated with different schedules for Colorado River entitlement holders, which the shortages will be based on. Once a year has been selected, the model will operate by selecting “process single shortage volume”. The Shortage Allocation Model calculates the amount of Stage 1 and Stage 2 Shortages (discussed in next section), and the amount of the shortage allocated to each of the Lower Division states, and to Mexico.[1] For purposes of discussion on this Appendix G, assumed water delivery reductions to Mexico will be referred to as “shortages”. The shortages to individual Colorado River entitlement holders are displayed on the State worksheets (Attachment A, Table Att. A-2 through A-4) and the CAP worksheet (Attachment A, Table Att. A-5). The links between the schedules, the Region worksheet, State worksheets, and CAP worksheet operate the Shortage Allocation Model.

The Shortage Allocation Model contains three State worksheets (Attachment A, Tables Att. A-2 through Att. A-4). Given any shortage volume, the State worksheets calculate the portion of the shortage amount that is allocated to the individual entitlement holders within each State. On the Arizona State worksheet, the adjusted delivery is calculated as a reduction to the scheduled use for each entitlement holder. On the California and Nevada State worksheets the reduced delivery

[1] Reclamation’s modeling assumptions are not intended to constitute an interpretation or application of the 1944 Treaty or to represent current United States policy or a determination of future United States policy regarding deliveries to Mexico. The United States will conduct all necessary and appropriate discussions regarding the proposed federal action and implementation of the 1944 Treaty with Mexico through the IBWC in consultation with the Department of State.

Appendix M and Appendix Q describe additional modeling assumptions used in the CRSS model for projected water reductions to Mexico, and Section G.6 in Appendix G describes the relationship between the Shortage Allocation Model and CRSS.

is calculated based upon an estimated full entitlement use schedule from 2004 water accounting data.

The Arizona State worksheet calculates the aggregate quantity of fourth priority water available to river users and CAP. In the Draft EIS, shortages were distributed between river users and CAP pro-rata based on scheduled use. The method used to distribute water delivery reductions within Arizona was modified to reflect the Arizona Department of Water Resources (ADWR) Director's Shortage Sharing Work Recommendations. This change basically related to the water delivery reductions to the Arizona Water Banking Authority (i.e. the unused apportionment in Arizona). Originally, in the modeling for the Draft EIS, the deliveries to the Arizona Water Banking Authority (AWBA) were reduced to zero before deliveries to any other water user in Arizona would occur. For the modeling used in the Final EIS, the Arizona water delivery reductions are distributed proportionally between the fourth priority mainstream river users and the CAP. However, for the portion of the water delivery reduction that is assigned to the CAP, the water deliveries to the AWBA are reduced to zero before the deliveries to any other CAP water user are reduced. Both ADWR's and Central Arizona Water Conservation District (CAWCD)'s recommendations were incorporated in the modeling assumptions for the Final EIS. Examples of how the water delivery reductions to Arizona were distributed in the Draft EIS and Final EIS are provided in Table Att. F-3 in Attachment F to this appendix.

The CAP worksheet imports the quantity of available water that is distributed to CAP on the Arizona worksheet, and distributes available water to CAP entitlement holders. The primary changes in the distribution of shortages within the CAP affected the Ak-Chin Indian Community and San Carlos Apache Tribe. Based on comments received on the Draft EIS, the Ak-Chin Indian Community was allocated up to 10,000 af annually of excess CAP water. For years in which water is available for banking by the ABWA, up to an additional 10,000 af is available for the Ak-Chin Indian Community pursuant to Section 2(b) of the Ak-Chin Indian Water Rights Settlement Act (Settlement). After the Secretary has met the water delivery obligation to the Ak-Chin Indian Community under the Ak-Chin Water Rights Settlement, any excess water is available for delivery to the San Carlos Apache Tribe. Estimated delivery losses of 4,500 af on the Santa Rosa Canal, incurred in the delivery of water to the Ak-Chin Indian Community, are charged to the Ak-Chin Indian Community's CAP Settlement. The resulting differences between the shortages modeled in the Draft EIS and Final EIS is provided in Attachment F, Table Att. F-3. Additionally, the Final EIS results of the CAP worksheet are displayed in the "Operational Worksheet: CAP" in Attachment A, Table Att. A-5.

Seven consumptive use schedules were provided by ADWR for use in the Shortage Allocation Model, for the period 2008 through 2060. The consumptive use schedules are listed below:

1) Arizona first through third priorities;

2) Arizona fourth priority;

3) CAP 2: municipal and industrial (M&I) priority user schedules (only provided to year 2035);

4) CAP 2: Tribal schedules;

5) CAP 3: Non-Indian Agricultural (NIA) priority schedules;

6) CAP 4: excess agricultural water schedules (only provided to year 2030); and

7) Arizona Summary Schedules.

The ADWR consumptive use schedules are shown in Appendix D.

Three water accounting spreadsheets are provided for each state: Arizona, California, and Nevada. The water accounting spreadsheets provide historical water accounting information which is used to calculate diversion to consumptive use ratios for entitlement holders in the Shortage Allocation Model.

The Shortage Allocation Model also includes two supporting worksheets which are Exhibit B of the Quantification Settlement Agreement (QSA) (Exhibit B) and a full list of Present Perfected Rights (PPRs). Exhibit B (Attachment F, Table Att. F-2) displays the quantification of certain Colorado River water entitlements and transfers of Colorado River water in the State of California in thousands of acre-feet. The quantified entitlements are incorporated in the Shortage Allocation Model, while the transfers are referenced in Exhibit B. The PPR worksheet displays a complete list of the PPRs in the Lower Division states in date order from lowest to highest priority without regard to state lines (Attachment F, Table Att. F-1). PPR diversion entitlements amount to approximately 4.1 maf and an estimated consumptive use entitlement of 3.4 maf in the Lower Basin. In the event of a severe shortage, where there is insufficient Colorado River water to satisfy the needs of the PPR entitlement holders, the PPR worksheet shows the order in which the limited water supply would be delivered to the PPR holders.

The Shortage Allocation Model may be used to simulate any future shortage allocation for any year based on projected water use, water orders, historical use, or average historical use. In a normal year, the Shortage Allocation Model may be used to simulate the amount of excess water that may be available for banking in any state.

G.4 Assumptions in the Shortage Allocation Model

G.4.1 Introduction

In accordance with Section II (B)(3) of the Consolidated Decree and Section 301(b) of the CRBPA, the Secretary has the authority to declare and allocate shortages to the Lower Division states. Although some guidance is given with regard to how shortages would be allocated (i.e., PPRs must be met first without regard to state lines and California does not incur shortages until water use under Arizona post-1968 water delivery contracts is eliminated), no further guidance exists for the Secretary’s shortage allocation decisions.

To determine the hydrologic impacts of the shortage alternatives, assumptions were made with regard to how shortages might be shared. These assumptions are made to facilitate analysis of the full range of potential impacts of each alternative and are not intended to represent current or future policy with respect to shortage sharing.

G.4.2 Stage 1 and Stage 2 Shortage Assumptions

In the Shortage Allocation Model, shortages in the Lower Basin are categorized as Stage 1 and Stage 2 Shortages. Shortages are first imposed under Stage 1 and would be applied to the most junior users within Arizona (those with post-1968 water rights, i.e., 4th and 5th priority rights within Arizona) and Nevada (primarily the Southern Nevada Water Agency [SNWA]). Stage 1 shortages continue until the deliveries to the post-1968 water rights holders in Arizona (including the CAP) are reduced to zero. The maximum amount of Stage 1 shortages during the period of analysis is dependent on the scheduled depletions for the post-1968 water rights holders and decreases over time from approximately 1.8 maf in 2008 to 1.7 maf in 2040. The post-1968 use decreases due to increasing water use of higher priorities.

After deliveries to the 4th and 5th priority rights within Arizona are reduced to zero, additional reductions are applied to Arizona, California, and Nevada. These shortages, referred to as Stage 2 shortages, continue to the shortage amount determined by the alternative.

The shortage sharing percentages are computed as follows:

- Shortage sharing for Stage 1: Arizona, Nevada, and Mexico take a water supply reduction.
  - Mexico: 16.67 percent reduction of the total shortage
    - computed as a ratio of Mexico’s 1944 Treaty allotment to the sum of the apportionments of the Lower Division states and Mexico’s 1944 Treaty allotment
    - 1.5 maf / 9.0 maf = 0.1667
  - Nevada: 3.33 percent reduction of the total shortage
    - computed as a ratio of Nevada’s apportionment to the sum of the apportionments of the Lower Division states and Mexico’s 1944 Treaty allotment
    - 0.3 maf / 9.0 maf = 0.0333
  - Arizona: 80 percent of the total shortage
    - computed as a ratio of Arizona and California’s apportionment to the sum of the apportionments of the Lower Division states and Mexico’s 1944 Treaty allotment
    - (2.8 maf + 4.4 maf) / 9.0maf = 0.80

- ♦ Shortage Sharing for Stage 2 Reductions (severe shortage after Arizona fourth and fifth priority use is reduced to zero and California shares in remaining shortage).
  - Mexico: 16.67 percent of the Stage 2 Shortage in addition to Stage 1 reductions
    - computed as a ratio of Mexico's 1944 Treaty allotment less the amount of shortage applied to Mexico under Stage 1, to the sum of the apportionments of the Lower Division states and Mexico's 1944 Treaty allotment less the total amount shorted to users under Stage 1
    - (1.5 maf - Mexico Stage 1 shortage) / (9.0 maf – total Stage 1 shortage) = 0.1667
  - Nevada: 3.33 percent of the Stage 2 Shortage in addition to Stage 1 Shortages
    - computed as a ratio of Nevada's apportionment less the amount of shortage applied to Nevada under Stage 1, to the sum of the apportionments of the Lower Division states and Mexico's 1944 Treaty allotment less the total amount shorted to users under Stage 1 Shortage
    - (0.3 maf - Nevada Stage 1 Shortage) / (9.0 maf – total Stage 1 Shortage) = 0.0333
  - Arizona: Arizona's Stage 2 shortage is approximately 20 percent and varies due to Arizona's one through three priority scheduled use
    - computed as a ratio of Arizona's apportionment less the amount of shortage applied to Arizona under Stage 1, to the sum of the apportionments of the Lower Division states and Mexico's 1944 Treaty allotment less the total amount shorted to users under Stage 1 Shortage
    - (2.8 maf - Arizona Stage 1 Shortage) / (9.0 maf – total Stage 1 Shortage)
  - California: California's Stage 2 Shortage is approximately 60 percent and varies due to Arizona's priority one through three scheduled use
    - computed as a ratio of California's apportionment, to the sum of the apportionments of the Lower Division states and Mexico's 1944 Treaty allotment less the total amount shorted to users under Stage 1 Shortage
    - (4.4 maf) / (9.0 maf – total Stage 1 Shortage)

G.4.3 Operations of Stage 1 and 2 Shortages

The Region worksheet, provided in Attachment A, Table Att. A-1, displays the calculations discussed above.

- listed along the left side of Attachment A, Table Att. A-1 are Stage 1 and 2 Shortages, and their respective entities: Mexico, Arizona, Nevada, and California. Along the top of the table are the corresponding consumptive use apportionments to each state and the 1944 Treaty allotment to Mexico, the available consumptive use, and the respective shortages;

- in Attachment A, Table Att. A-1, a 500,000 af shortage in year 2017 was not large enough to trigger a Stage 2 Shortage; therefore only Stage 1 consumptive use adjustments and reductions are calculated. In this example, consumptive use in Arizona is reduced by 400,000 af, consumptive use in Nevada is reduced by 16,667 af, and the delivery to Mexico is reduced by 83,333 af;

- in 2008, the first year of the proposed interim period, the maximum potential Stage 1 Shortage to the Lower Division states and Mexico is 1,827,557 af. The potential Stage 1 Shortage in 2008 is based on the projected use of 1,462,046 af for Arizona fourth priority, and a corresponding potential shortage for Nevada and Mexico based on their shortage sharing percentages;

- as Arizona priority one through priority three use increases over time to their respective full entitlement amount, Arizona fourth priority use decreases as does the volume of the Stage 1 Shortage volume. For example, in 2040, when Arizona reaches full entitlement use, priorities one through three are projected to use 1,428,510 af. The remainder of Arizona’s apportionment, 1,371,490 af, is subject to a Stage 1 Shortage, in addition to Nevada and Mexico’s corresponding potential shortage of 342,872 af. Therefore, the maximum potential Stage 1 Shortage to the Lower Division states and Mexico is 1,714,362 af in 2040. As compared to 2008, the total potential Stage 1 Shortage decreased by over 100,000 af.

G.4.4 General State Assumptions

- each State is assumed to be using its entire apportionment each year. Because State apportionments are based on consumptive use, all Lower Basin diversion entitlements had to be converted to estimated consumptive use entitlements, adjusted delivery, and shortages. For informational purposes the diversion values are calculated and displayed as well. The conversion ratios are based on actual 2004 Decree Accounting diversion and consumptive use ratios for each Lower Basin entitlement holder;

- entitlement holders with multiple priorities divert water by their highest (oldest) priority first;

- the Shortage Allocation Model uses the quantity of water projected to be ordered in a shortage year as a basis for distributing the available water supply to individual users;

- with the exception of PPRs, all entitlement holders within a priority class share in shortages on a pro-rata basis. Therefore, within any priority class other then PPRs, the Shortage Allocation Model does not consider entitlement dates;

- PPR holders are assumed to be diverting their full entitlement; and

- the Shortage Allocation Model does not address current and future paybacks of overruns or underruns under the Inadvertent Overrun and Payback Policy.

G.4.5 Nevada Assumptions

- the Shortage Allocation Model reflects that Nevada has eight water delivery priorities (see Attachment A, Table Att. A-2), as established in the Robert B. Griffith Water Project Contract No. 7-07-30-W0004 for delivery of Colorado River water signed by the United States and State of Nevada; and

- in the above contract, it is stated that SNWA is entitled to divert the balance of any remaining un-allocated, unused, and surplus water in Nevada.

G.4.6 California Assumptions

- the PPRs within California are displayed as having the highest priority in the state relative to the priorities contained in the Seven Party Agreement. The priorities within the Seven Party Agreement do not consider PPRs in California's allocation of 4.4 maf. Reclamation recognizes that the QSA helps California parties to meet the water needs of PPRs by agreeing that certain parties to the Seven Party Agreement would make water available to satisfy the requirements of the PPR holders while keeping the priorities within the Seven Party Agreement intact. In addition, the QSA helped quantify entitlements in the Seven Party Agreement, which is necessary to model shortages. Therefore the Shortage Allocation Model displays the quantified entitlements in the QSA for the Imperial Irrigation District and the Coachella Valley Water District, minus the amount specified for PPR use;

- additionally, while the Seven Party Agreement is recognized in the Shortage Allocation Model, protection is provided to Seven Party Agreement members with PPRs by making these the highest priority within the state;

- QSA transfers and exchanges are not modeled in the Shortage Allocation Model, however they are provided in Exhibit B of the QSA (see Attachment F, Table Att. F-2);

- although the Metropolitan Water District of Southern California (MWD) shows a Seven Party Agreement entitlement of 550,000 af in the Shortage Allocation Model, MWD's "Full Entitlement Use" is assumed to be the calculated entitlement resulting from the balance of California's State apportionment and full entitlement use of higher priorities. During shortage, MWD may acquire a minimum of 25,000 af from the Palo Verde Irrigation District; and

- to see the estimated entitlements associated with each California entitlement holder, please see Attachment A, Table Att. A-3.

G.4.7 Arizona Assumptions

- the ADWR Director's Shortage Sharing Workshop Recommendation was submitted to Reclamation in April 2007, and was modeled to show a redistribution of shortages to Arizona fourth priority users in accordance with the preference of Arizona cities, CAWCD, and ADWR;

- the ADWR Director's Shortage Sharing Workshop Recommendation provides that the fourth priority mainstream shortage water supply be calculated by determining the percentage derived by dividing the total fourth priority mainstream diversion entitlement by the available fourth priority consumptive use water supply (absent a shortage), and then multiplying this percentage by the quantity of fourth priority water available in that shortage year. The remaining fourth priority water supply, after the mainstream amount is subtracted, would be available for diversion by the CAP. Based on further telephone conversations with ADWR representatives, the adjusted delivery quantity to mainstream users would be proportionately distributed based on entitlements. If a user is allocated more than it can use under the scheduled use, the remaining balance flows to the CAP, rather than being available to other fourth priority mainstream users. The modeling and distribution of reductions in water deliveries to Arizona and Colorado River water users within Arizona in this Final EIS considers Arizona's shortage strategy; and

- all Arizona projected water use schedules in the Shortage Allocation Model were supplied by ADWR (see Appendix D). However, in accordance with ADWR, some of the original schedules were adjusted. The agreed upon changes are as follows:

  - the Cibola Valley Irrigation and Drainage District water contract has recently been split into three separate contracts: Hopi Tribe, Mohave County Water Authority, and Cibola Valley Irrigation and Drainage District. Reclamation developed a separate schedule for each of the three entities rather than showing one schedule for the district;

  - a projected water use schedule for Fort Yuma Indian Reservation in Arizona was added to allow for first priority use in accordance with the Consolidated Decree;

  - some projected water use schedules for entitlement holders were divided among their more specific contract entitlements or water rights;

  - other projected water use schedules for Lake Havasu City, Bullhead City, and the Mohave Water Conservation District were combined with their subcontracted water from the Mohave County Water Authority, so that impacts to these cities may be better assessed; and

  - schedules for Arizona fourth priority entitlement holders were reduced at the advice of ADWR, if they exceeded Reclamation's estimated entitlement computed from the diversion and consumptive use ratios used in the 2004 Decree Accounting.

G.4.8 CAP Framework and Assumptions:

The Shortage Allocation Model considers five priorities within the CAP. Within the Shortage Allocation Model, the most senior CAP priorities are the Ak-Chin Indian Community and several central Arizona cities who receive water secured by the Salt River Pima-Maricopa Indian Community Water Rights Settlement Act of 1988 (CAP 1). The second CAP priority is Municipal and Industrial (M&I) and Indian Priority Water (CAP 2). Next in priority within CAP is non-Indian Agriculture (NIA) Priority Water, which is available to specific M&I, Agricultural, and Indian entitlement holders (CAP 3). CAP excess water that is available to non-Indian agricultural entitlement holders is the next priority (CAP 4). The lowest priority within CAP is the AWBA which receives the balance of unused water in CAP (CAP 5).
A diagram of CAP entitlement classes, quantified in units of acre-feet is provided in Table G-2.

Table G-2
CAP Priorities Before and After 2044

<table>

It is noted that the water contracting framework for CAP is based on an assumption that at least 1,415,000 af will be available for diversion from the CAP aqueduct in a normal year. This quantity assumes that there is a five percent conveyance loss in the CAP aqueduct. Therefore, 1,490,000 af is required to be available at the CAP pumping plant on the Colorado River. In the event that the priority one, two, and three consumptive use within Arizona (excluding the 68,400 af of priority three water that is included within the CAP supply) exceeds 1,310,000 af of consumptive use in any year, the CAP entitlement holders would receive less than 1,415,000 af and the impact would be absorbed by the lowest CAP priorities. Table G-3 provides a list of specific entitlement holders within each CAP priority.

**The Ak-Chin Indian Community is entitled to an additional 10,000 af, not shown, if excess water is available in the CAP canal. After the Secretary has met the water delivery obligation to the Ak-Chin Indian Community under the Ak-Chin Water Rights Settlement, any excess water under the Ak-Chin Indian Community's CAP water delivery contract is available for delivery to the San Carlos Apache Tribe. Estimated delivery losses of six percent or 4,500 af on the Santa Rosa Canal, incurred in the delivery of water to the Ak-Chin Indian Community, are charged to the Community's CAP water delivery contract.*

G.4.9 General CAP Assumptions

- some of the Tribes or Nations lease their CAP water to cities. The Shortage Allocation Model does not address the shortage to the lessee, and assumes that it is up to the Tribe or Nation to administer the terms and conditions of its lease to determine the amount of water available to the lessee in the shortage year;

- in the projected water use schedules:

    - The original CAP projected water use schedules exceeded the available water for CAP on Arizona schedules, so the CAP projected water use schedules were reduced to keep Arizona within its 2.8 maf apportionment. The following entitlement holders were affected: the AWBA, excess agricultural water users, and the CAP 3 (NIA) Priority (consisting of Indian, M&I, and Agricultural entitlement holders);

- CAP 3 projected water use scheduled for the Maricopa-Stanfield Irrigation and Drainage District and Central Arizona Irrigation and Drainage District were adjusted from a combined total of 12,000 af to 9,026 af for the Arizona State Land Department to reflect the desire of that entity to subcontract for 9,026 af of CAP 3 priority water for irrigation use. All other agricultural water in the CAP 3 priority has been relinquished by the original subcontractors as part of the AWSA;

- ADWR projected CAP 2 M&I water use to year 2035, at which point almost all entitlement holders were using their full entitlement. With ADWR's concurrence, Reclamation adjusted the 2035 projected water use schedule to show full entitlement use by entitlement holders and extended the 2035 projected water use schedules to later years for which a projected water use schedule had not been available;

- for the Final EIS, CAP 2 schedules for the San Carlos Apache Tribe water rights settlement were adjusted to account for losses on the Santa Rosa Canal of 6 percent or 4,500 af; and

- under the implementing documents for the Salt River Pima Maricopa Indian Community Water Rights Settlement Act of 1988, there is a formula that provides for the distribution of the 20,900 af of acquired CAP 1 priority water among all CAP 2 M&I users during a time of shortage. In non-shortage years, this water is made available only to four Phoenix area cities. Reclamation has been informed that the present formula is inoperable and that a technical correction to the formula will have to be developed and agreed to by the appropriate parties. The Shortage Allocation Model does not attempt to model this element of the Salt River Pima Maricopa Indian Community Water Rights Settlement Agreement.

G.4.10 CAP 2 Shortage Assumptions:

The Shortage Allocation Model uses the following assumptions to allocate available CAP 2 water. These assumptions are based on Reclamation staff interpretation of the CAP shortage compromise that was incorporated as part of the Arizona Water Settlements Act (AWSA).

Step I. Under the AWSA, a CAP shortage exists if:

- ♦ prior to January 1, 2044, there is not enough water available to meet the CAP 2 scheduled water use of 981,902 af (638,823 af for M&I and 343,079 af for Indian); or

- ♦ after January 1, 2044, there is not enough water available to meet the CAP 2 scheduled water use of 1,029,205 af (686,126 af for M&I and 343,079 af for Indian).

Step II. If there is a shortage based on Step I above, the available CAP water is allocated between the CAP 2 M&I and Indian entitlement holders as follows:

- ♦ if the available CAP 2 water supply is less than 981,902 af and greater than 853,079 af, then the water is allocated as follows:
  - prior to January 1, 2044, the water allocated to the Indian portion is equal to 25.4 percent of the available CAP water plus 93,303 af. The remainder is allocated to the M&I priority; and
  - after January 1, 2044, the water allocated to the Indian portion is equal to 18.59 percent of the available CAP water plus 151,691 af. The remainder is allocated to the M&I priority.
- ♦ if the available CAP water is less than 853,079 af (or the sub-priority of Indian 4 has been reduced completely), then 36.38 percent of the available CAP water supply is allocated to the remaining Indian portions of CAP 2, and the remainder is allocated to the M&I portion of CAP 2.

Step III. Distribute the available CAP water to the individual entitlement holders within the M&I and Indian Portions:

- within the M&I priority, the quantity of the available water (determined above) is allocated to each entitlement holder proportionately based on each entitlement holder's scheduled delivery relative to the total delivery schedule; and
- within the Indian portion, the available water supply satisfies Indian sub-priorities in order of highest to lowest (Indian 1 to Indian 4). Within each sub-priority, available water is distributed proportionately to users (Table G-4) based on their scheduled use. A shortage occurs when there is not enough water to satisfy all scheduled users.

G.5 Operation of the Shortage Allocation Model

G.5.1 Operation of Regional and State Shortages

The Shortage Allocation Model is designed to allocate Colorado River water under normal and shortage conditions on the mainstream of the lower Colorado River. The model is operated by entering any normal or shortage volume in the "yellow box" labeled "total reduction" as shown below. Following the yellow box is a brown list-box in which any year between 2008 and 2060 may be selected (see below).

Once the year is selected and processed, the Shortage Allocation Model will collect the projected water use schedules for each Arizona user and determine the point at which a Stage 1 and Stage 2 Shortage will occur as discussed in the assumptions section above.

If a shortage is so severe that Arizona fourth priority users are reduced to a zero acre-foot water delivery, California begins to share in the Stage 2 Shortage. In the example below reflecting a 500,000 and a 1.8 million acre-foot shortage in year 2017, the first simulated shortage is not sufficient to cause a Stage 2 Shortage, while the second is. The simulated reductions to Arizona, Nevada, and Mexico are shown in the far right hand column of Table G-5.

Table G-5
Snapshot from Regional Worksheet

Run Mode	Total Reduction	500,000	PROCESS	
Arizona	2,400,000	400,000		
Nevada	283,333	16,667		
California	4,400,000	0		
Mexico	1,416,667	83,333

Nevada	3.33 %	57,664	0	57,664
California	0.00 %	0	0	0

Table G-5
Snapshot from Regional Worksheet

Stage II Shortage (When AZ 4th=0)		7,270,093	7,200,000	70,093
Mexico	16.67 %	1,211,682	1,200,000	11,682
United States				
Arizona	19.48 %	1,416,075	1,402,422	13,653
Nevada	3.33 %	242,336	240,000	2,336
California	60.52 %	4,400,000	4,357,578	42,422
Stage I & II Total		9,000,000	7,200,000	1,800,000

The “consumptive use reduction” column above shows the potential Stage 1 and Stage 2 Shortages for each state and Mexico. Given a regional shortage, the following columns show the “Deliverable Consumptive Use” and the “Consumptive Use Reduction”. These values are transferred to each state worksheet. Each state worksheet provides priority and entitlement information, as well as the selected year’s schedules. As seen in Attachment A, Table Att. A-2 through A-4 of the State worksheets, the last two columns show the adjusted delivery and reduction for each entitlement holder. Arizona entitlement holders are reduced from their scheduled use for the selected year. California and Nevada entitlement holders are reduced from full entitlement use, as projected use schedules were not programmed for these States. Shortages are equally shared pro-rata by all the users within the same priority, with the exception of PPRs.

Each State page is strung with formulas to calculate the adjusted delivery and reduction to each priority. For the users within each priority, shortages are simply calculated by subtracting the adjusted delivery from the projected consumptive use schedules (in Arizona and CAP) or full entitlement (in California and Nevada). For the CAP, the formulas are highly complicated and some even require programming due to time dependent changes expressed in the AWSA.

G.5.2 Operation of Arizona and CAP Shortages

In 2017, a simulated shortage of 500,000 af to the Lower Basin States and Mexico reduces users as displayed in Attachment A, Tables Att. A-2 through A-4. Within Arizona the 400,000 af shortage first reduces deliveries to Arizona fifth priorities (which are not modeled because Reclamation did not receive fifth priority schedules). Next, Arizona fourth priority river users are reduced 23 percent and CAP is reduced 29 percent. The available fourth priority CAP water from the Arizona worksheet, minus five percent losses, is inserted into the CAP worksheet. Table G-6 shows the remaining delivery to CAP is 876,371 af (71 percent). The CAP worksheet distributes shortages to CAP entitlement holders, by satisfying the highest CAP entitlement holders first.

The share of the available CAP water from Arizona fourth priority is first allocated to CAP 2 (a detailed description of Indian tribes impacted by the assumed Indian shortage sharing scheme is provided in Section G.4.7 CAP Framework and Assumptions). Based on the process described in Section G.4.7, the following formulas were created to allocate the proper volume of water to the Indian portion of CAP 2 under shortage conditions, where B6 is the available water for CAP:

= IF(B6>981902,343079,IF(B6>853079,(0.25438*B6+93303),(0.3637518*B6))

This formula is read as: If the available water supply to CAP is greater than 981,902 af, allocate to the Indian portion of CAP 2 the full entitlement of 343,079 af. If the available water supply is less than 981,902 af and greater than 853,079 af, allocate to the Indian portion 25.44 percent of the available water supply plus an additional 93,303 af. If the available water supply is less than 853,079 af, allocate to the Indian portion 36.38 percent of the available water supply to the CAP.

After 2044, the formula to calculate the CAP Indian priority adjusted entitlement is below, followed by a description:

= IF(B6>981902,343079,IF(B6>853079,(0.1859354*B6+151691),(0.3637518*B6))

This formula is read as: If the available water supply to CAP fourth priority is greater than 981,902 af, allocate to the Indian portion of CAP 2 the full entitlement of 343,079 af. If the available water supply is less than 343,079 af and greater than 853,079 af, allocate to the Indian portion 18.59 percent of the available water supply plus an additional 151,691 af. If the available water supply is less than 853,079 af, allocate to the Indian portion 36.38 percent of the water available to the CAP.

For example, the adjusted delivery to the M&I portion of CAP 2 is the difference between available water to CAP 2 and the delivery to the Indian portion. CAP 3 and CAP 4 receive the remaining available water, which would be “0” in this example. However, CAP 3 and CAP 4 users are entitled to unused entitlement from CAP 2. Before the unused entitlement is available to CAP 3 and CAP 4 users, M&I and Indian entitlement holders of CAP 2 are permitted to use the other portion’s unused entitlement, which is called “cross-over”.

Table G-6 shows that the M&I portion creates cross-over water, since M&I scheduled use (512,767 af) is less than the M&I entitlements (560,931 af) under the shortage condition. Therefore, 47,370 af of cross-over is available for Indian entitlement holders in the below example. The Indian priority needs to use 16,752 af of the cross-over to meet projected water schedules for 2017. The remaining 30,618 af is available to CAP 3. In this shortage scenario, CAP water is not available to CAP 4 or CAP 5.

Table G-6
2017 Shortage Allocation to CAP Priorities

Fourth Priority Water Available to CAP	876,371	**2017**			
			scheduled use

**The Ak-Chin Indian Community is entitled to an additional 10,000 af, not shown, if excess water is available in the CAP canal. After the Secretary has met the water delivery obligation to the Ak-Chin Indian Community under the Ak-Chin Water Rights Settlement, any excess water under the Ak-Chin Indian Community's CAP water delivery contract is available for delivery to the San Carlos Apache Tribe. Estimated delivery losses of six percent on the Santa Rosa Canal, incurred in the delivery of water to the Ak-Chin Indian Community, are charged to the Community's CAP water delivery contract.*

A summary of the above CAP shortages is displayed in Attachment A, Table Att. A-5.

G.5.3 Shortage Allocation Model Results

Attachment A provides detailed shortages at the regional, state, and CAP level for a 500,000 af shortage in year 2017. Attachment B displays Arizona and CAP diversion shortages to individual Indian agricultural entitlement holders. Attachment C displays Arizona and CAP diversion shortages to individual non-Indian agricultural entitlement holders. Attachment D displays Arizona and CAP consumptive use shortages to M&I entitlement holders. Attachment E displays a summary of consumptive use shortages to all priorities within the Lower Basin States. Attachment F displays supporting documents to the Shortage Allocation Model.

Shortages generated in Attachments B and C were aggregated by county and class of use for the analysis in Section 4.14 (Socioeconomics). Because some of Arizona's entitlements are shared between agricultural and M&I use, a ratio was developed to split the entitlement for analysis purposes. Thus, for such entitlements, the reduction in agricultural consumptive use is a proportion of the ratio of agricultural use to M&I use permitted in the entitlement holder’s contract. For unquantified contract entitlements, the specified M&I amount in the contract was subtracted from the scheduled use for the selected year.

A summary of shortages generated in Attachment E were used in Section 4.4 (Water Deliveries). All shortages displayed in he tables provided in Attachments B through E were based on the following years: 2008, 2017, 2026, 2027, 2040, and 2060.

G.6 Relationship between CRSS and the Shortage Allocation Model

The CRSS was used to model a variety of river and reservoir parameters in the Colorado River Basin, including shortage amounts, reservoir elevations, and river flows (Section 4.2 and Appendix A). The Shortage Allocation Model provides a more detailed allocation of shortages to the Lower Basin states, specifically to Arizona and the CAP. The Shortage Allocation Model distributes shortages according to the ADWR Director’s Shortage Sharing Workshop Recommendation for Arizona and according to the AWSA for the CAP.

In terms of the total Stage 1 and Stage 2 Shortages, CRSS and the Shortage Allocation Model generate similar results. The distribution of Stage 1 Shortages amongst Arizona fourth priority entitlement holder’s contrasts between the models as CRSS does not recognize the ADWR Director’s Shortage Sharing Workshop Recommendation. When the ADWR Director’s Shortage Sharing Workshop Recommendation was incorporated into the Shortage Allocation Model, ADWR requested that fourth priority schedules be adjusted to prevent them from exceeding Reclamation’s estimated entitlements displayed in the Shortage Allocation Model. Also, in the Final EIS the Shortage Allocation Model incorporated Brooke Water Company’s new contract for 120 af, Mohave County Water Authority’s recommended contract of 3,500 af, and the City of Needle’s quitclaimed PPR of 1,260 af from Atchison, Topeka, and Santa Fe Railway Company. For these reasons the results in the models differ slightly.

Furthermore, the distribution of shortages analyzed within California and Nevada are slightly different than CRSS, because CRSS uses schedules provided by California and Nevada, while the Shortage Allocation Model assumes entitlement holders in these states are using their full entitlement. This difference can only be seen at the maximum shortages analyzed and varies only slightly. Comparison of the Final EIS results between the two models is provided in Table G-10.

Table G-10
Comparison of CRSS and Shortage Allocation Model Results

Year	User	Shortage Allocation Model	CRSS	Difference (Shortage Allocation Model – CRSS)
2017 (500,000 Acre-Foot Shortage)				
	Mexico	83,333	83,333	0
	Nevada	16,667	16,667	0
	SNWA	16,667	16,667	0
	California	0	0	0
	MWD	0	0	0
	Arizona	400,000	400,000	0
	AZ 4th	400,000	400,000	0
	CAP	382,454	376,200	6,254
	River	17,546	23,800	-6,254
	AZ 2/3	0	0	0
2027 (1,921,236 Acre-Foot Shortage)				
	Mexico	320,206	320,206	0
	Nevada	64,041	64,041	0
	SNWA	64,041	64,041	0
	California	119,475	119,475	0
	MWD	119,475	119,475	0
	Arizona	1,417,514	1,417,514	0
	AZ 4th	1,378,928	1,378,928	0
	CAP	1,297,146	1,292,743	4,403
	River	81,782	86,185	-4,403
	AZ 2/3	38,587	38,587	0

One last difference between CRSS and the Shortage Allocation Model exists. In distributing the available water supply to individual users, CRSS models the quantity of water used by the individual entitlement holder in the previous year. The Shortage Allocation Model uses the quantity of water projected to be ordered in the shortage year as the basis for distributing the available water supply to individual users. In the example above, the Shortage Allocation Model results were computed based on the previous year's use to produce comparable results to CRSS.

Comparison of results generated in the Shortage Allocation Model for the Draft EIS and the Final EIS, is provided in Attachment F, Table Att. F-3. A list of all output and attachments is provided in the table of contents of this appendix.

Note: CU means Consumptive Use. All units are in acre-feet per year.
Subcontracts are displayed below the Entitlement Holder and indented five spaces.
[1]2004 Decree Accounting values and Diversion/CU conversion ratios were used to estimate not specified and unquantified entitlements.
[2]This unlimited entitlement is estimated based on 2004 use.
[3]In a shortage, PPR's are delivered water in order of priority date regardless of state lines.

	CALIFORNIA PERCENT									100%		0%

Note: CU means Consumptive Use; all units are in AFY (acre-feet annually).
These priorities are based on the California Seven Party Agreement, modified to include the PPR's identified by the Consolidated Decree.
Forbearances and transfers are displayed in Appendix G, Attachment 6, Table Att. 6-3
The Lower Colorado Water Supply Project exchanges non-project water for Colorado River water. During a declared shortage on the Colorado River, the Colorado Water Supply Project would not be shorted.
[1]2004 Decree Accounting values and Diversion/CU conversion ratios were used to estimate not specified and unquantified entitlements. Consumptive use on Lower Palo Verde Mesa lands assumed to be equal to 2007 Palo Verde Irrigation District request. PVID's estimated entitlement is based on 2004 Decree Accounting use.
[2]Coachella Valley Water District's estimated entitlement shown in this table is reduced by 3,000 af to permit the Secretary of the Interior to satisfy PPR use not covered by the Seven Party Agreement.
[3]IID's PPR protects 2,600,000 acre-feet of its Seven Party 3rd priority diversion entitlement, which is consumptively estimated to be 2,527,341 af. IID's 3rd priority estimated entitlement shown in this table is reduced by the PPR right and 11,500 af to permit the Secretary of the Interior to satisfy PPR use not covered by the Seven Party Agreement.
[4]A portion of this Seven Party Agreement entitlement is shown below under two separate PPR entitlements, the Fort Yuma Indian Reservation (PPR 23) and the Yuma Project, Reservation Division (PPR 28).
[5]Incorporation of Yuma Island pumpers' use within this priority does not represent either a final approval of this use by Reclamation or a final determination of the appropriate Decree accounting for this use; and is not an admission by any Colorado River contractor as to the legality of this use or diversion of Colorado River water. No Water Certificates have been issued for use of water on the Yuma Island in California.
[6]PVID's PPR protects 219,780 af of its Seven Party 1st priority diversion entitlement, which is consumptively estimated to be93,601. Dependent upon call, PVID will fallow a minimum of 25,000 af for the Metropolitan Water District of Southern California.
[7]In a shortage, PPRs are delivered water in order of priority date regardless of state lines. It is assumed that each PPR holders would divert and consumptively use all of its entitlement by 2017.

Note: CU means Consumptive Use; all units are in AFY (acre-feet annually).
Subcontracts are displayed below the Entitlement Holder and indented five spaces.
[1]2004 Decree Accounting values and Diversion/CU ratios were used to estimate not specified and unquantified entitlements.
[2]In a shortage, PPR's are delivered water in order of priority date regardless of state lines.
[3]These CAP users are subject to CAP conveyance losses which are assumed to be 5 percent.
[4]BLM Diversion entitlement is estimated from Consumptive Use Entitlement based on 2004 Decree Accounting.

*47,303 af NIA Priority water converts to M&I Priority on January 1, 2044 and 2,952 af is distributed to Chandler, 4,924 af to Mesa, 36,144 af to Phoenix, and 3,283 af to Scottsdale.

**After the Secretary has met the water delivery obligation to the Ak-Chin Indian Community under the Ak-Chin Water Rights Settlement, any excess water under the Ak-Chin Indian Community's CAP water delivery contract is available for delivery to the San Carlos Apache Tribe.

Estimated delivery losses of 6 percent on the Santa Rosa Canal, incurred in the delivery of water to the Ak-Chin Indian Community, are charged to the Community's CAP water delivery contract.

Attachment B

Indian Agricultural Distribution of Shortages (2008-2060)

This attachment to Appendix G contains tables produced by the Shortage Allocation Model that show the distribution of shortages to Indian agricultural tribes within Arizona. The shortages shown on these tables are based on the diversion volumes of the affected entities. The tables show the distribution of shortages to both tribes within the CAP and to other Arizona Indian tribes, for the years 2008, 2017, 2026, 2027, 2040, and 2060.

Attachment C

Non-Indian Agricultural Distribution of Shortages (2008-2060)

This attachment to Appendix G contains tables produced by the Shortage Allocation Model that show the distribution of shortages to non-Indian agricultural entitlement holders within Arizona. The shortages shown on these tables are based on the diversion volumes of the affected entities. The tables show the distribution of shortages to non-Indian agricultural entitlement holders within Arizona, for the years 2008, 2017, 2026, 2027, 2040, and 2060.

Attachment D

M&I Water Users
Distribution of Shortages (2008-2060)

This attachment to Appendix G contains tables produced by the Shortage Allocation Model that show the distribution of shortages to Municipal and Industrial (M&I) entitlement holders within Arizona. The shortages shown on these tables are based on the consumptive use volumes of the affected entities. The tables show the distribution of shortages to both M&I entitlement holders within the CAP and other Arizona M&I entitlement holders, for the years 2008, 2017, 2026, 2027, 2040, and 2060.
